      "operator": "<=",
      "value": "NOW() - 60 DAYS"
    },
    {
      "key": "atime",
      "operator": ">",
      "value": "NOW() - 90 DAYS"
    }
  ],
  "group_by": ["datasource"],
  "sort_by": [{"datasource": "asc"}]
}
```

- The following example lists the files or objects that are accessed in last 90 - 180 days. This report is created in the UI.

age_report_90-180_days_since_access_detail.json

```
{
  "name": "Age Report Detail. 90-180 Days",
  "query": "",
  "filters": [
    {
      "key": "atime",
      "operator": "<=",
      "value": "NOW() - 90 DAYS"
    },
    {
      "key": "atime",
      "operator": ">",

```

```

        "value": "NOW() - 180 DAYS"
    },
    ],
    "group_by": [],
    "sort_by": []
}

```

- The following example summarizes the files or objects that are accessed in last 90 - 180 days and are grouped by data source. This report is created in the UI.

age_report_90-180_days_since_access_summary.json

```

{
  "name": "Age Report Summary. 90-180 Days",
  "query": "",
  "filters": [
    {
      "key": "atime",
      "operator": "<=",
      "value": "NOW() - 90 DAYS"
    },
    {
      "key": "atime",
      "operator": ">",
      "value": "NOW() - 180 DAYS"
    }
  ],
  "group_by": ["datasource"],
  "sort_by": [{"datasource": "asc"}]
}

```

- The following example lists the files or objects that are accessed in last 180 - 360 days. This report is created in the UI.

age_report_180-360_days_since_access_detail.json

```

{
  "name": "Age Report Detail. 180-360 Days",
  "query": "",
  "filters": [
    {
      "key": "atime",
      "operator": "<=",
      "value": "NOW() - 180 DAYS"
    },
    {
      "key": "atime",
      "operator": ">",
      "value": "NOW() - 360 DAYS"
    }
  ],
  "group_by": [],
  "sort_by": []
}

```

- The following example summarizes the files or objects that are accessed in last 180 - 360 days and are grouped by data source. This report is created in the UI.

age_report_180-360_days_since_access_summary.json

```

{
  "name": "Age Report Summary. 180-360 Days",
  "query": "",
  "filters": [
    {
      "key": "atime",
      "operator": "<=",
      "value": "NOW() - 180 DAYS"
    },
    {
      "key": "atime",
      "operator": ">",
      "value": "NOW() - 360 DAYS"
    }
  ],
  "group_by": ["datasource"],
  "sort_by": [{"datasource": "asc"}]
}

```

- The following example lists the files or objects that are accessed in last 360 - 720 days. This report is created in the UI.

age_report_360-720_days_since_access_detail.json

```

{
  "name": "Age Report Detail. 360-720 Days",
  "query": "",
  "filters": [
    {
      "key": "atime",
      "operator": "<=",
      "value": "NOW() - 360 DAYS"
    },
    {
      "key": "atime",
      "operator": ">",
      "value": "NOW() - 720 DAYS"
    }
  ],
  "group_by": [],
  "sort_by": []
}

```

```

    }
  ],
  "group_by": [],
  "sort_by": []
}

```

- The following example summarizes the files or objects that are accessed in last 360 - 720 days and are grouped by data source. This report is created in the UI.

age_report_360-720_days_since_access_summary.json

```

{
  "name": "Age Report Summary. 360-720 Days",
  "query": "",
  "filters": [
    {
      "key": "atime",
      "operator": "<=",
      "value": "NOW() - 360 DAYS"
    },
    {
      "key": "atime",
      "operator": ">",
      "value": "NOW() - 720 DAYS"
    }
  ],
  "group_by": ["datasource"],
  "sort_by": [{"datasource": "asc"}]
}

```

- The following example lists the files or objects accessed that are not accessed in the last 720 days. This report is created in the UI.

age_report_720+_days_since_access_detail.json

```

{
  "name": "Age Report Detail. 720+ Days",
  "query": "",
  "filters": [
    {
      "key": "atime",
      "operator": "<=",
      "value": "NOW() - 720 DAYS"
    }
  ],
  "group_by": [],
  "sort_by": []
}

```

- The following example summarizes the files or objects that are accessed in last 720 days and are grouped by data source. This report is created in the UI.

age_report_720+_days_since_access_summary.json

```

{
  "name": "Age Report Summary. 720+ Days",
  "query": "",
  "filters": [
    {
      "key": "atime",
      "operator": "<=",
      "value": "NOW() - 720 DAYS"
    }
  ],
  "group_by": ["datasource"],
  "sort_by": [{"datasource": "asc"}]
}

```

2. SQL scripts

- This script provides the count of potentially duplicate files across the heterogeneous environment. This report is not created in the UI.

duplicate_files_by_count.sql

```

select filename, size, count(fkey) from metaocean group by filename,
size order by count(fkey) desc limit 20;

```

- This script provides the size of potentially duplicate files across the heterogeneous environment. This report is not created in the UI.

duplicate_files_by_total_size.sql

```

select filename,entrysize,entrycount,totalsize from (select filename,
size as entrysize, count(fkey) as entrycount, count(fkey)*size as TotalSize
from metaocean group by filename,size) where entrycount>1 order by totalsize desc;

```

- This script provides the size of potentially duplicate files across the heterogeneous environment. This report is not created in the UI.

size_snap.sql

```

select datasource,count(*),sum(size)/1024/1024/1024,max(mtime),max(atime)
from metaocean group by datasource with ur

```

- This script provides a view of the capacity that is consumed per collection. This report is not created in the UI.

space_per_collection.sql

```

select metaocean.collection,count(*),sum(size)/1024/1024/1024,max(mtime),datasource,
tier from metaocean group by metaocean.collection,datasource,tier order by max(mtime)

```

```
desc with ur
```

- This script provides a view of the capacity that is consumed per file type. This report is not created in the UI.

```
space_per_filetype.sql
```

```
select filetype,datasource,tier,count(*),sum(size)/1024/1024/1024 from metaocean
group by filetype,datasource,tier order by filetype,datasource,tier desc with ur
```

- This script provides a view of the capacity that is consumed per user. This report is not created in the UI.

```
space_per_user.sql
```

```
select owner,tier,count(*),sum(size)/1024/1024/1024,max(mtime),max(ctime) from metaocean
group by owner,tier order by owner,tier with ur
```

Reports can also be generated by using one of two CLI utilities that are provided with IBM Data Cataloging. Both exist on the IBM Data Cataloging nodes:

- /opt/ibm/metaocean/reports/generate_report.py

To run the utilities, log in to an IBM Data Cataloging node and run generate_report.py with the following usage:

```
python generate_report.py [-h] [-o filename] -u username [infile]
```

- Run a report with an SQL input file:

```
python generate_report.py -u sdadmin -o report.csv sql/space_per_user.sql
Enter password for SD user 'sdadmin':
```

- Run a report with a JSON input file:

```
python generate_report.py -u sdadmin sql/age_report_0-30_days_since_access_detail.json
Enter password for SD user 'sdadmin':
```

This requires a IBM Data Cataloging user name and input file. You must have the Data Admin role to generate reports. The tool prompts for a password

Input file examples are stored in the /opt/ibm/metaocean/reports/sql directory. There is a mix of JSON and SQL files in the directory. All JSON files create a report in the IBM Data Cataloging UI. The SQL files create a CSV file.

- /opt/ibm/metaocean/reports/generate_path_age_report.py

Important: This tool does not create reports in the IBM Data Cataloging UI.

Here is the usage of the tool:

```
generate_path_age_report.py [-h] -u username -r report -p pathlevel -a archive
```

optional arguments:

```
-h, --help            show this help message and exit
-u username, --user username
                        User name with authority to create reports
-r report, --report report
                        The report type to be generated (ARDS, ARDSOW, AROW, ARPL,
                        CPPL, FTMB, CPFT, FTMB50)
-p pathlevel, --pathlevel pathlevel
                        The level of path used in some reports
-a archive, --archive archive
                        The archive threshold in months
```

The generate_path_age_report.py tool needs a minimum of three parameters:

- pathlevel

The level of path used in some reports, for example:

```
1 = /x/, 2=/x/y/
```

If your report does not use this parameter a value of 1 must be used.

- archive

The archive threshold is the number of months since the last time a file is considered relevant for archiving for reporting purposes. If your report does not use this parameter a value of 1 must be used.

- report

The report type is one of the following codes:

```
ARDS   = Summary of archivable capacity grouped by datasource
ARDSOW = Summary of archivable capacity grouped by datasource
AROW   = Summary of archivable capacity grouped by owner
ARPL   = Summary of archivable capacity grouped by specified path level
CPPL   = Summary of capacity grouped by specified path level
FTMB   = Summary of filetype usage by month, previous 12 months
CPFT   = Summary of capacity grouped by filetype
FTMB50 = Summary of filetype usage by month, previous 12 months' top 50 filetypes
```

Here is an example of running the generate_path_age_report.py tool:

```
python generate_path_age_report.py -u sdadmin -r ARDSOW -p 2 -a 12
```

Starting to create report type 'ARDSOW' for user: sdadmin

Enter password for SD user 'sdadmin':

Setting up path level summary table

Generating path level summary table

Generating path level summary table complete.

Generating report

Generating report - building temporary table.

Generating report - querying temporary table.

Generating report - writing output file.

Report generated successfully. Results are in 'rpt_ar_ds_ow.csv'.

/db2whrest/v1/report: GET

Gets information on all the curation reports that are available in the system.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	X	X	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/ report -X GET
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

1. The following example shows how to get information on all the curation reports that are available in the system.

a. Submit the request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/ v1/report -X GET -H "Accept: application/json"
```

b. The following response is returned. In this example the system contained a total of only two reports, and the response displays the available information about both reports. The response data is in JSON format. The data has been manually reflowed to make it more readable.

```
{
  {
    "name": "Age Report Detail. 0-30 Days",
    "query": "{\"filters\": [{\"value\": \"NOW() - 30 DAYS\", \"key\": \"atime\", \"operator\": \">\"}], \"sort_by\": [{\"name\": \"Age Report Detail. 0-30 Days\", \"query\": \"\", \"group_by\": []}], \"size\": 208, \"report\": \"34d03123-4611-4f9f-9730-ffe89c6c53cb\", \"duration\": 0, \"filename\": \"Age Report Detail. 0-30 Days-2018-11-01_18:58:04.csv\", \"lastrun\": \"2018-11-01T18:58:04.000Z\", \"status\": \"complete\", \"schedule\": null",
  },
  {
    "name": "Age Report Summary. 0-30 Days",
    "query": "{\"filters\": [{\"value\": \"NOW() - 30 DAYS\", \"key\": \"atime\", \"operator\": \">\"}], \"sort_by\": [{\"datasource\": \"asc\"}], \"name\": \"Age Report Summary. 0-30 Days\", \"query\": \"\", \"group_by\": [\"datasource\"]\", \"size\": 21, \"report\": \"b5ff3126-353d-4d7d-857a-750cc20b8bab\", \"duration\": 0, \"filename\": \"Age Report Summary. 0-30 Days-2018-11-01_18:58:14.csv\", \"lastrun\": \"2018-11-01T18:58:14.000Z\", \"status\": \"complete\", \"schedule\": null",
  }
}
```

Note: To download the output of a report, use the download endpoint. For more information, see [/db2whrest/v1/report/<report_id>/download: GET](#).

/db2whrest/v1/report/<report_id>: GET

Gets information about a single curation report.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	X	X	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/report/ <report_id> -X GET
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

1. The following example shows how to get information about a single curation report.

a. Submit a request to display information about report ID "b5ff3126-353d-4d7d-857a-750cc20b8bab":

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/ report/b5ff3126-353d-4d7d-857a-750cc20b8bab -X GET -H 'Accept: application/json'
```

b. The following response is returned. The response data is in JSON format:

```
{
  "name": "Age Report Summary. 0-30 Days",
  "query": {
    "filters": [
      {
        "value": "NOW() - 30 DAYS",
        "key": "atime",
        "operator": ">"
      }
    ],
    "sort_by": [
      {
        "datasource": "asc"
      }
    ],
    "name": "Age Report Summary. 0-30 Days",
    "query": "",
    "group_by": [
      {
        "datasource": ""
      }
    ],
    "size": 21,
    "report": "b5ff3126-353d-4d7d-857a-750cc20b8bab",
    "duration": 0,
    "filename": "Age Report Summary. 0-30 Days-2018-11-01_18:58:14.csv",
    "lastrun": "2018-11-01T18:58:14.000Z",
    "status": "complete",
    "schedule": null
  }
}
```

In the following code block, the response data has been manually reflowed to make it easier to read:

```
{
  "name": "Age Report Summary. 0-30 Days",
  "query": {
    "filters": [
      {
        "value": "NOW() - 30 DAYS",
        "key": "atime",
        "operator": ">"
      }
    ],
    "sort_by": [
      {
        "datasource": "asc"
      }
    ],
    "name": "Age Report Summary. 0-30 Days",
    "query": "",
    "group_by": [
      {
        "datasource": ""
      }
    ],
    "size": 21,
    "report": "b5ff3126-353d-4d7d-857a-750cc20b8bab",
    "duration": 0,
    "filename": "Age Report Summary. 0-30 Days-2018-11-01_18:58:14.csv",
    "lastrun": "2018-11-01T18:58:14.000Z",
    "status": "complete",
    "schedule": null
  }
}
```

Note: To download the output of a report, use the download endpoint. For more information, see [db2whrest/v1/report/<report_id>/download](#): [GET](#).

/db2whrest/v1/report/<report_id>/download: GET

Downloads the output file of the specified curation report.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	X	X	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/report/ <report_id>/download -X GET
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- CSV

Status codes

- 200: The operation is successful.
- Any other status code value: The operation failed.

Examples

1. The following example shows how to download the output file of a specific report.

a. Submit a request to display the output from report ID "6baae44c-2b85-4954-ba44-d3e637d4b48d":

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/ report/6baae44c-2b85-4954-ba44-d3e637d4b48d/download
```

This report searches for files greater than 1 MiB in size and grouped by datasource.

b. The following response is returned. The output is in CSV format:

```
datasource,count,sum
filesystem1,346.0,685733316581
filesystem2,370213.0,249855575516039
```

/db2whrest/v1/bucket: GET

Gets information on all buckets that are supported.

Buckets influence the manner in which IBM Data Cataloging groups data for search faceting and in the user interface widgets. The predefined bucket types that are supported are:

- SizeRange
- TimeSinceAccess
- FileGroup

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	X	X	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/buckets -X GET
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

1. The following example shows how to get information on all the buckets that are supported by the bucket service.

a. Submit the request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/buckets -X GET -H 'Accept: application/json'
```

b. The following response is returned.

```
[
  {
    "data": "{\n\"type\": \"int\", \"source_field\": \"size\", \"ranges\": {\n\"extra small\": [0, 4096], \"small\": [4096, 1048576], \"extra large\": [1099511627776, \"INFINITY\"], \"large\": [1073741824, 1099511627776], \"medium\": [1048576, 1073741824]}, \"name\": \"SizeRange\"}\n",

    "data": "{\n\"name\": \"FileGroup\", \"type\": \"list\", \"ranges\": {\n\"pdf\": [\"pdf\"], \"doc\": [\"doc\", \"docx\", \"odt\"], \"xls\": [\"xls\", \"xls\", \"xlsx\", \"ods\"], \"image\": [\"jpg\", \"jpeg\", \"png\", \"gif\", \"tif\", \"ppt\": [\"pptx\", \"ppt\", \"pps\", \"odp\"], \"compressed\": [\"zip\", \"tar\", \"gz\", \"z\", \"7z\", \"xz\"], \"text\": [\"txt\", \"rtf\"], \"audio\": [\"mp3\", \"wav\"], \"video\": [\"mp4\", \"mov\", \"mpg\", \"mkv\"], \"medical_image\": [\"img\", \"hdr\", \"nii\", \"mnc\", \"dcm\"], \"genomics\": [\"bam\", \"sam\", \"vcf\"], \"semi_structured\": [\"csv\", \"tsv\", \"avro\", \"json\", \"xml\", \"parquet\"]}, \"source_field\": \"filetype\"}\n"
  }
]
```

/db2whrest/v1/buckets/<bucket>: GET

Gets information on a specific bucket that is supported.

Buckets influence the manner in which IBM Data Cataloging groups data for search faceting and in the user interface widgets. The predefined bucket types that are supported are:

- SizeRange
- TimeSinceAccess
- FileGroup

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	X	X	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/buckets/<bucket> -X GET
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

1. The following example shows how to get information on all the buckets that are supported by the bucket service.

a. Submit the request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/buckets/SizeRange -X GET -H "Accept: application/json"
```

b. The following response is returned.

```
[
  {
    "data": "{ \"type\": \"int\", \"source_field\": \"size\", \"ranges\": { \"extra small\": [0, 4096], \"small\": [4096, 1048576], \"extra large\": [1099511627776, \"INFINITY\"], \"large\": [1073741824, 1099511627776], \"medium\": [1048576, 1073741824] }, \"name\": \"SizeRange\" }",
    "name": "SizeRange"
  }
]
```

/db2whrest/v1/report/<report_id>: PUT

Runs the specified curation report. The old output file is replaced by the new one.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	X	X	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/report/ <report_id> -X PUT
```

Supported request types and response formats

Supported request types:

- PUT

Supported response formats:

- JSON

/db2whrest/v1/buckets/<bucket>: PUT

Modifies the bucket details.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	X	X	X

To modify the details of a bucket, you must create a JSON object that is modeled after the original (or existing) bucket definition as shown in the sample:

```
{
  "name": "SizeRange",
  "source_field": "size",
  "type": "int"
  "ranges": {
    "extra small": [ 0, 4096 ],
    "small": [ 4096, 1048576 ],
    "medium": [ 1048576, 1073741824 ],
    "large": [ 1073741824, 1099511627776 ],
    "extra large": [ 1099511627776, "INFINITY" ]
  }
}

{
  "name": "TimeSinceAccess",
  "source_field": "atime",
  "type": "date",
  "ranges": {
    "1 week\": [ 0, 7 ],
    "1 month": [ 7, 30 ],
    "1 quarter": [ 30, 90 ],
    "1 year": [ 90, 365 ],
    "1 year+": [ 365, "INFINITY" ]
  }
}

{
  "name": "FileGroup",
  "type": "list",
  "ranges": {
    "pdf": [ "pdf" ],
    "doc": [ "doc", "docx", "odt" ],
    "xls": [ "xls", "xlsm", "xlsx", "ods" ],
    "image": [ "jpg", "jpeg", "png", "gif", "tif" ],
    "ppt": [ "pptx", "ppt", "pps", "odp" ],
    "compressed": [ "zip", "tar", "gz", "z", "7z", "xz" ],
    "text": [ "txt", "rtf" ],
    "audio": [ "mp3", "wav" ],
    "video": [ "mp4", "mov", "mpg", "mkv" ],
    "medical_image": [ "img", "hdr", "nii", "mnc", "dcm" ],
    "genomics": [ "bam", "sam", "vcf" ],
    "semi_structured": [ "csv", "tsv", "avro", "json", "xml", "parquet" ]
  },
  "source_field": "filetype"
}
```

The JSON object must be based on the default values of the bucket. You can modify the range labels or values. The bucket name, source_field, and bucket types cannot be modified.

The three bucket types that are supported include:

int

For the "int" types, each range consists of a label and a minimum and maximum value. The only 'int' type bucket that is supported currently is *SizeRange*. The units for 'SizeRange' are in bytes. A sample int type appears as shown:

```
"small": [4096, 8192]
```

date

For the "date" types, each range consists of a label and a minimum and maximum value that represents the number of days. The only 'date' type bucket that is supported in the current version is *TimeSinceAccess*. A sample date range appears as shown:

```
"1_to_2_years": [365, 730]
```

list

For the "list" types, each range consists of a label and a list of at least one string value. The only 'list' type bucket that is supported in the current version is *FileGroup*. The list of values must be a list of file extensions to be grouped. A sample list range appears as shown:

```
"images": ["jpg", "jpeg", "gif", "png", "bmp"]
```

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/buckets/<bucket> -X PUT -d@bucket.json -H "Content-Type: application/json"
```

Supported request types and response formats

Supported request types:

- PUT

Supported response formats:

- JSON

Examples

The following example shows how to modify information for a single bucket.

1. Submit the request:

```
curl -k -H 'Authorization: Bearer <token>' https://<master_node>/db2whrest/v1/buckets/SizeRange -X PUT -d@bucket.json -H "Content-Type: application/json"
```

2. The following response is returned:

```
[
  {
    "status": "success"
  }
]
```

/db2whrest/v1/report/<report_id>: DELETE

Deletes the specified curation report definition and its output file.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	X	X	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/report/ <report_id> -X DELETE
```

Supported request types and response formats

Supported request types:

- DELETE

Supported response formats:

- JSON

/db2whrest/v1/sql_query?<sql>: GET

Retrieves data from a database with an SQL query in a GET command. You can use any standard SQL query. You must include the SQL query as a parameter of the URL. To send the query in an HTTP message body, see [/db2whrest/v1/sql_query: POST](#).

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	✓ ¹	✓ ¹	X	X

¹The search is restricted to documents that are tagged with collections to which the user has a datauser role assigned.

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/sql_query?<sql_statements> -X GET
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- CSV
- JSON

Examples

1. The following example shows how to get data from a database with an SQL query in a GET command. The SQL query is included as a parameter of the URL. This example specifies that the data must be returned in JSON format:

a. Submit the request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/sql_query?select%20*%20from%20meteor%20limit%202 -X GET -H "Accept: application/json"
```

b. The following response is returned:

```
{
  "datasource": "ctolib",
  "operation": "INDEX",
  "ingesttype": "SCAN",
  "revision": "MO1",
  "site": "Spectrum Scale",
  "cluster": "ctolib.cluster1",
  "inode": 4042,
  "owner": "user1",
  "group": "group1",
  "permissions": "-rw-r--r--",
  "fileset": "brother",
  "uid": null,
  "gid": null,
  "path": "\/ctolib\/brother\/dir1\/",
  "filename": "file1.txt",
  "filetype": "txt",
  "recordversion": "",
  "migstatus": "resdnt",

,,,,,,,,,,,,,
```

/db2whrest/v1/sql_query: POST

Gets data from a database with an SQL query in a POST command. You can use any standard SQL query. You must include the SQL query in the message body of the POST command.

To send the query as a parameter of the URL, see [/db2whrest/v1/sql_query?<sql>: GET](#). The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	✓ ¹	✓ ¹	X	X

¹The search is restricted to documents that are tagged with collections to which the user ID has a datauser role assigned.

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/ sql_query -X POST -d<sql.dat>
```

Supported request types and response formats

Supported request types:

- POST

Supported response formats:

- CSV
- JSON

Examples

1. The following example shows how to get the data from a database with an SQL query in a POST command. The SQL query is sent in the POST message body. The output format is plain text.

a. Write the record to be added to the database into a file named sql.dat.

b. Submit the request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/sql_query -X POST -d"select * from datasrv04 where owner='root'"
```

c. The following response is returned. The output is in plain text format:

```
0,filesystem1,INDEX,SCAN,MO1,,Spectrum Scale,filesystem1.university.edu,3067343,root,root,
-rw-r--r--,root,9,10,/filesystem1/cellranger-2.0.0/refdata-cellranger-ercc92-1.2.0/star/,
sjdbList.out.tab,tab,resdnt,NA,2016-11-14 19:40:10,2017-06-02 21:30:26,
2017-06-02 21:30:26,2018-07-24 16:32:47,system,0,1,filesystem1.university.edu,filesystem13067343,
.....
1,filesystem1,INDEX,SCAN,MO1,,Spectrum Scale,filesystem1.university.edu,3067333,root,root,
-rw-r--r--,root,9,10,/filesystem1/cellranger-2.0.0/refdata-cellranger-ercc92-1.2.0/star/,
chrLength.txt,txt,resdnt,NA,2016-11-14 19:40:10,2017-06-02 23:28:21,2017-06-02 21:30:26,
2018-07-24 16:32:47,system,412,1,filesystem1.university.edu,filesystem13067333,
.....
...
```

In the following code block, the information from the response is curtailed so that it is easier to read. Only the first 14 columns are shown here. You can see that both rows seem to have root as the owner:

```
0,filesystem1,INDEX,SCAN,MO1,,Spectrum Scale,filesystem1.university.edu,3067343,root,root,
-rw-r--r--,root,9,10,/filesystem1/. . . .
1,filesystem1,INDEX,SCAN,MO1,,Spectrum Scale,filesystem1.university.edu,3067333,root,root,
-rw-r--r--,root,9,10,/filesystem1/. . . .
...
```

- The following example shows how to get the data from a database with an SQL query in a POST command. The SQL query is sent in the POST message body. The output format is JSON.

- Write the SQL record in a file named sql.dat.
- Submit the request.

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/ sql_query -X POST -d@"sql.dat"
-H "accept: application/json"
```

- The following response is returned. The output is in JSON format:

```
[{"filesystem":"filesystem1","operation":"INDEX","source":"SCAN","revision":"MO1","site":"","

```

/db2whrest/v1/sql_query_async?<sql>: GET

Gets data from a database asynchronously with an SQL query in a GET command.

You can use any standard SQL query. You must include the SQL query as a parameter of the URL. To send the query in an HTTP message body, see [/db2whrest/v1/sql_query_async: POST](#). The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	✓ ¹	✓ ¹	X	X

¹The search is restricted to documents that are tagged with collections to which the user ID has a datauser role assigned.

The asynchronous endpoints are useful alternatives in situations where the operation takes a long time to complete or has a negative effect on the overall performance of the system. For more information, see the topic [Asynchronous endpoints](#).

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/sql_query_async?<sql_statements> -X GET
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- CSV
- JSON

Examples

1. The following example shows how to get data from a database asynchronously with an SQL query in a GET command. The SQL query is included as a parameter of the URL.

- a. Submit the request. The endpoint responds by displaying the field {"status": "work scheduled"} to indicate that the operation is running asynchronously.

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/sql_query_async?select%20*%20from%20datasrv04%20where%20owner%3D%27root%27 -X GET {"status": "work scheduled"}
```

The synchronous response to the request contains information about the asynchronously running task. The following is an example. For more information, see the topic [Asynchronous endpoints](#).

```
* HTTP 1.0, assume close after body
< HTTP/1.0 202 ACCEPTED
< Content-Type: text/html; charset=utf-8
< Content-Length: 28
< Location: https://data_cataloging_host/db2whrest/v1/task_status/25b2df40-8f0c-4e32-a2f9-999ff3b18ada
< Server: Werkzeug/0.14.1 Python/3.4.5
< Date: Thu, 15 Feb 2018 20:37:10 GMT
```

- b. Later, poll the URL that is provided in the **Location** field of the synchronous response header in Step (a).

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/task_status/25b2df40-8f0c-4e32-a2f9-999ff3b18ada
```

- c. When the operation is complete, the endpoint displays the rows of data that are returned in response to the SQL query in the request. In the following example only the first two rows of output are shown:

```
0,reflib,INDEX,SCAN,M01,,Spectrum Scale,reflib.university.edu,3067343,root,root,
-rw-r--r--,root,9,10,/reflib/cellranger-2.0.0/refdata-cellranger-ercc92-1.2.0/star/,
sjdbList.out.tab,tab,resdnt,NA,2016-11-14 19:40:10,2017-06-02 21:30:26,
2017-06-02 21:30:26,2018-07-24 16:32:47,system,0,1,reflib.university.edureflib3067343,
.....
1,reflib,INDEX,SCAN,M01,,Spectrum Scale,reflib.university.edu,3067333,root,root,
-rw-r--r--,root,9,10,/reflib/cellranger-2.0.0/refdata-cellranger-ercc92-1.2.0/star/,
chrLength.txt,txt,resdnt,NA,2016-11-14 19:40:10,2017-06-02 23:28:21,
2017-06-02 21:30:26,2018-07-24 16:32:47,system,412,1,reflib.university.edureflib3067333,
.....
...
```

/db2whrest/v1/sql_query_async: POST

Gets data from a database asynchronously with an SQL query in a POST command. You can use any standard SQL query. You must include the SQL query in the message body of the POST command.

To send the query as a parameter of the URL, see [/db2whrest/v1/sql_query_async<sql>: GET](#).

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	✓ ¹	✓ ¹	X	X

¹The search is restricted to documents that are tagged with collections to which the user ID has a datauser role assigned.

The asynchronous endpoints are useful alternatives in situations where the operation takes a long time to complete or has a negative effect on the overall performance of the system. For more information, see the topic [Asynchronous endpoints](#).

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/sql_query_async -X POST -d<sql.dat>
```

Supported request types and response formats

Supported request types:

- POST

Supported response formats:

- CSV
- JSON

Examples

1. The following example shows how to get data from a database asynchronously with an SQL query in a POST command. The SQL query is sent in the POST message body. The output format is JSON.

- a. Write the record to be added to the database into a file named sql.dat.
b. Submit the request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/sql_query_async -X POST -d"select * from metaccean where owner='root'" -H "accept: application/json"
```

The synchronous response to the request contains information about the asynchronously running task. The following is an example. For more information, see the topic [/db2whrest/v1/sql_query_async<sql>: GET](#).

```
* HTTP 1.0, assume close after body
< HTTP/1.0 202 ACCEPTED
< Content-Type: text/html; charset=utf-8
< Content-Length: 28
< Location: https://<data_cataloging_host>/db2whrest/v1/task_status/3e40cfeb-efc9-4091-8bc8-
b194ff49d728
< Server: Werkzeug/0.14.1 Python/3.4.5
< Date: Thu, 15 Feb 2018 20:37:10 GMT
```

c. Later, poll the URL that is provided in the **Location** field of the synchronous response header in Step (b):

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/task_status/ 25b2df40-8f0c-
4e32-a2f9-999ff3b18ada
```

d. When the operation is complete, the endpoint displays the rows of data that are returned in response to the SQL query in the request. In the following example only the first two rows of output are shown. The output format is JSON:

```
[{"filesystem":"reflib","operation":"INDEX","source":"SCAN","revision":"MO1","site":"","
"platform":"Spectrum Scale","cluster":"reflib.university.edu","inode":3067112,"owner":

]
```

/db2whrest/v1/task_status/<task_id>: GET and <task_id>/peek

Gets the status of the specified asynchronous task.

The following table shows which roles can access these two REST API endpoints:

Table 1. Access by role

Endpoint	Data admin	Data user	Collection Admin	Admin	Service user
/db2whrest/v1/task_status/<task_id>: GET	✓	✓	✓	X	X
/db2whrest/v1/task_status/<task_id>/peek: GET	✓	✓	✓	X	X

The peek variation of this endpoint returns the status of the asynchronous operation. The nonpeek version returns both the status of the operation and a response header that includes further information. For more information about using these endpoints, see the following examples, and also see the topic [Asynchronous endpoints](#).

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/task_status/ <task_id> -X GET
```

or

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/task_status/ <task_id>/peek -X GET
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- CSV
- JSON

Examples

1. In this example, the user discovers that the asynchronous operation completes and finds the location URI of the results of the operation. For more information on these steps, see the topic [Asynchronous endpoints](#). The user runs the `/db2whrest/v1/task_status/<task_id>: GET` endpoint on the location URI to get the results of the operation:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/ task_status/9c0db090-bd33-41c5-
969f-a1603ddf49ab
```

The results are returned in the response. Only the first two rows of the results are shown in this example:

```
0,reflib,INDEX,SCAN,M01,,Spectrum Scale,reflib.university.edu,3067343,root,root,
-rw-r--r--,root,9,10,/reflib/cellranger-2.0.0/refdata-cellranger-ercc92-1.2.0/star/,
sjdbList.out.tab,tab,rsdnt,NA,2016-11-14 19:40:10,2017-06-02 21:30:26,2017-06-02
21:30:26,2018-07-24 16:32:47,system,0,1,reflib.university.edureflib3067343,
.....
1,reflib,INDEX,SCAN,M01,,Spectrum Scale,reflib.university.edu,3067333,root,root,
-rw-r--r--,root,9,10,/reflib/cellranger-2.0.0/refdata-cellranger-ercc92-1.2.0/star/,
chrLength.txt,tab,rsdnt,NA,2016-11-14 19:40:10,2017-06-02 23:28:21,2017-06-02 21:30:26,
2018-07-24 16:32:47,system,412,1,reflib.university.edureflib3067333,
.....
...
```

2. In this example, the user learns that the asynchronous operation is in progress and finds the location URI of the asynchronous operation. For more information on these tasks, see the topic [Asynchronous endpoints](#). The user can do the following steps:
- Monitor the status of the asynchronous operation by running the `/db2whrest/v1/task_status/<task_id>/peek`: **GET** endpoint on the location URI of the asynchronous operation several times:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/task_status/9c0db090-bd33-41c5-969f-a1603ddf8888/peek
```

In the first few tries the response to the peek endpoint indicates that the asynchronous operation is still running:

```
{"status":work scheduled}
```

On the final try the response to the peek endpoint indicates that the asynchronous operation completes:

```
{"status":work scheduled}
```

- Find the location URI of the asynchronous operation. This location URI is already available in Step 2(a), where the peek endpoint is run on it.
- Get the location URI of the results of the operation. To accomplish this task, run the `/db2whrest/v1/task_status/<task_id>`: **GET** endpoint on the location URI of the asynchronous operation, which you obtained in Step 2(b). The response contains the location URI of the results of the operation.
- Get the results of the asynchronous operation. To accomplish this task, run the `/db2whrest/v1/task_status/<task_id>`: **GET** endpoint on the location URI of the results of the operation, which you obtained in Step 2(c):

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/task_status/9c0db090-bd33-41c5-969f-a1603ddf8888
```

The results of the asynchronous operation are returned in the response. Only the first two rows of the results are shown in this example:

```
0,reflib,INDEX,SCAN,M01,,Spectrum Scale,reflib.university.edu,3067343,root,root,
-rw-r--r--,root,9,10,/reflib/cellranger-2.0.0/refdata-cellranger-ercc92-1.2.0/star/,
sjdbList.out.tab,tab,rsdnt,NA,2016-11-14 19:40:10,2017-06-02 21:30:26,2017-06-02
21:30:26,2018-07-24 16:32:47,system,0,1,reflib.university.edureflib3067343,
.....
1,reflib,INDEX,SCAN,M01,,Spectrum Scale,reflib.university.edu,3067333,root,root,
-rw-r--r--,root,9,10,/reflib/cellranger-2.0.0/refdata-cellranger-ercc92-1.2.0/star/,
chrLength.txt,tab,rsdnt,NA,2016-11-14 19:40:10,2017-06-02 23:28:21,2017-06-02 21:30:26,
2018-07-24 16:32:47,system,412,1,reflib.university.edureflib3067333,
.....
...
```

For more information, see the topic [Asynchronous endpoints](#).

/db2whrest/v1/summary_tables -X GET

Gets information on all the summary tables that are available in the system.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	CollectionAdmin	Data user	Admin	Service user
✓	X	X	X	X

Synopsis of the request URL

```
curl -u <user>:<pass> https://<master_node>/db2whrest/v1/summary_tables -X GET
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

- The following example shows how to get information on all the summary tables that are available in the system.
 - Submit the request:

```
curl -u <user>:<pass> https://<master_node>/db2whrest/v1/summary_tables -X GET
```

b. The following response is returned. The response data is in JSON format. The data has been manually reflowed to make it more readable.

```
{
  "duplicates": {
    "enabled": false,
    "last_duration": null,
    "last_updated_time": "2019-07-10T18:39:58.348Z",
    "schedule": {
      "hour": 0,
      "minute": "14"
    },
    "update_running": false,
    "update_start_time": null
  },
  "mrcapacity": {
    "enabled": true,
    "last_duration": "0:01:10",
    "last_updated_time": "2019-07-10T21:45:02.462Z",
    "schedule": {
      "minute": "*/5"
    },
    "update_running": true,
    "update_start_time": "2019-07-10_21:50:01"
  }
}
```

/db2whrest/v1/summary_tables/<table> -X GET

Gets information for a particular summary table available in the system.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	CollectionAdmin	Data user	Admin	Service user
✓	X	X	X	X

Synopsis of the request URL

```
curl -u <user>:<pass> https://<master_node>/db2whrest/v1/summary_tables/<table> -X GET
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

1. The following example shows how to get information on a particular summary table that is available in the system.

a. Submit the request:

```
curl -u <user>:<pass> https://<master_node>/db2whrest/v1/summary_tables/mrcapacity
```

b. The following response is returned. The response data is in JSON format. The data has been manually reflowed to make it more readable.

```
{
  "enabled": true,
  "last_duration": "0:01:10",
  "last_updated_time": "2019-07-10T21:45:02.462Z",
  "schedule": {
    "minute": "*/5"
  },
  "update_running": true,
  "update_start_time": "2019-07-10T22:00:00.342Z"
}
```

/db2whrest/v1/summary_tables/<table> -X PUT

Change the summary table configuration for a particular summary table available in the system.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	CollectionAdmin	Data user	Admin	Service user
✓	X	X	X	X

Synopsis of the request URL

```
curl -u <user>:<pass> https://<master_node>/db2whrest/v1/summary_tables/<table> -X PUT -d@data.json -H "Content-Type: application/json"
```

Supported request types and response formats

Supported request types:

- PUT

Supported response formats:

- JSON

Examples

1. The following example shows how to disable auto scheduling for a particular summary table that is available in the system.

a. Submit the request:

```
curl -u <user>:<pass> https://<master_node>/db2whrest/v1/summary_tables/mrcapacity -X PUT -d '{"enabled": false}' -H "Content-Type: application/json"
```

b. The following response is returned.

```
{"status": "success"}
```

2. The following example shows how to enable auto scheduling for a particular summary table that is available in the system.

a. Submit the request:

```
curl -u <user>:<pass> https://<master_node>/db2whrest/v1/summary_tables/mrcapacity -X PUT -d '{"enabled": true, "schedule": {"minute": "*/5"}}' -H "Content-Type: application/json"
```

b. The following response is returned.

```
{"status": "success"}
```

3. The following example shows how to change the configuration schedule for a particular summary table that is available in the system.

a. Submit the request:

```
curl -u <user>:<pass> https://<master_node>/db2whrest/v1/summary_tables/mrcapacity -X PUT -d '{"enabled": true, "schedule": {"minute": "*/5"}}' -H "Content-Type: application/json"
```

b. The following response is returned.

```
{"status": "success"}
```

/db2whrest/v1/summary_tables/<table>/<action> -X PUT

Triggers a start or scheduled start action for a particular summary table.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	CollectionAdmin	Data user	Admin	Service user
✓	X	X	X	X

Synopsis of the request URL

```
curl -u <user>:<pass> https://<master_node>/db2whrest/v1/summary_tables/<table>/<action> -X PUT
```

Supported request types and response formats

Supported request types:

- PUT

Supported response formats:

- JSON

Examples

1. The following example shows how to start a table refresh on demand for a particular summary table that is available in the system.

a. Submit the request:

```
curl -u <user>:<pass> https://<master_node>/db2whrest/v1/summary_tables/mrcapacity/start -X PUT
```

b. The following response is returned.

```
{"status": "success"}
```

/db2whrest/v1/bulk_add_tags/docs: POST

Searches a database for data.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	✓ ¹	✓ ¹	X	X

¹The search is restricted to documents that are tagged with collections to which the user ID has a datauser role assigned.

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/bulk_add_tags/docs -X POST -d@bulk_of_docs.json -H "Content-type: application/json"
```

Supported request types and response formats

Supported request types:

- POST

Supported response formats:

- JSON

Examples

1. The following example shows how to define search parameters and format the data that is returned:

a. Step 1: Define the search parameters in a file named bulk_of_docs.json:

```
{
  "docs": {
    "fkey1": {
      "tags": {
        "tag1": "This is the value for tag1",
        "tag2": "This is the value for tag2",
        "tag3": "This is the value for tag3",
      }
    },
    "fkey2": {
      "tags": {
        "tag4": "This is the value for tag4",
        "tag5": "This is the value for tag5",
        "tag6": "This is the value for tag6",
      }
    }
  }
}
```

b. Step 2: Submit the request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/bulk_add_tags/docs -X POST -d@bulk_of_docs.json -H "Content-Type: application/json"
```

The following response is returned:

```
(200 OK)
{"status": "success"}
```

Endpoints for working with policy management

With the policy management API service, you can create, list, update, and delete the policies.

A policy API consists of the following elements:

pol_id

The name of the policy.

action_id

The action to perform.

action_params

The action contains the following elements:

tags

The type of actions. Currently, the only type of action is the AUTOTAG action. For information about using the AUTOTAG action, see the topic [Adding fields with the AUTOTAG action](#).

pol_filter

A search filter to select a set of documents to work on.

schedule

The schedule for processing the operation:

NOW

The action is done immediately.

dayOfWeek, hour, month, timezone, minute, dayOfMonth

The action is done at the specified time.

Note: The API supports the creation of a schedule by using a timezone parameter. Internally, this information is converted to Coordinated Universal Time (UTC). It is recommended that the timezone parameter is not used or that the default of Coordinated Universal Time (UTC) is used in the API, because the policy schedule time is not displayed in the GUI. The GUI assumes that all times are in Coordinated Universal Time (UTC).

The policy engine runs the specified policy based on the schedule and the action ID that are specified in the API. The policy operations are applied to the documents that are specified by the filter.

- [/policyengine/v1/policies: GET](#) and [/policyengine/v1/policies/<policy_name>: GET](#)
Lists the attributes of one or more policies.
- [/policyengine/v1/policies/<policy_name>/preview: GET](#)
Previews a policy.
- [/policyengine/v1/policies/<policy_name>/status: GET](#)
Gets policy status.
- [/policyengine/v1/policyhistory: GET](#)
Retrieves policy history information for all the policies.
- [/policyengine/v1/policyhistory/<pol_id>/<log_id>: GET](#)
Retrieves the policy run log for a policy execution.
- [/policyengine/v1/policies/<policy_name>/<action>: POST](#)
Applies action to policy.
- [/policyengine/v1/policies -d '<data>': POST](#)
Creates a policy.
- [/policyengine/v1/policies/<policy_name> -d '<data>': PUT](#)
Updates a policy.
- [/policyengine/v1/policies/<policy_name>: DELETE](#)
Deletes a policy.
- [/policyengine/v1/policyhistory: DELETE](#)
Deletes the policy execution history and logs.
- [/policyengine/v1/tags: GET](#)
Retrieves tag definitions.
- [/policyengine/v1/tags/: POST](#)
Updates tags definitions.
- [/policyengine/v1/tags/: PUT](#)
Adds one or more new tags to the list of existing definitions.
- [/policyengine/v1/tags/: DELETE](#)
Deletes an existing tag definition.
- [/policyengine/v1/regex: POST](#)
Registers the regular expression in the IBM Data Cataloging system.
- [/policyengine/v1/regex: GET](#)
Retrieves list of all the regular expressions registered in the IBM Data Cataloging system.
- [/policyengine/v1/regex/<regex_name>: GET](#)
Retrieves a single regular expression detail from the IBM Data Cataloging system.
- [/policyengine/v1/regex: PUT](#)
Updates the regular expressions in the IBM Data Cataloging system.
- [/policyengine/v1/regex: DELETE](#)
Deletes the regular expression with value from the IBM Data Cataloging system.
- [Adding fields with the AUTOTAG action](#)
With the AUTOTAG action you can create policies that automatically add fields either to a specified set of documents or to all the documents in the system.

/policyengine/v1/policies: GET and /policyengine/v1/policies/<policy_name>: GET

Lists the attributes of one or more policies.

These two endpoints list the attributes either of a specified policy or of all the policies in the system. The following table shows which roles can access these two REST API endpoints:

Table 1. Access by role

Endpoints	Data admin	Data user	Collection Admin	Collection user	Admin	Service user
/policyengine/v1/policies: GET	✓	✓	✓ ¹	✓	X	X
/policyengine/v1/policies/<policy_name>: GET	✓	✓	✓ ¹	✓	X	X

¹ Collection Admin user can list, update, and delete policies applied to the collections to which they have the Collection Admin role assigned.

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/policyengine/v1/ policies -X GET -H 'Accept: application/json'
```

or

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/policyengine/v1/ policies/<policy_name> -X GET -H 'Accept: application/json'
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

1. The following example returns information about all the policies that are configured in the system:

a. Issue the following request on one line:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host> /policyengine/v1/policies -X GET -H 'Accept: application/json'
```

b. The following response is returned:

```
[
  {
    "pol_id": "pol1",
    "action_id": "AUTOTAG",
    "action_params": {
      "tags": {
        "tag2": "val2",
        "tag3": "val3"
      }
    },
    "schedule": {
      "dayOfWeek": 4,
      "hour": 5,
      "minute": 15
    },
    "pol_state": "active",
    "pol_filter": "filetype='jpg'",
  },
  {
    "pol_id": "pol2",
    "action_id": "AUTOTAG",
    "action_params": {
      "tags": {
        "tag4": "val4",
        "tag5": "val5"
      }
    },
    "schedule": "NOW",
    "pol_state": "active",
    "pol_filter": "filetype='jpg'",
  }
]
```

2. The following example returns information about the specified policy:

a. Issue the following request on one line:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host> /policyengine/v1/policies/pol1 -X GET -H 'Accept: application/json'
```

b. The following response is returned:

```
[
  {
    "pol_id": "pol1",
    "action_id": "AUTOTAG",
    "action_params": {
      "tags": {
        "tag2": "val2",
        "tag3": "val3"
      }
    },
    "schedule": {
      "dayOfWeek": 4,
      "hour": 5,
      "minute": 15
    },
    "pol_filter": "filetype='jpg'",
    "pol_state": "active"
  }
]
```

/policyengine/v1/policies/<policy_name>/preview: GET

Previews a policy.

This endpoint helps to display policy preview information for a specific policy. The following information is available for preview:

Estimation information

Displays the total count and size of documents. The size of documents on the disk is calculated based on the list of documents the policy applies to and those that are returned.

Execution information

Displays whether the policy has been previously executed or is currently running. The information returned also includes the number and size of documents completed, the start time and, the duration of the policy in seconds.

Policy schedule

Displays the policy schedule, if any.

Policy run time

Displays the future run date and time that has been scheduled for the policy.

The following table displays the roles that can access the REST API endpoint.

Table 1. Access by role

Data admin	Data user	Collection Admin	Collection user	Admin	Service user
✓	✓	✓	✓	X	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/policyengine/v1/policies/policy1/preview -X GET -H 'Accept: application/json'
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example returns the policy preview information about a specific policy that is configured in the system.

Issue the following request in one line:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/policyengine/v1/policies/<policy_name>/preview -X GET -H 'Accept: application/json'
```

The following response is returned:

```
{
  "schedule": {
    "minute": "18",
    "hour": "12",
    "dayOfMonth": "*",
    "month": "*",
    "dayOfWeek": "*",
    "timezone": "UTC"
  },
  "next_run_time": "2020-03-19 12:18PM",
  "estimation_info": {
    "document_count": 152467,
    "total_size": 24935050549,
    "total_size_on_disk": 25610976130
  },
  "execution_info": {
    "start_time": "",
    "duration": 3000,
    "tier_count": 10345,
    "tier_size": 1000000,
    "failed_count": 0
  }
}
```

/policyengine/v1/policies/<policy_name>/status:GET

Gets policy status.

The status endpoint retrieves the policy status information for a specific policy.

The response includes the following information:

- total_count
- completed_count

- failed_count
- submitted_count
- start_time
- end_time

The response returned depends on three possible policy scenarios. These include Never Run, Running, and Finished. If the policy is never executed (Never Run), then the response only returns the policy status.

If the policy is running, the counts mentioned in the preceding list contain the current values and an end time is not returned.

If the policy is finished then the counts contain the final values and an end time is returned.

The following table displays the roles that can access the REST API endpoint.

Table 1. Access by role

Data admin	Data user	Collection Admin	Collection user	Admin	Service user
✓	¹ ✓	¹ ✓	✓	X	X
¹ Users with Collection Admin role can access this endpoint only if they are owners of the policy or can access one or more collections that are included in the policy. Users with Data User role can access the endpoint only if they are owners of the policy.					

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/policyengine/v1/policies/<policy_name>/status -X GET -H 'Accept: application/json'
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example returns policy status information about a specific policy.

Issue the following request in one line:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/policyengine/v1/policies/policy1/status -X GET -H 'Accept: application/json'
```

The following response is returned:

```
{
  "status": "running",
  "total_count": 15000,
  "completed_count": 14000,
  "failed_count": 0,
  "submitted_count": 15000,
  "start_time": "2020-03-27_11:12:10"
}
```

/policyengine/v1/policyhistory: GET

Retrieves policy history information for all the policies.

The /policyengine/v1/policyhistory retrieves the policy execution history details for all the policies that you have permission to view within the system. The entries contain detailed information on the specified policy execution. It also provides the location of the run log file.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Collection user	Admin	Service user
✓	✓	✓	✓	X	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/policyengine/v1/policyhistory -X GET -H 'Accept: application/json'
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example returns the policy history information for all policies for which you have view permissions.

1. Issue the following request in one line.

```
curl -k -H 'Authorization: Bearer ${TOKEN}' https://<data_cataloging_host>/policyengine/v1/policyhistory -X GET
```

2. The following response is returned.

```
[
  {
    "id": 893909178,
    "policyid": "patent_pol",
    "state": "complete",
    "status": null,
    "starttime": "2020-09-22T20:34:32.000Z",
    "endtime": "2020-09-22T20:35:19.000Z",
    "logfile": "/policy_logs/patent_pol-2020-09-22 20:34:32/run.log",

    "failedcount": 9,
    "skippedcount": 0,
    "successcount": 17,
    "totalsize": null,
    "policyfilter": "project='watson_health' and filetype='dcm'",
    "type": "CONTENTSEARCH",
    "additional_info": "{\"explicit\": \"true\"}"
  }
]
```

Response data

The response data can be explained as shown.

id

The response returns the unique run id for the specified policy execution.

policy_id

The response returns the name of the policy that is being run.

state

The response returns the current or final state of the policy execution.

status

The response returns the additional information about the run state (for example, a failure message).

starttime

The response returns the date or timestamp when the policy execution was started.

endtime

The response returns the date or timestamp when the policy execution completes if the policy is not still running.

logfile

The response returns the log file identifier for this policy execution.

startedby

This information field is reserved for future use.

scheduled

This information field is reserved for future use.

totalcount

The response returns the total number of records that meet the policy filter criteria.

failedcount

The response returns the number of records that are marked as failed during the policy execution.

skippedcount

The response returns the number of records that are marked as skipped during the policy execution.

successcount

The response returns the number of records that are marked as successfully processed after the policy execution is completed.

totalsize

This information field is reserved for future use.

policyfilter

The response returns the filter criteria that defined the set of records to be processed in the policy execution.

type
The response returns the type of policy that is being run.

additional_info/explicit
The response returns the Boolean value that displays *True* if the policy execution was for a user-defined policy or *False* if it was run for a system-generated policy.

/policyengine/v1/policyhistory/<pol_id>/<log_id>: GET

Retrieves the policy run log for a policy execution.

This endpoint helps you retrieve and view the policy run log information for all policy executions that you have access to. It provides you with a direct access to the policy execution log data without having to search for it on the file system.

The following table displays the roles that can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Collection user	Admin	Service user
✓	✓	✓	✓	X	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/policyengine/v1/policyhistory/<pol_id>/<log_id> -X GET -H 'Accept: application/json'
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example returns the policy log execution details for the policies that you have access to:

1. Issue the following request in one line.

```
curl -k -H 'Authorization: Bearer ${TOKEN}' https://<data_cataloging_host>/policyengine/v1/policyhistory/patent_pol/893909178 -X GET -H 'Accept: application/json'
```

2. The following response is returned.

```
{
  "log": "[2020-09-22 20:34:32] - Execution beginning for policy (patent_pol)\n[2020-09-22 20:34:33] - Policy status change to (running)\n[2020-09-22 20:34:33] - Policy stats update: {'pol_id': 'patent_pol', 'execution_info': {'start_time': '2020-09-22 20:34:32', 'total_count': 0, 'submitted_count': 0, 'failed_count': 0, 'completed_count': 0, 'skipped_count': 0, 'ctrl_submitted_count': 0, 'ctrl_completed_count': 0, 'contentsearch_count': 0, 'run_id': null}}\n[2020-09-22 20:34:33] - Policy stats update: {'pol_id': 'patent_pol', 'execution_info': {'start_time': '2020-09-22 20:34:32', 'total_count': 7, 'submitted_count': 0, 'failed_count': 0, 'completed_count': 0, 'skipped_count': 0, 'ctrl_submitted_count': 0, 'ctrl_completed_count': 0, 'contentsearch_count': 0, 'run_id': null}}\n[2020-09-22 20:34:35] - Applying action 'CONTENTSEARCH' to 7 documents\n[2020-09-22 20:34:38] - Policy stats update: {'pol_id': 'patent_pol', 'execution_info': {'start_time': '2020-09-22 20:34:32', 'total_count': 7, 'submitted_count': 7, 'failed_count': 0, 'completed_count': 0, 'skipped_count': 0, 'ctrl_submitted_count': 0, 'ctrl_completed_count': 0, 'contentsearch_count': 0, 'run_id': 'ab0d0623dd844fd7b21276fcea892d6ed'}}\n[2020-09-22 20:34:38] - Policy stats update: {'pol_id': 'patent_pol', 'execution_info': {'start_time': '2020-09-22 20:34:32', 'total_count': 7, 'submitted_count': 7, 'failed_count': 0, 'completed_count': 0, 'skipped_count': 0, 'ctrl_submitted_count': 0, 'ctrl_completed_count': 0, 'contentsearch_count': 0, 'run_id': 'ab0d0623dd844fd7b21276fcea892d6ed'}}\n[2020-09-22 20:34:45] - Policy stats update: {'pol_id': 'patent_pol', 'execution_info': {'start_time': '2020-09-22 20:34:32', 'total_count': 7, 'submitted_count': 7, 'failed_count': 0, 'completed_count': 0, 'skipped_count': 0, 'ctrl_submitted_count': 0, 'ctrl_completed_count': 0, 'contentsearch_count': 0, 'run_id': 'ab0d0623dd844fd7b21276fcea892d6ed'}}\n[2020-09-22 20:34:56] - Policy stats update: {'pol_id': 'patent_pol', 'execution_info': {'start_time': '2020-09-22 20:34:32', 'total_count': 7, 'submitted_count': 7, 'failed_count': 0, 'completed_count': 0, 'skipped_count': 0, 'ctrl_submitted_count': 0, 'ctrl_completed_count': 0, 'contentsearch_count': 0, 'run_id': 'ab0d0623dd844fd7b21276fcea892d6ed'}}\n[2020-09-22 20:35:06] - Policy stats update: {'pol_id': 'patent_pol', 'execution_info': {'start_time': '2020-09-22 20:34:32', 'total_count': 7, 'submitted_count': 7, 'failed_count': 0, 'completed_count': 0, 'skipped_count': 0, 'ctrl_submitted_count': 0, 'ctrl_completed_count': 0, 'contentsearch_count': 0, 'run_id': 'ab0d0623dd844fd7b21276fcea892d6ed'}}\n[2020-09-22 20:35:16] - Policy stats update: {'pol_id': 'patent_pol', 'execution_info': {'start_time': '2020-09-22 20:34:32', 'total_count': 7, 'submitted_count': 7, 'failed_count': 0, 'completed_count': 0, 'skipped_count': 0, 'ctrl_submitted_count': 0, 'ctrl_completed_count': 0, 'contentsearch_count': 0, 'run_id': 'ab0d0623dd844fd7b21276fcea892d6ed'}}\n[2020-09-22 20:35:19] - Policy stats update: {'pol_id': 'patent_pol', 'execution_info': {'start_time': '2020-09-22 20:34:32', 'total_count': 7, 'submitted_count': 7, 'failed_count': 0, 'completed_count': 7, 'skipped_count': 0, 'ctrl_submitted_count': 0, 'ctrl_completed_count': 0, 'contentsearch_count': 0, 'run_id': 'ab0d0623dd844fd7b21276fcea892d6ed'}}\n[2020-09-22 20:35:20] - Policy stats update: {'pol_id': 'patent_pol', 'execution_info': {'start_time': '2020-09-22 20:34:32', 'total_count': 7, 'submitted_count': 7, 'failed_count': 0, 'completed_count': 7, 'skipped_count': 0, 'ctrl_submitted_count': 0, 'ctrl_completed_count': 0, 'contentsearch_count': 0, 'run_id': 'ab0d0623dd844fd7b21276fcea892d6ed'}}\n[2020-09-22 20:35:20] - Policy patent_pol run ending\n[2020-09-22 20:35:20] - Policy patent_pol run completed\n[2020-09-22 20:35:20] - Policy status change to (complete)\n"
```

Response data

The response data can be explained as shown.

log

The response returns the policy run log output details that is displayed as a string.

/policyengine/v1/policies/<policy_name>/<action>: POST

Applies action to policy.

This API endpoint helps you start, kill, pause, and resume a policy. You need to add the required action start, pause, resume, kill to the following path: /policyengine/v1/policies/{pol_id}/{action}.

The table shows the roles that can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Collection user	Admin	Service user
✓	¹ ✓	¹ ✓	X	X	X

¹ Users with Collection Admin role can access this endpoint only if they are owners of the policy or can access one or more collections that are included in the policy. Users with Data User role can access this endpoint only if they are owners of the policy.

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/policyengine/v1/policies/policy_name/action -X POST -H 'Content-type: application/json'
```

Supported request types and response formats

Supported request types:

- POST

Supported response formats:

- JSON

Examples

The following example shows how to start a policy by applying the **start** action.

Issue the following request on one line:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/policyengine/v1/pol_2/start -X POST -H 'Content-type: application/json'
```

The following response is returned:

Accepted

/policyengine/v1/policies -d '<data>': POST

Creates a policy.

The /policyengine/v1/policies: **POST** endpoint creates a policy with the characteristics that are specified in the request data. For a description of the request parameters, see [Endpoints for working with policy management](#). The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Collection Admin	Collection user	Data user	Admin	Service user
✓	✓	X	✓ ^{1, 2}	X	X

¹The command allows access only if the schedule attribute is set to NOW.
²The command applies the policy only in collections where the user has a datauser role.

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/policyengine/v1/policies -d '<data>' -X POST -H 'Content-Type: application/json'
```

Supported request types, input fields, and response formats

Supported request types:

- POST

Supported response formats:

- JSON

Examples

1. The following example creates an AUTOTAG policy named **pol2** to start immediately:

- a. Issue the following request on one line:

```
curl -k -H 'Authorization: Bearer <token>'
https://<data_cataloging_host>/policyengine/v1/policies
-d '{
  "pol_id": "pol2",
  "pol_filter": "user='research1'",
  "action_id": "AUTOTAG",
  "action_params": { "tags": { "tag4": "val4", "tag5": "val5" } },
  "schedule": "NOW"
}'
-X POST -H "Content-Type: application/json"
```

- b. The following response is returned:

```
Policy 'pol2' added
```

2. The following example creates a AUTOTAG policy named **pol2** to start at a scheduled time:

Note: For information about using the AUTOTAG action, see the topic [Adding fields with the AUTOTAG action](#).

- a. Issue the following request on one line:

```
curl -k -H 'Authorization: Bearer <token>'
https://<data_cataloging_host>/policyengine/v1/policies
-d '{
  {
    "pol_id": "pol2",
    "action_id": "AUTOTAG",
    "action_params": {
      "tags": { "test_tag1": "test1" }
    },
    "pol_filter": "filename LIKE 'f0%'",
    "schedule": {
      "dayOfWeek": "*",
      "hour": "13",
      "month": "*",
      "timezone": "UTC",
      "minute": "31",
      "dayOfMonth": "*"
    }
  }
}'
-X POST -H "Content-Type: application/json"
```

Note: The API supports the creation of a schedule using a **timezone** parameter. Internally this is converted to Coordinated Universal Time (UTC). It is recommended that the **timezone** parameter is not used or that the default of Coordinated Universal Time (UTC) is used in the API, because the policy schedule time is not displayed in the GUI. The GUI assumes all times are in UTC.

- b. The following response is returned:

```
Policy 'pol2' added
```

To verify that the policy is created, issue a GET request to list the information about the specified policy or about all the policies in the system. For more information, see [/policyengine/v1/policies: GET](#) and [/policyengine/v1/policies/<policy_name>: GET](#).

/policyengine/v1/policies/<policy_name> -d '<data>': PUT

Updates a policy.

The `/policyengine/v1/policies/<policy_id> -d '<data>'` endpoint updates an existing policy with the attribute values that are specified in the request data. Attributes that are not updated keep the same values that they had before the update. The following attributes can be updated: **action_parameters**, **schedule**, **pol_filter**, and **pol_state**. The **action_id** attribute cannot be updated. However, you can delete an existing policy and then create a new one with the same name and attributes as the deleted policy but with a different **action_id**. For more information about the attributes in the request data, see [Endpoints for working with policy management](#).

Note: You cannot update a policy while it is running.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Collection user	Admin	Service user
✓	✓ ^{1,2}	X	X	X	X
¹ The command allows access only if the schedule attribute is set to NOW.					
² The command applies the policy only in collections where the user has a datauser role.					

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/policyengine/v1/policies/<policy_name> -d '<data>' -X
PUT -H "Content-Type: application/json"
```

Supported request types and response formats

Supported request types:

- PUT

Supported response formats:

- JSON

Examples

1. The following example updates a policy named pol2:

a. Issue the following request on one line:

```
curl -k -H 'Authorization: Bearer \<token>'
https://<data_cataloging_host>
/policyengine/v1/policies/<policy_name>
-d '{
  "pol_filter": "user='research1'",
  "pol_state": "active"
  "action_params": {"tags": {"tag4": "val4", "tag5": "val5"}},
  "schedule": "NOW"
}'
-X POST -H "Content-Type: application/json"
```

b. The following response is returned:

```
Policy 'pol2' updated
```

To verify that the policy is created, issue a GET request to list the information about the specified policy or about all the policies in the system. For more information, see [/policyengine/v1/policies: GET](#) and [/policyengine/v1/policies/<policy_name>: GET](#).

/policyengine/v1/policies/<policy_name>: DELETE

Deletes a policy.

The `/policyengine/v1/policies/<policy_name>: DELETE` endpoint deletes the specified policy. The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	✓	X	X	X

Important: You cannot delete the "Collection" and "Temperature" tags.

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/policyengine/v1/policies/pol2 -X DELETE
```

Supported request types and response formats

Supported request types:

- DELETE

Supported response formats:

- JSON

Examples

1. The following example deletes a policy named pol2:

a. Issue the following request on one line:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/policyengine/v1/policies/<policy_name> -X
POST
```

b. The following response is returned:

```
Deleted policy pol2
```

To verify that the policy is deleted, issue a GET request to list the information about the specified policy or about all the policies in the system. For more information, see [/policyengine/v1/policies: GET](#) and [/policyengine/v1/policies/<policy_name>: GET](#).

/policyengine/v1/policyhistory: DELETE

Deletes the policy execution history and logs.

This endpoint helps you delete the policy execution history and logs of all policies that you can access.

The following table displays the roles that can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Collection user	Admin	Service user
✓	✓	✓	X	X	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/policyengine/v1/policyhistory -X DELETE -H 'Accept: application/json' [-d '{"days_older_than": <int>}']
```

Note: You can specify an override to the default retention of 30 days in the JSON input data field, `{"days_older_than": <int>}`. When specified, it ensures that only the policy history records and log files that are older than the input value provided, are removed.

Supported request types and response formats

Supported request types:

- DELETE

Supported response formats:

- JSON

Examples

The following example deletes the policy history entries and run logs, for any policy executions that you have permission to view and that are older than 30 days.

1. Issue the following request in one line.

```
curl -k -H 'Authorization: Bearer ${TOKEN}' https://<data_cataloging_host>/policyengine/v1/policyhistory -X DELETE -H 'Accept: application/json'
```

2. The following response is returned.

```
[{"status": "Success. Deleted 12 policy history records."}]
```

Response data

The response data can be explained as shown.

status

The response returns an indication whether the request succeeded or failed. For a successful request, this information field also indicates the number of policy execution history entries and the corresponding log files that were purged.

/policyengine/v1/tags: GET

Retrieves tag definitions.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Collection user	Admin	Service user
✓	✓	✓	✓	X	X

Synopsis of the request URL

```
$ curl -H "Authorization: Bearer <token>" -k https://<data_cataloging_host>:443/policyengine/v1/tags
```

Supported request types and response formats

Supported request types:

- GET

Note: When a request type is not specified, curl defaults to a GET operation.

Supported response formats:

- JSON

Examples

The following response is returned:

```
[
  {
    "tag": "project",
    "type": "Open",
    "value": "[]"
  },
  {
    "tag": "chargeBack",
    "type": "Restricted",
    "value": "[\"dept1\", \"dept2\", \"dept3\"]"
  },
  {
    "tag": "classification",
    "type": "Restricted",
    "value": "[\"public\", \"confidential\", \"internal\", \"restricted\", \"other\"]"
  },
  {
    "tag": "demotag",
    "type": "Open",
    "value": "[]"
  },
  {
    "tag": "instrument",
    "type": "Restricted",
    "value": "[\"spectrometer\", \"microscopeA\", \"microscopeB\"]"
  }
]
```

/policyengine/v1/tags/: POST

Updates tags definitions.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Collection user	Admin	Service user
√ ¹	√ ²	√	X	X	X
¹ Has read/write access to 'Open', 'Restricted', and 'Characteristics' types of tags.					
² Has read-only access to 'Open' and 'Restricted' types of tags, and read/write access to 'Characteristics' tags.					

To create an 'Open' tag, run this command:

```
$ curl -k -H "Authorization: Bearer <token>" https://<data_cataloging_host>:443/policyengine/v1/tags -d '{"tag": "project", "type": "Open"}' -X POST -H "Content-Type: application/json"
```

Synopsis of the request URL

```
$ curl -k -H "Authorization: Bearer <token>" https://<data_cataloging_host>:443/policyengine/v1/tags -d '{"tag": "department", "type": "Restricted", "value": ["Finance", "HR", "IT"]}' -X POST -H "Content-Type: application/json"
```

```
$ curl -k -H "Authorization: Bearer <token>" https://<data_cataloging_host>:443/policyengine/v1/tags -d '{"tag": "annotations", "type": "Characteristics"}' -X POST -H "Content-Type: application/json"
```

Supported request types and response formats

Supported request types:

- POST
- Specify one of the following tag "type" options:

```
"Open" | "Restricted" | "Characteristics"
```

Note:

- "Open" allows the unrestricted setting of tag values with a maximum string length of 256 characters.
- "Restricted" allows the definition of specified tag values with a maximum string length of 256 characters.
- "Characteristics" allows the definition of unspecified tag values with a maximum string length of 4096 characters.

Supported response formats:

- JSON

/policyengine/v1/tags/: PUT

Adds one or more new tags to the list of existing definitions.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection admin	Collection user	Admin	Service user
√ ¹	√ ²	√	X	X	X
¹ READ/WRITE access to 'Open', 'Restricted', and 'Characteristics' types of tags.					
² READ Only access to 'Open' and 'Restricted' types of tags, READ/WRITE access to 'Characteristics' tags.					

Synopsis of the request URL

```
$ curl -H "Authorization: Bearer <token>" -k https://<data_cataloging_host>:443/policyengine/v1/tags/<tag_name> -d '{"value": ["dept1", "dept2", "dept3", "dept4"]}' -X PUT -H "Content-Type: application/json"
```

Supported request types and response formats

Supported request types:

- PUT

Supported response formats:

- JSON

Note: Tag **payload** update requests are applied to the existing tag. Update tag requests overwrite the existing attributes of a tag. However, you cannot change the tag type.

/policyengine/v1/tags/: DELETE

Deletes an existing tag definition.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Collection user	Admin	Service user
√ ¹	X ²	X	X	X	X
¹ For read/write access to 'Open', 'Restricted', and 'Characteristics' types of tags.					
² For read-only access to 'Open' and 'Restricted' types of tags, and read/write access to 'Characteristics' tags.					

Important: You cannot delete the "Collection" and "Temperature" tags.

Synopsis of the request URL

```
$ curl -H "Authorization: Bearer <token>" -k https://<data_cataloging_host>:443/policyengine/v1/tags/<tag_name> -X DELETE
```

Supported request types and response formats

Supported request types:

- DELETE

Supported response formats:

- JSON

Examples

1. If a tag specified from the set of currently defined tags is "in-use" (its nondefault value is set in at least one document) the delete tag operation returns an error:

```
< HTTP/1.0 403 FORBIDDEN
< Content-Type: text/html; charset=utf-8
< Content-Length: 102
< Server: Werkzeug/0.14.1 Python/2.7.5
< Date: Wed, 09 May 2018 17:20:05 GMT
<
Cannot delete tag <tag_name> because it is in use in '38' records. Force deletion with
'force' option.
```

2. To force deletion of an in-use tag, use the 'force' option as follows:

```
$ curl -H "Authorization: Bearer <token>" -k https://<data_cataloging_host>:443/policyengine/v1/tags/<tag_name> -X DELETE -d '{"force": "true"}' -H "Content-Type: application/json"
```

Important: The force option results in the deletion of the tag and its values are set by default to **NULL** or empty string.

/policyengine/v1/regex: POST

Registers the regular expression in the IBM Data Cataloging system.

The table shows the roles that can perform create operation on the endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	✓	✓	X	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://$SDHOST/policyengine/v1/regex -d @regex.json -H "Content-type:application/json" -X POST
```

Supported request types and response formats

Supported request types:

- POST

Supported response formats:

- JSON

Examples

The following example shows how to register a regular expression.

Issue the following request on one line:

```
curl -k -H "Authorization: Bearer ${TOKEN}" https://$SDHOST/policyengine/v1/regex -d @regex.json -H "Content-type:application/json" -X POST
```

Example: Request JSON file

```
{
  "regex_id": "US-SSN-blank-delimited",
  "pattern": "\\b\\d{3}\\s\\d{2}\\s\\d{4}\\b",
  "description": "US SSN delimited by white space, not dashes."
}
```

The following response is returned:

201 (Created)

/policyengine/v1/regex: GET

Retrieves list of all the regular expressions registered in the IBM Data Cataloging system.

The following table shows roles that can perform read operation on the endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	✓	✓	X	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://$SDHOST/policyengine/v1/regex -X GET -H 'Accept: application/json'
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example returns all the regular expressions registered for which you have read permission.

1. Issue the following request in one line.

```
curl -k -H "Authorization: Bearer ${TOKEN}" https://$SDHOST/policyengine/v1/regex -X GET
```

2. The following response is returned.

200 (OK)

[

```

{
  "regex_id": "EmailID",
  "pattern": "\\b[\\w\\.-]+@[\\w\\.-]+\\.([\\w]{2,3})\\.b",
  "description": "Matching Email IDs like : John.Smith@example.com"
},
{
  "regex_id": "US-SSN",
  "pattern": "\\b\\d{3}-\\d{2}-\\d{4}\\.b",
  "description": "Matching United States Social Security Numbers (SSN) like: 513-84-7329"
},
{
  "regex_id": "IPV4-Address",
  "pattern": "\\b([\\d]{1,3}\\.){3}[\\d]{1,3}\\.b",
  "description": "Matching IPV4 address like: 192.168.1.1"
},
{

  "description": "Matching Credit Card Verification Value number like: 670,0927"
},
{
  "regex_id": "Currency",
  "pattern": "\\b(\\d+(\\.\\d{2})?)\\.b",
  "description": "Matching currency like: 123, 25.50"
}
}

```

/policyengine/v1/regex/<regex_name>: GET

Retrieves a single regular expression detail from the IBM Data Cataloging system.

The following table shows the roles that can perform read operation on the endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
------------	-----------	------------------	-------	--------------

Data admin	Data user	Collection Admin	Admin	Service user
✓	✓	✓	X	X

Synopsis of the request URL

```
curl -k -H "Authorization: Bearer ${TOKEN}" https://$SDHOST/policyengine/v1/regex/$REGEXNAME -H "Content-type:application/json" -X GET
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example returns the single regular expression detail registered for which you have read permission.

1. Issue the following request in one line.

```
curl -k -H "Authorization: Bearer ${TOKEN}" https://$SDHOST/policyengine/v1/regex/EmailID -H "Content-type:application/json" -X GET
```

2. The following response is returned.

```
200 (OK)
{
  "regex_id": "EmailID",
  "pattern": "\\b[\\w\\.\\-]+@[\\w\\.\\-]+\\.([\\w]{2,3})\\b",
  "description": "Matching Email IDs like : John.Smith@example.com"
}
```

/policyengine/v1/regex: PUT

Updates the regular expressions in the IBM Data Cataloging system.

The table shows the roles that can perform update operation on the endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	✓	✓	X	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://$SDHOST/policyengine/v1/regex -d @regex.json -H "Content-type:application/json" -X PUT
```

Supported request types and response formats

Supported request types:

- POST

Supported response formats:

- JSON

Examples

The following example shows how to update a regular expression.

Issue the following request on one line:

```
curl -k -H "Authorization: Bearer ${TOKEN}" https://$SDHOST/policyengine/v1/regex -d @regex.json -H "Content-type:application/json" -X PUT
```

Example: Request JSON payload

```
{
  "regex_id": "US-SSN-blank-delimited",
  "pattern": "\\b\\d{3}\\s\\d{2}\\s\\d{4}\\b",
  "description": "US SSN delimited by white space, not dashes."
}
```

The following response is returned:

/policyengine/v1/regex: DELETE

Deletes the regular expression with value from the IBM Data Cataloging system.

The table shows the roles that can perform delete operation on the endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	X	X	X

Synopsis of the request URL

```
curl -k -s -o response.txt -H "Authorization: Bearer ${TOKEN}" https://${SDHOST}/policyengine/v1/regex/${REGEX_NAME} -X DELETE
```

Supported request types and response formats

Supported request types:

- DELETE

Supported response formats:

- JSON

Examples

The following example shows how to delete a regular expression record.

Issue the following delete request:

```
curl -k -s -o response.txt -H "Authorization: Bearer ${TOKEN}" https://${SDHOST}/policyengine/v1/regex/US-SSN-blank-delimited -X DELETE
```

The following response is returned:

204 (No Content)

Note: When you perform DELETE operation, the resource gets deleted successfully but there is no response message in the output.

Adding fields with the AUTOTAG action

With the AUTOTAG action you can create policies that automatically add fields either to a specified set of documents or to all the documents in the system.

Two methods are available for adding new fields. One method is to add fields that contain initial values. The other method is to add fields that contain values that are extracted from existing fields of the same document. The following topics describe these two methods.

For more information about creating a policy, see the topic [/policyengine/v1/policies -d '<data>': POST](#).

- [Adding fields that contain initial values](#)
With the AUTOTAG action you can create a policy that automatically adds fields with initial values to a specified set of documents.
- [Adding fields that are extracted by rule from existing fields](#)
Create a new field whose value is extracted from an existing field.

Adding fields that contain initial values

With the AUTOTAG action you can create a policy that automatically adds fields with initial values to a specified set of documents.

This method is useful when you want to add fields to a set of documents and you know beforehand the values that you want the fields to contain. For example, you might want to add a "billingaddress" field that contains the initial value "100 Corporation Street, Metropolis, USA" to every document that has a "username" field that contains the value "mjsmith". Or you might want to add an "ownerid" field that contains the initial value "admin02" to every document that lies in a certain directory path.

For more information about creating a policy, see the topic [/policyengine/v1/policies -d '<data>': POST](#).

The following example shows how to create a policy that adds a project number and a department code to each document that contains a particular user name:

```
$ curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/policyengine/v1/policies/autotagpoll -d '{ "pol_filter": "user='research1'", "action_id": "AUTOTAG", "action_params": { "tags": { "ProjectNumber": "1404", "DepartmentCode": "H8AC" } } }
```

```
"schedule": "NOW"
}',
-X POST -H "Content-Type: application/json"
```

The preceding example adds the fields "ProjectNumber": "1404" and "DepartmentCode": "H8AC" to every document in which the "user" field is set to 'research1'.

Adding fields that are extracted by rule from existing fields

Create a new field whose value is extracted from an existing field.

With the **AUTOTAG** action you can create a policy that adds a field to a document, where the new field contains a value that is extracted by rule from an existing field in the same document. Two types of rule are available. With the first type of rule, you can extract a value from an existing field by parsing tokens in the field value that are separated by a specified delimiter. With the second type of rule, you can extract a value from an existing field by searching the field value with a regular expression. Note: The new field can contain a maximum of 256 characters. If the extracted value contains more than 256 characters, it is trimmed to 256 characters before it is assigned to the new field.

In the following two examples, the documents contain a **filepathActiveUsers** field in which the parts of the path are separated by forward slashes (/) and in which the second part of the path contains the project name. For example:

```
"filepathActiveUsers": "'/Lab1/ProjectHA48/users/active'"
```

You want to add a field **projectname** that contains the project name, and you want to add the field to all documents that contain the field **user**: **'research1'**.

1. The first example shows how to extract the project name by parsing the path into tokens that are separated by a forward slash. Follow these steps:
 - a. Create a file `autotag_rule_pol_split.dat` that contains the parameters for the new policy. The following code block shows the contents of the file:

```
{
  "action_id": "AUTOTAG",
  "action_params": {
    "rule": {
      "name": "setFromExistingField",
      "action": "split",
      "existingField": "filepathActiveUsers",
      "delimiter": "/",
      "fieldNo": 2,
      "newField": "projectname"
    }
  },
  "schedule": "NOW",
  "pol_filter": "user='research1'"
}
```

- b. Create the policy and apply it:

```
curl -k -H 'Authorization: Bearer <token>'
https://<data_cataloging_host>/policyengine/v1/policies/autotagpol2
-d @autotag_rule_pol_split.dat
-X POST
-H "Content-Type: application/json"
```

The policy extracts the second token, the project name, from the path and assigns the value to the new field **projectname**.

2. The second example shows how to extract the project name from the path with a regular expression. Follow these steps:
 - a. Create a file `autotag_rule_pol_regex.dat` that contains the parameters for the new policy. The following code block shows the contents of the file:

```
{
  "action_id": "AUTOTAG",
  "action_params": {
    "rule": {
      "name": "setFromExistingField",
      "action": "regex",
      "existingField": "filepathActiveUsers",
      "regexPattern": "[^/]+",
      "matchNo": 3,
      "newField": "projectname"
    }
  },
  "schedule": "NOW",
  "pol_filter": "user='research1'"
}
```

- b. Create the policy and apply it:

```
curl -k -H 'Authorization: Bearer <token>'
https://<data_cataloging_host>/policyengine/v1/policies/autotagpol2
-d @autotag_rule_pol_regex.dat
-X POST
-H "Content-Type: application/json"
```

The policy extracts the third match to the regex pattern, the project name, from the path and assigns the value to the new field **projectname**.

Endpoints for working with connection management

With the connection management API service you can create, update, delete, and get information about data source connection entries in the connection table.

A data source connection contains the following attributes:

name
Indicates the name of the connection.

type
Indicates the type of the connection.

cluster
Indicates the cluster in which the data source is located.

datasource
Indicates the file system or vault in which the data is stored.

site
Indicates the location in which the cluster is maintained.

Note: To determine cluster and data source values for a connection in an IBM Spectrum Scale cluster, follow these steps:

1. Open a console on a node in the IBM Spectrum Scale cluster.
2. Run the following command to get information about the cluster:

```
/usr/lpp/mmfs/bin/mmfscluster
```

The command output displays information about the cluster similar to the following example:

```
GPFS cluster information
=====
GPFS cluster name:      modevml9.metro.labs.cpr.com
GPFS cluster id:       7146749509622277333
GPFS UID domain:       modevml9.metro.labs.cpr.com
Remote shell command:  /usr/bin/ssh
Remote file copy command: /usr/bin/scp
Repository type:       CCR

Node  Daemon node name      IP address  Admin node name      Designation
-----
1     modevml9.metro.labs.cpr.com  9.11.201.74 modevml9.metro.labs.cpr.com quorum-manager
```

3. Make a note of the IBM Spectrum Scale cluster name, which in the preceding example is `modevml9.metro.labs.cpr.com`. Use this value as the `cluster` attribute for the connection.
4. Run the following command to get information about all the mounted file systems in the cluster:

```
/usr/lpp/mmfs/bin/mmfsmount all
```

The command output displays information about mounted file systems as in the following example:

```
File system gpfs0 is mounted on 1 nodes.
```

5. Make a note of the name of the file system that you want to create a connection for. For example, in the preceding example only one file system is mounted and its name is `gpfs0`. Use this value as the `datasource` attribute for the connection.
- [/connmgr/v1/connections: GET](#) and [/connmgr/v1/connections/<connection_name>: GET](#)
Lists the attributes of one or more connections.
 - [/connmgr/v1/scan/<connection>/partitions: GET](#)
Gets the list of fileset (IBM Storage Scale) or Shares (SMB/CIFS) on the target system.
 - [/connmgr/v1/connections -d '<data>': POST](#)
Creates a connection.
 - [/connmanager/v1/scan/<connection>/partial: POST](#)
Initiates a partial scan of the datasource connection.
 - [/connmgr/v1/connections/<connection_name> -d '<data>': PUT](#)
Updates a connection.
 - [/connmgr/v1/connections/<connection_name>: DELETE](#)
Deletes a connection.
 - [/connmgr/v1/scan/<connection_name>: POST](#)
Starts the scan of a connection.
 - [/connmgr/v1/scan/<connection_name>: GET](#)
Gets the current scan status of a single connection.
 - [/connmgr/v1/scan: GET](#)
Gets the scan status of all running scans.
 - [/connmgr/v1/scan/<connection_name>: PUT](#)
Stops a scan.

/connmgr/v1/connections: GET and /connmgr/v1/connections/<connection_name>: GET

Lists the attributes of one or more connections.

These two endpoints list the attributes either of a specified connection or of all the connections in the connection table. The following table shows which roles can access these two REST API endpoints:

Table 1. Access by role

Endpoints	Data admin	Data user	Collection Admin	Admin	Service user
/connmgr/v1/connections: GET	✓	X	✓	X	X
/connmgr/v1/connections/<connection_name>: GET	✓	X	✓	X	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/connmgr/v1/ connections -X GET
```

or

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/connmgr/v1/ connections/<connection_name> -X GET
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON
- text/plain

Examples

1. The following example returns information about all the connections in the connection table:

a. Run the following request on one line:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/connmgr/v1/connections -X GET -H 'Accept: application/json'
```

The following response is returned. The response lists the information for all the connections in the connections table. For example, this table contains two connections, `con01` and `con02`:

```
[
  {
    "name": "con01",
    "type": "general",
    "cluster": "modevml9.metro.labs.cpr.com",
    "datasource": "gpfs0",
    "site": "datasite03"
  },
  {
    "name": "con02",
    "type": "general",
    "cluster": "modevml9.metro.labs.cpr.com",
    "datasource": "gpfs1",
    "site": "datasite03"
  }
]
```

2. The following example returns information about connection `con02`:

a. Run the following request on one line:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/connmgr/v1/connections/con02 -X GET -H 'Accept: application/json'
```

The following response is returned:

```
[
  {
    "name": "con02",
    "type": "general",
    "cluster": "modevml9.metro.labs.cpr.com",
    "datasource": "gpfs1",
    "site": "datasite03"
  }
]
```

/connmgr/v1/scan/<connection>/partitions: GET

Gets the list of fileset (IBM Storage Scale) or Shares (SMB/CIFS) on the target system.

This API endpoint fetches the list of filesets (IBM Storage Scale) or shares (SMB/CIFS) on the target system. Only an IBM Data Cataloging user with the data admin role can get the list of partitions.

The following table displays the roles that can access the REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	¹ ✓	X	X

¹ The Collection Admin user, can list the partitions for connections assigned to the collections which are assigned to them.

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/connmgr/v1/scan/<connection_name>/partitions -X GET
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

1. The following example returns partition (fileset) information from an IBM Storage Scale connection:

```
• Run the following request on one line:

curl -k -H 'Authorization: Bearer <token>'
https://<data_cataloging_host>/connmgr/v1/scan/ssl -X GET -H 'Accept: application/json'

{"root", "fileset1", "fileset2"}
```

2. The following example returns partition (share) information from an SMB/CIFS connection:

```
Run the following request on one line:

curl -k -H 'Authorization: Bearer <token>'
https://<data_cataloging_host>/connmgr/v1/scan/smb1 -X GET -H 'Accept: application/json'

{"root", "dir1"}
```

/connmgr/v1/connections -d '<data>': POST

Creates a connection.

The /connmgr/v1/connections -d '<data>': POST endpoint creates a new connection entry in the connections table. The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	X	X	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/connmgr/v1/connections/ -d '<data>' -X POST -H "Content-Type: application/json"
```

Supported request types, input fields, and response formats

Supported request types:

- POST

Supported input fields:

JSON input is expected. Use a **Content type: application/json** header in the HTTP protocol request.

- name
The unique name of this connection.
- cluster
The cluster ID of the IBM Storage Scale cluster or IBM Cloud® Object Storage system UUID.
- platform
["Spectrum Scale" | "IBM® COS" | "NFS" | "S3" | "IBM Storage Protect"] | "SMB/CIFS"
- datasource
Name of individual filesystem or vault. (For example, **scratch**)
- site
Physical location of data from this connection. This field is optional.
- host
The hostname or IP address of the interface node for scanning. This field is not mandatory for creating a connection, but is required for automated scan support.
- mount_point
The network path to be scanned. This field is only used for NFS and SMB/CIFS connections. For any other connection types, it is an optional field. For NFS, the 'mount_point' is the export path, for example, /export1/dir1. For SMB/CIFS, the 'mount_point' is the network share path, for example, \\SMBSERVER\share1\.
- user
The username to connect to the source data system with. This field is not mandatory for creating a connection but is required for automated scan support.
- password
The password on the source data system belonging to the user ID specified earlier. This field is not mandatory for creating a connection, but is required for automated scan support for connections other than NFS.
- additional_info
Connection-type specific information. This field is not mandatory for creating a connection, but is required for automated scan support. This information varies by platform as follows:
 - IBM Cloud Object Storage (IBM COS)
 - accessor_address
The hostname or IP address of the IBM COS accessor system.

accesser_access_key
the access key for the corresponding accessor address specified by the **accesser_address**.

accesser_secret_key
The accessor's secret key, corresponding to the IBM COS **accesser_address**.

manager_username
User name of the manager for the IBM COS system.

manager_password
Password of the IBM COS manager user name specified earlier.

SMB/CIFS

auth_type
Denotes SMB authentication type parameter.

IBM Storage Scale

working_dir
Directory on the IBM Storage Scale system to be used for the IBM Data Cataloging files used during scans of the IBM Storage Scale file system. This directory must exist before the connection is established.

nodes
Specify a list of one or more nodes in the IBM Storage Scale cluster or the keyword **all** to enable the IBM Data Cataloging scans to execute across all nodes. The node names must match the names used by the IBM Storage Scale cluster configuration. For example, the nodes shown by the **mmlscluster** command executed on a node.

scan_dir
The directory path within the IBM Storage Scale file system that is to be scanned. For example, **/scale/zoo**.

NFS

NFSv4
Denotes NFS protocol.

S3

access_key
Access key for the S3 data connection.

secret_key
The secret key corresponding to this S3 data connection.

IBM Storage Protect

port
The Open Database Connector (ODBC) port for the IBM Storage Protect server. This field is set to **51500** by default.

Supported response formats:

- JSON

Examples

1. The following example creates a connection that is named con01:

- a. Issue the following request on one line:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/connmgr/v1/connections -d '{"name":"con01","platform":"Spectrum Scale","cluster":"modevml9.metro.labs.cpr.com","datasource":"gpfs1","site":"datasite03"}' -X POST -H "Content-Type: application/json"
```

- b. The following response is returned:

```
Connection 'con01' added
```

To verify that the connection is created, issue a GET request to list the information about the specified connection or about all the connections in the connection table. For more information, see [/connmgr/v1/connections: GET and /connmgr/v1/connections/<connection_name>: GET](#).

2. The following examples demonstrate to create a connection using SMB parameter **auth_type** and NFSv4 protocol:

- POST request using SMB parameter **auth_type**

```
curl -s -k -H "Authorization: Bearer <token>" -H "Content-Type: application/json" -X POST http://<data_cataloging_host>/connmgr/v1/connections -d '{"name":"perffs","platform":"Spectrum Scale","cluster":"gkscale4app-nd-1.fyre.ibm.com","datasource":"perffs","site":"svl","host":"host_ip","user":"root","password":"P@ssw0rd","additional_info":{"working_dir":"/gpfs/perffs","nodes":"all","scan_dir":"/gpfs/perffs","auth_type":"password"}}'
```

- POST request using NFS protocol **NFSv4**

```
curl -s -k -H "Authorization: Bearer <token>" -H "Content-Type: application/json" -X POST <data_cataloging_host>/connmgr/v1/connections -d '{"name":"nfs4test","platform":"NFS","cluster":"cluster1","datasource":"nfs4test","site":"Tucson","host":"<host_ip>","mount_point":"/ifs/sdiscover/Data/nfs4test","protocol":"nfs"}'
```

/connmanager/v1/scan/<connection>/partial: POST

Initiates a partial scan of the datasource connection.

This API endpoint initiates a partial scan of the datasource connection by specifying a list of one or more partitions to be scanned.

The table shows the roles that can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	¹ ✓	X	X

¹Collection Admin users can initiate a partial scan of connections for collections to which they have been assigned.

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>'
https://<data_cataloging_host>/connmanager/v1/scan/connection/partial -X POST -H 'Content-type: application/json'
```

Supported request types and response formats

Supported request types:

- POST

Supported input fields:

- JSON input in the following form:

```
{"partitions": ["partition1", "partition2", "etc."]}
```

- JSON input in the following form for NFS partial scanning:

```
{"partitions": [{"dir": "/exports/example/a", "recursive": true}, {"dir": "/exports/example/b", "recursive": false}]}
```

where each subdirectory to scan is an item of the array with the following structure:

```
{
  "dir": "/exports/example/a", // Directory path that starts with the mount point of the NFS connection
  "recursive": false // true if directories inside of the provided path should be scanned recursively
}
```

Supported response formats:

- JSON
Returns the status of whether or not the scan was started successfully. Error messages are displayed if JSON is malformed or if a specified partition is not found on the filesystem.

Examples

Issue the following request in one line:

```
curl -k -H 'Content-Type: application/json' -X POST
https://<data_cataloging_host>/connmgr/v1/scan/smb1/partial -H "Accept:application/json" -H "Content-type: application/json"
-X POST -d '{"partitions": [{"dir1"}]}'
```

Issue the following NFS partial scan request:

```
curl -k -H 'Content-Type: application/json' -X POST
https://<data_cataloging_host>/connmgr/v1/scan/nfs-1/partial -H "Accept:application/json" -H "Content-type: application/json"
-X POST -d '{"partitions": [{"dir": "/exports/data", "recursive": true}]}'
```

The following response is returned:

```
{"status": "Success"}
```

/connmgr/v1/connections/<connection_name> -d '<data>': PUT

Updates a connection.

The /connmgr/v1/connections/<connection_name> -d '<data>': PUT endpoint updates an existing connection with the attribute values that are specified in the request data. Attributes that are not updated keep the same values that they had before the update. The following attributes can be updated: **name**, **type**, **cluster**, **datasource**, and **site**. For more information about the attributes in the request data, see [Endpoints for working with connection management](#). The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	X	X	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/connmgr/v1/ connections/<connection_name> -d '<data>' -X PUT -H "Content-Type: application/json"
```

Supported request types, input fields, and response formats

Supported request types:

- PUT

Supported input fields:

JSON input is expected. Use a **Content type: application/json** header in the HTTP protocol request.

name

The unique name of this connection.

cluster

The cluster ID of the IBM Storage Scale cluster or IBM Cloud® Object Storage system UUID.

platform

["Spectrum Scale" | "IBM® COS" | "NFS" | "S3" | "IBM Storage Protect"].

datasource

Name of individual file system or vault. For example, **scratch**.

site

Physical location of data from this connection. This field is optional.

host

The hostname or IP address of the interface node for scanning. This field is not mandatory for creating a connection, but is required for automated scan support.

user

The username to connect to the source data system with. This field is not mandatory for creating a connection, but is required for automated scan support.

password

The password on the source data system belonging to the user ID specified in the previous field. This field is not mandatory for creating a connection, but is required for automated scan support.

additional_info

Connection-type specific information. This field is not mandatory for creating a connection, but is required for automated scan support.

Supported response formats:

- JSON

Examples

1. The following example updates connection **con01** to **con02**:

a. Issue the following request on one line:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/connmgr/v1/ connections/con01 -d '{"name": "con02", "platform": "Spectrum Scale", "cluster": "modevml9.metro.labs.cpr.com", "datasource": "gpfs1", "site": "datasite03"}' -X PUT -H "Content-Type: application/json"
```

b. The following response is returned:

```
Connection 'con02' updated
```

To verify that the policy is updated, issue a GET request to list the information about the specified connection or about all the connections in the system. For more information, see [/connmgr/v1/connections: GET](#) and [/connmgr/v1/connections/<connection_name>: GET](#).

/connmgr/v1/connections/<connection_name>: DELETE

Deletes a connection.

The `/connmgr/v1/connections/<connection_name>: DELETE` endpoint deletes the specified connection from the connection table. The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	X	X	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/connmgr/v1/ connections/<connection_name> -X DELETE
```

Supported request types and response formats

Supported request types:

- DELETE

Supported response formats:

- JSON

Examples

1. The following example deletes a connection named con02:

- a. Issue the following request on one line:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/connmgr/v1/connections/con02 -X DEL
```

- b. The following response is returned:

```
Connection 'con02' deleted
```

To verify that the connection is deleted, issue a GET request to list the information about the specified connection or about all the connections in the connection table. For more information, see [/connmgr/v1/connections: GET](#) and [/connmgr/v1/connections/<connection_name>: GET](#).

/connmgr/v1/scan/<connection_name>: POST

Starts the scan of a connection.

The `/connmgr/v1/scan/<connection_name>`: POST endpoint starts the scan of a connection. Only an IBM Data Cataloging user with data admin role or collection admin role can start a scan. The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	✓ ¹	X	X

¹ Collection Admin user can start, stop, and get the status of the scans that are applied to the collections to which they have the Collection Admin role assigned.

Synopsis of the request URL

```
curl -k -H "Authorization: Bearer <token>" -X POST https://<data_cataloging_host>/connmgr/v1/scan/<connection_name>
```

Supported request types, input fields, and response formats

Supported request types:

- POST

Supported response formats:

- JSON

Examples

Follow these steps to start a scan:

1. Obtain an auth token by using the credentials of the data admin user as shown:

```
curl -k https://<data_cataloging_host>/auth/v1/token -u "<user_name>:<password>"
```

For a valid user, the auth token is returned in the `X-Auth-Token` response header.

2. Start the scan of a connection with name `sdconnection` using the following request:

```
curl -k -H "Authorization: Bearer <token>" -X POST https://<data_cataloging_host>/connmgr/v1/scan/sdconnection
```

Response

The following table displays the common response statuses:

Table 2. Common response statuses

Status code	Message	Description
400	Must specify a connection name for the scan endpoint.	Connection name in the URL is not specified.
	Scan already currently in-progress for <connection_name>.	Scan already in progress.
404	Could not locate connection document for <connection_name>. Aborting scan.	Connection with the given name does not exist.
403	User does not have permission to view connection.	User does not have access to the collection to which the connection belongs.
200	-	Scan successfully started.

Note: A user with a collection admin role can only start a scan for a connection if an associated collection is set, and if it is a collection the collection admin user administers.

A successful scan displays the following response:

```
"Status": "Success"
```

The following displays an error response example:

```
"status": "Connection name in URL not specified."
```

/connmgr/v1/scan/<connection_name>: GET

Gets the current scan status of a single connection.

The /connmgr/v1/scan/<connection_name>: GET endpoint gets the current scan status of a single connection. Only an IBM Data Cataloging user with data admin role or collection admin role can get the status of a scan. The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	✓ ¹	X	X
¹ Collection Admin user can start, stop, and get the status of the scans that are applied to the collections to which they have the Collection Admin role assigned.				

Synopsis of the request URL

```
curl -k -H "Authorization: Bearer <token>" -X GET https://<data_cataloging_host>/connmgr/v1/scan/<connection_name>
```

Supported request types, input fields, and response formats

Supported request types:

- POST

Supported response formats:

- JSON

Examples

Follow these steps to get the scan status of a connection:

1. Obtain an auth token by using the credentials of the data admin user as shown:

```
curl -k https://<data_cataloging_host>/auth/v1/token -u "<user_name>:<password>"
```

For a valid user, the auth token is returned in the **X-Auth-Token** response header.

2. Get the scan status of a connection with name **sdconnection** using the following request:

```
curl -k -H "Authorization: Bearer <token>" -X GET https://<data_cataloging_host>/connmgr/v1/scan/sdconnection
```

Response

The following table displays the common response statuses:

Table 2. Common response statuses

Status code	Message	Description
200	Scan status JSON.	Scan status successfully retrieved.

Note: A user with a collection admin role can only get the scan status for a connection if an associated collection is set, and if it is a collection the collection admin user administers. Therefore, in the response, a collection admin user is only presented with the status of connections that belong to the connections the collection admin user administers.

A successful scan displays the following response:

```
[
{
  "Name": "sdconnection",
  "status": "Running",
  "message": "Crawling NFS mount",
  "Phase": 2,
  "Total_phases": 3
},
{
  "Name": "ss",
  "status": "Running",
  "message": "Preparing to scan connection",
  "Phase": 1,
  "total_phases": 4
}
]
```

/connmgr/v1/scan: GET

Gets the scan status of all running scans.

The /connmgr/v1/scan endpoint gets the current scan status of all connections. Only an IBM Data Cataloging user with data admin role or collection admin role can get the status of all running scans. The following table shows which roles can access /connmgr/v1/scan endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
------------	-----------	------------------	-------	--------------

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	✓ ¹	X	X

¹ Collection Admin user can start, stop, and get the status of the scans that are applied to the collections to which they have the Collection Admin role assigned.

Synopsis of the request URL

```
curl -k -H "Authorization: Bearer <token>" -X GET https://<data_cataloging_host>/connmgr/v1/scan
```

Supported request types, input fields, and response formats

Supported request types:

- POST

Supported response formats:

- JSON

Examples

Follow these steps to get the scan status of all the running scans:

1. Obtain an auth token by using the credentials of the Data Admin user as shown:

```
curl -k https://<data_cataloging_host>/auth/v1/token -u "<user_name>:<password>"
```

For a valid user, the authentication token is returned in the **X-Auth-Token** response header.

2. Get the scan status of all the running scans by using the following request:

```
curl -k -H "Authorization: Bearer <token>" -X GET https://<data_cataloging_host>/connmgr/v1/scan
```

Response

The following table displays the common response statuses:

Table 2. Common response statuses

Status code	Message	Description
404	No scan is in progress for <connection_name>.	No scan is in progress for the specified connection.
403	User does not have permission to get scan status for connection <connection_name>.	User cannot access the collection to which the connection belongs.
200	Scan status JSON.	Scan status successfully retrieved.

Note: A user with a collection admin role can get only the current scan status for a connection if an associated collection is set, and if it is a collection the Collection Admin user administers.

A successful scan displays the following response:

```
{
  "Name": "sdconnection",
  "status": "Running",
  "message": "Crawling NFS mount",
  "Phase": 2,
  "total_phases": 3
}
```

The following displays an error response example:

```
{
  "status": "Connection name in URL not specified."
}
```

/connmgr/v1/scan/<connection_name>: PUT

Stops a scan.

The /connmgr/v1/scan/<connection_name>: PUT endpoint stops a running scan. Only an IBM Data Cataloging user with data admin role or collection admin role can stop a scan. The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	✓ ¹	X	X

¹ Collection Admin user can start, stop, and get the status of the scans that are applied to the collections to which they have the Collection Admin role assigned.

Synopsis of the request URL

```
curl -k -H "Authorization: Bearer <token>" -X PUT https://<data_cataloging_host>/connmgr/v1/scan/<connection_name>/stop
```

Supported request types, input fields, and response formats

Supported request types:

- POST

Supported response formats:

- JSON

Examples

Follow these steps to stop a scan:

1. Obtain an auth token by using the credentials of the data admin user as shown:

```
curl -k https://<data_cataloging_host>/auth/v1/token -u "<user_name>:<password>"
```

For a valid user, the auth token is returned in the **X-Auth-Token** response header.

2. Stop the scan using the following request:

```
curl -k -H "Authorization: Bearer <token>" -X PUT https://<data_cataloging_host>/connmgr/v1/scan/sdconnection/stop
```

Response

The following table displays the common response statuses:

Table 2. Common response statuses

Status code	Message	Description
400	Must specify a connection name for the scan endpoint.	Connection name in the URL is not specified.
	Must specify an action for the scan endpoint.	The stop action is not specified in the URL.
	Available action endpoints are: /pause , /resume , and /stop .	
	No scan is currently in progress for <connection_name> .	No scans currently in progress for the given connection.
	Unsupported action <action specified in url> .	Unsupported action specified.
404	Could not locate connection document for <connection_name> .	Connection with the given name does not exist.
403	User does not have permission to control connection.	User does not have access to the collection to which the connection belongs.
200	-	Scan successfully stopped.

Note: A user with a collection admin role can only stop a scan for a connection if an associated collection is set, and if it is a collection the collection admin user administers.

A successful scan displays the following response:

```
"Status": "Stop of sdconnection scan submitted."
```

The following displays an error response example:

```
"Status": "No scan is currently in progress for sdconnection."
```

Application management by using APIs

The application management APIs provide options to get the details of the available applications, install or upgrade an application, and delete an application. You must have the Admin role to access the application management endpoints.

You can change the self-signed certificate that IBM Data Cataloging uses. For more information, see [IBM Data Cataloging REST APIs](#). For more information, see the topic *IBM Spectrum® Discover REST APIs in the Data Cataloging: Administration Guide*.

- **/policyengine/v1/applications: POST**
The /policyengine/v1/applications registers an action agent. Only an IBM Data Cataloging user with *data admin* role can register the application with IBM Data Cataloging.
- **/policyengine/v1/applications/<application name>: GET**
Gets the details of a specific application that is configured in the system.
- **/policyengine/v1/tlscert: GET**
Gets a CA-certified TLS certificate.
- **/policyengine/v1/action_ids: GET**
Retrieves and displays a list of actions IDs of all the registered applications.
- **/policyengine/v1/applications/<deployment name>/schema?action_id=<action id>: GET**
Gets the application schema for a specified application.
- **/policyengine/v1/application_names?action_id=<action id>: GET**
Gets a list of applications that support a specified action ID.
- **/policyengine/v1/applications: DELETE**
Deletes an application.

/policyengine/v1/applications: POST

The /policyengine/v1/applications registers an action agent. Only an IBM Data Cataloging user with *data admin* role can register the application with IBM Data Cataloging.

The following table shows which roles can access /policyengine/v1/applications endpoint:

Table 1. Access by role

Data admin	Collection Admin	Data user	Admin	Service user
✓	X	X	X	X

Synopsis of the request URL

```
curl -k -H "Authorization: Bearer <token>" -H "Content-Type: application/json" -X POST
https://<data_cataloging_host>/policyengine/v1/applications
```

Supported request types and response formats

Supported request types:

- POST

Supported response formats:

- JSON

Examples

Registering an application involves the following steps.

1. Obtain an auth token by using credentials of the data admin user as shown in the following example:

```
curl -k https://<data_cataloging_host>/auth/v1/token -u "<user_name>:<password>"
```

For a valid user, the auth token is returned in the "X-Auth-Token" response header.

2. Create a .json file with application details:

```
cat agentregmsg.json

{
  "action_agent": "extractapplication",
  "action_id": "DEEPINSPECT",
  "action_params": ["extract_tags"]
}
```

Note: Only DEEPINSPECT is supported as a valid action_id and must always be in upper case. The action_agent parameter must be a maximum of 64 characters long and can contain alpha-numeric characters and '.', '_' or '-' characters. However, the action parameters that are converted to string can be a maximum of 256 characters long.

3. Submit the following request:

```
curl -k https://<data_cataloging_host>/policyengine/v1/applications -H "Content-Type: application/json" -X POST -d
@agentregmsg.json -H "Authorization: Bearer <token>"
```

Response:

```
Content-Type: application/json
{
  "broker_ip": 9.11.200.114,
  "broker_port": 9093,
  "work_q": "extractapplication_work",
  "completion_q": "extractapplication_compl"
}
```

Multiple application instances

If you want to run multiple copies of an application, then only the first application registration attempt receives a success response. Any subsequent applications receive a 409 Conflict response. In such cases, use the /policyengine/v1/agents/<agent name> endpoint to find the required Kafka information to proceed.

Example GET response:

```
{
  "broker_ip": "localhost",
  "work_q": "extractapplication_work",
  "auth": "extractapplication_user:extractapplication_password",
  "params": "[\"tags\"]",
  "agent": "extractagent",
  "broker_port": "9093",
  "completion_q": "extractapplication_compl",
  "action_id": "\"DEEPINSPECT\""
}
```

- [Example: Create a DeepInspect policy using the application](#)

Use the POST /policyengine/v1/policies/extractpol endpoint to create a policy that makes use of the registered application.

Example: Create a DeepInspect policy using the application

Use the POST /policyengine/v1/policies/extractpol endpoint to create a policy that makes use of the registered application.

Synopsis of the request URL

```
curl -k -H "Authorization: Bearer <token>" -H "Content-Type: application/json" -X POST
https://<data_cataloging_host>:443/policyengine/v1/policies/extractpol
```

Supported request types and response formats

Supported request types:

- POST

Supported response formats:

- JSON

Examples

Registering an application involves the following steps.

1. Define the policy details in a JSON file as shown in the following example:

```
cat testpol
{
  "action_params": {
    "extract_tags": ["vin", "sensor"],
    "agent": "extractapplication"
  },
  "pol_id": "extractpol",
  "schedule": "NOW",
  "pol_filter": "size>23",
  "action_id": "DEEPIINSPECT"
}
```

2. Submit the following request:

```
curl -k -H "Authorization: Bearer <token>" https://<data_cataloging_host>/policyengine/v1/policies/extractpol -X POST -d
@testpol -H "Content-Type: application/json"
```

As the policy is created, as the policy schedule is 'NOW'. The job request messages are immediately pushed to the Kafka work topic corresponding to the registered application as shown in the following example:

The following example provides a JSON message request.

```
{
  "mo_ver": "1.0",
  "action_id": "deepinspect",
  "action_params": {
    "agent": "extractapplication",
    "tags": {"extract_tags": ["vin", "sensor"]}
  },
  "agent": "extractapplication",
  "policy_id": "extractpol",
  "docs": [
    {
      "path": "/fs1/path1/file1.txt", "fkey": "spectrumscale.cluster.example",
      "path": "/fs1/path1/file2.txt", "fkey": "spectrumscale.cluster.example",
      .....
      {"origpath": "/fs1/path1/file3.txt", "fkey": "spectrumscale.cluster.example"}
    ]
}
```

The following table lists the job request message format.

Table 1. Job request message format

Field	Value Type	Description
mo_ver	Float	The message version
policy_id	String	The name of the policy ID that requested the job.
action_id	String	The name of the action ID
agent	String	The name of the application
action_params	Object	JSON object of custom application parameters
docs	Array	The array of JSON objects, each containing information about documents (files or objects) to be inspected.

The following example provides a JSON message response:

```
{
  "mo_ver": "1.0",
  "policy_id": "extractpol",
  "docs": [
    {
      "status": "success", "tags": {"vin": "vin-value", "sensor": "sensor-value"}, "path": "/fs1/path1/file1.txt", "fkey":
"spectrumscale.cluster.example "},
    {
      "status": "success", "tags": {"vin": "vin-value", "sensor": "sensor-value"}, "path": "/fs1/path1/file1.txt", "fkey":
"spectrumscale.cluster.example "},
    {
      "status": "failed", "tags": {}, "path": "/fs1/path1/file1.txt", "fkey": "spectrumscale.cluster.example "
    }
  ]
}
```

The following table lists the job response message format.

Table 2. Job response message format

Field	Value Type	Description
mo_ver	Float	The message version
policy_id	String	The name of the policy ID that requested the job.
docs	Array	The array of JSON objects, each containing information about documents (files/objects) to be inspected.

/policyengine/v1/applications/<application name>: GET

Gets the details of a specific application that is configured in the system.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	CollectionAdmin	Data user	Admin	Service user
✓	X	✓	X	X

Synopsis of the request URL

```
curl -k -H "Authorization: Bearer <token>" -H "Content-Type: application/json"
https://<data_cataloging_host>/policyengine/v1/application/<application_name>
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example shows how to get the details of a specific application.

Request:

```
curl -k -H "Authorization: Bearer <token>" -H "Content-Type: application/json"
https://<data_cataloging_host>/policyengine/v1/application/extractapplication"
```

Response:

```
{
  "broker_ip": "localhost",
  "work_q": "
extractagent_work",
  "auth": "extractapplication_user:extractapplication_password",
  "params": "[\"tags\"]",
  "agent": "extractagent",
  "broker_port": "9093",
  "completion_q": "extractapplication_compl",
  "action_id": "deepinspect"
}
```

/policyengine/v1/tlscert: GET

Gets a CA-certified TLS certificate.

The IBM Data Cataloging uses TLS protocol for encrypting the communication in-flight between the IBM Data Cataloging nodes (the Kafka topics) and the applications. It uses TLS client certificates to securely authenticate the applications. The certificates that are provided by the IBM Data Cataloging admin upon registration are used by applications to authenticate to the Kafka brokers in IBM Data Cataloging.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	CollectionAdmin	Data user	Admin	Service user
✓	X	✓	X	X

Synopsis of the request URL

```
curl -k -H "Authorization: Bearer <token>" https://<data_cataloging_host>/policyengine/v1/ tlscert
```

Supported request types and response formats

Supported request types:

Supported response formats:

- JSON

Examples

The following example shows how to get a CA-certified TLS certificate.

Request:

```
curl -k -H "Authorization: Bearer <token>" https://<data_cataloging_host>/policyengine/v1/ tlscert
```

Response:

[illegible]

```
KfRlkCJTnbPKfI34HxOE/k/wpOJSample==
-----END CERTIFICATE-----
```

The response contains the client certificate and the client key, followed by the root certificate. Based on the response output, the organization of the response is as follows:

```
-----BEGIN CERTIFICATE-----
client certificate
-----END CERTIFICATE-----
Bag Attributes
...
Key Attributes:
...
-----BEGIN PRIVATE KEY-----
client key
-----END PRIVATE KEY-----
-----BEGIN CERTIFICATE-----
root certificate
-----END CERTIFICATE-----
```

These certificates and key are required for the secure communication connection to the Kafka brokers in IBM Data Cataloging.

Note: Before you connect to the Kafka brokers in IBM Data Cataloging, the application must complete the additional settings for the secure connection.

/policyengine/v1/action_ids: GET

Retrieves and displays a list of actions IDs of all the registered applications.

This API endpoint provides a unique list of action IDs for the registered applications.

The following table displays the roles that can access the REST API endpoint.

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	✓	✓	X	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<spectrum_discover_host>/policyengine/v1/
action_ids -X GET -H 'Accept: application/json'
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example returns a list of action IDs of registered applications that are configured in the system.

Issue the following request in one line:

```
curl -k -H 'Authorization: Bearer <token>'
https://<data_cataloging_host>
/policyengine/v1/action_ids -X GET -H 'Accept: application/json'
```

The following response is returned:

```
[
  "CONTENTSEARCH",
  "COPY",
  "AUTOTAG",
  "TIER"
]
```

/policyengine/v1/applications/<deployment_name>/schema?action_id=<action_id>: GET

Gets the application schema for a specified application.

This endpoint returns the schema from the application registration message. The schema is used by the UI to dynamically generate policy creation views for the registered application. If the action ID is not specified as a query parameter, the endpoint returns the whole schema. For the specified action ID, a subset of the registration schema is returned.

The following table displays the roles that can access the REST API endpoint.

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	✓	✓	X	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<spectrum_discover_host>/policyengine/v1/
applications/<deployment_name>/schema?action_id=<action_id> -X GET -H 'Accept: application/json'
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example returns the application schema for a specified application and a specified action ID that is registered on the system.

Issue the following request in one line:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/policyengine/v1/applications/ScaleILM/schema?action_id=MOVE -X GET -H 'Accept: application/json'
```

The following response is returned:

```
{
  "properties": {
    "destination_tier": {
      "description": "Tier name which can be a Spectrum Scale internal pool name or an external pool name like 'tape-archive'
to tier the files to a LTFS Tape library configured on the Spectrum Scale cluster. Internal pool names are mentioned as-is,
while the external pools are mentioned as 'external:tape-archive:pool1@lib1' or 'external:cos' (future use). External pool name
'tape-archive' is an IBM Spectrum Discover defined pool name for the LTFSEE Tape pool configured on the Spectrum Scale
system.",
      "type": "string"
    },
    "source_connection": {
      "description": "Defines platform name of the source data connection.",
      "type": "string"
    }
  },
  "required": [
    "source_connection",
    "destination_tier"
  ],
  "type": "object"
}
```

/policyengine/v1/application_names?action_id=<action_id>: GET

Gets a list of applications that support a specified action ID.

This API endpoint provides a unique list of application names with the specified action ID.

If an action ID is not provided as a query parameter then the endpoint returns all the application names on the system.

The following table displays the roles that can access the REST API endpoint.

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	✓	✓	X	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<spectrum_discover_host>/policyengine/v1/
application_names?action_id=<action_id> -X GET -H 'Accept: application/json'
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example returns a list of application names with the given action id that are configured in the system.

Issue the following request in one line:

```
curl -k -H 'Authorization: Bearer <token>'
https://<data_cataloging_host>
/policyengine/v1/action_ids -X GET -H 'Accept: application/json'
```

The following response is returned:

```
[
  "WKCCConnector",
  "contentsearchagent",
  "ScaleILM"
]
```

/policyengine/v1/applications: DELETE

Deletes an application.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	CollectionAdmin	Data user	Admin	Service user
✓	X	X	X	X

Synopsis of the request URL

```
curl -k -H "Authorization: Bearer <_token_>" -X DELETE
https://<data_cataloging_host>/policyengine/v1/applications/<application_name>
```

Supported request types and response formats

Supported request types:

- DELETE

Examples

Deleting an application involves the following steps.

1. Obtain an auth token by using credentials of the data admin user as shown in the following example:

```
curl -k https://<data_cataloging_host>/auth/v1/token -u "<user_name>:<password>" -v
```

For a valid user, the auth token is returned in the "X-Auth-Token" response header.

2. Submit the following request:

```
curl -k https://<data_cataloging_host>/policyengine/v1/applications/<application_name> " -X DELETE -H "Authorization:
Bearer <_token_> "
```

Response:

```
204 No Content
```

RBAC management by using APIs

The IBM Data Cataloging resource-based access control (RBAC) is a REST API service that enables role-based access to the IBM Data Cataloging services. This service uses OpenStack Keystone as a backend for providing Identity and Access Management (IAM) across multiple domains that are attached to the IBM Data Cataloging.

The authentication service uses a default user with user name *sdadmin* and password *PasswOrd* in the domain named *default*. This user has the administrative role and can be used to do the following actions:

- This user can create other users and user groups.
- This user can register new domains with the authentication service.
- This user can create projects.
- This user can assign roles to the users at project or domain level.

The following are the predefined user roles with the corresponding access levels:

admin

Default user role created by the system. Users with this role can create other users, projects, domains, and assign roles. Users with this role cannot see metadata records.

dataadmin

The users with this role can see all metadata records across projects.

collectionadmin

The users with this role can access metadata that is collected. But, metadata access is restricted to the records that are associated with the collections to which the user has the Collection Admin or Data User role assigned.
Important: The Collection Admin role is available as a technology preview in the 2.0.1.1 release. For limitations on the usage of the Collection Admin role, see the *IBM Spectrum® Discover Release Notes*.

datauser

This role is ideal for a researcher or data scientist. Users with this role can see records that are associated with projects to which they belong.

serviceuser

This user role intended for service personnel. Users with this role have read-only access to the system logs.

IBM Data Cataloging integrates with the enterprise LDAP connected to IBM Spectrum Scale. Using the authentication service APIs, admin users can add an LDAP domain definition to IBM Data Cataloging. The users and groups from the registered LDAP domain are automatically imported into IBM Data Cataloging and the administrators can add these users and groups to different projects while they assign them the Data User role.

Admin users can also assign the Data Admin role to some of the users and user groups to give access to the entire IBM Data Cataloging index for searches and policies.

The authentication API service endpoint has the following basic structure: `https://<host address>/auth/v1/<endpoint>`

For example, the following endpoint gets authentication token for the users: `curl -k -u <user>:<pass> https://<host address>/auth/v1/token`

- **Managing tokens**
The users need to get an authentication token from the authentication server by using their user name and password. Then, they need to use that token to access the services offered by the IBM Data Cataloging system.
- **Managing users**
All the create, read, update, and delete operations are allowed on the *default* domain. But the read-only (GET) access is allowed for the users and groups that are imported from the registered Lightweight Directory Access Protocol (LDAP) or Cloud Storage Object domains.
- **Managing user roles**
The authorization or access privileges of users and user groups are defined with the help of user roles.
- **Managing user groups**
You can create user groups for better manageability of users. Defining user groups also provides flexibility of assigning specific roles to a group of users rather than assigning the roles individually.
- **Managing collections**
You can create and manage collections by using REST APIs.
- **Managing domains**
You can create and manage user domains by using REST APIs.

Managing tokens

The users need to get an authentication token from the authentication server by using their user name and password. Then, they need to use that token to access the services offered by the IBM Data Cataloging system.

For more information on the authentication process, see [Authentication process](#).

The following endpoint is available to manage tokens:

- **/auth/v1/token: GET**
Gets authentication token for the user.

/auth/v1/token: GET

Gets authentication token for the user.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	✓	✓	✓	✓

Synopsis of the request URL

Users from an external LDAP or COS domain must include domain name in the user name as `<domain>/<user>` to get an authentication token.

```
curl -k -u ldap/user1:pass https://<data_cataloging_host>/auth/v1/token -v
```

```
curl -k -u cos/user1:pass https://<data_cataloging_host>/auth/v1/token -v
```

```
curl -k -u cos/<access_key_id>:<secret_key> https://<data_cataloging_host>/auth/v1/token -v
```

Without specifying domain name as part of user name:

```
curl -k -u user1:pass https://<data_cataloging_host>/auth/v1/token -v
```

Note: When using curl, add the -v parameter to see the response headers that contain the token.

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Default response data is in CSV format. For results in JSON format, use the "Accept: application/json" header.

Examples

The following example shows a request and the corresponding response.

Request that contains domain as part of the user name:

```
curl -k -u ldap/user1:pass https://<data_cataloging_host>/auth/v1/token -v
```

Request that does not contain domain as part of the user name:

```
curl -k -u user1:pass https://<data_cataloging_host>/auth/v1/token -v
```

Response:

```
< HTTP/1.0 200 OK
< X-Auth-Token: gAAAAABbUdgLOLk67Zk_XQ00bbJt_qe4suz449m7XLM-D6e0jUzDxBW574L38y5xF5y3wc-Xq0Bp43uQH13QN-wTsioPoOf0lbyrN5avBag2iHUKCOgXyA46TvY5LdGu46LEs-gO-qidQgUCg5im4QF3Zvw5enCTvQd2N1bAg186CVoc8Qk5o1ldJGd5inL3ELts0LsVg9F4oPhv9HixwZf1h1CsuPg1Gw
< Content-Type: text/html; charset=utf-8
< Content-Length: 0
< Server: Werkzeug/0.14.1 Python/2.7.5
< Date: Fri, 20 Jul 2018 12:39:39 GMT
```

You need to use the token that is obtained in the previous step to access the services offered by IBM Data Cataloging.

The following example shows how to use the token that is obtained to get the list of from the policy engine:

```
curl -v -k -H 'Authorization: Bearer gAAAAABbUdgLOLk67Zk_XQ00bbJt_qe4suz449m7XLM-D6e0jUzDxBW574L38y5xF5y3wc-Xq0Bp43uQH13QN-wTsioPoOf0lbyrN5avBag2iHUKCOgXyA46TvY5LdGu46LEs-gO-qidQgUCg5im4QF3Zvw5enCTvQd2N1bAg186CVoc8Qk5o1ldJGd5inL3ELts0LsVg9F4oPhv9HixwZf1h1CsuPg1Gw' https://<data_cataloging_host>/policyengine/v1/policies
```

Managing users

All the create, read, update, and delete operations are allowed on the *default* domain. But the read-only (GET) access is allowed for the users and groups that are imported from the registered Lightweight Directory Access Protocol (LDAP) or Cloud Storage Object domains.

- [/auth/v1/users: GET](#)
Gets the details of the users that are created in the system.
- [/auth/v1/users: POST](#)
Creates a user.
- [/auth/v1/users/<user ID>/password: POST](#)
Changes the user password.
- [/auth/v1/users/<user ID>: GET](#)
Gets the details of a specific user.
- [/auth/v1/users/<user ID>: PATCH](#)
Updates an existing user.
- [/auth/v1/users/<user ID>: DELETE](#)
Deletes a specific user.
- [/auth/v1/users/<user ID>/groups: GET](#)
Gets the details of the groups to which a specific user belongs.
- [/auth/v1/users/<user ID>/collections: GET](#)
Gets the list of collections that are assigned to a user.
- [/auth/v1/users/<user ID>/roles: GET](#)
Gets the list of roles that are assigned to a user.
- [/auth/v1/users/<user ID>/role assignment: GET](#)
Returns a list of the roles and associated collections assigned to the user where applicable. This does not include any role assignments inherited from groups that the user belongs to.
- [/auth/v1/users/users summary: GET](#)
Gets the list of users and their domain details.

/auth/v1/users: GET

Gets the details of the users that are created in the system.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
√ ¹	√ ¹	√	√	√ ¹

¹The specified user ID must be the same as the requesting user ID. Otherwise the command fails with error 403, "Not authorized".

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/users
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example shows how to get the details of the users who are created in the system.

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/users
```

Response:

```
(200 OK):
{
  "users": [

  ]
}
```

/auth/v1/users: POST

Creates a user.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
X	X	X	✓	X

Synopsis of the request URL

```
curl -k -H 'Content-Type: application/json' -H 'Authorization: Bearer <token>' -X POST https://<data_cataloging_host>/auth/v1/users -d '<json details of user>'
```

The details of a user can be the following:

- Name
- Password
- Email
- Description
- Project
- Default project

Supported request types and response formats

Supported request types:

- POST

Supported response formats:

- JSON

Examples

The following example shows how to create a user.

Request:

```
curl -k -H 'Content-Type: application/json' -H 'Authorization: Bearer <token>' -X POST https://<data_cataloging_host>/auth/v1/users -d '{"name":"testuser","password":"testpass","email":"testuser@ibm.com"}'
```

Response:

```
201 Created
```

/auth/v1/users/<user_ID>/password: POST

Changes the user password.

The table shows the roles that can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	✓	✓	✓	✓

Synopsis of the request URL

```
curl -k -H 'Content-Type: application/json' -X POST https://<data_cataloging_host>/auth/v1/users/user_id/password -d '<json details of user>'
```

Required Parameters in the JSON payload:

- password - new password
- original_password - old/current password

Supported request types and response formats

Supported request types:

- POST

Supported response formats:

- JSON

Examples

The following example shows how to change a user password.

Request:

```
curl -k -H 'Content-Type: application/json' -X POST
https://<data_cataloging_host>/auth/v1/users/a26f98ab046449bebce70c4832b22ac2/password -X POST-H"Content-Type:application/json"
-d '{"password": "NewPassw0rd", "original_password": "Passw0rd"}'
```

Response:

204 No Content

/auth/v1/users/<user ID>: GET

Gets the details of a specific user.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
√ ¹	√ ¹	√	√	√ ¹
¹ The specified user ID must be the same as the requesting user ID. Otherwise the command fails with error 403, "Not authorized". An exception is if the user ID is "me", the result is the details of the current user.				

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/users/<user_ID>
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example shows how to get the details of a specific user.

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/users/4ee5b47f439640d29b6fac7253a64290
```

Response:

```
200 OK:
{
  "domain_id": "default",
  "email": "testuser@ibm.com",
  "enabled": true,
  "id": "5b3cd6af1c38479aa3a8cb220230c651",
  "name": "testuser",
  "options": {},
  "password_expires_at": null
}
```

The following special case returns the current user's details.

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/users/me
```

/auth/v1/users/<user_ID>: PATCH

Updates an existing user.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
X	X	X	√	X

Synopsis of the request URL

```
curl -k -H 'Content-Type: application/json' -H 'Authorization: Bearer <token>'
https://<data_cataloging_host>/auth/v1/users/<user_ID> -X PATCH -d '<json details to update>'
```

Supported request types and response formats

You can update the following attributes of a user:

- Name
- Password
- Email
- Description
- Project
- Default project

Supported request types:

- PATCH

Supported response formats:

- JSON

Examples

The following example shows how to update an existing user.

Request:

```
curl -k -H 'Content-Type: application/json' -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/users/4ee5b47f439640d29b6fac7253a64290 -X PATCH -d '{ "name": "testuser-updated", "password": "newpassword" }'
```

Response:

```
200 OK
```

/auth/v1/users/<user_ID>: DELETE

Deletes a specific user.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
X	X	X	✓	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/users/<user_ID> -X DELETE
```

Supported request types and response formats

Supported request types:

- DELETE

Supported response formats:

- JSON

Examples

The following example shows how to delete a user.

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/users/4ee5b47f439640d29b6fac7253a64290
```

Response:

```
204 No Content
```

/auth/v1/users/<user_ID>/groups: GET

Gets the details of the groups to which a specific user belongs.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓ ¹	✓ ¹	✓	✓	✓ ¹

¹The specified user ID must be the same as the requesting user ID. Otherwise the command fails with error 403, "Not authorized".

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/users/<user_ID>/groups
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example shows how to get the details of the groups to which a specific user belongs.

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/users/4ee5b47f439640d29b6fac7253a64290/groups
```

Response:

```
{
  "groups": [
    {
      "name": "test-group1",
      "description": "Test Group 1",
      "domain": "default"
    },
    {
      "name": "test-group2",
      "description": "Test Group 2",
      "domain": "default"
    }
  ]
}
```

/auth/v1/users/<user_ID>/collections: GET

Gets the list of collections that are assigned to a user.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
√ ¹	√ ¹	√	√	√ ¹
¹ The specified user ID must be the same as the requesting user ID. Otherwise the command fails with error 403, "Not authorized".				

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/users/<user_ID>/collections
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example shows how to get the details of the collections to which the user is assigned.

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/users/4ee5b47f439640d29b6fac7253a64290/collections
```

Response:

```
(200 OK):
{
  "collections": [
    {
      "description": "",

```

```

    "domain_id": "default",
    "enabled": true,
    "id": "c64cafe7f69349d0ba79a8fe931be8d2",
    "is_domain": false,
    "name": "spectrum-discover",
    "parent_id": "default",
    "tags": []
  }
]
}

```

/auth/v1/users/<user_ID>/roles: GET

Gets the list of roles that are assigned to a user.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
√ ¹	√ ¹	√	√	√ ¹

¹The specified user ID must be the same as the requesting user ID. Otherwise the command fails with error 403, "Not authorized".

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/users/<user_ID>/roles
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example shows how to get the list of roles that are assigned to a user.

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/users/4ee5b47f439640d29b6fac7253a64290/roles
```

Response:

```

(200 OK):
{
  "roles": [
    {
      "domain_id": null,
      "id": "4a5415cb9cc5460aafe12a6f6206448e",
      "name": "datauser"
    }
  ]
}

```

/auth/v1/users/<user_ID>/role_assignment: GET

Returns a list of the roles and associated collections assigned to the user where applicable. This does not include any role assignments inherited from groups that the user belongs to.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	✓	✓	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/users/<user_id>/role_assignments
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example shows how to get the details of the roles that is assigned to a specific user:

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/users/4ee5b47f439640d29b6fac7253a64290/role_assignments
```

Response:

Returns 200 OK:

```
{
  "roles": [
    {
      "collections": [
        {
          "description": "Bootstrap project for initializing the cloud.",
          "domain_id": "default",
          "enabled": true,
          "id": "09dd9136eaa6416784d6c5bdf3fa2f78",
          "is_domain": false,
          "name": "data-cataloging",
          "parent_id": "default",
          "tags": []
        }
      ],
      "domain_id": "domain_id",
      "id": "5f365cf289d14c93a986b8bea976f92b",
      "name": "collectionadmin"
    }
  ]
}
```

/auth/v1/users/users_summary: GET

Gets the list of users and their domain details.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	✓ ¹	✓	✓	✓ ¹

¹ The specified user ID must be the same as the requesting user ID. Otherwise the command fails with error 403, "Not authorized". Data users can access this API to retrieve only those user details they are entitled to view.

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/users/users_summary
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example shows how to get the user details.

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/users/users_summary
```

Response:

```
(200 OK):
{
  "users": [
    {
      "domain_id": "default",
      "domain_name": "Default",
      "enabled": true,
      "id": "7d040d976f924d60b5f39f0648950d1b",
      "name": "sdadmin",
      "options": {},
      "password_expires_at": null
    },
    {
      "domain_id": "a69001e854174dc1a4e0c98f712744bb",
      "domain_name": "lldap",
      "id": "1e8155daee6f021008a09aca09e1473d823ca7128d16ba25b3a10a7c1aa3433e",
      "name": "user2_NoGroup",
      "options": {},
      "password_expires_at": null
    },
    {
      "domain_id": "a69001e854174dc1a4e0c98f712744bb",
      "domain_name": "lldap",
      "id": "38f5434fe9d12fcb3278deb29fb104441b87d040f5774bd545a2d1d0c7adaa7f",
      "name": "user5_SystemAdmin",
      "options": {},
      "password_expires_at": null
    }
  ]
}
```

Managing user roles

The authorization or access privileges of users and user groups are defined with the help of user roles.

The following are the predefined user roles with the corresponding access levels:

admin

Users with this role can create other users, projects, domains, and assign roles. Users with this role cannot see metadata records. This role is a default user role that is created by the system.

dataadmin

Users with this role can see all metadata records across projects.

collectionadmin

Users with this role can access metadata that is collected. However, metadata access is restricted to the records that are associated with the collections to which the user has the Collection Admin or Data User role assigned.

Important: The Collection Admin role is available as a technology preview in the 2.0.1.1 release. For limitations on the usage of the Collection Admin role, see the *IBM Spectrum® Discover Release Notes*.

datauser

Users with this role can see records that are associated with projects to which they belong. This role is ideal for a researcher or data scientist.

serviceuser

Users with this role have read-only access to the system logs. This user role intended for service personnel.

- [/auth/v1/roles/<role_ID>: PUT](#)
Assigns a role to users or user groups.
- [/auth/v1/roles/<role_ID>: GET](#)
Gets the details of a specific user role.
- [/auth/v1/roles: GET](#)
Gets the details of user roles.
- [/auth/v1/roles/<role_ID>: DELETE](#)
Removes the role that is assigned to a user, group, collection, or domain.

/auth/v1/roles/<role_ID>: PUT

Assigns a role to users or user groups.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
X	X	✓	✓	X

The following roles can be assigned to a user:

admin

Default user role created by the system. Users with this role can create other users, projects, domains, and assign roles. Users with this role cannot see metadata records.

dataadmin

The users with this role can see all metadata records across projects.

datauser

This role is ideal for a researcher or data scientist. Users with this role can see records that are associated with projects to which they belong.

serviceuser

This user role intended for service personnel. Users with this role have read only access to the system logs.

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' -X PUT https://<data_cataloging_host>/auth/v1/roles/<role_ID> -d '<details of where role is to be assigned>'
```

You can specify the following details in the **roles** endpoint to assign roles to the corresponding component. An example follows this list.

user_id

The user ID to which the role must be assigned.

group_id

The group to which the role must be assigned.

project_id

The project to which the role must be assigned.

domain_id

The domain to which the role must be assigned.

The following examples illustrate how to specify these fields to assign a role to a domain or collection:

```
{
  "user_id": <string> [optional],
  "group_id": <string> [optional],
  "collection_id": <string> [optional],
  "domain_id": <string> [optional]
}
example [assign role to user in default domain]
{
  "user_id": "5b3cd6af1c38479aa3a8cb220230c651"
}
example [assign role to user in specific domain]
{
  "user_id": "5b3cd6af1c38479aa3a8cb220230c651",
  "domain_id": "4bfa9a9f71154dbeb554261a1c8d9a53"
}
example [assign role to user in specific collection]
{
  "user_id": "5b3cd6af1c38479aa3a8cb220230c651",
  "collection_id": "3b8c501b173c4ebcb99f322a4f7cf60e"
}
```

Supported request types and response formats

Supported request types:

- PUT

Supported response formats:

- JSON

Examples

Example 1: Assigning a role to a specific user.

Request:

```
curl -k -H 'Content-Type: application/json' -H 'Authorization: Bearer <token>' -X PUT https://<data_cataloging_host>/auth/v1/roles/4a5415cb9cc5460aafe12a6f6206448e -d '{"user_id": "5b3cd6af1c38479aa3a8cb220230c651"}'
```

Response:

200 OK

Example 2: Assigning a role to a group.

Request:

```
curl -k -H 'Content-Type: application/json' -H 'Authorization: Bearer <token>' -X PUT https://<data_cataloging_host>/auth/v1/roles/4a5415cb9cc5460aafe12a6f6206448e -d '{"group_id": "6c4de7af1c38479aa3a8cb220230d762"}'
```

Response:

200 OK

Example 3: Assigning role for a user in a collection.

Request:

```
curl -k -H 'Content-Type: application/json' -H 'Authorization: Bearer <token>' -X PUT
https://<data_cataloging_host>/auth/v1/roles/4a5415cb9cc5460aafe12a6f6206448e
-d '{"user_id": "5b3cd6af1c38479aa3a8cb220230c651", "domain_id": "af1c38479a5b3cd6c651a3a8cb220230"}'
```

Response:

200 OK

/auth/v1/roles/<role_ID>: GET

Gets the details of a specific user role.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
√ ¹	√ ¹	√ ¹	√	√ ¹
¹ The specified role must be one that is assigned to the requesting user ID. Otherwise the command fails with error 403, "Not authorized".				

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/roles/<role_ID>
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example shows how to get the details of a specific user role.

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/roles/4a5415cb9cc5460aafe12a6f6206448e
```

Response:

```
200 (OK):
{
  "domain_id": null,
  "id": "4a5415cb9cc5460aafe12a6f6206448e",
  "name": "datauser"
}
```

/auth/v1/roles: GET

Gets the details of user roles.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
√ ¹	√ ¹	√ ¹	√	√ ¹
¹ The specified role must be one that is assigned to the requesting user ID. Otherwise the command fails with error 403, "Not authorized".				

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/roles
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example shows how to get the details of user roles.

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/roles
```

Response:

```
{
  "roles": [
    {
      "domain_id": null,
      "id": "0ce17850c81a4e5da06ecd93f8ea0393",
      "name": "admin"
    },
    {
      "domain_id": null,
      "id": "383d4b371f244a2a8529a35b665b5c01",
      "name": "datauser"
    },
    {
      "domain_id": null,
      "id": "7d9f6d213b6d4317a395bbf248fdd9b6",
      "name": "collectionadmin"
    },
    {
      "domain_id": null,
      "id": "103bc9b8f1864c19af5663ec357f8d51",
      "name": "dataadmin"
    },
    {
      "domain_id": null,
      "id": "8388af928ce546bea7a0cd804a427b7c",
      "name": "serviceuser"
    }
  ]
}
```

/auth/v1/roles/<role_ID>: DELETE

Removes the role that is assigned to a user, group, collection, or domain.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
X	X	✓	✓	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' -X DELETE https://<data_cataloging_host>/auth/v1/roles/<role_ID> -d '<the component for which the role must be revoked >'
```

You can specify one of the following items for which you need to revoke the role:

- user_id
- group_id
- collection_id
- domain_id

Supported request types and response formats

Supported request types:

- DELETE

Supported response formats:

- JSON

Examples

Example 1: Revoking role from a user.

Request:

```
curl -k -H 'Content-Type: application/json' -H 'Authorization: Bearer <token>' -X DELETE https://<data_cataloging_host>/auth/v1/roles/4a5415cb9cc5460aafef12a6f6206448e
```

```
-d '{"user_id": "5b3cd6af1c38479aa3a8cb220230c651"}'
```

Response:

204 No Content

Example 2: Revoking role from a group.

Request:

```
curl -k -H 'Content-Type: application/json' -H 'Authorization: Bearer <token>' -X DELETE https://<data_cataloging_host>/auth/v1/roles/4a5415cb9cc5460aaf12a6f6206448e -d '{"group_id": "6c4de7af1c38479aa3a8cb220230d762"}'
```

Response:

204 No Content

Example 3: Revoking role for a user of a collection.

Request:

```
curl -k -H 'Content-Type: application/json' -H 'Authorization: Bearer <token>' -X DELETE https://<data_cataloging_host>/auth/v1/roles/4a5415cb9cc5460aaf12a6f6206448e -d '{"user_id": "5b3cd6af1c38479aa3a8cb220230c651", "collection_id": "c38479aa35b3cd6af1a8cb220230c651"}'
```

Response:

204 No Content

Example 4: Revoking role for a group of a domain.

Request:

```
curl -k -H 'Content-Type: application/json' -H 'Authorization: Bearer <token>' -X DELETE https://<data_cataloging_host>/auth/v1/roles/4a5415cb9cc5460aaf12a6f6206448e -d '{"user_id": "5b3cd6af1c38479aa3a8cb220230c651", "domain_id": "af1c38479a5b3cd6c651a3a8cb220230"}'
```

Response:

204 No Content

Managing user groups

You can create user groups for better manageability of users. Defining user groups also provides flexibility of assigning specific roles to a group of users rather than assigning the roles individually.

- [/auth/v1/groups: GET](#)
Gets the list of groups that are created in the system.
- [/auth/v1/groups: POST](#)
Creates a group in the system.
- [/auth/v1/groups/<group ID>: GET](#)
Gets the details of a specific group.
- [/auth/v1/groups/<group ID>: PATCH](#)
Updates the attributes of an existing group.
- [/auth/v1/groups/<group ID>: DELETE](#)
Deletes a specific user group.
- [/auth/v1/groups/<group ID>/collections: GET](#)
Gets the details of the collections that are assigned in a group.
- [/auth/v1/groups/<group ID>/roles: GET](#)
Gets the details of the user roles that are assigned to a group.
- [/auth/v1/groups/<group id>/role_assignments: GET](#)
Returns a list of the roles and associated collections assigned to the group where applicable.
- [/auth/v1/groups/<group ID>/users: GET](#)
Gets the details of the users who are part of a specific group.
- [/auth/v1/groups/<group ID>/user/<user ID>: DELETE](#)
Removes a specific user from a group.
- [/auth/v1/groups/<group ID>/user/<user ID>: PUT](#)
Assigns a user to a group.
- [/auth/v1/groups/groups_summary: GET](#)
Gets the list of groups and their domain details.

/auth/v1/groups: GET

Gets the list of groups that are created in the system.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
√ ¹	√ ¹	√	√	√ ¹

Data admin	Data user	Collection Admin	Admin	Service user
¹ The specified group must be one that is assigned to the requesting user ID. Otherwise the command fails with error 403, "Not authorized".				

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/groups
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example shows how to get the details of the uses that are created in the system.

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/groups
```

Response:

```
(200 OK):
{
  "groups": [
    {
      "id": "a51f84bfeb034b12a9a362109d78bec3",
      "name": "test-group1",
      "description": "Test Group 1",
      "domain": "default"
    },
    {
      "id": "b62g95bfeb034b12a9a362109d89cfd4",
      "name": "test-group2",
      "description": "Test Group 2",
      "domain": "default"
    }
  ]
}
```

/auth/v1/groups: POST

Creates a group in the system.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
X	X	✓	✓	X

Synopsis of the request URL

```
curl -k -H 'Content-Type: application/json' -H 'Authorization: Bearer <token>' -X POST
https://<data_cataloging_host>/auth/v1/groups -d '<json details of group>'
```

You can specify the following details of a group:

- "name": Name of the group.
- "description": A meaningful description for the group.
- "domain_id": The domain to which the group belongs.

Supported request types and response formats

Supported request types:

- POST

Supported response formats:

- JSON

Examples

The following example shows how to create a group.

Request:

```
curl -k -H 'Content-Type: application/json' -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/groups -d '{"name": "test-group"}'
```

Response:

```
201 Created
```

/auth/v1/groups/<group ID>: GET

Gets the details of a specific group.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
√ ¹	√ ¹	√ ¹	√	√ ¹
¹ The specified group must be one that is assigned to the requesting user ID. Otherwise the command fails with error 403, "Not authorized".				

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/groups/<group_ID>
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example shows how to get the details of a specific group.

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/groups/a51f84bf8b034b12a9a362109d78bec3
```

Response:

```
(200 OK):
{
  "id": "a51f84bf8b034b12a9a362109d78bec3",
  "name": "test-group1",
  "description": "Test Group 1",
  "domain": "default"
}
```

/auth/v1/groups/<group_ID>: PATCH

Updates the attributes of an existing group.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
X	X	X	√	X

Synopsis of the request URL

```
curl -k -H 'Content-Type: application/json' -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/groups/<group_ID> -X PATCH -d '<json details to update>'
```

Supported request types and response formats

You can update the following attributes of a group.

- Name
- Description
- Domain ID

You can update one or more attributes in a single call.

Supported request types:

- PATCH

Supported response formats:

- JSON

Examples

The following example shows how to update the attributes of a group:

Request:

```
curl -k -H 'Content-Type: application/json' -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/groups/a51f84bfeb034b12a9a362109d78bec3 -X PATCH -d '{"name": "AdminGroup", "description": "Verifies installations", "domain_id": "Default"}'
```

Response:

```
200 OK
```

/auth/v1/groups/<group_ID>: DELETE

Deletes a specific user group.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
X	X	X	✓	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/groups/<group_id> -X DELETE
```

Supported request types and response formats

Supported request types:

- DELETE

Supported response formats:

- JSON

Examples

The following example shows how to delete a group.

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/groups/a51f84bfeb034b12a9a362109d78bec3 -X DELETE
```

Response:

```
204 No Content
```

/auth/v1/groups/<group_ID>/collections: GET

Gets the details of the collections that are assigned in a group.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
X	X	X	✓	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/groups/<group_ID>/collections
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example shows how to get the details of the collections assigned within a user group.

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/groups/a51f84bfeb034b12a9a362109d78bec3/collections
```

Response:

```
((200 OK):
[
  {
    "description": "This is a test collection",
    "domain_id": "default",
    "enabled": true,
    "id": "51d5bf6c7c4e4fd3b35c53ca91d95705",
    "is_domain": false,
    "name": "test-collection",
    "parent_id": "default",
    "tags": [
      "tag1",
      "tag2"
    ]
  }
]
```

/auth/v1/groups/<group_ID>/roles: GET

Gets the details of the user roles that are assigned to a group.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
X	X	X	✓	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/groups/<group_ID>/roles
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example shows how to get the details of the user roles that are assigned to a user group.

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/groups/a51f84bfeb034b12a9a362109d78bec3/roles
```

Response:

```
((200 OK):
[
  {
    "domain_id": "default",
    "id": "1bdcad2ec7f2414793e71b8b505515b1",
    "name": "datauser"
  }
]
```

/auth/v1/groups/<group_id>/role_assignments: GET

Returns a list of the roles and associated collections assigned to the group where applicable.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	✓	✓	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/groups/<group_id>/role_assignments
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example shows how to get the details of the roles that is assigned to a specific group:

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/groups/a51f84bfeb034b12a9a362109d78bec3/role_assignments
```

Response:

```
Returns 200 OK:
{
  "roles": [
    {
      "collections": [
        {
          "description": "Bootstrap project for initializing the cloud.",
          "domain_id": "default",
          "enabled": true,
          "id": "09dd9136eaa6416784d6c5bdf3fa2f78",
          "is_domain": false,
          "name": "spectrum-discover",
          "parent_id": "default",
          "tags": [
            ]
        },
        {
          "description": "kutle",
          "domain_id": "default",
          "enabled": true,
          "id": "40b0ea6fca7a4bafa38581cb508aa373",
          "is_domain": false,
          "name": "some-collection",
          "parent_id": "default",
          "tags": [
            ]
        }
      ],
      "domain_id": null,
      "id": "5f365cf289d14c93a986b8bea976f92b",
      "name": "collectionadmin"
    }
  ]
}
```

/auth/v1/groups/<group_ID>/users: GET

Gets the details of the users who are part of a specific group.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
X	X	X	✓	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/groups/<group_ID>/users
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example shows how to get the details of the users that are part of a user group.

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/groups/a51f84bfeb034b12a9a362109d78bec3/users
```

Response:

```
(200 OK):
[
  {
    "domain_id": "default",
    "email": "testuser@ibm.com",
    "enabled": true,
    "id": "dfdb2cadca0d4e9da26e6c40e5cadbd5",
    "name": "datauseruser",
    "options": {},
    "password_expires_at": null
  },
  {
    "domain_id": "default",
    "email": "testuser@ibm.com",
    "enabled": true,
    "id": "106999c5eb7f4148932be6d24b6b772c",
    "name": "test-datauser-1",
    "options": {},
    "password_expires_at": null
  }
]
```

/auth/v1/groups/<group_ID>/user/<user_ID>: DELETE

Removes a specific user from a group.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
X	X	X	✓	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/groups/<group_id>/user/<user_ID> -X DELETE
```

Supported request types and response formats

Supported request types:

- DELETE

Supported response formats:

- JSON

Examples

The following example shows how to remove a user from a group.

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/groups/a51f84bfeb034b12a9a362109d78bec3/user/4ee5b47f439640d29b6fac7253a64290 -X DELETE
```

Response:

```
204 No Content
```

/auth/v1/groups/<group_ID>/user/<user_ID>: PUT

Assigns a user to a group.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
X	X	X	✓	X

Synopsis of the request URL

```
curl -k -H 'Content-Type: application/json' -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/groups/<group_ID>/user/<user_ID> -X PUT
```

Examples

The following example shows how to assign a user to a group:

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/groups/a51f84bfeb034b12a9a362109d78bec3/user/4ee5b47f439640d29b6fac7253a64290 -X PUT -H 'Content-Type: application/json'
```

Response:

200 if the command is successful.

/auth/v1/groups/groups_summary: GET

Gets the list of groups and their domain details.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	✓ ¹	✓	✓	✓ ¹

¹ The specified user ID must be the same as the requesting user ID. Otherwise the command fails with error 403, "Not authorized". Data users can access this API to retrieve details only for the groups to which they belong.

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/groups/groups_summary
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example shows how to get the domain names to which the group is associated.

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/groups/groups_summary
```

Response:

```
(200 OK):
{
  "groups": [
    {
      "description": "",
      "domain_id": "default",
      "domain_name": "Default",
      "id": "86f7a42ea54d4659bb60fc6d5c620f2d",
      "name": "bugfix5"
    },
    {
      "domain_id": "a69001e854174dc1a4e0c98f712744bb",
      "domain_name": "lldap",
      "id": "d3b1ae0d1b5efb0c064797bf8239165cce32aaf3c057151279198a780bc8cf0b",
      "name": "Sales"
    },
    {
      "domain_id": "a69001e854174dc1a4e0c98f712744bb",
      "domain_name": "lldap",
      "id": "18326a0d724b4ffaa26a228fc88b6852198a1d10a3a51bc732632afe4d112dc9",
      "name": ""
    }
  ]
}
```

```

    "name": "HumanResources"
  }
}

```

Managing collections

You can create and manage collections by using REST APIs.

- [/auth/v1/collections: GET](#)
Gets the details of the collections that are available in the system.
- [/auth/v1/collections: POST](#)
Creates a collection.
- [/auth/v1/collections/<collection_ID>: GET](#)
Gets the details of a specific collection.
- [/auth/v1/collections/<collection_ID>: PATCH](#)
Updates the attributes of an existing collection.
- [/auth/v1/collections/<collection_ID>: DELETE](#)
Deletes a specific collection.
- [/auth/v1/collections/<collection_ID>/groups: GET](#)
Gets a list of the user groups that can access a collection.
- [/auth/v1/collections/<collection_ID>/users: GET](#)
Gets a list of the users who can access a collection.
- [/auth/v1/collections/<collection_id>/role_assignments: GET](#)
Returns a list of the users and groups and their roles that are assigned to the collection.

/auth/v1/collections: GET

Gets the details of the collections that are available in the system.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	✓ ¹	✓ ¹	✓	X

¹ The list that is returned comprises the set of collections that are assigned to the requesting User ID. If no collections are assigned, then an empty response is returned.

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/collections
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example shows how to get the details of collections that are available in the system.

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/collections
```

Response:

```

(200 OK):
{
  "collections": [
    {
      "description": "Bootstrap project for initializing the cloud.",
      "domain_id": "default",
      "enabled": true,
      "id": "dfd993527cb34b0bbcd700fab121264e",
      "is_domain": false,
      "name": "spectrum-discover",
      "parent_id": "default",
      "tags": []
    },
    {
      "description": "This is a test collection",
      "domain_id": "default",
      "enabled": true,

```

```

    "id": "51d5bf6c7c4e4fd3b35c53ca91d95705",
    "is_domain": false,
    "name": "test-collection",
    "parent_id": "default",
    "tags": [
      "tag1",
      "tag2"
    ]
  }
}

```

/auth/v1/collections: POST

Creates a collection.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	X	✓	X

Synopsis of the request URL

```

curl -k -H 'Content-Type: application/json' -H 'Authorization: Bearer <token>' -X POST
https://<data_cataloging_host>/auth/v1/collections -d '{details of the collection}'

```

The details that can be specified are:

- Name
- Description
- Tags

Important: IBM Data Cataloging does not use collection tags. These collection tags are not related to the IBM Data Cataloging metadata tags.

Supported request types and response formats

Supported request types:

- POST

Supported response formats:

- JSON

Examples

The following example shows how to create a collection.

Request:

```

curl -k -H 'Content-Type: application/json' -H 'Authorization: Bearer <token>'
https://<data_cataloging_host>/auth/v1/collections -d '{"name": "test-collection", "description": "Test Collection 1", "tags":
["tag1", "tag2"]}'

```

Response:

201 Created

/auth/v1/collections/<collection_ID>: GET

Gets the details of a specific collection.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	✓ ¹	✓ ¹	✓	X
¹ The specified collection must be the one that is assigned to the requesting user ID. If no collection is assigned, then the command fails with error 403, "Not authorized".				

Synopsis of the request URL

```

curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/collections/<collection_ID>

```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example shows how to get the details of a specific collection.

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/collections/51d5bf6c7c4e4fd3b35c53ca91d95705
```

Response:

```
(200 OK):
{
  "description": "This is a test collection",
  "domain_id": "default",
  "enabled": true,
  "id": "51d5bf6c7c4e4fd3b35c53ca91d95705",
  "is_domain": false,
  "name": "test-collection",
  "parent_id": "default",
  "tags": [
    "tag1",
    "tag2"
  ]
}
```

/auth/v1/collections/<collection_ID>: PATCH

Updates the attributes of an existing collection.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	✓	✓	X

Synopsis of the request URL

```
curl -k -H 'Content-Type: application/json' -H 'Authorization: Bearer <token>'
https://<data_cataloging_host>/auth/v1/collections/<collection_ID> -X PATCH
-d '<json_details_to_update>'
```

Supported request types and response formats

You can update the following attributes of a collection.

- Name
- Description
- Tags

You can update one or more attributes in a single call.

Supported request types:

- PATCH

Supported response formats:

- JSON

Examples

The following example shows how to update the attributes of a collection:

Request:

```
curl -k -H 'Content-Type: application/json' -H 'Authorization: Bearer <token>'
https://<data_cataloging_host>/auth/v1/collections/a51f84bfeb034b12a9a362109d78bec3
-X PATCH -d '{"name": "General", "description": "ThirdQuarter", "tags": {"ProjectNumber": "1404", "DepartmentCode": "H8AC"}}'
```

Response:

```
200 OK
```

/auth/v1/collections/<collection_ID>: DELETE

Deletes a specific collection.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	X	✓	X

Synopsis of the request URL

```
curl -k -H 'Content-Type: application/json' -H 'Authorization: Bearer <token>' -X DELETE https://<data_cataloging_host>/auth/v1/collections/<collection_ID>
```

Supported request types and response formats

Supported request types:

- DELETE

Supported response formats:

- JSON

Examples

The following example shows how to delete a specific collection.

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/collections/dfd993527cb34b0bbcd700fab121264e -X DELETE
```

Response:

```
204 No Content
```

/auth/v1/collections/<collection_ID>/groups: GET

Gets a list of the user groups that can access a collection.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	¹ ✓	✓	X

¹ The specified collection must be one that is assigned to the requesting user ID. If no collection is assigned, then the command fails with error 403, "Not authorized".

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/collections/<collection_ID>/groups
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example shows how to get details of user groups that belong to a specific collection.

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/collections/a51f84bfeb034b12a9a362109d78bec3/groups
```

Response:

```
(200 OK):  
[  
  {  
    "description": "",  
    "domain_id": "default",  
    "id": "d1c1f64d62df4585ad8c76b345e0a651",  
    "name": "test-group-1"
```

```
}  
1
```

/auth/v1/collections/<collection_ID>/users: GET

Gets a list of the users who can access a collection.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	¹ ✓	✓	X

¹ The specified collection must be one that is assigned to the requesting user ID. If no collection is assigned, then the command fails with error 403, "Not authorized".

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/collections/<collection_ID>/users
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example shows how to get details of users who belong to a specific collection.

Request:

```
curl -k -H 'Authorization: Bearer <token>'  
https://<data_cataloging_host>/auth/v1/collections/a51f84bfeb034b12a9a362109d78bec3/users
```

Response:

```
(200 OK):  
[  
  {  
    "domain_id": "default",  
    "email": "testuser@ibm.com",  
    "enabled": true,  
    "id": "106999c5eb7f4148932be6d24b6b772c",  
    "name": "test-datauser-1",  
    "options": {},  
    "password_expires_at": null  
  },  
  {  
    "domain_id": "default",  
    "enabled": true,

    "name": "datauseruser",  
    "options": {},  
    "password_expires_at": null  
  }  
]  
1
```

/auth/v1/collections/<collection_id>/role_assignments: GET

Returns a list of the users and groups and their roles that are assigned to the collection.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	¹ ✓	✓	X

The specified collection must be one that is assigned to the requesting user ID. If no collection is assigned, then the command fails with error 403, "Not authorized".

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/collections/<collection_id>/role_assignments
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example shows how to get the list of groups to which the collection belongs:

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/collections/a51f84bfeb034b12a9a362109d78bec3/role_assignments
```

Response:

```
{
  "groups": [
    {
      "description": "",
      "domain_id": "default",
      "id": "fccc7d34eeld43128f2fda479f9f63e9",

          "name": "collectionadmin"
        }
      ]
    }
  ]
}
```

Managing domains

You can create and manage user domains by using REST APIs.

- [/auth/v1/domains/<domain_ID>: GET](#)
Gets the details of a specific domain.
- [/auth/v1/domains: POST](#)
Creates a domain.
- [/auth/v1/domains/<domain_ID>: PATCH](#)
Updates the attributes of an existing domain.
- [/auth/v1/domains/<domain_ID>: DELETE](#)
Deletes a specific domain.

/auth/v1/domains/<domain_ID>: GET

Gets the details of a specific domain.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
X	X	X	✓	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/domains/<domain ID>
```

Supported request types and response formats

Supported request types:

- GET

Supported response formats:

- JSON

Examples

The following example shows how to get details of a specific domain.

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/domains/7a2251243611437cae707fb1aa5acf2c
```

Response:

```
(200 OK):
{
  "description": "Open LDAP Domain",
  "enabled": true,
  "id": "7a2251243611437cae707fb1aa5acf2c",
  "name": "ldap",
  "tags": []
}
```

/auth/v1/domains: POST

Creates a domain.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
X	X	X	✓	X

Synopsis of the request URL

```
curl -k -H 'Content-Type: application/json' -H 'Authorization: Bearer <token>' -X POST
https://<data_cataloging_host>/auth/v1/domains -d '<json domain details>'
```

In case of LDAP domain, you can specify the following attributes:

- "id"
- "type"
- "host"
- "port"
- "binddn"
- "bindpassword"
- "basedn"

Supported request types and response formats

Supported request types:

- POST

Supported response formats:

- JSON

Examples

The following example shows how to create the domain and pull in a list of LDAP users.

```
Type LDAP
Name LDAPForum
URL ( LDAP IP or host.domainname ) ldap.forumsys.com
Port 389
```

```
user cn=read-only-admin,dc=example,dc=com
password password
Suffix / Base DN dc=example,dc=com
Group Name Attribute cn
Group Object Class
Group Tree DN ou=mathematicians,dc=example,dc=com
Username Attribute uid
User Object Class person
User Tree DN dc=example,dc=com
```

/auth/v1/domains/<domain_ID>: PATCH

Updates the attributes of an existing domain.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
X	X	X	✓	X

Synopsis of the request URL

```
curl -k -H 'Content-Type: application/json' -H 'Authorization: Bearer <token>'
https://<data_cataloging_host>/auth/v1/domains/<domain_ID> -X PATCH -d '<json_details_to_update>'
```

Supported request types and response formats

In an LDAP domain, you can update the following attributes:

- "id"
- "type"
- "host"
- "port"
- "binddn"
- "bindpassword"
- "basedn"

You can update one or more attributes in a single call.

Supported request types:

- PATCH

Supported response formats:

- JSON

Examples

The following example shows how to update the attributes of a domain:

Request:

```
curl -k -H 'Content-Type: application/json' -H 'Authorization: Bearer <token>'
https://<data_cataloging_host>/auth/v1/domains/a51f84bf034b12a9a362109d78bec3 -X PATCH
-d '{"id":"7a2251243611437cae707fb1aa5acf2c", "type":"Default"}'
```

Response:

```
200 OK
```

/auth/v1/domains/<domain_ID>: DELETE

Deletes a specific domain.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
X	X	X	✓	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/domains/<domain_id> -X DELETE
```

Supported request types and response formats

Supported request types:

- DELETE

Supported response formats:

- JSON

Examples

The following example shows how to delete a specific domain.

Request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/domains/7a2251243611437cae707fblaa5acf2c -X DELETE
```

Response:

```
204 No Content
```

Data protection

Data protection features in IBM Spectrum Discover support backup, disaster recovery, and restore operations to protect catalog metadata and system configurations.

- [Backup and restore](#)
IBM Spectrum® Discover includes a set of procedures for safely backing up and restoring your database and file system for both Virtual appliance and the Red Hat® OpenShift® deployment.
- [Disaster recovery procedures](#)
Disaster recovery procedures describe how to recover an IBM Spectrum Discover system from the loss of a single node or an entire deployment, including deployments on Red Hat OpenShift.

Backup and restore

IBM Spectrum® Discover includes a set of procedures for safely backing up and restoring your database and file system for both Virtual appliance and the Red Hat® OpenShift® deployment.

- [Backup and restore scripts](#)
Backup and restore script is written in Python to run Db2 commands inside the Db2u pod in the OpenShift environment.

Backup and restore scripts

Backup and restore script is written in Python to run Db2 commands inside the Db2u pod in the OpenShift® environment.

Before you begin

1. Install the Python 3 and **oc** CLI and logged in to the environment.
2. Export the project name variable with the name of the environment. The default variable is **ibm-data-cataloging**.
3. For restore, check whether the **dcs-Backup** folder contains the tar.gz file that is generated from the previous backup.

About this task

The backup and restore script works in various steps, which require a stable IBM Data Cataloging environment. It must not be in use because it needs to scale IBM Data Cataloging pods to 0. The process consists of the following steps:

- Scale pods to 0
- Shutdown Db2
- Run backup or restore with Db2 move.
- Get the tar archive of backup files.
- Clean files from the Db2 pod
- Start Db2
- Scale pods to 1

Procedure

Follow the steps to run the script:

- a. Get the script from the utility scripts repo [resources repo](#) then run it with the following command.

```
python3 backup_restore.py
```

- b. The script contains a basic menu with the following options:
 - i. Backup
 - ii. Restore
 - iii. Shutdown Db2

- iv. Start Db2
- v. Exit

The first option does not need any steps. It must start with the steps that are described in the overview. At the end, the backup tar.gz file must be in a directory that is named **dcsc-Backup**, where the script runs.

The second option lists **dcsc-Backup**tar.gz files. You can select one from those and run it with the steps that are described in the overview. After the restore is done, you need to go to the IBM Data Cataloging user interface and refresh the summary database to see the imported records.

After one of the first two options is finished, the system starts the scale pods. Some of them can fail in crashloop or error, but after the depending pods are running, they must recover after running state pods.

The third and fourth options are only used if the backup fails, leaving the environment in **maintenance mode**. To restore the state of IBM Data Cataloging, you need to scale pods manually.

Disaster recovery procedures

Disaster recovery procedures describe how to recover an IBM Spectrum Discover system from the loss of a single node or an entire deployment, including deployments on Red Hat® OpenShift®.

Use this process to recover from a disaster that involves an IBM Data Cataloging system and discusses the following scenarios:

- Recovery from the entire loss of a single node IBM Data Cataloging deployment.
- Recovery from the entire loss of an IBM Data Cataloging deployment on Red Hat OpenShift.
- [Preparations for disaster recovery](#)
Before you need to perform disaster recovery, there are several tasks that must be accomplished to ensure the ability to recover.
- [Running disaster recovery for Red Hat OpenShift](#)
The disaster recovery procedure for Red Hat OpenShift is similar to its backup and restore procedures.

Preparations for disaster recovery

Before you need to perform disaster recovery, there are several tasks that must be accomplished to ensure the ability to recover.

Procedure

1. Take a backup of the IBM Data Cataloging system as described in [Backup and restore](#).
2. Record the installation configuration, including:
 - Network settings
 - Storage settings
 - CPU and memory
 - IBM Data Cataloging version
3. Ensure that the physical and virtual infrastructure is available to replace the system that might fail.
4. You cannot recover to a different version of IBM Data Cataloging. If a change of version is required, you need to recover to the current version before you install the upgrade.
If you perform a recovery on a system that is upgraded, it is recovered directly to the upgraded IBM Data Cataloging version. For example, if IBM Data Cataloging 2.0.0.3 is deployed and then upgraded to IBM Data Cataloging 2.0.1 and then recovered from a failure, the recovery goes directly to the 2.0.1.

Running disaster recovery for Red Hat OpenShift

The disaster recovery procedure for Red Hat® OpenShift® is similar to its backup and restore procedures.

On successfully repairing or rebuilding your Red Hat OpenShift cluster, you can restore your system from an appropriate backup.

For more information, see [Restoring deployed on](#).

Using a third-party data movement application to manage data

Introduction to data movement with IBM Data Cataloging.

Before you begin

- The third-party application must be registered with IBM Data Cataloging.
- IBM Data Cataloging must scan both the source and destination data sources before the data movement.
- The application must be configured to access the same source and destination data sources.

You can see the third-party application documentation for details.

About this task

The capabilities of IBM Data Cataloging can be extended by applications; for example, data mover applications can be used to move data between data sources, based on the IBM Data Cataloging insights. Applications register with IBM Data Cataloging providing details of the operations they support and the parameters they need to fulfill the operation.

The following table lists the supported data movement operations:

Table 1. Data movement operations

Operation	Source Type	Destination Type
MOVE	NFS	NFS
	S3	S3
	COS	COS
	SMB/CIFS	SMB/CIFS
COPY	NFS	NFS
	S3	S3
	COS	COS
	SMB/CIFS	SMB/CIFS
TIER	NFS	NFS
	S3	S3
	COS	COS
	SMB/CIFS	SMB/CIFS

Note:

For now, it is not possible for an application to register new operations beyond the records listed in the Data movement operations table.

You can create data movement policies that identify files and objects that are candidates for data operations, by using registered data movement Applications. The IBM Data Cataloging policy engine generates job request messages in JSON format. It contains a batch of files or objects with the source and target information, and any additional options such as preserving source system timestamps.

The job request messages are put onto a Kafka egress topic. The data movement application reads the messages from the topic and performs the necessary data movement operation, and provides response messages in JSON format on a Kafka ingress topic.

IBM Data Cataloging can interact with third-party data movement applications to move, copy, or tier data between data sources. Create data management policies on IBM Data Cataloging, and specify the set of documents to process by using a policy filter. The policy filter can be based on the system metadata or the custom metadata of documents that are collected by IBM Data Cataloging.

The third-party application registers with IBM Data Cataloging providing the operations that it supports (move, copy or tier). For each operation, it gives the list of parameter values that it needs to perform the operation.

When you create the data management policy in IBM Data Cataloging the user defines the filter, the parameter values, and when the policy must run. When the policy runs, IBM Data Cataloging sends the list of files to the data movement application and any additional parameters. The application processes the files and returns a status summary to IBM Data Cataloging. The summary is displayed to the user.

Note:

- During data migration, the migrated files need to preserve the IBM Data Cataloging tags. You can follow a manual procedure to preserve the tags. For more information, see [Preserving tags during data movement](#).
- A third-party data movement application can register a schema, defining the parameters it requires for data movement. You need to set these parameters in the application user interface (UI) while creating the policy. Invalid parameters cause an error when you submit a policy.

However, in few cases, due to the complexity of the schema, the error may not point to the precise location of the problem or may indicate that a valid parameter is invalid. Therefore, when an error is raised when you submit a policy, and it is not definite where the problem is, it is recommended that you check all the policy parameters.

Procedure

1. Log in to the IBM Data Cataloging GUI.
2. Go to Admin > Management Policies.
3. To create a policy, click Add Policy.
4. Click the slider control and set the status to one of the following values:

Active

An active policy runs whenever its scheduling event is reached.

Inactive

An inactive policy does not run even when its scheduling event is reached (including a NOW event).

5. Enter a policy name.
6. Enter a policy filter.

The policy filter includes the criteria for selecting the files for moving or copying. For example, filetype="pdf" selects all files of type PDF.

Note:

- IBM Data Cataloging tracks the last known migration status for each file in the 'STATE' facet. This can be used when defining data movement policies to either target or avoid files in a particular state. The following values represent the file status:

migrtd (migrated)
File contents are only present on the target system but a stub file exists on the source.
resdnt (resident)
File contents are only present on the source system.

- The following are the scenarios where it is useful to filter the file status by 'STATE' facet are:
 - In a TIER policy where files that are already migrated must not be migrated again.
 - In a COPY policy where files that are migrated must not be copied, as this would result in a recall of the data.
 - In a TIER policy where some files are being recalled in preparation for a workload. Any files that are already resident do not need to be recalled.
 - To target files that are resident, add "state = 'resdnt'" to the filter criteria. To target files that are NOT resident, add "state <> 'resdnt'" to the filter criteria.
7. To select the policy type, click Next Step.
 8. Select MOVE, COPY, or TIER as the policy type.
 9. Select the agent name as the Agent.
 10. Enter the remaining parameters. The parameters that are displayed depend on the application, and these parameters might include:

Source connection type
Indicates the type of connection that the files currently reside on.
Source connection
Indicates the name of the connection that the files currently reside on.
Destination connection type
Indicates the type of connection that the files are being moved or copied to.
Destination connection
Indicates the name of the connection name that the files are being moved or copied.
Force migrate
Indicates whether to force demigration or recall of the file at source location when it is migrated to other location before you perform the operation.
Overwrite
Indicates what value to give when a file exists at the destination.
Preserve attributes, timestamp, or permissions
Indicates the parameters to control whether the files metadata is preserved.

11. To enter a schedule, select Next Step.
The schedule indicates when you want to start the move of the copy.
12. To review the policy, select Next Step.
13. To create the policy, select Submit. The policy runs at the scheduled time.
14. When the policy runs or completes an execution status summary, view it by clicking Policy Preview.

- **Data movement with IBM Data Cataloging and Moonwalk**
Policy-based data movement and management with integration of IBM Data Cataloging and Moonwalk applications.
- **Preserving tags during data movement**
Preserve tags during data movement by generating a report of files and their tags before migration, then reapplying the tags using AUTOTAG policies after the destination connection is rescanned.

Data movement with IBM Data Cataloging and Moonwalk

Policy-based data movement and management with integration of IBM Data Cataloging and Moonwalk applications.

Moonwalk data mover application

Moonwalk is a heterogeneous Data Management System. It automates and manages the movement of data from primary storage locations to lower-cost file systems, object stores, tape, or cloud storage services. Files can be moved from source storage locations to target storage locations. These files are demigrated transparently when accessed by a user or an application. Moonwalk also provides capability to copy and move files along with a range of Disaster Recovery options.

Moonwalk provides a data movement application that integrates with IBM Data Cataloging, enabling to move, copy, or migrate/tier data from the IBM Data Cataloging user interface.

The moonwalk application is certified against the IBM Data Cataloging 2.0.4.

For more information about Moonwalk application and integrating the application with IBM Data Cataloging, see [Moonwalk documentation](#).

Preserving tags during data movement

Preserve tags during data movement by generating a report of files and their tags before migration, then reapplying the tags using AUTOTAG policies after the destination connection is rescanned.

Before you begin

Generate a report of the files to be moved or copied before you start the data movement process. This report includes the relevant tags for each source file. A sample report is shown in the following table:

Table 1. Report generated for moving files

Path	Filename	Filetype	Datasource	tagA	tagB
/	Chrysanthemum.jpg	jpg	dir1	image	value1
/	Lighthouse.jpg	jpg	dir1	image	value1
/	newtextfile.txt	txt	dir1	text	value2
/	Hydrangeas.jpg	jpg	dir1	jpg	value1

Path	Filename	Filetype	Datasource	tagA	tagB
/	Thumbs.db	db	dir1	unknown	value1
/	Koala.jpg	jpg	dir1	jpg	value1
/	Desert.jpg	jpg	dir1	jpg	value1

About this task

If IBM Data Cataloging tags must be preserved during data migration, then you can follow a manual procedure to ensure that the tags are preserved in the moved or the copied files.

Procedure

1. Run the data movement process.
2. Rescan the destination connection after the data movement completes successfully.
3. Refer to the information provided in the report, shown in [Table 1](#) that was generated before you started the data movement process, to identify the files for which you need to preserve the tags.

Note: You can define a filter to identify and select the correct set of files that must be tagged. For example, if we want to move files shown in [Table 1](#) to a new datasource (ddsource), you can define filters that include the actions to be taken for the tag values. For a filter defined as shown:

```
datasource in ('ddsource') and filetype in ('jpg')
```

You can create an AUTOTAG policy that sets the value of **tagA** to **image**.

This process assumes either of the two things.

- No other files belonging to these filetypes exist in the destination datasource.
- Those files can also be tagged with the **tagA** values.

4. Reapply the tags (for example, **tagA**) on the moved or copied files by using the auto tagging capability of IBM Data Cataloging.

Note:

You must perform a search using the preceding filters to check that it retrieves the correct documents that are being selected. You can also sort, based on the report headings in MS Excel, to identify a suitable filter.

It is not easy to identify a suitable filter to reapply the **tagB** values shown in [Table 1](#) which indicates the difficulty in manually reapplying the tags.

This solution is feasible only where you can define a small number of filters that identify the groups of files to which you need to apply the tags. If filters cannot be defined then you must run several AUTOTAG policies, which might be an impractical and tedious process.

Monitoring IBM Data Cataloging

This section provides information on how to monitor the IBM Data Cataloging capabilities.

- [Monitoring data sources](#)
You can use the Home page to monitor the data sources that are connected to your IBM Spectrum® Discover environment. Use the Data Source Connections page view details about data source connections.
- [Monitoring the IBM Data Cataloging service environment](#)
You can monitor the health and status of the IBM Data Cataloging service environment and obtain audit log information.
- [Health check monitoring](#)
Provides series of checkpoints to check IBM Data Cataloging health status.

Monitoring data sources

You can use the Home page to monitor the data sources that are connected to your IBM Spectrum® Discover environment. Use the Data Source Connections page view details about data source connections.

- [Viewing data source status](#)
Use the Home page to monitor your environment for storage system capacity, used capacity, records indexed, and duplicate files. You can also view data usage for a specific area of your organization.
- [Viewing data source connections](#)
Use the Data Source Connections page to view connection information for the data sources that are connected to your IBM Data Cataloging environment.
- [Recommended to move](#)
In the IBM Data Cataloging dashboard, you can categorize data as Recommended to move.
- [Deleting or editing a connection](#)
Use the following information to delete or edit a connection.

Viewing data source status

Use the Home page to monitor your environment for storage system capacity, used capacity, records indexed, and duplicate files. You can also view data usage for a specific area of your organization.

The data in the home page is updated periodically. The last update is indicated by a time stamp.

Viewing storage system capacity

Use the Data source capacity area to view capacity usage compared to the allocated capacity for all data sources that are registered with IBM Spectrum® Discover. The data sources can be a mixture of file systems and object vaults. A graph provides a convenient view of the current capacity of data sources and whether any are close to running out of space. This view also indicates the number of files to move or archive, based on user-defined policies.

Hover over a data source in the graph to view details about the data source. Click a data source to open the Search page and perform a search of the selected data source.

Note: Data sources that do not have data residing in them are not displayed in the graph.

Figure 1. Datasource capacity

Understanding size and capacity differences

IBM Spectrum Discover collects size and capacity information. Generally:

- Size refers to the size of a file or object in bytes.
- Capacity refers to the amount of space the file or object consumes on the source storage in bytes.

For objects, size and capacity values always match. For files, size and capacity values can be different because of file system block overhead or sparsely populated files.

Note: Storage protection overhead (such as RAID values or erasure coding) and replication overhead are not captured in the capacity values.

The Data source capacity area contains a view to visualize the data in a tabular representation. To see the view, click on the table button on the chart toolbar.

The tabular representation provides a complementary view to the analysis of the information on the chart. On the Group column, you can see the recommended to move, used, and free values that indicate the number of files to move or archive based on user-defined policies. On the y-value column, you can see the names of the data sources, and on the x-value column, you can see the size and capacity information in bytes.

Tabular representation

Group	y-value	x-value
Recommended to move	NFS-v4	0
Used	NFS-v4	708,633,088
Free	NFS-v4	122,850,862,374,400
Recommended to move	Scale-OCP-Cluster	0
Used	Scale-OCP-Cluster	42,981,236,736
Free	Scale-OCP-Cluster	3,178,244,235,264

Download as CSV

Primary and Spectrum Protect sources

Viewing used capacity

Use the Capacity Used by area to view graphs with an aggregated display of capacity usage for selected metadata attributes. You can view capacity for both primary and backup sources. The graphs provide details about capacity usage by aggregating across different attributes that are available from standard system metadata.

Use the Capacity Used by list to select an attribute and display the capacity consumers of that attribute in the graphs.

The Used graph displays the highest consumers of capacity for the selected attribute, in order of consumption.

The data source graph displays the percentage of overall usage per data source for the selected attribute. You can select a specific capacity consumer to display in the graph.

Hover over a value in a graph to view details. Click a value in a graph to open the Search page and search the selected item.

Figure 2. Example of the capacity that is being used

Viewing records indexed

Use the Records Indexed area to view both the total number of records and the capacity of the records that are indexed by IBM Spectrum Discover. This view provides a summary view of total storage usage.

Records Indexed

19,180,153

Total Records Indexed

322.41 TiB

Total Capacity Indexed

Last Updated : 2018-10-23 19:30:08

Click the Total Records Indexed value to open the Search page and perform a search of the indexed records.

Viewing duplicate file information

Use the Duplicate File Information area to view information about possible duplicate files within the storage environment. Possible duplicate files are files with the same name and size but different paths or object names. The number of duplicates and the capacity that is consumed by these files is displayed. You can also use a report that provides detailed and sorted information for the potential duplicates.

Click the Duplicate Records value to open the Search page and perform a search of duplicate records.

Duplicate File Information

10,913,954

Duplicate Records

1.11 TiB

Total Capacity Consumed

Last Updated : 2018-10-23 00:15:39

Identifying potential duplicates can be resource-intensive on IBM Data Cataloging. By default, the background task that refreshes potential duplicate information is disabled. However, you can update potential duplicate information either on demand or on a specific schedule. If you disable duplicate background task, the dashboard shows the following message:

To view and manage how often data in the home page is updated, navigate to Data connections > Discover database under Data source management window.

Figure 3. Run table refresh button in the Discover database window

From here, you can enable or disable the automatic updating of summary information. You can update information on the home page on demand by clicking the Run table refresh.

Viewing data source connections

Use the Data Source Connections page to view connection information for the data sources that are connected to your IBM Data Cataloging environment.

The following connections details are available:

Source Name

A name that uniquely identifies the connection to the data source. A data source can have multiple connections.

Platform

The platform of the data source - IBM Storage Scale system or IBM Cloud® Object Storage system.

Cluster

The cluster address of the data source.

Data source name

The full name of the data source.

Site

The physical location of the data source.

Recommended to move

In the IBM Data Cataloging dashboard, you can categorize data as Recommended to move.

[Figure 1](#) shows an example of a data source capacity widget.

Figure 1. Example of a data source capacity widget

Use the **data source capacity** area to view capacity usage compared to the allocated capacity for all data sources that are registered with IBM Data Cataloging. The data sources can be a mixture of file systems and object vaults. A graph provides a convenient view of the current capacity of data sources and whether any are close to running out of space. This view also indicates the number of files to move or archive, based on user-defined policies.

Hover over a data source in the graph to view details about the data source. Click a data source to open the Search page and perform a search of the selected data source.

The data source capacity widget displays any files or objects that have the TEMPERATURE tag set to a value of ARCHIVE as Recommended to move. You can create an AUTOTAG policy to look for files and objects, which meet your archive criteria and set the TEMPERATURE tag to a value of ARCHIVE.

Any files that match the criteria of the AUTOTAG policy filter are tagged as ARCHIVE. The filter might be age-based or more complex. For example, the filter might match only certain file types, or files over some size threshold.

Figure 2 shows an example of a screen that shows the TEMPERATURE tag.

Figure 2. Example of a screen that shows the TEMPERATURE tag

Figure 3 shows an example of an AUTOTAG policy to identify files and objects that have not been accessed for more than a year.

Figure 3. Example of an AUTOTAG policy to identify files and objects that have not been accessed in more than one year

Deleting or editing a connection

Use the following information to delete or edit a connection.

About this task

You can delete or edit a connection by using the graphical user interface.

Procedure

1. Click Data connections to display a listing of existing connections as shown in Figure 1

Figure 1. Example of a listing of existing connections

- Click Remove to start the process to remove the data source connection as shown in [Figure 2](#).

Figure 2. Starting the process to delete a data source connection

- Clicking Remove displays a screen as shown in [Figure 3](#). If you are sure you want to delete the connection, click Delete.

Figure 3. Example of a screen that shows how to delete a connection

4. To edit a connection, click Edit.
 - a. Edit the appropriate fields in the window for Edit Data Source Connection.
 - b. Click Update Connection.

Figure 4. Example of a screen that shows how to edit a connection

Monitoring the IBM Data Cataloging service environment

You can monitor the health and status of the IBM Data Cataloging service environment and obtain audit log information.

- [Audit log](#)
Use the audit log entries to monitor activity of REST API calls within the IBM Spectrum® Discover environment, including the API endpoint that was used.
- [Configurable log trimmer handler](#)
Log trimmer configurable feature provides the capability to interact with IBM Db2 components to remove unnecessary logs with a certain age, whose accumulation might impact storage and filesystem performance.
- [SD-Monitor](#)
SD monitor obtains metrics about the Kafka messages that are fetched from the Kafka topics.

Audit log

Use the audit log entries to monitor activity of REST API calls within the IBM Spectrum® Discover environment, including the API endpoint that was used.

To view audit log entries, extract the output from the compressed file that is generated by the FFDC script. You can use a text editor to read the FFDC output. Audit log entries are in JSON format and are identified in the FFDC output by the string AUDIT in the type field.

For more information about API endpoints in the IBM Spectrum Discover environment, see *REST API in IBM Data Cataloging: REST API Guide* [REST API for IBM Data Cataloging](#).

The audit log includes the following fields:

service

The service that processed the request. The service and node name are included. The following details are optional: **namespace**, **serviceInstance**, and **containerId**.

requestId

The request ID that is returned back to the client, or a correlation tag that is used for internal tracking.

timestampStart

The time that the request was received.

request

The API endpoint that made the request.

serverAddress

The IP address of the server or node that processed the request.

userAgent

The identification string of the user agent that made the request.

type

The log entry type: **AUDIT**

responseSize

Size of the response, in bytes, sent back to the client.

hostname

The IP address from which the request originates.

protocol

The protocol of the request.

requestLatency
The latency of the request in milliseconds.

responseStatus
The return code that is provided to the client.

auth
The user name and the authentication scheme, bearer (for LDAP) or basic (for local authentication).

Configurable log trimmer handler

Log trimmer configurable feature provides the capability to interact with IBM Db2 components to remove unnecessary logs with a certain age, whose accumulation might impact storage and filesystem performance.

By default, the job to erase log files is configured to run at midnight daily and erase logs older than 12 hours.

To configure age for log clean up, a config map is defined. Use the following example to configure it:

```
export NAMESPACE=ibm-data-cataloging
export TIME_DELETION=720
oc patch configmap db2-log-trimmer -n $NAMESPACE --type merge -p "{\"data\":{\"time-limit-min\":\"${TIME_DELETION}\"}}
```

TIME_DELETION vary in minutes.

SD-Monitor

SD monitor obtains metrics about the Kafka messages that are fetched from the Kafka topics.

About this task

The SD monitor provides information about the Kafka messages that are fetched from the Kafka topics.

In the IBM Data Cataloging service, each Kafka topic represents a type of connection, such as NFS, IBM Storage Scale, COS, and S3, which has multiple consumers fetch the messages that are sent from the producers when they connect to a data source and scan data from it.

You can retrieve the following metrics from the SD monitor:

- Current committed offset for the set of topics and partitions.
- Log end offset (highest offset in the partition).
- Lag, the difference between the current committed offset and log end offset values.

Procedure

Follow the steps to get SD monitor information is as follows:

- a. Run the following command to get the logs of the SD monitor pod.

```
(oc logs $( oc get pods -n ibm-data-cataloging | grep sdmonitor | awk '{print $1}' ) -n ibm-data-cataloging) | grep Fetch
```

- b. Locate the array that contains the metrics about the connection type that you want to debug.
An example array for NFS connections.

```
'file-scan-topic': {0: [30768, 30768, 0], 1: [31050, 31050, 0], 2: [30897, 30897, 0], 3: [30788, 30788, 0], 4 : [30608, 30608, 0], 5: [30525, 30525, 0], 6: [30908, 30908, 0], 7: [30610, 30610, 0], 8: [30726, 30726, 0], 9 : [30959, 30959, 0]}
```

Note: Each sub-array 0: [30768, 30768, 0] indicates the metrics that are related to one of the consumers. In this sub-array, the first value represents the current committed offset. The second value is the log end offset, and the third value represents the lag.

It is important to consider the following points when you read the log information:

- The SD monitor provides a condensed metric of the Kafka messages that are received by each one of the consumers.
For example, if you run two different NFS scans, the expectation is to get the metrics of all the Kafka messages sent by the two scans.
- The SD monitor runs every 30 seconds, which means that you can see a small lag between the progress of the scans and the metrics they are reported in the SD monitor log.

Health check monitoring

Provides series of checkpoints to check IBM Data Cataloging health status.

It provides IBM Data Cataloging health status and different commands that might be used for continuous monitoring of the health check.

When scanning is running, different checkpoints can be made to ensure that they are scanned properly.

Monitor connection manager and db2whrest pods frequently to avoid overhead on database

One of the issues that might disrupt IBM Data Cataloging function is overrunning the database, causing malfunctions in different components such as the user interface or connection manager.

The top memory and CPU consumption for connection manager and db2whrest pods is around 85% of their limits.

It is recommended to run the following commands to ensure that those limits are met for regular usage:

1. Check the current usage of connmgr pod and db2whrest.

```
$oc adm top pod isd-connmgr-795544f666-125mc
$oc adm top pod isd-db2whrest-7c574c7bf-x719t
```

Example output:

```
$oc adm top pod isd-connmgr-795544f666-125mc
NAME                                CPU (cores)   MEMORY (bytes)
isd-connmgr-scheduler-795544f666-125mc  0m           34Mi

$oc adm top pod isd-db2whrest-7c574c7bf-x719t
NAME                                CPU (cores)   MEMORY (bytes)
isd-db2whrest-7c574c7bf-x719t         21m          512Mi
```

2. Compare current usage with the limits set and make sure that it is not greater than 85% for a long period of time.

```
$oc describe pod isd-connmgr-795544f666-125mc | grep -A2 Limits
Limits:
  cpu:      1
  memory:   4Gi
$oc describe pod isd-db2whrest-7c574c7bf-x719t | grep -A2 Limits
Limits:
  cpu:      2
  memory:   8Gi
```

Note: IBM Data Cataloging recommends having 10 parallel scans at most to avoid malfunction or reduce significantly performance on the product.

Check request latency of a connection filtering db2whrest log

This checkpoint is important for checking the time for a request query to be processed, the following example uses one connection to see the time for the request to respond. Values < 2000 (milliseconds) are expected.

1. This checkpoint is important for checking the time for a request query to be processed, the following example uses one connection to see the time for the request to respond. Values < 2000 (milliseconds) are expected.
2. Run the following command to check the pod that is associated with db2whrest.

```
$oc get pods | grep db2whrest
```

Example output:

```
$oc get pods | grep db2whrest
isd-db2whrest-7x574c7bf-c719t      1/1      Running      0      43h
```

3. Get the logs and filter them.

For example:

```
$oc logs isd-db2whrest-7x574c7bf-c719t | grep -E '${connectionName}.*requestLatency'
{"type": "AUDIT", "hostname": "172.17.47.184", "serverAddress": "172.21.166.189", "userAgent": "python-requests/2.31.0",
```

4. It is also acceptable if the requested latency value is less than 2000. This is an important checkpoint that can give you clues about database behavior when you submit a new scan.

Monitor Kafka lag as complementary signal of a healthy product

When a scan is being processed, one signal of a healthy environment is the lag, which is the difference between indexed records and scanned records.

A healthy state would be when the lag is less than 30%. A state of unhealthiness occurs when the number of scanned records continues to increase without progress in indexing, resulting in a significant lag and a sustained difference more than 30% for an extended period.

To resolve that situation, it is recommended to reduce the number of parallel scans, giving more time for the ingestion rate to increase properly and reducing the lag.

Check average insert rate of a scan and batch size

The following checkpoints give clues to the health of the insert rate into the database and the batch size of Kafka.

1. Insert rate values might vary depending on different factors. However, the expected rate is around 200 messages per second. It means 200 messages per second get inserted into the database per consumer.
2. Regarding the batch size of Kafka, it is the amount of data that is accumulated and sent as a batch by a Kafka producer. This value is expected to be around 50,000 overall. If the value decreases significantly for a long period, it might be a sign of misbehavior.
3. Run the following command to get the consumer pod details.

```
$oc get pods | grep consumer-file-scan
```

Note: In this case, the consumer is the file, because it is an NFS scan and should be 10 pods.

Example output:

```
isd-consumer-file-scan-6d6bbf8487-45c6c      1/1      Running      0      7d13h
isd-consumer-file-scan-6d6bbf8487-6zfv9      1/1      Running      0      7d13h
isd-consumer-file-scan-6d6bbf8487-77g7v      1/1      Running      0      7d13h
isd-consumer-file-scan-6d6bbf8487-97cfv      1/1      Running      0      7d13h
isd-consumer-file-scan-6d6bbf8487-bwmr5      1/1      Running      0      7d13h
isd-consumer-file-scan-6d6bbf8487-c5cb9      1/1      Running      0      7d13h
isd-consumer-file-scan-6d6bbf8487-ljkws      1/1      Running      0      7d13h
isd-consumer-file-scan-6d6bbf8487-m96hc      1/1      Running      0      7d13h
isd-consumer-file-scan-6d6bbf8487-w55lr      1/1      Running      0      7d13h
isd-consumer-file-scan-6d6bbf8487-z8hqd      1/1      Running      0      7d13h
```

4. Get the logs and filter them.

For example:

```
$oc logs isd-consumer-file-scan-6d6bbf8487-45c6c | grep -A5 "Avg Insert"
... omitted ...
DB Avg Insert Rate (msg/sec): { current: 210, min: 1, max: 245 }
2023-06-22 13:54:40.611 > offset_commit_cb: success, offsets: [{part: 1, offset: 79452963, err: none}]
2023-06-22 13:56:25.588 > Consumed= 50014 Dup_id= 13 Skipped= 0 |Last_Batch: Att= 50000 Succ= 50000 Fail= 0 |Total:
```

```

Att= 50001 Succ= 50001 Fail= 0 | Batch_Time(ms): E= 160 B= 36155 L= 68659 KC= 0 TH= 0 Tot= 104974
DB Avg Insert Rate (msg/sec): { current: 192, min: 1, max: 245 }
2023-06-22 13:56:25.605 > offset_commit_cb: success, offsets:[{part: 1, offset: 79502976, err: none}]
2023-06-22 13:59:44.298 > Consumed= 100024 Dup_id= 23 Skipped= 0 |Last Batch: Att= 50000 Succ= 50000 Fail= 0 |Total:
Att= 100001 Succ= 100001 Fail= 0 | Batch_Time(ms): E= 139 B= 11888 L= 186663 KC= 1 TH= 0 Tot= 198691
DB Avg Insert Rate (msg/sec): { current: 196, min: 1, max: 245 }
2023-06-22 13:59:44.314 > offset_commit_cb: success, offsets:[{part: 1, offset: 79552986, err: none}]
2023-06-22 14:03:04.724 > Consumed= 150031 Dup_id= 30 Skipped= 0 |Last Batch: Att= 50000 Succ= 50000 Fail= 0 |Total:
Att= 150001 Succ= 150001 Fail= 0 | Batch_Time(ms): E= 155 B= 1594 L= 197868 KC= 1 TH= 0 Tot= 200408
DB Avg Insert Rate (msg/sec): { current: 206, min: 1, max: 245 }

```

Check Qpart assignment when a new connection is submitted for scan

This checkpoint shows that when a scan is assigned to the different partitions, the health status must be associated with the correct assignment of the 10 Qparts (0–9), and scangen must be constant.

1. Run the following command to get the producer pod details.

```
$oc get pods|grep producer-file-scan
```

Note: In this case, the producer is the file, because it is an NFS scan only one producer is acceptable.

Example output:

```

$oc get pods|grep producer-file-scan
isd-producer-file-scan-79c45bbc77-jm5v6          1/1      Running    4 (7d14h ago)    7d14h

```

2. Get the logs from one and filter the connection name and COMMITSCAN.

For example:

```

$oc logs isd-producer-file-scan-79c45bbc77-jm5v6|grep -E ${connectionName}.*COMMITSCAN'
Built commit scan message [connection:${connectionName},eventname:COMMITSCAN,scangen:1,qpart:0]
Built commit scan message [connection:${connectionName},eventname:COMMITSCAN,scangen:1,qpart:1]
Built commit scan message [connection:${connectionName},eventname:COMMITSCAN,scangen:1,qpart:2]
Built commit scan message [connection:${connectionName},eventname:COMMITSCAN,scangen:1,qpart:3]
Built commit scan message [connection:${connectionName},eventname:COMMITSCAN,scangen:1,qpart:4]
Built commit scan message [connection:${connectionName},eventname:COMMITSCAN,scangen:1,qpart:5]
Built commit scan message [connection:${connectionName},eventname:COMMITSCAN,scangen:1,qpart:6]
Built commit scan message [connection:${connectionName},eventname:COMMITSCAN,scangen:1,qpart:7]
Built commit scan message [connection:${connectionName},eventname:COMMITSCAN,scangen:1,qpart:8]
Built commit scan message [connection:${connectionName},eventname:COMMITSCAN,scangen:1,qpart:9]

```

In case 1, it is acceptable for the connection to be assigned to 10 different partitions and scangen to be constant.

Check connections progressing and scan in progress state when a new scan started

These requests can be made to the connection manager API endpoint to check the status of a connection. It would be necessary to create a token to be ready to consume the API properly. For more information about how to get the token, see [/auth/v1/token: GET](#).

At this stage, the token is saved in the `$(TOKEN)` variable, `hostRoute` and `connectionName` are identified, and `jq` is installed for JSON formatting purposes.

For example:

```

$ curl -q -H "Authorization: Bearer $TOKEN" https://<<hostRoute>/connmgr/v1/connections/<<connectionName>>|jq
{
  "name": "exports",
  "platform": "NFS",
  "cluster": "nfs-1.nfs.svc.cluster.local",
  "datasource": "exports",
  "current gen": 3,
  "password": null,
  "site": "",
  "online": 1,
  "scan_topic": "file-scan-connector-topic",
  "le_topic": "file-le-connector-topic",
  "le_enabled": 1,
  "host": "nfs-1.nfs.svc.cluster.local",
  "mount_point": "/exports",
  "protocol": "nfs",
  "user": null,
  "additional_info": "{\"working_dir\": \"\\nfs-scanner\\\", \"local_mount\": \"\\nfs-scanner/da68f4b426134c5d9fb498a15219857f\\\"}\",
  "scan_in_progress": 1,
  "total_records": 10162,
  "scan_compl_rec": 0,
  "schedule": null
}

```

As shown, there is a scan in progress for that specific connection, and total records must be augmenting over time. It would be necessary to give some seconds to get data reflected on the endpoint.

These are some of the checkpoints that can be used for checking the state of the connections. This was one example of the many endpoints that can be consumed by the IBM Data Cataloging API. For more information, see [REST API for IBM Data Cataloging](#).

Check database records increasing while scan is progressing

If querying the API or scanning progress on the user interface does not show any progress, it might give the impression that the system is not responding properly. However, that might not be accurate. It is necessary to establish a connection to the database and make some queries to ensure that the system is actually making insertions into the proper table.

Warning: The database is stressed when doing several transactions. Be careful when you query the database directly. Also, avoid doing complex queries when one or several scans are occurring; this might cause unnecessary overhead and impact the unusual behavior of the database.

1. Run the following command to get db2 head pod and access it.

```

$ headPodName=$(oc -n ${projectName} get po --selector name=dashmpp-head-0|grep isd|awk '{print $1}')
$ oc -n ${projectName} rsh ${headPodName}

```

2. Change user to db2inst1 and connect to bludb database.

```
sh-4.4$ su db2inst1 -
[db2inst1@c-isd-db2u-0 - Db2U ]$ db2 connect to bludb

Database Connection Information

Database server      = DB2/LINUX8664 11.5.7.0
SQL authorization ID = DB2INST1
Local database alias = BLUDB

#Do couple counting queries against metaocean table and make sure it's progressing leaving couple of seconds from one
query to another

[db2inst1@c-isd-db2u-0 - Db2U ]$ select count(fkey) from bluadmin.metaocean

1
-----
10364.

1 record(s) selected.

[db2inst1@c-isd-db2u-0 - Db2U ]$ select count(fkey) from bluadmin.metaocean

1
-----
10952.

1 record(s) selected.
```

Collecting logs and metrics

Steps to collect logs and metrics for the IBM Data Cataloging.

Procedure

1. Run the following `oc` login command.

```
oc login --token=<OCP_TOKEN> --server=<OCP_SERVER>
```

For more information about CLI login, see [CLI login](#).

2. Export `OCP_TOKEN`, `PROJECT_NAME`, and `TIMESTAMP` environment variables.

```
export OCP_TOKEN=$(oc whoami --show-token) # or the actual token if not logged in
export PROJECT_NAME=ibm-data-cataloging
export TIMESTAMP=$(date +%Y%m%d%H%M%S")
```

3. Run the following command to create a secret with a token to use in the script that collects resources.

```
oc -n $PROJECT_NAME create secret generic dcs-must-gather --from-literal=token=$OCP_TOKEN
```

4. Create `dcs-must-gather-pod.yaml` file.

```
cat >> dcs-must-gather-pod.yaml << EOF

apiVersion: v1
kind: Pod
metadata:
  name: dcs-must-gather
  labels:
    app: isd
    component: discover
    role: must-gather
spec:
  containers:
    - name: must-gather
      env:
        - name: WORKDIR
          value: /tmp
        - name: OCP_TOKEN
          valueFrom:
            secretKeyRef:
              name: dcs-must-gather
              key: token
      image: cp.icr.io/cp/ibm-spectrum-discover/must-gather:2.1.3
      imagePullPolicy: Always
      resources:
        requests:
          cpu: 50m
          memory: 128Mi
          ephemeral-storage: 2Gi
        limits:
          cpu: 2
          memory: 8Gi
          ephemeral-storage: 5Gi
      command:
        - '/bin/bash'
        - '-c'
        - '/opt/must-gather/must-gather.sh; while true; do sleep 60; done'
```

EOF

5. Run the following command to create a must gather pod.

```
oc -n $PROJECT_NAME create -f dcs-must-gather-pod.yaml
```

6. Monitor the logs until it reports that the `tar` file has been created.

```
oc -n $PROJECT_NAME logs -f dcs-must-gather
```

Example output:

```
2023-09-12 04:12:12 - INFO - Archiving completed: dcs-must-gather.tar.xz
```

7. Copy the `tar` file.

```
oc -n $PROJECT_NAME cp dcs-must-gather:/tmp/dcs-must-gather.tar.xz dcs-must-gather-$TIMESTAMP.tar.xz
```

8. Remove the must gather resources.

```
oc -n $PROJECT_NAME delete pod dcs-must-gather
oc -n $PROJECT_NAME delete secret dcs-must-gather
```

Data Cataloging Harvester CLI

IBM Data Cataloging Harvester is a new capability that is designed to import external data to the IBM Data Cataloging service catalog database. It imports the data even if it is not coming from a Db2 database that uses the same schema.

Before you begin

- Ensure you have the following installations:
 - Python +3.11 or later version
 - `curl tar gzip sed pip3` packages
 - Red Hat® OpenShift® CLI.

With the IBM Data Cataloging Harvester, it is possible to import the external data to the catalog database even if it is not coming from a Db2 table using the exact same schema. IBM Fusion 2.8.0 supports importing data associated to a single data source also known as a connection. After using the CLI against a valid SQLite file, then it should create a connection and import all metadata stored in the import file records or additional tags depending on the command that is executed.

Supported import formats

The Harvester CLI helps to read records in the specified format and sends them to the import service component that runs on the cluster to use by Db2 after it is validated. Not only the input file is in the format that the Harvester supports, but also the schema rules that succeed during analyzing tasks.

The IBM Data Cataloging harvester needs the following schemas. The IBM Data Cataloging harvester requires at least two tables to work with:

Connections table

It is used to store information about the data source.

```
CREATE TABLE CONNECTIONS (
  name TEXT,
  platform TEXT,
  cluster TEXT,
  datasource TEXT,
  site TEXT,
  host TEXT,
  mount_point TEXT,
  application_code TEXT,
  local_mount TEXT,
  total_records INTEGER,
  current_gen TEXT,
  password TEXT,
  online TEXT,
  scan_topic TEXT,
  le_topic TEXT,
  le_enabled INTEGER
)
```

Metaocean table

It contains all the base metadata present in the data source.

```
CREATE TABLE METAOCLEAN (
  INODE INTEGER,
  OWNER TEXT,
  [GROUP] TEXT,
  PERMISSIONS TEXT,
  UID INTEGER,
  GID INTEGER,
  PATH TEXT,
  FILENAME TEXT,
  MTIME TEXT,
  ATIME TEXT,
  CTIME TEXT,
  SIZE INTEGER,
  TYPE TEXT,
  STATE TEXT
)
```

The SQLite database might have more optional tables if you want to import tag values for additional metadata. The additional tables cannot be processed unless the tags mode in the Harvester CLI defines tables by their names.

Example of additional tags table:

Note: Inode and filename are only the required columns, and rest are the names of already created tags on Data Cataloging.

```
CREATE TABLE META (
  inode TEXT,
  filename TEXT,
  fkey TEXT,
  ExampleCustomTag1 TEXT,
  ExampleCustomTag2 TEXT,
  ExampleCustomTag3 TEXT,
)
```

Setting up the external host

1. Log in to the Red HatOpenShift CLI. For procedure, see [Red Hat OpenShift CLI](#).
2. If the Harvester CLI runs on hosts outside of the OpenShift cluster, then it is possible to face SSL problems caused by self-signed certificates. To resolve SSL problems, you can use the following commands to download the router certificate in the host that running the Harvester and then use environment variables to use them.

- a. Run the following command to download the OpenShift router TLS certificate.

```
oc -n openshift-ingress get secret router-certs-default -o json | jq -r '.data."tls.crt"' | base64 -d > $(pwd)/router_tls.crt
```

- b. Run the following command to export the environment variables to define the path of the TLS certificate.

```
export IMPORT_SERVICE_CERT=$(pwd)/router_tls.crt
export DCS_CERT=$(pwd)/router_tls.crt
```

3. Download the Harvester CLI.

```
export DCS_NAMESPACE=ibm-data-cataloging
export DCS_IMPORT_SVC_HOST=$(oc -n $DCS_NAMESPACE get route isd-import-service -o jsonpath="{.spec.host}")
export DCS_CONSOLE_HOST=$(oc -n $DCS_NAMESPACE get route console -o jsonpath="{.spec.host}")
export DCS_USERNAME=$(oc -n $DCS_NAMESPACE get secret keystone -o jsonpath="{.data.user}" | base64 -d)
export DCS_PASSWORD=$(oc -n $DCS_NAMESPACE get secret keystone -o jsonpath="{.data.password}" | base64 -d)
```

```
curl "https://${DCS_IMPORT_SVC_HOST}/v1/download_harvester" --output harvester.tar.gz --insecure
tar xf harvester.tar.gz
rm -vf harvester.tar.gz
```

4. Run the following set up script to start by using the Harvester CLI.

```
chmod +x ./harvester/setup.sh
./harvester/setup.sh
```

Running the Harvester CLI

1. Ensure that you export the records with all the base metadata.

```
SQLITE_FILE_PATH=/tmp/example.sqlite
CONFIG_FILE=$(pwd)/harvester/config.ini
python3 harvester metaocean $SQLITE_FILE_PATH -c $CONFIG_FILE
```

2. Use `-p nfs` option if you want to import NFS-based metadata.

```
SQLITE_FILE_PATH=/tmp/example.sqlite
CONFIG_FILE=$(pwd)/harvester/config.ini
python3 harvester metaocean $SQLITE_FILE_PATH -c $CONFIG_FILE -p nfs
```

3. Run the following command to import values after they are created by using either the user interface or API.

```
SQLITE_FILE_PATH=/tmp/example.sqlite
CONFIG_FILE=$(pwd)/harvester/config.ini
python3 harvester tags $SQLITE_FILE_PATH -c $CONFIG_FILE
```

4. Use `-p nfs` option if you want to import NFS-based metadata.

```
SQLITE_FILE_PATH=/tmp/example.sqlite
CONFIG_FILE=$(pwd)/harvester/config.ini
python3 harvester metaocean $SQLITE_FILE_PATH -c $CONFIG_FILE -p nfs
```

Configuring the Harvester

The `config.ini` file inside the harvester directory provides critical support in the data import behavior. The following are the available variables to configure:

BlockSizeBytes

It indicates the block size configured in the datasource that is being imported. Normally, the value is set to 4096 bytes, which helps to calculate the real capacity allocated on the filesystem based on the blocks required to store the file.

AvailableMOVW

It must be set to 10 as it is the only supported value for optimal data ingestion. It helps the harvester to calculate the pieces of a set of records that can be divided for parallel insertion.

MaxProcessingWorkers

It is an ignored variable, and use a one worker process always. If a higher level of parallelism is required, then run another harvester to process an additional SQLite file.

IngestRequestRetries

After the harvester finishes processing the metadata from the SQLite file, it sends it using an HTTP request to the import service for it to be indexed in the database. But it is possible to fail to do so for different reasons, such as a temporary network unavailability or a considerable API overload blocking incoming requests. By default, the harvester tries to send the metadata 120 times, depending on the highest value and the time limit. The suggested range is 120 to 240.

StatusRequestRetries

After the ingest request is sent, the harvester follows up with additional requests to get the status of the ingest operation to confirm whether it finished successfully. It might take a long time, so retrying is required. The suggested range is 240 to 360.

TagsWorkdir

The name of the directory that is presented inside the harvester directory is where temporary files are stored during tag harvesting. By default, `tmp` is the name of this directory, but it can be updated in case it is necessary to have a more descriptive directory name.

MOBatchSize and TagsBatchSize

Number of rows to read from the SQLite and load into memory at a time, a higher value is associated to a higher memory usage. It is not recommended to use a value higher than 1,00,000 because it does not represent a performance benefit. The suggested values are 10000, 50000 and 100000.

MOBatchesPerSegment and TagsBatchesPerSegment

Number of batches to process before sending them using an ingestion request, a higher value is associated with bigger files. Using a value higher than 100 does not translate to a direct performance benefit. The suggested values are 10, 50 and 100.

Data ingestion system requirements

Ensure that you must have the following system requirements:

- 4 CPU cores and 16GB of RAM.
- At least 1.5x the size of the SQLite file to import must be available as free space on the filesystem. For example, if the SQLite file is 1GB, then make sure at least 1.5GB of storage is available.
- Python 3.11 or higher.

Installation

Run the following commands to download and install IBMFDC.

Optionally, you can set up a virtual environment to benefit from an isolated installation.

Note: Before proceeding, ensure you have an active and authenticated session in the OpenShift console. This is necessary for the `oc` command to retrieve route information correctly. For more information, see [Red Hat Documentation](#).

```
DCS_NS="ibm-data-cataloging"
DCS_IMPORT_SVC_HOST=$(oc -n ${DCS_NS} get route isd-import-service -o jsonpath='{.spec.host}')

curl -O -J "https://${DCS_IMPORT_SVC_HOST}/v1/ibmfdc" --insecure
WHEEL_FILE=$(ls ibmfdc-*.whl)
pip3 install ${WHEEL_FILE}
rm -f ${WHEEL_FILE}
```

Preparing the CLI configuration file

By default, the `ibmfdc` command looks for a file named `config.ini` in the current working directory. If you want to specify a different configuration file, use the `oc` command-line argument.

Configuration file format:

```
ConsoleRouteURL = <DCS_CONSOLE_URL>
ImportCSVRouteURL = <DCS_IMPORT_SVC_URL>
AdminUsername = <DCS_USERNAME>
AdminPassword = <DCS_PASSWORD>
```

For example:

```
ConsoleRouteURL = https://console-ibm-data-cataloging.apps.<domain>
ImportCSVRouteURL = https://isd-import-service-ibm-data-cataloging.apps.<domain>
AdminUsername = sdadmin
AdminPassword = Passw0rd
```

Ingesting remote metadata using the IBMFDC Harvester

The IBMFDC Harvester supports ingesting both base and additional metadata simultaneously. However, all necessary tags must be created beforehand, otherwise the meta table in the SQLite file will be ignored. This is because none of its columns matches any existing tag names.

Importing base and additional metadata:

```
ibmfdc harvester -m meta <path_to_sqlite_file>
```

Importing only base metadata (ignores tags):

```
ibmfdc harvester <path_to_sqlite_file>
```

FKEY migration script

The FKEY migration script is a fix to avoid potential rare collisions in the FKEY file identifier when ingesting billions of records.

About this task

The FKEY migration script fix consists of a script that needs to be run in the Db2 terminal of IBM Data Cataloging.

Procedure

1. Run the following command to do SSH to the `c-Db2u-0` pod.

```
oc -n ibm-data-cataloging rsh c-isd-db2u-0
su - db2inst1
```

2. Create a file named `FKEY_Updater.sh` with the FKEY migration script.

The script iterates over a list of data sources, fixes the FKEY in all the files, and ingests them in each data source of the previous IBM Data Cataloging service versions.

```
# =====
# How to invoke
# Send the list of datasources to fix as follows:
# ./FKEY_Updater.sh datasource1 datasource2 datasource3
# =====

start_date=`date +%s.%N`
datasourcearray=( "$@" )

echo "Connecting to database..."
db2 connect to bludb
echo "Connected to BLUDB."
printf '\n'
echo "List of datasources to update:"
printf ' - %s\n' "${datasourcearray[@]}"
printf '\n'

for datasource in "${datasourcearray[@]}"
do
    echo "Starting update procedures for datasource '${datasource}'..."
    printf '\n'
    echo "Updating table ACESMAPLOADBASE..."
    db2 "update bludadmin.acesmaploadbase amlb set amlb.fkey=(mo.cluster || '_' || mo.datasource || '_' || mo.inode)
from bludadmin.metaocean mo where amlb.fkey=mo.fkey and mo.datasource='${datasource}';"
    echo "ACESMAPLOADBASE table updated successfully."
    printf '\n'
    echo "Updating table ACOGMAPLOADBASE..."
    db2 "update bludadmin.acogmaploadbase acmlb set acmlb.fkey=(mo.cluster || '_' || mo.datasource || '_' || mo.inode)
from bludadmin.metaocean mo where acmlb.fkey=mo.fkey and mo.datasource='${datasource}';"
    echo "ACOGMAPLOADBASE table updated successfully."
    printf '\n'
    echo "Updating table ACESMAP (This action could take several minutes)..."
    db2 "update bludadmin.acesmap am set am.fkey=(mo.cluster || '_' || mo.datasource || '_' || mo.inode) from
bludadmin.metaocean mo where am.fkey=mo.fkey and mo.datasource='${datasource}';"
    echo "ACESMAP table updated successfully."
    printf '\n'
    echo "Updating table ACOGMAP (This action could take several minutes)..."
    db2 "update bludadmin.acogmap acm set acm.fkey=(mo.cluster || '_' || mo.datasource || '_' || mo.inode) from
bludadmin.metaocean mo where acm.fkey=mo.fkey and mo.datasource='${datasource}';"
    echo "ACOGMAP table updated successfully."
    printf '\n'
    echo "Updating table METAOCLEAN (This action could take several minutes)..."
    db2 "update bludadmin.metaocean mo set mo.fkey=(mo.cluster || '_' || mo.datasource || '_' || mo.inode) where not
REGEXP_LIKE(mo.fkey, mo.cluster || '_' || mo.datasource || '_' || mo.inode) and mo.datasource='${datasource}';"
    echo "METAOCLEAN table updated successfully."
    printf '\n'
    echo "Updates on datasource '${datasource}' done successfully."
    printf '\n'
done
printf '\n'
end_date=`date +%s.%N`
runtime=$(echo "$end_date - $start_date" | bc -l)

echo "Execution time was $runtime seconds."
```

3. Run the script.

```
./FKEY_Updater.sh datasource1 datasource2 datasource3
```

The final execution time of the script depends on the number of files that are ingested in the database.

Configurable Db2 log trimmer

Db2 log trimmer tool provides a mechanism to trim the informative logs that are generated by scanning a data source. It uses the Harvester CLI to ingest data into the IBM Data Cataloging.

Configurable Db2 log trimmer tool helps to better handle the filesystem usage by deleting informative files placed in the Db2 PVC.

From IBM Fusion 2.8.x release, the capabilities of the Db2 log trimmer are extended by a **ConfigMap** that gives an option of setting the currency for running the trimmer (in minutes). It selects and deletes the old files and **.BAD** extension files.

Important:

- The Db2 **.BAD** files are log files that are generated by failed transactions in Db2 when trying to ingest data.
- If there is failure at the Db2 level that requires the guidance of a Db2 expert, those **.BAD** files can be indispensable to perform the root cause analysis and it is recommended NOT TO DELETE those files unless needed.

The fields in the **ConfigMap** are the following:

- **time-limit-min** - default value is "720" (files with more than 720 minutes of last modification)
- **bad-file-erase** - default value is "0" (not to delete the **.BAD** files)
- **frequency-min** - default value is "720" (run the log trimmer each 720 minutes)

You can edit the values of the **ConfigMap** by using the following command.

```
oc edit configmap db2-log-trimmer -n ibm-data-cataloging
```

IBM Data Cataloging service installation and upgrade issues

Use this troubleshooting information to resolve install and upgrade problems that are related to the IBM Data Cataloging service.

Installation stuck because of resource quota

Problem statement

The IBM Data Cataloging installation is stuck because of resource quota set on IBM Fusion and IBM Data Cataloging namespaces. until both the resource quota were removed

Resolution

Set the resource quota values for IBM Data Cataloging as follows:

```
kind: ResourceQuota
apiVersion: v1
metadata:
  name: dcs-resource-quota
  namespace: ibm-data-cataloging
spec:
  hard:
    limits.cpu: '100'
    limits.memory: 180Gi
    pods: '120'
    requests.cpu: '20'
    requests.memory: 40Gi
```

Data cataloging upgrade stuck for more than 1 hour

Problem statement

IBM Data Cataloging upgrade is stuck for more than 1 hour and the progress shows 15%.

Symptoms

The IBM Data Cataloging upgrade runs for more than 1 hour and gets stuck at 15%. On the OpenShift® Console, the installed operator shows just the IBM Data Cataloging operator and not **IBM DB2 and Streams for Apache Kafka** operators under the **ibm-data-cataloging** namespace.

Also, the Subscription for the IBM Data Cataloging operator shows **InstallPlanPending**, Reason **"RequiresApproval"**.

Resolution

1. In the OpenShift console, go to Operators, > Installed Operators tab.
2. Select IBM Storage Discover operator.
3. Go to Subscriptions tab, and select InstallPlan.
4. Approve the InstallPlan.

There is an alternative method using OpenShift CLI as follows:

- a. Run the following command to get the InstallPlan that is not approved.

```
oc get ip -n ibm-data-cataloging -o=jsonpath='{.items[?(@.spec.approved==false)].metadata.name}'
```

- b. Run the following command to get the InstallPlan name.

```
oc patch installplan $(oc get ip -n ibm-data-cataloging -o=jsonpath='{.items[?(@.spec.approved==false)].metadata.name}') -n ibm-data-cataloging --type merge --patch '{"spec":{"approved":true}}'
```

5. Wait for the upgrade process to complete.

Data Cataloging import service pod in CrashLoopBackOff state

Diagnosis

1. Check for CrashLoopBackOff on the import service pod.

```
oc -n ibm-data-cataloging get pod -l role=import-service
```

2. Confirm that the logs show **permission denied** error:

```
oc -n ibm-data-cataloging logs -l role=import-service
```

Resolution

1. Debug import service pod.

```
oc -n ibm-data-cataloging debug deployment/isd-import-service --as-user=0
```

2. Update the directory permissions.

```

chmod 775 /uploads
mkdir -p /uploads/failed_requests
chmod 775 /uploads/failed_requests
exit

```

IBM Data Cataloging database schema job is not in a completed state during installation or upgrade

Note: This procedure is applicable to recover DB2 that goes into an unavailable mode after the service installation and related to a degraded state of the IBM Data Cataloging service.

Symptoms

The `isd-db2whrest` or `isd-db-schema` pods report a not ready or error state.

Run the following command to view the common logs:

```
oc -n ibm-data-cataloging logs -l 'role in (db2whrest, db-schema)' --tail=200
```

Go through the logs to check whether the following error exists:

```
Waiting on c-isd-db2u-engn-svc port 50001...
```

```
db2whconn - ERROR - [FAILED]: [IBM][CLI Driver] SQL1224N The database manager is not able to accept new requests, has
terminated all requests in progress, or has terminated the specified request because of an error or a forced interrupt.
SQLSTATE=55032
```

```
Connection refused
```

Resolution

1. Restart Db2:

```

oc -n ibm-data-cataloging rsh c-isd-db2u-0
sudo wvcli system disable -m "Disable HA before Db2 maintenance"
su - ${DB2INSTANCE}
db2stop
db2start
db2 activate db BLUDB
exit
sudo wvcli system enable -m "Enable HA after Db2 maintenance"

```

2. Confirm that Db2 HA-monitoring is active:

```

sudo wvcli system status
exit

```

3. Check whether the problem occurred during installation or upgrade or a post installation problem.
4. If this occurs during an upgrade or installation, recreate the `isd-db-schema` job and monitor the pod until it gets to a completed state.

```

SCHEMA_OLD="isd-db-schema-old.json"
SCHEMA_NEW="isd-db-schema-new.json"
oc -n ibm-data-cataloging get job isd-db-schema -o json > $SCHEMA_OLD
jq 'del(.spec.template.metadata.labels."controller-uid") | del(.spec.selector) | del (.status)' $SCHEMA_OLD >
$SCHEMA_NEW
oc -n ibm-data-cataloging delete job isd-db-schema
oc -n ibm-data-cataloging apply -f $SCHEMA_NEW

oc -n ibm-data-cataloging get pod | grep isd-db-schema

```

5. If this is a post installation problem, restart db2whrest.

```
oc -n ibm-data-cataloging delete pod -l role=db2whrest
```

IBM Data Cataloging installation is stuck for more than 1 hour

Note: This procedure must be used only during installation problems, not for upgrades or any subsequent issues.

Symptoms

The IBM Data Cataloging installation running for more than an hour, and it stuck somewhere between 35% and 80% (both inclusive).

Resolution

1. Run the following command to scale down the operator.

```
oc -n ibm-data-cataloging scale --replicas=0 deployment/spectrum-discover-operator
```

2. Run the following command to scale down workloads.

```
oc -n ibm-data-cataloging scale --replicas=0 deployment,statefulset -l component=discover
```

3. Run the following command to remove the DB schema job if present.

```
oc -n ibm-data-cataloging delete job isd-db-schema --ignore-not-found
```

4. Run the following commands to delete the Db2 instance and the password secret.

```

oc -n ibm-data-cataloging delete db2u isd
oc -n ibm-data-cataloging delete secret c-isd-ldapblueadminpassword --ignore-not-found

```

- Wait until the Db2 pods and persistent volume claims get removed.

```
oc -n ibm-data-cataloging get pod,pvc -o name | grep c-isd
```

- Run the following command to scale up the operator.

```
oc -n ibm-data-cataloging scale --replicas=1 deployment/spectrum-discover-operator
```

IBM Data Cataloging service is not installed successfully on IBM Fusion HCI with GPU nodes

Problem statement

The data catalog service is in installing state for hours.

Resolution

To resolve the problem, do the following steps:

- Patch FSD with new affinity to not schedule `isd` workload on those nodes:

```
oc -n <Fusion_namespace> patch fusionservicedefinitions.service.isf.ibm.com data-cataloging-service-definition --patch "$(cat fsd_dcs_patch.yaml)"
```

The `fsd_dcs_patch.yaml` file:

```
cat >> fsd_dcs_patch.yaml << EOF

apiVersion: service.isf.ibm.com/v1
kind: FusionServiceDefinition
metadata:
  name: data-cataloging-service-definition
  namespace: <Fusion_namespace>
spec:
  onboarding:
    parameters:
      - dataType: string
        defaultValue: ibm-data-cataloging
        descriptionCode: BMYSRV00003
        displayNameCode: BMYSRV00004
        name: namespace
        required: true
        userInterface: false
      - dataType: storageClass
        defaultValue: ''
        descriptionCode: BMYDC0300
        displayNameCode: BMYDC0301
        name: rwx_storage_class
        required: true
        userInterface: true
      - dataType: bool
        defaultValue: 'true'
        descriptionCode: descriptionCode
        displayNameCode: displayNameCode
        name: doInstall
        required: true
        userInterface: false
      - dataType: json
        defaultValue: '{"accept": true}'
        descriptionCode: descriptionCode
        displayNameCode: displayNameCode
        name: license
        required: true
        userInterface: false
      - dataType: json
        defaultValue: '{"nodeAffinity":{"requiredDuringSchedulingIgnoredDuringExecution":{"nodeSelectorTerms":
[{"matchExpressions": [{"key": "nvidia.com/gpu", "operator": "NotIn", "values": ["Exists"]}]}]}}'
        descriptionCode: descriptionCode
        displayNameCode: displayNameCode
        name: affinity
        required: true
        userInterface: false
EOF
```

If the output shows this error message `Error from server (UnsupportedMediaType): the body of the request was in an unknown format - accepted media types include: application/json-patch+json, application/merge-patch+json, application/apply-patch+yaml`, then you need to follow the steps to resolve this issue:

- Go to OpenShift Container Platform web console.
- Go to Operators, Installed Operators tab, under `<Fusion_namespace>`, select the IBM Fusion operator.
- Select the IBM Fusion service instance tab, and select the `data-cataloging-service-instance`.
- Select the YAML tab, and edit the YAML file for the `data-cataloging-service-instance`. Under `spec.onboarding.parameters`, ensure you add the following lines.

```
- dataType: json
  defaultValue: '{"nodeAffinity":{"requiredDuringSchedulingIgnoredDuringExecution":
{"nodeSelectorTerms": [{"matchExpressions": [{"key": "isf.ibm.com/nodeType", "operator": "NotIn", "values":
["gpu"]}]}]}}'
  descriptionCode: descriptionCode
  displayNameCode: displayNameCode
  name: affinity
  required: true
  userInterface: false
```

2. Display the patch FSD:

```
oc -n <Fusion_namespace> get fusion servicedefinitions.service.isf.ibm.com data-cataloging-service-definition -o yaml
```

3. Install from the user interface.

IBM Data Cataloging database pods stuck during initialization phase

Symptoms

Multiple Db2 pods use the host port 5002, which can cause pods to stay in the `init` phase.

Resolution

1. Uninstall the IBM Data Cataloging service. For procedure, see [Uninstalling IBM Data Cataloging](#).
2. Create a file with the IBM Data Cataloging `FusionServiceDefinition` patch.

```
cat >> fsd_dcs_patch.yaml << EOF
apiVersion: service.isf.ibm.com/v1
kind: FusionServiceDefinition
metadata:
  name: data-cataloging-service-definition
  namespace: ibm-spectrum-fusion-ns
spec:
  onboarding:
    parameters:
      - dataType: string
        defaultValue: ibm-data-cataloging
        descriptionCode: BMYSRV00003
        displayNameCode: BMYSRV00004
        name: namespace
        required: true
        userInterface: false
      - dataType: storageClass
        defaultValue: ''
        descriptionCode: BMYDC0300
        displayNameCode: BMYDC0301
        name: rwx_storage_class
        required: true
        userInterface: true
      - dataType: bool
        defaultValue: 'true'
        descriptionCode: descriptionCode
        displayNameCode: displayNameCode
        name: doInstall
        required: true
        userInterface: false
      - dataType: json
        defaultValue: '{"accept": true}'
        descriptionCode: descriptionCode
        displayNameCode: displayNameCode
        name: license
        required: true
        userInterface: false
      - dataType: json
        defaultValue: '{"size":1,"mIn":2,"storage":{"activelogs":{"requests":"300Gi"},"data":{"requests":"600Gi"},"meta":{"requests":"100Gi"},"activelogs":{"tempts":"100Gi"}}}'
        descriptionCode: descriptionCode
        displayNameCode: displayNameCode
        name: dbwh
        required: true
        userInterface: false
EOF
```

3. Apply the patch to downsize the Db2 cluster.

```
oc -n ibm-spectrum-fusion-ns patch fusion servicedefinitions.service.isf.ibm.com data-cataloging-service-definition --type=merge --patch-file fsd_dcs_patch.yaml
```

4. Install IBM Data Cataloging service from the IBM Fusion user interface. For procedure, see [Installing IBM Data Cataloging](#).

IBM Data Cataloging known issues

List of all issues in the IBM Data Cataloging service along with its resolution.

The following known issues exist in IBM Data Cataloging service, with workarounds included wherever possible. If you come across an issue that cannot be solved by using these instructions, contact [IBM support](#).

Resource quota limitation

With resource quota set on IBM Fusion and IBM Data Cataloging namespaces, the IBM Data Cataloging installation gets stuck until both the resource quota are removed.

Live events stopped working after IBM Data Cataloging

Problem statement

Live events functionality stopped updating record events after the IBM Data Cataloging is upgraded.

Resolution

Follow the steps to resolve this issue:

- Delete the watcher on IBM Storage Scale without deleting the connection on the IBM Data Cataloging service as follows:

1. Run the following command to list the watchers.

```
/usr/lpp/mmfs/bin/mmwatch all list
```

Example output:

Filesystem testing has 1 watcher(s):

Cluster ID	WatchID/PID	Type	Start Time	Path	Description
13748412159870826098	CLW1733515374	FSYS	Fri Dec 06 12-02-55 2024	/ibm/testing	

2. Run the following command to delete the watchers.

```
sudo /usr/lpp/mmfs/bin/mmwatch testing disable --watch-id CLW1733515374
```

Example output:

```
[I] Successfully checked or deleted Clustered Watch policy skip partitions for watch: CLW1733515374
[I] Successfully removed Clustered Watch policy rules for watch: CLW1733515374
[I] Successfully removed Clustered Watch configuration file from the CCR for watch: CLW1733515374
[I] Successfully removed Clustered Watch configuration directory for watch: CLW1733515374
[I] Successfully checked or removed Clustered Watch global catchall and config fileset skip partitions for watch: CL
[I] Successfully disabled Clustered Watch: CLW1733515374
```

3. Run the command again to list the watchers to verify the watcher deletion.

```
/usr/lpp/mmfs/bin/mmwatch all list
```

Example output:

Cluster ID	WatchID/PID	Type	Start Time	Path	Description
Filesystem testing has no watchers.					

4. Run the following command to export cluster's URL and IBM Storage Scale working directory as environmental variables.

```
export CLUSTER_URL = "yourcluster.ibm.com"
export WD_PATH="/example/path/wd"
```

5. Run the following command to manually add the watcher on the IBM Storage Scale.

```
sudo /usr/lpp/mmfs/bin/mmwatch testing enable --event-handler kafkasink --sink-brokers "isd-kafka-tlsect-
bootstrap-ibm-data-cataloging.apps.qa-bm-CLUSTER_URL:443" --sink-topic scale-le-connector-topic --sink-auth-
config $WD_PATH/kafka/auth.file --events
IN_ATTRIB,IN_CLOSE_WRITE,IN_MODIFY,IN_CREATE,IN_DELETE,IN_MOVED_FROM,IN_MOVED_TO
```

Example output:

```
[I] Beginning enablement of Clustered Watch with newly created watch ID: CLW1733516766
[I] Verified the watch type is FSYS for filesystem testing
[I] Successfully added Clustered Watch configuration file into CCR for watch: CLW1733516766
[I] Successfully added Clustered Watch configuration in the Spectrum Scale file system: testing for watch: CLW173351
[I] Successfully added Clustered Watch policy rules for watch: CLW1733516766
[I] Successfully checked or created Clustered Watch global catchall and config fileset skip partitions for watch: CL
[I] Successfully checked or created Clustered Watch policy skip partitions for watch: CLW1733516766
[I] Successfully enabled Clustered Watch: CLW1733516766
```

6. Run the command again to list the watchers to verify the watcher creation.

```
/usr/lpp/mmfs/bin/mmwatch all list
```

Example output:

Filesystem testing has 1 watcher(s):

Cluster ID	WatchID/PID	Type	Start Time	Path	Description
13748412159870826098	CLW1733516766	FSYS	Fri Dec 06 12-26-07 2024	/ibm/testing	

7. On IBM Data Cataloging, re-scan the IBM Storage Scale connection.

8. Any modifications on the scanned IBM Storage Scale folder should be monitored through live events and automatically updated on IBM Data Cataloging.

IBM Data Cataloging service in Metro-DR setup shows in Degraded state

Diagnosis

1. IBM Data Cataloging service is in degraded state
2. Run the following command to check whether the Pod `isd-db2whrest` is not ready:

```
oc -n ibm-data-cataloging get pod -l role=db2whrest
```

3. Run the following command to check whether Db2 retries the network check and fails because of the timeout:

```
oc -n ibm-data-cataloging logs -l type=engine --tail=100
```

Example output:

```
+ timeout 1 tracepath -l 29 c-isd-db2u-1.c-isd-db2u-internal
+ [[ 17 -lt 120 ]]
```

```
+ (( n++ ))
+ echo 'Command failed. Attempt 18/120:'
Command failed. Attempt 18/120:
```

Resolution

Increase the time before timeout, usually change from 1 second to 3-5 seconds.

1. Modify the timeout from 1 to 3 in `isd-db2u-0`:

```
oc -n ibm-data-cataloging exec c-isd-db2u-0 -- sudo sed -i 's/timeout 1 tracepath/timeout 3 tracepath/g'
/db2u/scripts/include/common_functions.sh
```

2. Wait until the current attempt exceeds the predefined 120 retries. After it restarts, it picks the updated value:

```
oc -n ibm-data-cataloging logs -l type=engine --tail=50
```

3. Monitor `db2whrest` pod readiness:

```
oc -n ibm-data-cataloging get pod -l role=db2whrest -w
```

COS connection reporting scan aborted due to inactivity

If a COS connection scan fails with the error “Scan aborted because of a long period of inactivity”, it can be resolved by editing the settings file `connections/cos/scan/scanner-settings.json` within the data PV and choosing a higher value for `notifier_timeout` than the default value of 120 seconds. The change will be picked on the next scan. No pod restart is required.

Database connection issue after reboot

If an unexpected cluster update or node reboot causes database connection issues. For resolution, see the steps mentioned in the *IBM Data Cataloging database schema job is not in a completed state during installation or upgrade* section. .

Image pull error due to authentication failure

Problem statement

The OpenShift® Container Platform login token expires occasionally, and as this is the container image registry password, this breaks the service account access to the registry.

Resolution

If a pod is failing to pull an image from the registry with an authentication error, then re-create the `image-registry-pull-secret` and relink the service accounts to the new secret:

```
oc delete secret image-registry-pull-secret
HOST=$(oc get route default-route -n openshift-image-registry --template='{{ .spec.host }}')
oc create secret docker-registry image-registry-pull-secret \
  --docker-server="${HOST}" \
  --docker-username=kubeadmin \
  --docker-password="$(oc whoami -t)"
for account in spectrum-discover-operator strimzi-cluster-operator spectrum-discover-ssl-
zookeeper spectrum-discover-sasl-zookeeper; do oc secrets link $account image-registry-pull-
secret --for=pull; done
```

Visual query builder search terms overrides SQL search when going into individual mode

If a search is started in the query builder, then changed to SQL mode, the initial group search is as expected but if expanded to individual records it uses the query builder terms as the base. A workaround is to clear the visual query before changing to SQL query.

LDAPS configuration failing if dollar sign is in password

Currently, the dollar sign is not supported on passwords for ldaps configuration. A workaround is to create a password without the dollar sign in it.

Content search policy missing files

If there are issues with the incorrect expected data count while running a policy, you must verify that the connection is active, and rescan to get the latest data ingested to IBM Data Cataloging. After successful upgrade of IBM Data Cataloging, a rescan of existing connections is recommended.

REST API returns token with unprintable characters

It is a noted issue that a carriage return (`\r`) is included at the end of HTTP response headers due to an issue with curl. This has been known to occasionally break scripts that use an auth token from the IBM Data Cataloging appliance as shown here:

```
$ curl -k -H "Authorization: Bearer ${TOKEN}" https://$SDHOST/policyengine/v1/tags
curl: (92) HTTP/2 stream 0 was not closed cleanly: PROTOCOL_ERROR (err 1)
```

As such, it is recommended to filter out the `\r` character. If you have a line like the following in bash:

```
`TOKEN=$(curl -i -k https://$SDHOST/auth/v1/token -u "$SDUSER:$SDPSWD" | grep -i x-auth-token |
awk '{print $2}')`
```

Add a `| tr -d '\r'` at the end to avoid running into this issue:

```
`TOKEN=$(curl -i -k https://$SDHOST/auth/v1/token -u "$SDUSER:$SDPSWD" | grep -i x-auth-token |
awk '{print $2}' | tr -d '\r')`
```

Adding S3 connection gives false negative

Problem statement

When a connection of type S3 is added through IBM Data Cataloging user interface, it gives an undefined error message.

Resolution

Refreshing the browser removes the error message, and the connections table shows that the S3 connection was successful.

Scale datamover AFM and ILM capabilities not working properly due to SDK misleading function when deploying an application

Problem statement

When deploying IBM Data Cataloging service deployments pods `scaleafmdatamover` and `scaleilmdatamover` might show an error on logs when application is deployed.

For example:

```
2023-07-20 02:51:54,311 - ibm_spectrum_discover_application_sdk.ApplicationLib - INFO - Invoking conn manager at http://172.30.255.202:80/connmgr/v1/internal/connections
Traceback (most recent call last):
File "/application/ScaleAFMDataMover.py", line 1023, in
APPLICATION = ScaleAFMApplicationBase(REGISTRATION_INFO)
File "/application/ScaleAFMDataMover.py", line 112, in init
self.conn_details = self.get_connection_details()
File "/usr/local/lib/python3.9/site-packages/ibm_spectrum_discover_application_sdk/ApplicationLib.py", line 492, in
get_connection_details
raise Exception(err)
UnboundLocalError: local variable 'err' referenced before assignment
2023-07-20 02:51:54,367 INFO exited: scaleafm-datamover (exit status 1; not expected)
2023-07-20 02:51:55,368 INFO gave up: scaleafm-datamover entered FATAL state, too many start retries too quickly
```

Cause

SDK bug when deploying applications on DCS, causing deployed applications not to behave properly and pods in the incorrect state to show errors.

Resolution

After identified this behavior, then follow the steps to resolve this issue:

1. Verify the connmgr API is running and accessible through HTTP (curl to the connmgr service would be enough).
2. Check the application pod and remove it to be redeployed.

Policies are not finished, resulting in a hanging state

Problem statement

The policies are not finished, which results in a hanging state.

Cause

Inconsistent behavior on policies results in a no finish status. The issue is still under investigation.

Resolution

Identify the policy engine pod and eliminate it; OpenShift Container Platform will create another pod automatically, and policies will be executed and finished properly after the pod creation.

Example:

```
oc -n ibm-data-cataloging delete pod -l role=policyengine
```

IBM Data Cataloging service goes degraded state after IBM Fusion HCI rack restart

Problem statement

The IBM Data Cataloging service goes degraded after some of the nodes are restarted or after IBM Fusion HCI rack restart. Several pods go pending with the following errors Unable to attach or mount volumes: unmounted volumes=[spectrum-discover-db2wh], unattached volumes=[], failed to process volumes=[]: timed out waiting for the condition and MountVolume.Setup failed for volume "xxx" : rpc error: code = Internal desc = staging path yyy for volume zzz is not a mountpoint.

Resolution

Run the following steps to resolve this issue:

1. Run the following commands to make the compute nodes unschedule and drain them one after one.

```
oc adm cordon worker4.fusion-test-zlinux.cp.fyre.ibm.com
oc adm drain worker4.fusion-test-zlinux.cp.fyre.ibm.com --ignore-daemonsets --force --delete-emptydir-data
```

2. After the node is drained, ensure it schedules again and then proceed to another node with the same process.
It removes stale directory entries from nodes that are detected as mount points.
3. The issue automatically resolves and IBM Data Cataloging service must be in a healthy state after all the nodes are backed up.

Db2 license does not display correctly on the upgrade set up

Problem statement

The Db2 license displays incorrectly on the IBM Data Cataloging service upgrade set up.

Resolution

Run the following steps to resolve this issue:

1. Run the following command to get the subsequent IBM Data Cataloging scoped content.

```
oc project ibm-data-cataloging
```

2. For the new license to take effect, delete the Db2 engine pods for the `Db2uCluster` or `Db2uInstance`:

```
oc delete $(oc get po -l type=engine,formation_id=isd -oname)
```

3. After the new Db2 pod is ready, verify the updated Db2 license:

```
oc exec -it c-isd-db2u-0 -- su - db2inst1 -c "db2licm -l"
```

For more about Db2 community edition license certificate key, see [Upgrading your Db2 Community Edition license certificate key](#).

ConstraintsNotSatisfiable for db2u-operator

Problem statement

The Db2 version used by IBM Data Cataloging service 2.1.6 got removed from the latest version of the IBM Operator Catalog.

Resolution

Follow the steps to resolve the issue:

1. Add or update the IBM Catalog Source object `ibm-operator-catalog` in the `openshift-marketplace` namespace during install or upgrade.

```
apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: ibm-operator-catalog-old
  namespace: openshift-marketplace
spec:
  displayName: IBM Operator Catalog
  publisher: IBM
  sourceType: grpc
  image: icr.io/cpopen/ibm-operator-catalog:sha256:c2538264cb1882b1c98fea5ef162f198ce38ed8c940e82e3b9db458a9a46cb15
  updateStrategy:
    registryPoll:
      interval: 45m
```

2. Update the `ibm-operator-catalog` source with the latest tag after the installation or upgrade completed.

```
apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: ibm-operator-catalog-old
  namespace: openshift-marketplace
spec:
  displayName: IBM Operator Catalog
  publisher: IBM
  sourceType: grpc
  image: icr.io/cpopen/ibm-operator-catalog:latest
  updateStrategy:
    registryPoll:
      interval: 45m
```

ConstraintsNotSatisfiable for db2u-operator

Problem statement

The Db2 version used by IBM Data Cataloging service 2.1.6 got removed from the latest version of the IBM Operator Catalog.

Resolution

Follow the steps to resolve the issue:

1. Add or update the IBM Catalog Source object `ibm-operator-catalog` in the `openshift-marketplace` namespace during install or upgrade.

```
apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: ibm-operator-catalog-old
  namespace: openshift-marketplace
spec:
  displayName: IBM Operator Catalog

  sourceType: grpc
  image: icr.io/cpopen/ibm-operator-catalog:latest
  updateStrategy:
```

```
registryPoll:  
interval: 45m
```

Content-Aware Storage (CAS)

The IBM Fusion Content-Aware Storage service is engineered to enhance the value of customers' AI applications, such as retrieval augmented generation (RAG) for faster time to insights, reduced cost, improved performance, enhanced security, and streamlined operations.

CAS provides turn-key processing of unstructured data for use in multi-modal RAG applications using [IBM Docling Multimodal](#) services and [NVIDIA NeMo Retriever Extraction](#) microservices. It supports automated extraction of text, tables, and charts from Enterprise documents and makes the extracted information available for use in RAG applications. NVIDIA GPUs are used to accelerate the data extraction processing. For more information on CAS-related frequently asked questions, see [Content-Aware Storage FAQs](#).

CAS uses IBM Storage Scale to cache existing Enterprise data residing on S3 sources to optimize processing with the IBM Docling Multimodal services and NVIDIA NeMo Retriever Extraction microservices without having to manage multiple copies of data. CAS also supports automated processing of data residing in the IBM Storage Scale filesystem. Incremental change processing is used to detect when data is modified in the IBM Storage Scale filesystem and automatically process the changed data for use in RAG applications.

Architecture

The objective of the Content-Aware Storage (CAS) architecture is to facilitate smooth interactions between LLMs and extensive quantities of unstructured data, amplifying insight derivation and suggestion functionalities.

The IBM Fusion CAS service uses IBM Fusion Global Data Platform service to remote mount a IBM Storage Scale cluster. This cluster can be Storage Scale software-based, or Storage Scale Server 3500 or 6000-based. CAS automatically processes files that are stored on the remote IBM Storage Scale cluster into parsed content, and metadata is normalized and stored along with vector embeddings in its managed vector database. Document processing is available with IBM's Docling Multimodal services or NVIDIA NeMo Retriever Extraction microservices.

IBM Storage Scale watch folders are used to detect changed data in the remote IBM Storage Scale filesystem, which triggers ingest processing by CAS of just the changed content.

Files stored in external S3 data sources are ingested through Active File Management (AFM) running in Global Data Platform. No external IBM Storage Scale filesystem is required. CAS performs a scan of the AFM-S3 fileset automatically to determine the data that needs to be ingested.

The CAS service provides a search API that aggregates semantic and keyword search to return the most accurate results. NVIDIA's reranking is an optional search component that can be added to provide more accuracy.

Customer applications such as a chatbot can send natural language searches to the CAS search API. Upon receiving the request, CAS creates a vector representation of the natural language search and performs a query against the vector database that uses the search method that is specified in the API (semantic, keyword, or hybrid). In the NVIDIA Multimodal pipeline, the top 100 results are sent to a CAS aggregator component that uses additional keyword and optionally vendor reranking to produce the top number of requested results. The optimized results are passed to a reranking function, which performs an additional optimization of the results before returning them to the search API.

In a customer provided RAG client, the CAS search API can be used to retrieve relevant search results, which can then be combined with the original prompt or question and sent to a large language model (LLM) to generate a response for the end user. IBM provides a sample RAG client in the form of a chatbot that customers can use to explore CAS capabilities or as a foundation for developing their own chatbot or RAG-based solution.

Note: CAS uses natural language processing (NLP) and AI technologies to extract semantic meaning from only unstructured text data.

Important: To know about the resource usage like, vCPU, memory, storage, and GPU, see [Planning and prerequisites](#).

- **Understanding user personas**

The personas of IBM Fusion Content-Aware Storage (CAS) service include Scale Admin, Data Engineer, and Developer. The Developer connects RAG application for working with the ingested content.

Understanding user personas

The personas of IBM Fusion Content-Aware Storage (CAS) service include Scale Admin, Data Engineer, and Developer. The Developer connects RAG application for working with the ingested content.

Scale Admins

Scale Admins are individuals responsible for managing storage software, such as IBM Storage Scale clusters and storage infrastructure. The Scale Admin deploys CAS with IBM Fusion and AI pipeline onto OpenShift® Container Platform cluster. The Scale Admin can see events for CAS in the same interface as IBM Fusion for a consistent serviceability experience.

The key responsibilities of a Scale Admin are as follows:

- Deploy, configure, and manage IBM Storage Scale clusters to ensure optimal performance and reliability.
- Configure and fine-tune IBM Storage Scale to efficiently handle high-throughput, low-latency AI data processing, ensuring integration with GPUs and AI frameworks.
- Work with Data Engineer to oversee data ingestion, preprocessing, and movement across storage tiers.
- Monitor system health of the Scale environment, implement caching strategies, and optimize data placement to prevent bottlenecks in AI model training and deployment.
- Use automation tools and scripts to streamline data lifecycle management, scaling storage resources dynamically to meet AI workload demands.

Data Engineer

Data engineers use data lakehouses as a flexible and scalable solution to store, process, and analyze diverse data types. Data Engineer defines a fileset on its storage content and connects it to an AI pipeline. In addition, the Data Engineer monitors the execution of the AI pipeline to understand the amount and timeliness of processing changes in content. As a Data Engineer, I can configure an Nvidia NIM pipeline to my Scale Fileset through CRs.

The key responsibilities of a Data Engineer are as follows:

- Storage of raw data in its original format. Including structured, semi-structured and unstructured data.
- Design and implement data ingestion pipelines that extract data from various sources, ensuring that all relevant data is available via a single interface for analysis and reporting.
- Maintain/curate metadata catalogs that capture information about data sources, data transformations, and data dependencies.
- Transform, augment, cleanse, and derive new datasets from existing data in accordance with their consumer's needs.
- Define access controls, data security measures, and data privacy policies to ensure compliance with policy and regulatory requirements.
- Enable data scientists, analysts, and other stakeholders to explore and analyze data.

Application Developer

The Application Developer queries and chats using the client enterprise application.

Installing Content-Aware Storage (CAS)

Initiate the installation of CAS from the user interface of IBM Fusion. It installs Kafka, CAS operator, and CNPG.

Before you begin

- Proceed with the installation only after all the prerequisites are met. For more information about prerequisites, see [Planning and prerequisites](#).
- Ensure that you have storage class and is marked as default. For example, **ibm-spectrum-fusion**. For more information about how to mark a storage class as default, see [Prerequisites](#) topic.
- Ensure all Scale projects and pods are running.

About this task

Use this procedure to install the CAS service from the Services page of the IBM Fusion user interface. You can also install the CAS service using CLI. For more information about CLI usage, see [Configuring Content-Aware Storage \(CAS\) through CLI](#).

Follow the procedure if:

- Your data resides on an external IBM Storage Scale filesystem.
- You prefer to use an external IBM Storage Scale filesystem as cache filesystem for your S3 data source.

Otherwise, follow the procedure in [Installing CAS without a remotely mounted IBM Storage Scale filesystem](#).

Procedure

1. In the IBM Fusion user interface, go to Services page.
2. In the Available section, click the CAS tile.
3. In the CAS page, go through the features and capabilities of the service and click Install.

If the pre-check raises a warning, then resolve it at OpenShift® level.

The installation starts and a notification appears on the Services page. You can see the progress of the installation in the Services > **Installed** section. After the installation is completed successfully, you can see the status as Healthy. A success notification gets displayed. It disappears automatically after some time.

From the ellipsis menu, you can download logs and view documentation.

4. In the Install service window, select storage class and click Install.
5. Validate the installation.
 - Verify the CAS installation from the IBM Fusion user interface:

After you enable the CAS service, you can view the service version and health status. From the ellipsis menu, you can download logs and view documentation. After you successfully collect the logs, a success notification is displayed. The notification disappears automatically after some time.
 - Verify the CAS installation from the OpenShift Container Platform web console:
 - In the OpenShift console, go to Home > Projects.
 - In the Projects page, search and check for the availability of a namespace with string `ibm-cas`.
 - Go to Operators > Installed Operators and check for the availability of CAS.
 - Open Content Aware Storage and check whether a CAS service definition is available.
 - After you enable the CAS service, you can view the service version and health status. From the ellipsis menu, you can download logs and view documentation. After you successfully collect the logs, a success notification is displayed. The notification disappears automatically after some time.

What to do next

- To verify the percentage completion of prerequisites post installation, do the following steps:
 1. Open IBM Fusion user interface.
 2. Go to Content-Aware Storage > Overview.
 3. In the Jump right in section, click Getting started with CAS tile.
 4. A side panel opens with the status of the following prerequisites:
 - Integrate NVIDIA NIM
 - Set up of Kafka Broker
 - Connect caching file system
- After you successfully install CAS, set up a Scale user to enable watch creation, configure vector stores and data sources. Map the vector store to the data source. For more information about these procedures, see [Configuring Content-Aware Storage \(CAS\)](#).
- [Planning and prerequisites](#)

Go through the Content-Aware Storage (CAS) installation prerequisites before you install the service.
- [Installing CAS without a remotely mounted IBM Storage Scale filesystem](#)

Install CAS on bare metal without a remotely mounted IBM Storage Scale filesystem using local Data Foundation storage and S3 buckets as the data source.
- [Installing NVIDIA NeMo Retriever Library](#)

The Content-Aware Storage (CAS) Document Processor Engine can either use IBM Docling Multimodal or NVIDIA NeMo Retriever Extraction for document extraction.
- [Configuring NVIDIA Inference Microservices \(NIMs\)](#)

After you install CAS, the `cas-config` configmap must be created. It provides the NeMo Retriever Library endpoint information.
- [Configuring a Multi-Instance GPU \(MIG\) with CAS](#)

Multi-Instance GPU (MIG) partitions a single NVIDIA GPU into multiple isolated instances. Each instance operates as an independent GPU, enabling resource sharing across multiple deployments.
- [Configuring IBM Storage Scale user to enable watch creation](#)

Configure an IBM Storage Scale user with all the needed privileges to enable watch creation.

Planning and prerequisites

Go through the Content-Aware Storage (CAS) installation prerequisites before you install the service.

General requirements

Ensure that you meet the following prerequisites for the CAS solution:

- Ensure that you have IBM Fusion 2.13.0 or higher version.

Important:

- CAS service installation can be performed only if IBM Fusion is installed by using the default **ibm-spectrum-fusion-ns** namespace. If the IBM Fusion installation is performed by using a custom namespace, the CAS installation cannot be completed.
- IBM Fusion Access for Storage Area Network (SAN), Global Data Platform, and CAS are mutually exclusive services. If IBM Fusion Access for SAN is planned or installed, you cannot deploy the Global Data Platform or CAS services. Review your architectural requirements and deployment goals before installing these services.
- [Resource requirements](#)
- * IBM Storage Scale requirements. See [IBM Storage Scale requirements](#).
- * Configure Scale remote filesystems. See [Configure Scale remote file systems](#).
- * Ensure that you have the latest IBM Storage Scale 5.2.3.x or higher version.
- * After at least one IBM Storage Scale remote filesystem is configured, in the OpenShift® console, go to Storage > Storage Class and verify whether the storage class created from the IBM Storage Scale remote filesystem is available for CAS. For example, if you enter **ibm-spectrum-fusion**, verify whether it is available.
- Configure NIMs. See [Configuring NVIDIA Inference Microservices \(NIMs\)](#).

* Skip these requirements if you are [installing CAS without a remotely mounted IBM Storage Scale filesystem](#).

Configuring flags in CAS ConfigMap

To use the NVIDIA re-ranker service, you can add the **NVMM_NEMO_RANKER** and **NVMM_NEMO_RANKER_SERVICE** flags to the cas-config ConfigMap.

For more information, see [Configuring NVIDIA Inference Microservices \(NIMs\)](#).

Allowlist for proxy

Add the following URLs to the allowlist for proxy installation:

- **apigee.googleapis.com**: Using Apigee Hybrid runtime, you can learn about proxies, shared flows, and other key components. It also provides information about configuration and system health.
- **apigeeconnect.googleapis.com**: Needed for **apigee-mart-server** and **apigee-connect** communication when **VPC-SC** is enabled.
- **binaryauthorization.googleapis.com**: Optional, only for Anthos if the binary authorization is enabled.
- **gcr.io**: Google Container Registry where the container images are hosted.
- **raw.githubusercontent.com**: To install the operator manifest.

Resource requirements

Work with IBM representative to ensure you have all the hardware components that are necessary for the CAS solution. Allocate three OpenShift compute nodes.

- The following resources are required for CAS to run on the three compute nodes:
 - 3 x NVIDIA L40S or H100 GPUs
 - An additional L40S or H100 GPU is needed for the optional re-ranker service.
 - 166 vCPU (83 physical cores)
 - 1024GB memory
 - 1TB IBM Storage Scale
 - Most common IBM Storage Scale ESS configuration is 48 NVMe drives with the capacity of 30TB in the ESS 6000 with 4 CX-7 network adapters (1.5 TB memory).
 - When using the Docling Multimodal Processing Engine, see [System requirements](#).
 - For CAS service system requirements, see [System requirements](#) for each of the components in addition to the resource requirements.
- Note: Content-Aware Storage (CAS) depends upon IBM Fusion management software and the Global Data Platform service.

Enabling GPUs in OpenShift

To enable GPUs in the OpenShift cluster, following components must be installed to support GPU workloads:

- Red Hat®'s Node Feature Discovery Operator - See the [Red Hat documentation](#).
- NVIDIA's GPU operator version - See the [NVIDIA documentation](#).

To deploy GPU operators in a disconnected or airgapped environment, see the [NVIDIA documentation](#).

NVIDIA Multimodal Document Processing Engine requirements

- The NVIDIA GPU operator, multi-modal RAG blueprint, and NVIDIA NIM operator are pulled from external NVIDIA NGC registry. As part of this process, you must provide NVIDIA NGC license keys to pull the NVIDIA components.
NVIDIA NIM is a set of optimized cloud-native microservices that are designed to simplify the deployment of generative AI models anywhere, across cloud, data center, and GPU-accelerated workstations. Initially, you must deploy the NVIDIA NeMo Retriever. For more information about the procedure to deploy, see [NVIDIA documentation](#).
- Optional: NVIDIA text reranking:
The NVIDIA text reranker is an optional component that requires an additional supported GPU. This component takes the initial set of search results and uses additional scoring from NVIDIA to return the top ranked results. For more information about deploying NeMo Retriever text reranking NIM, see [NVIDIA documentation](#).
- Contact IBM for the following details:
 - For optimization and performance of L40S or H100 GPU utilization of the NVIDIA NeMo Retriever Library multimodal PDF Ingest blueprint.
 - To configure NeMo Retriever Library NIM components with Multi-Instance GPU (MIG) for optimal use of supported GPUs or with time slicing. For more information, see [Configuring a Multi-Instance GPU \(MIG\) with CAS](#).
 - Additional tuning parameters required to optimize pipeline performance.

Compatibility matrix for NVIDIA's NeMo Retriever Library Multimodal blueprint with CAS

Content-Aware Storage (version)	NVIDIA NeMo Retriever Library Multimodal blueprint
---------------------------------	--

Content-Aware Storage (version)	NVIDIA NeMo Retriever Library Multimodal blueprint
v1.0.6, v1.0.7, v1.1.0	v25.9.0
v1.1.1, v1.1.2, v1.1.3, v1.1.4	v26.1.2
v1.1.5 and newer	v26.3.0

IBM Storage Scale requirements

If your datasource is on S3:

- Active File Management (AFM) is required to be configured on IBM Storage Scale remote file system. For more information, see [Configuring Active File Management](#).
- IBM Storage Scale cluster must be at version 5.2.3.1 or above.

Configure Scale remote file systems

To configure remote file systems, see [Connecting to remote IBM Storage Scale file systems](#). For software requirement levels, see [Software requirement levels](#). Important:

- When you setup the Global Data Platform user to create the connection to the remote file system, the user must be part of either the **CsiAdmin** or **ContainerOperator** groups. However, these groups do not have enough privileges to allow watcher creation. As a prerequisite to enable successful watcher creation, add these users to the **StorageAdmin** group. Create a user with all the privileges needed as a prerequisite. For more information about this configuration, see [Configuring IBM Storage Scale user to enable watch creation](#).
- After the remote file system installation is complete, mark your storage class, for example, **ibm-spectrum-fusion**, as default, by running the following command:

```
oc patch storageclass ibm-spectrum-fusion -p '{"metadata": {"annotations":{"storageclass.kubernetes.io/is-default-class":"true"}}}'
```

Offline installation

Content-Aware Storage supports usage of the Docling Multimodal document processing engine in an offline environment. For more information about the procedure to deploy offline, see [Mirroring Content-Aware Storage \(CAS\) images](#).

Installing CAS without a remotely mounted IBM Storage Scale filesystem

Install CAS on bare metal without a remotely mounted IBM Storage Scale filesystem using local Data Foundation storage and S3 buckets as the data source.

Before you begin

- Proceed with the installation only after all the prerequisites are met. For more information about prerequisites, see [Planning and prerequisites](#).
- For IBM Fusion services and platform support matrix, see [Support matrix for IBM Fusion versions](#).

Supported environment

- IBM Fusion Bare Metal
- Data Foundation is installed or intended to be used as the local storage provider.
- Data resides on AWS or IBM S3 buckets only.
- OpenShift® Hosted Control Plane (HCP) clusters

About this task

To install CAS without a remotely mounted IBM Storage Scale filesystem, follow the instructions in [README.md](#).

Limitations

- The automation script creates a local IBM Storage Scale filesystem named **cache-fs**. This filesystem is reserved exclusively as a cache for S3 data and must not be used by other applications.
- The **cache-fs** filesystem is not expandable.
- If your CAS data source is connected but I/O ingestion is slow, check whether:
 - Data Foundation shows a warning alert **SystemMemoryExceedsReservation**.
 - Any Object Storage Daemon (OSD) pod has **restarts**:

```
oc get pods -n openshift-storage -l app=rook-ceph-osd
```

For pods that have **restarts**, check if termination reason is **OOMKilled**:

```
oc describe pod rook-ceph-osd-xxx -n openshift-storage
```

Use the following procedure to increase the OSD pod memory from the default 8 GB:

<https://access.redhat.com/solutions/6959127>

- The system supports the shutdown or failure of only one quorum node at any specific time.

Installing NVIDIA NeMo Retriever Library

The Content-Aware Storage (CAS) Document Processor Engine can either use IBM Docling Multimodal or NVIDIA NeMo Retriever Extraction for document extraction.

Note: NVIDIA Ingest (nv-ingest) has been renamed to NeMo Retriever Library.

For more information about installing the GPU operator, see [Enabling GPUs in OpenShift](#).

For more information about installing NVIDIA NeMo Retriever Library, see the [NVIDIA documentation](#).

Verify the PodPidsLimit

To ensure compatibility and stability, you must update your cluster and deployment settings when using NeMo Retriever Library v26.3.0 with CAS v1.1.5 or newer.

1. To retrieve the current configuration, run the following command:

```
oc get KubeletConfig
```

2. To increase the pod PID limit, modify the `kubeletConfig` by adding the following `podPidsLimit` to the `spec` section:

```
spec:
  kubeletConfig:
    podPidsLimit: 12228
```

Note: After updating the configuration, all worker nodes in the cluster get restarted which can cause a temporary disruption.

For more information on changing the `podPidsLimit` when using the ROSA environment, see the [Red Hat® documentation](#).

Install the NIM Operator

NeMo Retriever Library requires that the NIM Operator is deployed and running. It is required to install the NIM Operator first before running the NeMo Retriever Library Helm chart. The operator can be installed from the OpenShift® marketplace. Search for The NVIDIA NIM Operator for Kubernetes, and install using the default options.

Select NVIDIA Inference Microservices (NIMs)

Before installing NIMs from the Helm chart, select the NIMs that are needed to extract your documents. For example, if your documents include audio files, installation of the audio NIM is required. Each NIM requires one GPU resource, which can either be a full GPU, or a GPU slice using a Multi-Instance GPU (MIG). The audio, reranking, and image captioning NIMs require a full GPU to run properly. By default, the NeMo Retriever Library Helm chart deploys five NIMs as indicated in the following table. For more information about MIG, see [Configuring a Multi-Instance GPU \(MIG\) with CAS](#).

NIM	Usage	Parameter in Helm chart	Default setting
llama-nemotron-embed-1b-v2	Text embedding	nimOperator.embedqa.enabled	true
nemotron-page-elements-v3	Object detection within documents	nimOperator.page_elements.enabled	true
nemotron-graphic-elements-v1	Chart extraction	nimOperator.graphic_elements.enabled	true
nemotron-table-structure-v1	Table extraction	nimOperator.table_structure.enabled	true
nemotron-ocr-v1	Optical character recognition (OCR)	nimOperator.ocr.enabled	true
nemotron-nano-12b-v2-v1	Vision language model (VLM) image captioning	.nemotron_nano_12b_v2_v1.enabled	false
audio	Audio extraction	nimOperator.audio.enabled	false
llama-nemotron-rerank-1b-v2	Reranker for query accuracy	nimOperator.rerankqa.enabled	false

Install NeMo Retriever Library

To install NeMo Retriever Library, follow these steps:

1. Create a new project called `nv-ingest`:

```
oc new-project nv-ingest
```

2. In your command line session, set the following bash variables:

```
NGC_API_KEY=<api key>
NAMESPACE=nv-ingest
```

Tip: To generate an NVIDIA NGC API key, see [Generate Your NGC Keys](#).

3. Add `helm` repositories:

```
# Nvidia nemo-microservices NGC repository
helm repo add nemo-microservices https://helm.ngc.nvidia.com/nvidia/nemo-microservices --username='$oauthtoken' --password=<NGC_API_KEY>
```

```
# Nvidia NIM NGC repository
helm repo add nvidia-nim https://helm.ngc.nvidia.com/nim/nvidia --username='$oauthtoken' --password=<NGC_API_KEY>
```

```
# NVIDIA NIM Base repository
helm repo add nim https://helm.ngc.nvidia.com/nim --username='$oauthtoken' --password=<NGC_API_KEY>
```

```
# Nvidia NIM baidu NGC repository
helm repo add baidu-nim https://helm.ngc.nvidia.com/nim/baidu --username='$oauthtoken' --password=<NGC_API_KEY>
```

4. Deploy NeMo Retriever Library using the `helm` chart. To select NIMs, see [Select NVIDIA Inference Microservices \(NIMs\)](#).

Example 1: Deploy NeMo Retriever Library with the five default NIM services deployed

```
helm upgrade \
--install \
nv-ingest \
https://helm.ngc.nvidia.com/nvidia/nemo-microservices/charts/nv-ingest-26.3.0.tgz \
-n ${NAMESPACE} \
--username '$oauthtoken' \
--password "${NGC_API_KEY}" \
--set ngcImagePullSecret.create=true \
--set ngcImagePullSecret.password="${NGC_API_KEY}" \
--set ngcApiSecret.create=true \
--set ngcApiSecret.password="${NGC_API_KEY}" \
--set image.repository="nvcr.io/nvidia/nemo-microservices/nv-ingest" \
--set image.tag="26.3.0" \
--set milvusDeployed=false
```

Example 2: Deploy NeMo Retriever Library with the default NIM services (same as Example 1) along with the audio Riva NIM

```
helm upgrade \
--install \
nv-ingest \
https://helm.ngc.nvidia.com/nvidia/nemo-microservices/charts/nv-ingest-26.3.0.tgz \
-n ${NAMESPACE} \
--username '$oauthtoken' \
--password "${NGC_API_KEY}" \
--set ngcImagePullSecret.create=true \
--set ngcImagePullSecret.password="${NGC_API_KEY}" \
--set ngcApiSecret.create=true \
--set ngcApiSecret.password="${NGC_API_KEY}" \
--set nimOperator.audio.enabled=true \
--set image.repository="nvcr.io/nvidia/nemo-microservices/nv-ingest" \
--set image.tag="26.3.0" \
--set milvusDeployed=false
```

Example 3: Deploy NeMo Retriever Library with the default NIM services (same as example 1) along with the audio Riva NIM and the reranking NIM

```
helm upgrade \
--install \
nv-ingest \
https://helm.ngc.nvidia.com/nvidia/nemo-microservices/charts/nv-ingest-26.3.0.tgz \
-n ${NAMESPACE} \
--username '$oauthtoken' \
--password "${NGC_API_KEY}" \
--set ngcImagePullSecret.create=true \
--set ngcImagePullSecret.password="${NGC_API_KEY}" \
--set ngcApiSecret.create=true \
--set ngcApiSecret.password="${NGC_API_KEY}" \
--set nimOperator.audio.enabled=true \
--set nimOperator.rerankqa.enabled=true \
--set image.repository="nvcr.io/nvidia/nemo-microservices/nv-ingest" \
--set image.tag="26.3.0" \
--set milvusDeployed=false
```

Example 4: Minimum configuration

For a minimum configuration installation that extracts only text from files (text or PDF), the text embedding NIM is required. However, the other NIM services can be disabled.

```
helm upgrade \
--install \
nv-ingest \
https://helm.ngc.nvidia.com/nvidia/nemo-microservices/charts/nv-ingest-26.3.0.tgz \
-n ${NAMESPACE} \
--username '$oauthtoken' \
--password "${NGC_API_KEY}" \
--set ngcImagePullSecret.create=true \
--set ngcImagePullSecret.password="${NGC_API_KEY}" \
--set ngcApiSecret.create=true \
--set ngcApiSecret.password="${NGC_API_KEY}" \
--set nimOperator.graphic_elements.enabled=false \
--set nimOperator.page_elements.enabled=false \
--set nimOperator.table_structure.enabled=false \
--set nimOperator.ocr.enabled=false \
--set image.repository="nvcr.io/nvidia/nemo-microservices/nv-ingest" \
--set image.tag="26.3.0" \
--set milvusDeployed=false
```

5. Check the PVC sizes created for the NIMCache:

```
oc get pvc -n nv-ingest
```

Note: You are recommended to increase the audio NIM to 250Gi, reranker NIM to 100Gi, and the **embedqa** NIM to 100Gi to avoid issues downloading the required models.

Expand the following PVCs:

a. **embedqa** NIM PVC

```
oc patch pvc llama-nemotron-embed-1b-v2-pvc -n nv-ingest --type merge -p '{"spec":{"resources":{"requests":{"storage":"100Gi"}}}}'
```

b. Audio NIM PVC (only applicable when the audio NIM is enabled)

```
oc patch pvc audio-pvc -n nv-ingest --type merge -p '{"spec":{"resources":{"requests":{"storage":"250Gi"}}}}'
```

c. Reranker NIM PVC (only applicable when the reranking NIM is enabled):

```
oc patch pvc llama-nemotron-rerank-1b-v2-pvc -n nv-ingest --type merge -p '{"spec":{"resources":{"requests":{"storage":"100Gi"}}}}'
```

6. Verify that the pods are running:

```
oc get deployments -n nv-ingest
```

Example output:

NAME	READY	UP-TO-DATE	AVAILABLE	AGE
audio	1/1	1	1	5d23h
llama-nemotron-embed-1b-v2	1/1	1	1	5d23h
llama-nemotron-rerank-1b-v2	1/1	1	1	5d23h
nemotron-graphic-elements-v1	1/1	1	1	5d23h
nemotron-nano-12b-v2-v1	1/1	1	1	5d23h
nemotron-ocr-v1	1/1	1	1	5d23h
nemotron-page-elements-v3	1/1	1	1	5d23h
nemotron-table-structure-v1	1/1	1	1	5d23h
nv-ingest	1/1	1	1	5d18h
nv-ingest-opentelemetry-collector	1/1	1	1	5d18h
nv-ingest-zipkin	1/1	1	1	5d18h

Configuring NVIDIA Inference Microservices (NIMs)

After you install CAS, the `cas-config` configmap must be created. It provides the NeMo Retriever Library endpoint information.

To determine the NeMo Retriever Library endpoint information, you must know the namespace in which NeMo Retriever Library is installed. The endpoints are constructed by using the pattern `http(s)://.svc.cluster.local`. When you use the default installation namespace of NeMo Retriever Library and because it does not support `https` by default, it results in the following URLs:

CAS 1.1.5 and later

- Embed service URL: `http://llama-nemotron-embed-1b-v2.nv-ingest.svc.cluster.local`
- Ingest service URL: `http://nv-ingest.nv-ingest.svc.cluster.local`

Prior to CAS 1.1.5

- Embed service URL: `http://llama-32-nv-embedqa-1b-v2.nv-ingest.svc.cluster.local`
- Ingest service URL: `http://nv-ingest.nv-ingest.svc.cluster.local`

Note: These URLs must not end with the `/` character.

To complete this activity, use the `oc` command line tool and run the following command:

```
oc apply -f - <<EOF
apiVersion: v1
kind: ConfigMap
metadata:
  name: cas-config
  namespace: ibm-cas
data:
  NVMM_EMBED_SERVICE: <Embed Service URL as determined above>
  NVMM_NIM_SERVICE: <Ingest Service URL as determined above>
EOF
```

NVIDIA re-ranker

Optionally, you can set `NVMM_NEMO_RANKER` in the `CasInstall` CR to enable the NVIDIA re-ranker service. This service analyzes semantic relevance and reorders search results to improve precision in enterprise search and streamline AI-driven workflows. For more information, see the [NVIDIA](#) documentation.

- Re-ranker service URL: `http://llama-32-nv-rerankqa-1b-v2.nv-ingest.svc.cluster.local`

Note: The service URL must not end with the `/` character.

To enable the NVIDIA re-ranker service, set the `NVMM_NEMO_RANKER` flag to `YES` and the `NVMM_NEMO_RANKER_SERVICE` flag to the re-ranker service URL in the `cas-config` ConfigMap:

```
spec:
oc patch configmap cas-config \
  -n ibm-cas \
  --type merge \
  -p '{"data":{"NVMM_NEMO_RANKER": "YES", "NVMM_NEMO_RANKER_SERVICE": "<Re-ranker service URL as determined above>"}}'
```

Configuring a Multi-Instance GPU (MIG) with CAS

Multi-Instance GPU (MIG) partitions a single NVIDIA GPU into multiple isolated instances. Each instance operates as an independent GPU, enabling resource sharing across multiple deployments.

Before you begin

MIG support requirements

Only specific NVIDIA GPUs support MIG. For more information on the supported models and their configurations, see the [NVIDIA](#) documentation.

Note: The NeMo Retriever Library NIMs support only a subset of the GPUs that support MIG.

Before you configure MIG, plan how to partition each GPU by using the supported profiles. Each profile defines the amount of memory and compute engines that the slice can use.

The following table shows the minimum recommended MIG profile for each NIM service by GPU model:

NIM service	H100	H200	RTX PRO 6000
nemotron-embed	mig-7g.80gb	mig-7g.141gb	mig-1g.24gb
nemotron-page-elements	mig-1g.10gb	mig-1g.18gb	mig-1g.24gb
nemotron-graphic-elements	mig-1g.10gb	mig-1g.18gb	mig-1g.24gb
nemotron-table-structure	mig-1g.10gb	mig-1g.18gb	mig-1g.24gb
nemotron-ocr	mig-1g.20gb	mig-1g.18gb	mig-1g.24gb
audio	mig-7g.80gb	mig-7g.141gb	mig-4g.96gb
nemotron-nano	mig-7g.80gb	mig-7g.141gb	

For more information about each of these NIM services, see [Select NVIDIA Inference Microservices \(NIMs\)](#).

For further examples, see [NVIDIA MIG User Guide](#).

Example: An RTX PRO 6000 GPU can be partitioned in the following way:

- One 96 GB slice with 4 compute engines
- Two 48 GB slices with 2 compute engines each

Each RTX PRO 6000 GPU contains four compute engines. Ensure that the total number of compute engines across all slices on a GPU do not exceed four.

Note: For optimal ingestion performance, assign a full GPU MIG profile to the **nemotron-embed** NIM service to increase GPU compute capacity.

About this task

This task configures MIG on NVIDIA GPUs that support the MIG feature. The steps involve enabling MIG, defining GPU partitions, applying the MIG configuration to your nodes, and assigning deployment to specific GPU slices.

To configure MIG on NVIDIA GPUs, perform the following steps:

Procedure

1. Apply the following configmap in the **nvidia-gpu-operator** namespace:

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: nv-ingest-mig
data:
  config.yaml: |
    version: v1
    mig-configs:
      all-disabled:
        - devices: all
          mig-enabled: false
      nv-ingest-mig-config:
        - devices: [0, 1]
          mig-enabled: true
          mig-devices:
            "2g.20gb": 2
            "3g.40gb": 1
```

2. Temporary stop any pods that use the GPUs. The MIG manager cannot reconfigure GPUs that are in use.
3. Patch the **gpu-cluster-policy** and set the MIG strategy value to "mixed".

```
kubectl patch clusterpolicies.nvidia.com/gpu-cluster-policy \
  --type='json' \
  -p='[{"op": "replace", "path": "/spec/mig/strategy", "value": "mixed"}]'
```

4. Label one or more nodes with the GPUs that you want to configure your MIG settings, referencing the MIG configuration defined in the configmap. Then set the correct value to the **NODE** variable:

```
NODE=ip-10-0-9-79.us-west-2.compute.internal
MIG_CONFIGURATION=nv-ingest-mig-config
oc label node $NODE nvidia.com/mig.config=$MIG_CONFIGURATION --overwrite
```

5. Monitor the pods in the **nvidia-gpu-operator** namespace. The configuration must recycle several pods, including the **gpu-feature-discovery** pods.
6. To verify the MIG configuration, run the following command:

```
nvidia-smi
```

You can see MIG slices with memory usage metrics after NeMo Retriever Library is activated. Initially, the memory usage appears as 1 MiB until the pods start to use the slices.

MIG devices:												
GPU	GI	CI	MIG	Memory-Usage			Vol	Shared				
ID	ID	ID	Dev	BAR1-Usage		SM	Unc	CE	ENC	DEC	OFA	JPG
							ECC					
0	2	0	0	3590MiB / 40192MiB		42	0	3	0	2	0	0
				2MiB / 32767MiB								
0	3	0	1	2959MiB / 19968MiB		28	0	2	0	1	0	0

- [Creating a data source](#) or [Creating a vector store and connecting with data source](#)

Tip: Starting from CAS v1.1.1, CAS installation automatically configures the Kafka broker connection on IBM Storage Scale.

You can also configure CAS service using CLI. For more information about CLI usage, see [Configuring Content-Aware Storage \(CAS\) through CLI](#).

Note: Before you begin the configuration, ensure you have met all the prerequisites and installed CAS successfully. For the procedure to install, see [Installing Content-Aware Storage \(CAS\)](#).

Quick start to configuration:

Note: If the Getting started with CAS section is not available, it indicates that all the prerequisites are not met.

1. In the IBM Fusion user interface, go to Content-Aware Storage > Overview.
2. In the Jump right in section, you can click the following tiles to quick start configuration to streamline data preparation, chunking and delivery to embedding or inference systems:
 - Connect a data source
 - Create a vector store
 - View Search APIs
3. To view the percentage completion of the configuration, do the following steps:
 - a. In the Jump right in section, click Getting started with CAS tile.
 - b. A side panel opens with the status of the following Data ingestion:
 - Connect a data source
 - Create a vector store
 - View Search APIs

- [Integrating CAS and IBM Data Cataloging](#)

Rule-based integration between IBM Data Cataloging and Content-Aware Storage (CAS) ensures selective, policy-driven data ingestion into CAS vector stores.

- [Creating a data source](#)

A data source is a repository or a system that stores and provides data for use in applications or systems. They are storage locations that provide data to use in AI workflows.

- [Creating a vector store and connecting with data source](#)

Vector stores collect, transform, and transfer data from multiple data sources to a destination, enabling efficient data flow for analysis and AI models.

- [Configuring Document Processor Engine](#)

Steps to configure Document Processor Engines: IBM Docling Multimodal and NVIDIA Multimodal.

- [Configuring Content-Aware Storage \(CAS\) through CLI](#)

You can use the CRs to configure CAS.

- [Using your own Hugging Face access token with CAS for NVIDIA Multimodal](#)

NVIDIA NeMo Retriever Library uses models that are downloaded from Hugging Face to do token-based splitting on the content extracted from documents. NVIDIA recommends to use the meta-llama/Llama-3.2-1B tokenizer, however this model is gated and requires a Hugging Face token in order access it. A Hugging Face access token is a personal API key that is used to securely authenticate programmatic access to Hugging Face services.

- [Configuring CAS Query Access Control and Security](#)

Content-Aware Storage (CAS) supports vector store-level authorization, Identity Provider integration, and optional file-level security to control query access.

Integrating CAS and IBM Data Cataloging

Rule-based integration between IBM Data Cataloging and Content-Aware Storage (CAS) ensures selective, policy-driven data ingestion into CAS vector stores.

By integrating IBM Data Cataloging with CAS, organizations can apply advanced pre-filtering through configurable, rule-based policies that control which files are ingested into CAS.

Administrators can define criteria such as file type, size, location, and content patterns to ensure that only relevant data is stored in CAS vector stores. Custom tags and attributes further enhance this capability by providing fine-grained control over the ingestion process. For more information, see [Managing IBM Data Cataloging rules when integrated with CAS](#).

- [Integrating IBM Data Cataloging for file filtering](#)

You can enable integration of IBM Data Cataloging with Content-Aware Storage (CAS) to configure file ingestion filtering. Any file from a data source that meets the filtering criteria can be ingested into the corresponding vector store. Filtering is enforced across all vector stores within the same IBM Fusion cluster.

- [Using IBM Data Cataloging attributes with CAS](#)

Content-Aware Storage (CAS) integrates with IBM Data Cataloging service (DCS) to support automated file categorization through flexible, attribute-based tagging.

- [IBM Data Cataloging and Content-Aware Storage insights](#)

IBM Data Cataloging and Content-Aware Storage (CAS) introduce data insights dashboards that provide immediate visibility into data once sources are connected and scanned. This experience is enabled when both IBM Data Cataloging and CAS are integrated. The provided insights surface key indicators of data composition on each established data source.

Integrating IBM Data Cataloging for file filtering

You can enable integration of IBM Data Cataloging with Content-Aware Storage (CAS) to configure file ingestion filtering. Any file from a data source that meets the filtering criteria can be ingested into the corresponding vector store. Filtering is enforced across all vector stores within the same IBM Fusion cluster.

Before you begin

- Ensure that you have IBM Fusion 2.12.0 version.
- Install IBM Data Cataloging 2.3.0. For more information, see [Installing IBM Data Cataloging](#).
- Connect to Scale Remote Filesystem from IBM Data Cataloging by using these instructions: [Creating an IBM Storage Scale data source connection](#). For more information, see [IBM Storage Scale data source connections](#).
- Understand the default filtering criteria. For more information, see [Managing IBM Data Cataloging rules when integrated with CAS](#).

Enable or disable filtering through CLI

Enable filtering

To enable filtering by using IBM Data Cataloging, run the following command:

```
oc patch casinstall ibm-cas-service-instance -n ibm-cas --type=merge -p '{"spec":{"enabled_features":{"dcs":{"enable":true,"instance_name":"data-cataloging-service-instance","namespace":"ibm-data-cataloging"}}}}'
```

To confirm filtering is enabled, run the following command:

```
DCS_CR=$(oc get SpectrumDiscover -n ibm-data-cataloging -o jsonpath="{.items[*].metadata.name}")
oc get SpectrumDiscover $DCS_CR -n ibm-data-cataloging -o jsonpath="{.status.conditions[*]}{"\n"}'
```

Tip: You must see the type **ContentAwareStorage** listed as **SuccessfullyEnabled**:

```
{"lastTransitionTime":"2025-09-10T08:33:42Z","message":"","reason":"SuccessfullyEnabled","status":"True","type":"ContentAwareStorage"}
```

Disable filtering

To disable filtering, run the following command:

```
oc patch casinstall ibm-cas-service-instance -n ibm-cas --type=merge -p '{"spec":{"enabled_features":{"dcs":{"enable":false,"instance_name":"data-cataloging-service-instance","namespace":"ibm-data-cataloging"}}}}'
```

To confirm filtering is disabled, run the following command:

```
DCS_CR=$(oc get SpectrumDiscover -n ibm-data-cataloging -o jsonpath="{.items[*].metadata.name}")
oc get SpectrumDiscover $DCS_CR -n ibm-data-cataloging -o jsonpath="{.status.conditions[*]}{"\n"}'
```

Tip: You must no longer see the type **ContentAwareStorage** listed in the output.

One-click installation and enablement integration experience

CAS provides a one-click installation of IBM Data Cataloging directly from the Content-Aware Storage > Settings page. This integration streamlines the setup process by enabling administrators to install and configure IBM Data Cataloging without leaving the CAS user interface, improving the integration between both data services.

Overview

When IBM Data Cataloging is not installed, the Advanced filtering and scanning section in the Content-Aware Storage > Settings page displays an Install Data Cataloging button. Clicking this button launches the same installation flow that is used in the Services page. As a result, no additional configuration is required outside of CAS.

After installation completes, the same section enables controls to manage IBM Data Cataloging filtering:

- Modify rulesets: Opens the OpenShift® Container Platform custom resource editor to configure filtering rulesets. For more information, see [Managing IBM Data Cataloging rules when integrated with CAS](#).
- Enable / Disable toggle: Enables or disables IBM Data Cataloging-based advanced filtering without uninstalling the service.

Prerequisites

Before starting the installation, ensure that you meet the following prerequisites:

- CAS v1.1.5 is deployed and the Content-Aware Storage > Settings page is accessible.
- The cluster meets the resource requirements for IBM Data Cataloging.

Installing IBM Data Cataloging

1. In the IBM Fusion console, go to Content Aware Storage > Settings.
2. Locate the Advanced filtering and scanning section. If IBM Data Cataloging is not installed, the section displays an Install Data Cataloging button.
3. Click Install Data Cataloging. An installation progress indicator that shows the current percentage replaces the button.
Installation follows the same setup process as the Services page. If the installation fails, an error message is displayed in the same section with details to help you troubleshoot or check Fusion Events.
4. Wait for the installation to complete. The progress indicator disappears when IBM Data Cataloging is fully installed.

Managing IBM Data Cataloging after installation

After IBM Data Cataloging is installed, the Advanced filtering and scanning section updates to show the management controls.

Control	Description
Modify rulesets	Opens the OpenShift Container Platform custom resource for IBM Data Cataloging, where you can configure the filtering rulesets that determine which content CAS processes.
Enabled / Disabled toggle	Enables or disables IBM Data Cataloging based advanced filtering. Disabling does not uninstall the service.

Modifying rulesets

Click Modify rulesets to open the OpenShift Container Platform custom resource editor. Update the ruleset configuration as needed and save the resource. The changes take effect immediately. For more information, see [Managing IBM Data Cataloging rules when integrated with CAS](#).

Enabling and disabling filtering

Use the toggle in the Advanced filtering and scanning section to enable or disable IBM Data Cataloging filtering at any time. When filtering is disabled, CAS continues to operate without IBM Data Cataloging-based content analysis until filtering is re-enabled.

Using IBM Data Cataloging attributes with CAS

Content-Aware Storage (CAS) integrates with IBM Data Cataloging service (DCS) to support automated file categorization through flexible, attribute-based tagging.

Attributes can be applied in DCS either before or after files are ingested into CAS, enabling administrators to enrich data with meaningful metadata such as document type, department, project, or other custom attributes. After attributes are applied in DCS, you can use the CAS [Query Service API](#) to perform filtered queries that return only the most relevant content chunks.

Creating a tag

In DCS, additional metadata is applied by creating tags. A tag is a custom metadata field that enhances existing metadata with organization-specific information and supports data classification, search, and reporting.

To create a tag, follow these steps:

1. In the IBM Fusion Data Cataloging UI, open the menu and go to Metadata > Tag management.
2. Open the Tags section, and click Add Tag.

The Create a new tag window opens.

3. In the Name field, specify a tag name, and click Add.

For additional details about tags and how to create them, see [Managing tags](#).

Creating a policy

After a tag is created, a DCS policy must be defined to associate documents with that tag. The policy uses a user-defined query to classify documents, and when the policy is executed, the tag is automatically populated with values for all matching documents.

To create a policy, follow these steps:

1. In the IBM Fusion Data Cataloging UI, open the menu and go to Metadata > Tag management.
2. Open the Policies section, and click Add Policy.

Policy	Type	Schedule (UTC)	State	Status	Collections	Last modified by	Last modified
APPROVEDFILE	AUTOTAG	Done	Active	Complete		cluster-admin	4/16/2026, 5:10:04 PM
cas_sensitive_data	CONTENTSEARCH	Done	Active	Running		seedma	4/17/2026, 6:08:47 PM
FILE_AFTER_UPGRADE_2	AUTOTAG	Done	Active	Complete		cluster-admin	4/22/2026, 9:04:53 PM

The Add new policy window opens.

Add new policy

Define | Configure | Schedule | Review

Name: POLICY_SAMPLE

Policy type: AUTOTAG

Cancel | Continue to configure

3. In the Name field, specify a name for the new policy.
4. Select the Policy Type. The default value is AUTOTAG policy.
5. Click Continue to configure.
6. Configure the policy. This action includes specifying a filter, which is used by the mechanism to tag files by tagging only those files that match the specified filter. In addition, specify the tag to be used and the value to assume.

IBM Fusion Data Cataloging

Add new policy

10. Review the information before creating the policy. Then, click Submit.

You can monitor the policy's progress by reviewing the Policy history records.

Policy name	Type	Started	Ended	Status	Total records	Successful	Skipped	Failed
POLICY_SAMPLE	AUTOTAG	5/1/2026, 7:32:13 AM	5/1/2026, 7:32:20 AM	Complete	192	192	0	0

For additional instructions on creating policies, see [Adding policies](#).

IBM Data Cataloging and Content-Aware Storage insights

IBM Data Cataloging and Content-Aware Storage (CAS) introduce data insights dashboards that provide immediate visibility into data once sources are connected and scanned. This experience is enabled when both IBM Data Cataloging and CAS are integrated. The provided insights surface key indicators of data composition on each established data source.

The UI dashboard surfaces foundational indicators of the associated data sources from the storage. No additional configuration is required to start using the dashboard.

Prerequisites

- Content-Aware Storage v1.1.5
- IBM Data Cataloging v2.5.3
- IBM Storage Scale v6.0.0.2 or later
- Ensure that both services are integrated. For more information, see [Integrating IBM Data Cataloging for file filtering](#).

Overview

When a data source is added on CAS, the dashboards display insights that are scoped to that source.

You can go to Fusion UI > Content-Aware Storage > Data Sources > Details View.

The experience is organized into the following sections:

- Data source summary: High-level file and storage metrics.
- Data composition: Breakdown of file types and file size distribution.

Data source summary

At the top of the Data source view, four summary cards display key metrics for the selected data source.

Metric	Description
Total files	Total number of files that are indexed by IBM Data Cataloging across all data sources and prefixes for the data source.
Total storage	Aggregate storage capacity consumed, reported in GiB.
Ready to process	Number and percentage of files that match the CAS ingestion criteria defined in the active ruleset. For more information, see Managing IBM Data Cataloging rules when integrated with CAS . When IBM Data Cataloging and CAS are integrated, this value reflects the result of the rules that are specified in the custom resource.
Sensitive data	Count of files flagged as containing sensitive content. See the Sensitive data section for details on how this count is determined.

Data composition

The Data composition section provides a structural breakdown of the cataloged dataset across two dimensions.

File types and formats

Files are grouped by category (Documents, Images, Videos, Audio, Other). Each category shows the total file count and storage size, and distinguishes between formats that CAS can process and those it cannot. Expanding a category reveals the individual extensions within each group.

The following file formats are supported for CAS ingestion:

pdf, doc, docx, txt, html, markdown, md, pptx, jpeg, png, bmp, xlsx, asciidoc, adoc, xhtml, csv, webp, wav, ogg, opus, mp3

For more information, see [Managing IBM Data Cataloging rules when integrated with CAS](#). All other extensions appear under the Not Supported label within their category.

File size distribution

A horizontal bar chart shows the number of files that are grouped by size range. The buckets used are: < 1 MB, 1-10 MB, 10-100 MB, 100 MB-1 GB, and > 1 GB.

This metric is derived from a single aggregated API query against the IBM Data Cataloging catalog.

Creating a data source

A data source is a repository or a system that stores and provides data for use in applications or systems. They are storage locations that provide data to use in AI workflows.

Before you begin

- For prerequisites specific to S3 type data source, see [S3 type data source](#).
- For prerequisites and limitations specific to NFS data sources, see [Network File System \(NFS\) type data source](#).

About this task

- The data source serves as the foundation for feeding information into the data pipeline.
You have the options of:
 - Object Storage such as Amazon S3
 - IBM Storage Scale
 - Network File System (NFS)
- Content-Aware Storage (CAS) does not directly interface with S3 storage providers. It accesses S3 storage through the IBM Storage Scale S3 filesystem and with Active File Management (AFM) feature enablement provides a cached copy of the S3 content.
- Up to 25 CAS data sources are supported. Each data source can be one of the following:
 - An external S3 bucket using a IBM Storage Scale AFM fileset to ingest the S3 content.
 - A fileset residing on the IBM Storage Scale filesystem attached to CAS (without AFM).
- CAS supports multiple IBM Storage Scale filesystems. However, all remote filesystems must belong to a single remote IBM Storage Scale cluster.
- The following constraints exist for change notifications for filesets that reside in the IBM Storage Scale file system is remote mounted by IBM Fusion Global Data Platform service (without AFM):
 - Up to 10 million files per fileset
 - Up to 100 million files total monitored
- Only independent fileset is supported.

Procedure

- From the menu, go to Content-aware storage > Data source.
- In the Data sources page, click Connect data source.
- Enter the name of the Data source.
- Select the storage type and click Next.
The available storage types are IBM Cloud, Storage Scale, AWS, S3 Compliant, and NFS.
- Enter the following details in the Connection details page.
The Connection details page vary based on your storage type selection.
 - IBM Cloud, AWS, or S3 Compliant
 - Enter the Endpoint.
It refers to the URL through which you can access the bucket and its contents. For more information about Endpoint rules, see [AWS documentation](#).
 - Enter the name of the S3 Bucket.
For more information about the bucket naming guidelines, see [AWS documentation](#).
 - For AWS, enter the Region. It is the Amazon Web Services region where the bucket is located.

- Enter the Access key and Secret access key
These are security credentials needed to access the contents of the bucket.
 - In the Certificate settings section, enter the Secret name for certificate.
This is an optional parameter. SSL secured object storage locations require certificates for authentication. Create an OpenShift® TLS secret in the **ibm-spectrum-fusion-ns** namespace or your IBM Fusion namespace. Provide the secret name for the credentials. For more information about creating a secret, see [Creating a secret](#).
 - Storage Scale
Enter the Path. It is the junction path.
 - NFS
Provide the following information:
 - NFS server: Enter the NFS server hostname or IP address.
Note: Although this field is defined as a list, only a single NFS server is supported in the CAS 1.1.5 release.
 - Export path: Enter the NFS export path to monitor. For example: /home/user/data
6. In the Caching filesystem section, select the file system where the cache of this data source must be stored.
If there is only one remote file system detected, it gets automatically selected and this field is not available for selection.
7. Click Connect to submit the information so that CAS can be enabled for the data source.

What to do next

For an IBM Storage Scale type data source, verify that the CAS pod has the correct group permissions on the junction path before you start ingestion.

Permissions required for IBM Storage Scale data sources

When CAS reads files from an IBM Storage Scale fileset, it does so from inside an OpenShift pod that runs under a specific Linux user and group identity. IBM Storage Scale enforces standard POSIX permissions, so OpenShift roles (including **cluster-admin**) have no effect on whether the pod can read a file. The only thing Scale checks is whether the pod's effective group ID (GID) matches the group that owns the file or directory.

Find the pod's runtime identity

Before you configure permissions on the IBM Storage Scale side, find out which GID the DocumentProcessor pod runs under:

```
oc exec -n <namespace> <documentprocessor-pod> -- id
```

Example output:

```
uid=1001(default) gid=0(root) groups=0(root),1000830000
```

The supplementary group (1000830000 in this example) is the GID that Scale evaluates against every file the pod tries to read.

Check the junction path permissions

Log in to your IBM Storage Scale cluster and inspect the junction path. For example, if your junction path is /gpfs/gpfs3/my-data/:

```
cd /gpfs/gpfs3/
ls -la
```

Example output:

```
drwxr-x--- 2 root cas 4096 May 22 19:50 my-data
```

Check the following items:

What to check	Why it matters
Group owner of the directory	The pod's GID must match this group. If it does not match, the pod cannot enter the directory.
Group execute (x) permission on the directory	Required for the pod to access and traverse the directory path. A matching GID grants access only when this permission is present.
Group read (r) permission on each file	Required for the pod to read file contents.

Resolve a GID mismatch

If the group owner shown by **ls -la** does not match the pod's supplementary GID, use one of the following options:

Option A: Annotate the DataSource with the correct GID (recommended)

1. Look up the numeric GID of the group that owns the junction path:

```
getent group cas | cut -d: -f3
```

Example output: 310

2. Annotate the DataSource so that CAS uses that GID when mounting the path:

```
oc annotate DataSource <datasource-name> group-id='<gid>' --overwrite
```

3. Replace **<datasource-name>** with the name of your DataSource CR and **<gid>** with the numeric value that is returned in step 1, for example 310.

Option B: Change the owning group of the files to match the pod's GID

Important: Use this option only for test or development filesets. Do not change ownership on production files until the intended CAS access group is confirmed with your Scale administrator.

```
chgrp <pod-gid> /gpfs/gpfs3/my-data/*.pdf
chmod g+x /gpfs/gpfs3/my-data
```

Verify access before ingesting

After you make either change, verify that the pod can read the files before you start ingestion:

```
oc exec -n <namespace> <documentprocessor-pod> -- \
sh -c 'cat /gpfs/gpfs3/my-data/<file>.pdf >/dev/null && echo "OK"'
```

If the command prints **OK**, the pod has the required access and ingestion can proceed. If the command returns **Permission denied**, check the group owner and GID annotation again.

- [Prerequisites for S3 and NFS type data sources](#)

Prerequisites for creating S3 and NFS type data sources in CAS, including Active File Management requirements, version constraints, and AWS permissions.

- [Deploying an S3 data source with custom SSL certificate](#)

Deploy an S3 data source with a custom SSL certificate on IBM Storage Scale 6.0.0.x by manually creating the AFM fileset before connecting the data source.

Prerequisites for S3 and NFS type data sources

Prerequisites for creating S3 and NFS type data sources in CAS, including Active File Management requirements, version constraints, and AWS permissions.

S3 type data source

Prerequisites

Ensure that you meet the following prerequisites if you plan to use an S3 type data source:

- If you choose a remote filesystem as the cache filesystem for your S3 type data source,
 - Enable Active File Management (AFM) on the remote IBM Storage Scale cluster. For more information, see the [Scale documentation](#).
 - The remote IBM Storage Scale cluster must be at least at version 5.2.3 and the IBM Fusion cluster must be at least at IBM Fusion level 2.10.
- Starting with IBM Storage Scale 6.0.1, the Amazon Web Services account used to provide the access key and secret key for bucket authentication must be granted both **AmazonSNSFullAccess** and **AmazonSQSFullAccess** permissions. For more information, see the [Scale AFM documentation](#).

Network File System (NFS) type data source

Prerequisites

Ensure that you meet the following prerequisites if you plan to use an NFS type data source:

- If you choose a remote filesystem as the cache filesystem for your NFS type data source,
 - Enable Active File Management (AFM) on the remote IBM Storage Scale cluster. For more information, see the [Scale documentation](#).
 - The remote IBM Storage Scale cluster must be at least at version 5.2.3.
- The IBM Fusion cluster must be at least at IBM Fusion level 2.13 and Fusion Data Foundation must be at 4.21.x.

Limitations and considerations

The following limitations apply to NFS data sources:

- In this CAS release 1.1.5, the integration with IBM Data Cataloging is not supported.
- Only a single NFS server per NFS export path is supported.
- Only new NFS filesets that are created through CAS are supported. NFS data source does not support existing NFS filesets that are previously created in IBM Storage Scale.
- Kerberos-enabled NFS exports are not supported.
- File-level access control lists (ACLs) are not supported. Only vector store-level ACLs are applicable.
- The NFS server and export path are fixed at data source creation time and cannot be updated later due to AFM limitations.

Deploying an S3 data source with custom SSL certificate

Deploy an S3 data source with a custom SSL certificate on IBM Storage Scale 6.0.0.x by manually creating the AFM fileset before connecting the data source.

Important: The following procedure applies only to IBM Storage Scale version 6.0.0.x.

For IBM Storage Scale 6.0.1.x and later, custom Transport Layer Security (TLS) certificates are configured automatically when you create a data source. Specify the certificate secret name in the Certificate settings section. Certificate rotation occurs automatically when the secret is updated. Follow the standard procedure described in [Creating a data source](#).

Procedure (IBM Storage Scale 6.0.0.x only)

1. For Filesystem with IBM Storage Scale version 6.0.0.x, create a data source for an S3 bucket, which has a custom Secure Sockets Layer (SSL) certificate by adding bucket name, end-point, secret key, and access key details as mentioned in [Creating a data source](#). The data source status is updated to **Authentication Failure** as the SSL cannot be processed.

2. Log in to the IBM Storage Scale 6.0.0.x cluster.

3. Get the AFM cache fileset name by listing the configuration details on the filesystem with the following command, and identify the one for the S3 bucket you just tried to add:

```
mmafmcoskeys all get --report
```

4. Retrieve the **fileset-name** from the export map, which is in the following format:

```
<bucket-name>:<fileset-name>-exportmap=<keys>
```

5. Copy the TLS certificate on a path, for example at `/var/cas/tls-cert/sample-cert.pem`.

6. Run the following command to re-create the fileset and make it **Active**:

```
mmafmcosconfig <fs> <fileset-name> --endpoint 'https://<fileset-name>-exportmap:443' --object-fs --bucket <bucket-name> --tmpdir '.cachevolumetmp' --gid <gid> --mode 'iw' --ssl-cert-verify --ssl-cert-path <cert-with-full-path> --async-prefetch-interval 60 --makeactive
```

The fileset must be deployed with the following output:

```
Partition <fileset-name> is created and policy broadcasted to all nodes.
```

7. Check the status of the fileset:

```
/usr/lpp/mmfs/bin/mmfsctl <fs> getstate -j <fileset-name>
```

Remember: The fileset must be in the **Active** state and the contents of S3 bucket must be readable in the fileset.

8. Delete the previously failed data source and redeploy it with the same bucket information.

Results

The data source gets **Connected** as it can be able to use the manually created fileset.

Creating a vector store and connecting with data source

Vector stores collect, transform, and transfer data from multiple data sources to a destination, enabling efficient data flow for analysis and AI models.

About this task

When you configure a vector store, you automatically configure the **DocumentProcessorCR**. The processor streamlines data flow for analysis, reporting, and powering AI models effectively.

Procedure

1. Go to Content-aware Storage > Vector stores.
 2. Click Create vector store.
 3. In the Create vector store dialog, enter the name of the vector store and select the document processor engine.
Note: NVIDIA multimodal requires NVIDIA NIM to be configured first.
 4. Click Next.
 5. Select the content types to be processed by the vector store (only applicable to NVIDIA multimodal). Then click Next.
 6. Select an option to either connect a new data source or use an existing one.
 - a. If you choose to use an existing data source, click Finish. The vector store gets created.
 - b. If you choose to connect a new data source, click Next and proceed with the next steps to enter the required data source details. For more information about the data source fields, see [Creating a data source](#). Upon completing, both the data source and vector store get created.
- If the status of the data source gets stuck in connecting state, ensure that you enable watch creation. For more information about the configuration, see [Configuring Scale user to enable watch creation](#).

Note: You can delete a vector store from the Vector store details page only if no data source exists for it.

What to do next

You can view file processing metrics and data source status for each vector store. Metrics include the total number of files and the file size within the selected vector store that provides improved visibility into data volume and processing activity.

The screenshot displays the 'Vector stores' management interface. At the top, the breadcrumb 'Vector stores /' is shown. The main header for the selected store 'gt20' includes an 'Actions' dropdown menu. Below this, there are two tabs: 'Overview' (selected) and 'Access control'. The 'Overview' tab is divided into two sections: 'Details' and 'Files Processed'. The 'Details' section shows the ID 'c083e011-6237-45ed-8dc0-2214a41a829d' and the creation date 'Sep 2, 2026, 2:11 PM'. The 'Files Processed' section shows 'Files: 20' and 'Size: 0.09 GiB'. Below these sections is a 'Collections' section with a search bar. At the bottom, there is a table listing the vector stores. The table has columns for Name, Status, Document processor engine, Data sources, Total files, and Total size (GiB). The row for 'gt20' shows a status of 'Connected', 'NVIDIA Multimodal' engine, 'gt20' data source, 20 total files, and 0.09 GiB total size. At the very bottom, there is a pagination bar showing 'Items per page: 25' and '1-1 of 1 item'.

Name	Status	Document processor engine	Data sources	Total files	Total size (GiB)
gt20	Connected	NVIDIA Multimodal	gt20	20	0.09

Tip: To customize the metrics polling interval, set the **METRICS_POLLING_INTERVAL_MS** parameter in the **cas-config** ConfigMap located in the CAS installation namespace:

```
kind: ConfigMap
apiVersion: v1
metadata:
  name: cas-config
  namespace: ibm-cas
data:
  ENABLE_FILE_LEVEL_SECURITY: 'true'
  HF_ACCESS_TOKEN_SECRET_NAME: hf-access-token
  METRICS_POLLING_INTERVAL_MS: '60000' ---> Metrics Polling interval in millisecond
  NVMM_EMBED_SERVICE: 'http://nv-ingest-embedqa.nv-ingest.svc.cluster.local'
  NVMM_NIM_SERVICE: 'http://nv-ingest.nv-ingest.svc.cluster.local'
```

Configuring Document Processor Engine

Steps to configure Document Processor Engines: IBM Docling Multimodal and NVIDIA Multimodal.

- [Supported document types](#)
List of supported document types for IBM Docling Multimodal and NVIDIA Multimodal document processing engines.
- [IBM Docling Multimodal processing engine](#)
IBM Docling Multimodal is an open source, document processing engine that is designed to convert unstructured documents into structured, machine-readable formats for use in AI applications. It enables you to extract, parse, embed, and store document vectors by using Docling with Granite embedding models.
- [NVIDIA Multimodal processing engine settings](#)
This section enables you to configure the NVIDIA Multimodal pipeline.

Supported document types

List of supported document types for IBM Docling Multimodal and NVIDIA Multimodal document processing engines.

IBM Docling Multimodal

The supported document types for text-based extraction include:

- .pdf
- .txt
- .md
- .asciidoc
- .csv
- .html
- .xhtml
- .docx
- .pptx
- .xlsx

As of now, other file types without text are not supported (for example, image and audio files).

NVIDIA Multimodal

The supported document types for NeMo Retriever Library include:

- .docx
- .html
- .json
- .md
- .pdf
- .pptx
- .sh
- .txt

The following image file types are supported with Image Extraction enabled with the `nvidia_multimodal` pipeline. This configuration requires the image captioning NIM to be deployed and configured:

- .bmp
- .tiff
- .png
- .jpeg

The following audio file types are supported with the `nvidia_multimodal` pipeline. This configuration requires the audio NIM to be deployed and configured:

- .mp3
- .wav

IBM Docling Multimodal processing engine

IBM Docling Multimodal is an open source, document processing engine that is designed to convert unstructured documents into structured, machine-readable formats for use in AI applications. It enables you to extract, parse, embed, and store document vectors by using Docling with Granite embedding models.

Enabling Docling Multimodal document processor engine

To enable the Docling Multimodal document processor engine through command line, access the **CasInstall** Custom Resource (CR) and add the following configuration under the **spec** section:

```
documentProcessingEngine:
  docling_multimodal:
    enabled: true
```

Alternatively, the **CasInstall** CR instance can be patched to enable **docling_multimodal**, as shown in the following example:

```
oc patch casinstalls.cas.isf.ibm.com ibm-cas-service-instance -n ibm-cas --type=merge -p '{"spec":{"documentProcessingEngine":{"docling_multimodal":{"enabled":true}}}}'
```

Disabling Docling Multimodal document processor engine

Disabling the Docling Multimodal document processor engine removes the Docling services and no longer allows ingestion or query to any vector stores, which are configured to use Docling Multimodal.

To disable the Docling Multimodal document processor engine through command line, access the **CasInstall** CR and add the following configuration under the **spec** section:

```
documentProcessingEngine:
  docling_multimodal:
    enabled: false
```

Alternatively, the **CasInstall** CR instance can be patched to disable **docling_multimodal**, as shown in the following example:

```
oc patch casinstalls.cas.isf.ibm.com ibm-cas-service-instance -n ibm-cas --type=merge -p '{"spec":{"documentProcessingEngine":{"docling_multimodal":{"enabled":false}}}}'
```

- [Configuring Docling Multimodal GPUs](#)

This section describes how to configure Docling Multimodal GPUs.

Configuring Docling Multimodal GPUs

This section describes how to configure Docling Multimodal GPUs.

The default GPU resource that is used by the Docling services is [nvidia.com/gpu](#). If the GPUs are configured to use [Multi-Instance GPU \(MIG\)](#), then a corresponding MIG profile must be assigned to each service for it to start properly. The IBM Docling Multimodal resources can be overridden in the **CasInstall** Custom Resource (CR). Each deployment that requires a GPU has an override flag for use with alternative resource configurations.

To alter the Docling Multimodal GPU targets from the command line, access the **CasInstall** CR and add the following flags under the **spec** section:

```
spec:
  flags:
    - VLLM_VISION_GPU=<gpu target>
    - VLLM_EMBEDDING_GPU=<gpu target>
    - DOCLING_GPU=<gpu target>
```

For example, to specify an alternative Multi-Instance GPU (MIG) indicator for all, add the following flags under the **spec** section:

```
spec:
  flags:
    - VLLM_VISION_GPU=nvidia.com/mig-7g.80gb
    - VLLM_EMBEDDING_GPU=nvidia.com/mig-7g.80gb
    - DOCLING_GPU=nvidia.com/mig-7g.80gb
```

Result: The GPU resource indicator is then automatically detected and a new deployment is rolled out.

NVIDIA Multimodal processing engine settings

This section enables you to configure the NVIDIA Multimodal pipeline.

The **DocumentProcessor** custom resource (CR) supports the following configuration options for controlling the NVIDIA Multimodal file processing engine. Each option affects content chunking, processing performance, and search quality. When you select a processing approach, consider the tradeoffs among these factors.

NVIDIA Multimodal **DocumentProcessor** CR configuration options and considerations

Option	Valid option values	Description	Considerations
<code>spec > tasks > name > nvidiaExtract > extractText</code>	True/False (Default: True)	Extracts the actual text from a document, including the text in tables, charts, and infographics.	Extract text is the most performant for ingestion.
<code>spec > tasks > name > nvidiaExtract > extractTables</code>	True/False (Default: True)	Extracts text by summarizing each table.	A second chunk is created if extractText is also selected.

Option	Valid option values	Description	Considerations
<code>spec > tasks > name > nvidiaExtract > extractCharts</code>	True/False (Default: True)	Extracts text by summarizing each chart.	A second chunk is created if <code>extractText</code> is also selected.
<code>spec > tasks > name > nvidiaExtract > extract > infographics</code>	True/False (Default: True)	Extracts text by summarizing each infographic.	A second chunk is created if <code>extractText</code> is also selected.
<code>spec > tasks > name > nvidiaExtract > extractImages</code>	True/False (Default: True)	Extracts caption by summarizing each image.	Impacts the time of ingestion.
<code>spec > tasks > name > nvidiaExtract > tableOutputFormat</code>	Enumeration: <code>markdown</code> , <code>pseudo_markdown</code> , <code>simple</code> (Default: <code>pseudo_markdown</code>)	Extracted tables are returned in a particular format to be returned as the text that is vectorized.	N/A
<code>spec > tasks > name > nvidiaExtract > extractTextDepth</code>	Enumeration: <code>page</code> , <code>document</code> (Default: <code>page</code>)	Extracts text at levels of granularity.	Impacts the number of chunks that are stored and the size of text returned.
<code>spec > tasks > name > nvidiaSplit > chunkSize</code>	Numeric (Default: 1024)	Size of each chunk in number of bytes.	For more information on all splitting options, see Split Documents .
<code>spec > tasks > name > nvidiaSplit > chunkOverlap</code>	Numeric (Default: 150)	Number of bytes to overlap between consecutive chunks.	
<code>spec > tasks > name > nvidiaSplit > tokenizer</code>	String (Default: <code>meta-llama/Llama-3.2-1B</code>)	Identifies the embedding model to split the content with.	
<code>spec > tasks > name > nvidiaSplit > splitSourceTypes</code>	Array of Strings (Default: <code>empty</code>)	Identifies the file types to apply the prior <code>nvidiaSplit</code> configuration.	

During the [Creating a vector store and connecting with data source](#) procedure, the CAS user interface creates a **Domain** custom resource (CR) and an associated NVIDIA Multimodal **DocumentProcessor** CR. The **DocumentProcessor** CR configures the processing engine to use the default settings, which include extracting text only and processing content on a per-page basis. To apply more configuration options, you must create or modify the NVIDIA Multimodal **DocumentProcessor** CR by using the OpenShift® console or the CLI.

Configuring NVIDIA Multimodal pipeline

After you create a **Domain** CR in the CAS user interface, a corresponding **DocumentProcessor** CR is generated for that vector store. Update the `spec` section of the **DocumentProcessor** CR with the required configuration options.
Note: Changes to processing options affect only newly ingested or updated documents. Previously processed documents are reingested with the new settings only when the original document is modified.

1. Find the **DocumentProcessor** CR that is associated with the **Domain**.

Tip: The **DocumentProcessor** CR has the same name as the **Domain**.

Example:

- `oc get domains.cas.isf.ibm.com -n ibm-cas`
- `oc get documentprocessors.cas.isf.ibm.com -n ibm-cas`

2. View the current configuration of the **DocumentProcessor** CR.

Example:

```
oc get documentprocessors.cas.isf.ibm.com mydomain -n ibm-cas -o yaml
```

3. Ensure that the type is `nvidia_multimodal`. Example: `type: nvidia_multimodal`
4. Modify the **DocumentProcessor** CR according to the options added in the [table](#).
5. Save the **DocumentProcessor** CR.

Results

The CAS operator automatically reconciles the **Deployment** associated with the **DocumentProcessor** CR and the corresponding processing engine pods are restarted with new settings.

Configuring Content-Aware Storage (CAS) through CLI

You can use the CRs to configure CAS.

Ensure all the prerequisites are met. See [Planning and prerequisites](#). To install CAS from the user interface of IBM Fusion, see [Installing Content-Aware Storage \(CAS\)](#).

Create a Scale datasource

```
oc apply -f - <<EOF
apiVersion: cas.isf.ibm.com/v1beta1
kind: DataSource
metadata:
```

```

  name: <datasource name>
spec:
  scale:
    fileName: <filesystem name>
    path: <fileset path>
EOF

```

Create a S3 datasource

For prerequisites, create a key/value secret from the OpenShift® console in CAS namespace. For other prerequisites, see [Prerequisites for S3 and NFS type data sources](#).

The following example is based on Amazon AWS.

```

apiVersion: cas.isf.ibm.com/v1beta1
kind: DataSource
metadata:
  name: <datasource name>
  namespace: ibm-cas
spec:
  s3:
    bucket: <bucket name>
    endpoint: <endpoint>
    credentials:
      accessKeyRef:
        key: ""
      secretKeyRef:
        key: ""
      secretName: <Secret name>
    fileName: <filesystem name>
    provider: aws

```

If a Group ID is defined for the underlying fileset, run the following command to add the annotation to the previously created datasource previously:

```
oc annotate DataSource <datasource name> group-id='310' --overwrite
```

Where, <datasource name> and 310 are example values that can change depending on the datasource name and the GID set in Scale.

Create a NFS data source

For prerequisites, see [Prerequisites for S3 and NFS type data sources](#).

```

apiVersion: cas.isf.ibm.com/v1beta1
kind: DataSource
metadata:
  name: <datasource name>
  namespace: ibm-cas
spec:
  nfs:
    servers:
      - <server>
    path: "<path>"
    fileName: <filesystem name>

```

Create a vector store (Domain CR) and add data source to it

```

kubectl apply -f - <<EOF
apiVersion: cas.isf.ibm.com/v1beta1
kind: Domain
metadata:
  name: <vector store name>
spec:
  dataSources:
    - <datasource name>
  collections:
    - name: "<vector store name>"
EOF

```

Create a document processor

Document processor **type** field refers to the document processing engine that is used to ingest documents. CAS can be configured to use either [NVIDIA Multimodal Services](#) or [Docling Multimodal Services](#).

The keys for each type are as follows:

- NVIDIA Multimodal Processing Engine - `nvidia_multimodal`

```

oc apply -f - <<EOF
apiVersion: cas.isf.ibm.com/v1beta1
kind: DocumentProcessor
metadata:
  name: <vector store name>
spec:
  type: nvidia_multimodal
  domains:
    - <vector store name>
EOF

```

- Docling Multimodal Processing Engine - `docling_multimodal`

```
oc apply -f - <<EOF
apiVersion: cas.isf.ibm.com/v1beta1
kind: DocumentProcessor
metadata:
  name: <vector store name>
spec:
  type: docling_multimodal
  domains:
  - <vector store name>
EOF
```

Advanced configuration for the NVIDIA Multimodal document processor

To extract content from tables, charts, and images, from the documents in the dataset, enable additional settings in the document processor custom resource (CR).

Note: Enabling these options increases document processing time.

Supported file types for NVIDIA Multimodal document processor: `.pdf`, `.txt`, `.html`, `.json`, `.md`, `.docx`, `.pptx`, `.bmp`, `.jpeg`, `.png`, `.tiff`, `.sh`

Supported options for `nvidia_multimodal` extract task:

- `extractCharts`: Extracts chart graphs from documents.
- `extractTables`: Extracts tabular data from documents.
- `extractImages`: Extracts content from image files and images that are contained within documents.

The following example shows how to configure these options in the `nvidia_multimodal` extract task.

```
oc apply -f - <<EOF
apiVersion: cas.isf.ibm.com/v1beta1
kind: DocumentProcessor
metadata:
  name: <vector store name>
spec:
  type: nvidia_multimodal
  tasks:
  - name: Extract
    nvidiaExtract:
      extractCharts: true
      extractImages: true
      extractTables: true
      extractText: true
      extractTextDepth: page
  - name: Split
    nvidiaSplit:
      chunkOverlap: 150
      chunkSize: 1024
      tokenizer: meta-llama/Llama-3.2-1B
  - name: Embed
    nvidiaEmbed: {}
  domains:
  - <vector store name>
EOF
```

If you want to configure file ingestion filtering by using Data Cataloging, add the additional supported file types for NVIDIA Multimodal document processor to Data Cataloging's filtering rule:

```
oc patch rule allowed-filetypes -n ibm-data-cataloging --type merge -p '{"spec": {"metadata": [{"field": "filename", "operator": "in", "value": ["doc", "docx", "pdf", "txt", "gif", "html", "json", "md", "pptx", "bmp", "jpeg", "png", "tiff", "sh" ]}]}}'
rule.datacataloging.ibm.com/allowed-filetypes patched
```

Note: You must update the filtering rule every time you enable Data Cataloging filtering, if you later disable it.

Create a CAS Resource Access Control (CRAC) CR

```
apiVersion: cas.isf.ibm.com/v1beta1
kind: CasResourceAccessControl
metadata:
  name: <CR name: "<vector store name>-access">
  namespace: <CAS installation namespace>
spec:
  #Determines whether file level permission checking can be done for a given vector store
  fileACL: <true/false>
  resourceRef:
    name: <vector store name>
    type: Domain
  subjects:
    groups:
      - name: <Name of the IDP/OpenShift group who needs access of given vector store>
        role: READER
      # Special group for granting access to all authenticated users
      - name: cas-all-authenticated
        role: READER
    users:
      - name: <Name of the IDP/OpenShift user who needs access of given vector store>
        role: READER
```

Note: The `cas-all-authenticated` special group grants vector store access to any user who has a valid OpenShift or identity provider (IDP) authentication token.

When this group is configured, the system bypasses individual user and group access control (ACL) checks for the vector store. This capability is useful for environments where simplified access control is required.

The CAS Resource Access Control (CRAC) CR status contains validation details for resources, users, and groups.

- If resource is not valid, the condition status indicates the exact error.
- If users in the specific user list are not valid, the condition status indicates the name of invalid users.

- If groups in the specific group list are not valid, the condition status indicates the name of invalid groups.
- If the resource, users, and groups are valid, the condition status reflects the validation status message. The following example shows how the status message appears in the CRAC CR:

```
status:
  conditions:
    - lastTransitionTime: '2025-08-29T02:15:42Z'
      message: 'Resource: gt20 is validated'
      observedGeneration: 1
      reason: AsExpected
      status: 'True'
      type: ValidatedResource
    - lastTransitionTime: '2025-08-29T02:15:42Z'
      message: 'Users are validated'
      observedGeneration: 1
      reason: AsExpected
      status: 'True'
      type: ValidatedUsers
    - lastTransitionTime: '2025-08-29T02:15:42Z'
      message: 'Groups are validated'
      observedGeneration: 1
      reason: AsExpected
      status: 'True'
      type: ValidatedGroups
```

To configure CAS to restrict specific users to specific CAS vector stores through user interface, see [Configuring CAS Resource Access Control \(CRAC\)](#).

To remove search access for a vector store through CLI, delete the relevant users and groups from the CRAC CR and save the changes. Removed users and groups then lose authorization to access the query search API for the vector store.

Configuring network policies

CAS automatically deploys and manages Kubernetes network policies that enforce a zero-trust communication model across its internal services.

To disable the network policies:

```
oc patch casinstall <install name> -n <cas namespace> \
--type merge -p '{"spec":{"networkPolicy":{"enabled":false}}}'
```

To enable the network policies:

```
oc patch casinstall <install name> -n <cas namespace> \
--type merge -p '{"spec":{"networkPolicy":{"enabled":true}}}'
```

Note: The changes are applied automatically, and a restart is not required. You can disable network policies if you want to apply custom policies.

Using your own Hugging Face access token with CAS for NVIDIA Multimodal

NVIDIA NeMo Retriever Library uses models that are downloaded from Hugging Face to do token-based splitting on the content extracted from documents. NVIDIA recommends to use the meta-llama/Llama-3.2-1B tokenizer, however this model is gated and requires a Hugging Face token in order access it. A Hugging Face access token is a personal API key that is used to securely authenticate programmatic access to Hugging Face services.

Before you begin

You must have a valid token to access Meta's Llama 3.2 language models and evals gated repository.

About this task

In Content-Aware Storage (CAS), a Hugging Face access token is used to securely interact with Hugging Face's APIs and services that support intelligent content processing.

For more information about Hugging Face access tokens, see [Hugging Face User Access Tokens](#).

To provide your Hugging Face access token for the meta-llama/Llama-3.2-1B model, perform the following steps:

Procedure

1. Encode the generated Hugging Face access token in Base64 format by using the following command. The resulting value is referred to as the HUGGING_FACE_ACCESS_TOKEN in the next step.

```
echo "hf_XXXXXXXXXX" | base64
```

2. Create a secret in the CAS installation namespace:

```
kind: Secret
apiVersion: v1
metadata:
  name: hf-access-token
  namespace: ibm-cas
data:
  hf_access_token: HUGGING_FACE_ACCESS_TOKEN
type: Opaque
```

3. Use the encoded access token and update the `cas-install` CR 'spec' section:

```
spec:
  flags:
    - HF_ACCESS_TOKEN_SECRET_NAME=hf-access-token
```

Configuring CAS Query Access Control and Security

Content-Aware Storage (CAS) supports vector store-level authorization, Identity Provider integration, and optional file-level security to control query access.

You can configure Content-Aware Storage (CAS) query access control and security to suit your requirements and environment by selecting one of the following methods:

- Authorize CAS query users to CAS vector stores:
 - By default, all users of the Red Hat® OpenShift® cluster where CAS is deployed can issue CAS queries, depending on the vector stores they are authorized to access. In this context, they are referred to as CAS query users.
 - Configure CAS to authorize users to specific CAS vector stores. If an unauthorized CAS query user of a vector store runs CAS queries, the query API fails with status code 403 (Invalid Access). For more information, see [Configuring CAS Resource Access Control \(CRAC\)](#).
- Manage CAS users with your own Identity Provider (IDP):
 - Configure CAS to connect to your own IDP. Without this configuration, CAS serves only the Red Hat OpenShift users. For more information, see [Configuring CAS to connect to your Identity Provider \(IDP\)](#).
- Limit certain users to certain files:
 - To enforce stricter access control, you can configure CAS to serve only the content from files for which users have explicit file-level read permissions. Without this configuration, CAS returns results from all ingested data within a vector store to any user who has vector store-level access, regardless of file-level read permissions. For more information, see [Configuring file-level access control in CAS](#).

Security type	Red Hat OpenShift users	External IDP users
Vector store-level access control (mandatory)	Supported	Supported
File-level access control (optional)	Unsupported	Supported; an external IDP is required to federate user information from the Directory server used by the file system.

- CAS query user setup: To designate users of Red Hat OpenShift or external IDP or Directory server as CAS query users, you must either configure the users or their groups through CAS Resource Access Control (CRAC). For more information, see [Configuring CAS Resource Access Control \(CRAC\)](#).
- [Configuring CAS Resource Access Control \(CRAC\)](#)
Configure users and groups that can access specific Content-Aware Storage (CAS) vector stores by using the CRAC custom resource.
- [Configuring CAS to connect to your Identity Provider \(IDP\)](#)
An Identity Provider is a system or service that creates, maintains, and manages identity information for users and provides authentication services to applications or other systems. It acts as a trusted third party that authenticates users and shares their identity information with other services.
- [Configuring file-level access control in CAS](#)
File-level security in Content-Aware Storage (CAS) ensures that users can access only the data they are authorized to read from the file system.

Configuring CAS Resource Access Control (CRAC)

Configure users and groups that can access specific Content-Aware Storage (CAS) vector stores by using the CRAC custom resource.

You can define users and groups that can have access to a vector store by using [CRAC API Custom Resource \(CR\)](#).

To configure CAS to restrict specific users to specific CAS vector stores, follow these steps:

1. Open the IBM Fusion UI.
2. Go to Content-aware Storage > Vector stores.
3. Click the vector store name that you want to open.
4. Click Actions and select Share search access.
The Share search access dialog opens.

5. In the Username or Group field, add the username or group name to which you want to grant the vector store access.

6. From the Choose type dropdown, select the type as User or Group.

Tip: To add all users or groups at the same time, click Add.

7. Click Share.

Note: When IDP CR is configured on your system, you can provide the external IDP token to the query search API for semantic search execution.

Granting global access to all authenticated users

To simplify access control, you can grant vector store access to all authenticated users at once by using the **cas-all-authenticated** special group. This approach removes the need to add individual users or groups.

Important: The **cas-all-authenticated** group grants access to any user with a valid OpenShift® or identity provider (IDP) authentication token. Specific user and group assignments provide more granular security control and are recommended when restricted access is required.

Removing search access

You can remove users and groups that have access to specific vector stores.

To remove users or groups from specific CAS vector stores, follow these steps:

1. Open the IBM Fusion UI.
2. Go to Content-aware Storage > Vector stores.
3. Click the vector store name that you want to open.
4. Click Actions and select Remove search access.
The Remove search access dialog opens.
5. Select the users or groups whose search access is to be removed.
6. Click Remove.
Removed users and groups lose authorization to access the query search API for the vector store.

Configuring CAS to connect to your Identity Provider (IDP)

An Identity Provider is a system or service that creates, maintains, and manages identity information for users and provides authentication services to applications or other systems. It acts as a trusted third party that authenticates users and shares their identity information with other services.

About this task

An IDP can be integrated with CAS to enhance security, access control, and compliance. It helps CAS by providing:

- **Secure Access:** It ensures that only authorized users access sensitive content.
- **Single Sign-On (SSO):** It enables you to log in once to access multiple systems.
- **Compliance:** It helps meet regulatory requirements with audit trails and access controls.
- **User Management:** It simplifies onboarding, offboarding, and role-based access.

Configure CAS with client ID and client secret

- Client ID: It is the ID created in the IDP to allow CAS API access.
- Client secret: It is the password that is associated with the client ID for secure access to IDP APIs.

To enable user and group validation through the Security Identity Manager (SIM) client, CAS uses the client ID and client secret to authenticate with the IDP. To obtain the client ID and client secret, perform the following steps:

1. Create and enable API access in your IDP.
2. Configure CAS with the credentials that are provided by the IDP, as the client ID and client secret. CAS then uses this client ID and client secret to query the user and group APIs from the IDP.

To connect your IDP to the CAS deployment, perform the following steps:

Procedure

1. Configure an IDP secret for CAS by creating a secret that is named `idp-sec` in CAS installation namespace with `client_id` and `client_secret` in Base64 format:

```
kind: Secret
apiVersion: v1
metadata:
  name: idp-sec
  namespace: ibm-cas
data:
  client_id: <client ID in base64 format>
  client_secret: <client secret in base64 format>
type: Opaque
```

2. Create a CAS `IdentityProvider` CR to specify the custom configuration details of your IDP. Specify the following fields based on your IDP configurations:
 - email: It is the list of claims whose value must be used as the email address.
 - groups: It is the list of claims whose value must be used as groups.
 - name: It is the list of claims whose value must be used as name.
 - sub: It is the list of claims whose value must be used as subject.
 - issuer: It is the issuer URL of the external IDP. For example: `https://keycloak-keycloak-automation.apps.com/auth/realms/master`
 - groupUrl: It is the IDP URL for retrieving all groups. For example: `https://keycloak-keycloak-automation.apps.com/auth/admin/realms/master/groups`
 - userUrl: It is the IDP URL for retrieving all users. For example: `https://keycloak-keycloak-automation.apps.com/auth/admin/realms/master/users`

```
apiVersion: cas.isf.ibm.com/v1beta1
kind: IdentityProvider
metadata:
  name: identityprovider-sample
  namespace: ibm-cas
spec:
  identityProvider:
    claims:
      email:
        - <email>
      groups:
        - <groups>
      name:
        - <preferred_username>
      sub:
        - <subject>
    issuer: <Issuer URL of IDP>
    mappingMethod: claim
    name: openid
    scimClient:
      clientSecretName: <OpenShift secret storing client_id and client_secret parameters of IDP client>
      groupUrl: <IDP URL to retrieve all groups>
      userUrl: <IDP URL to retrieve all users>
    type: OpenidProvider
```

3. To enable file-level security, add the following claims of the external IDP in the `claims` section:

```
spec:
  identityProvider:
    claims:
      groupID:
        - gidNumber
      supplementalGroups:
        - supplementalGroups
      userID:
        - uidNumber
```

Configuring file-level access control in CAS

File-level security in Content-Aware Storage (CAS) ensures that users can access only the data they are authorized to read from the file system.

Overview

File-level security uses an external identity provider (IDP) integrated with a directory server to retrieve your numeric user ID, numeric group ID, and supplemental group IDs. At the time of query, it performs a real-time access check to verify whether the user has the read permission for the parent file of each matching vector.

When file-level security is enabled, users and groups that are authorized through CAS Resource Access Control (CRAC) can still run CAS queries. However, query results are limited to files for which the user has 'read' access. File-level security is configured at the CAS deployment level and applies to all document processors and vector stores, both existing and newly created.

This feature requires CAS to be integrated with an external IDP that federates users from the same LDAP directory that is used to authenticate file system users. Note: Without file-level security configuration, CAS returns results from all ingested data within a vector store to any user who has vector store-level access, regardless of file-level read permissions.

Before you begin

File-level access control in CAS requires the following setup:

- A directory server, such as OpenLDAP must store information about a user's numeric user ID and numeric group ID, and supplemental group IDs.
- An external Identity Provider (IDP) that uses OpenID standard, such as Keycloak. The IDP must use the directory server for user federation to retrieve and provide the following user attributes to the `/userinfo` endpoint:
 - `userID`
 - `groupID`
 - `supplementalGroups`

Note: The `supplementalGroups` must contain the numeric IDs for the user's groups, such as `userID` and `groupID`.

Note: The attribute names (`userID`, `groupID`, and `supplementalGroups`) are used as examples. You can use custom attribute names in the directory server. During the claim-mapping configuration (in the CRAC CR), these custom attribute names are mapped to the standard names recognized by CAS: `userID`, `groupID`, and `supplementalGroups`.
- File system clients
 - File system clients remote mount the storage file system of the CAS data source. For more information, see [Mounting a remote GPFS file system](#) in IBM Storage Scale documentation.
 - The file system client machines are then configured to use the same directory server for user authentication. For more information, see [Setting up authentication servers to configure protocol user access](#) in IBM Storage Scale documentation.
- CAS
 - Configure CAS to connect to the IDP that is configured to federate users from the same directory server used by the file system client machines. For more information, see [Configuring CAS to connect to your Identity Provider \(IDP\)](#).

Modifying file-level access control for a vector store

Using command line

To enable or disable file-level permissions for a specific vector store, add `fileACL: true/false` under the `spec` section in the `CasResourceAccessControl` instance for the vector store. For more information, see [Create a CAS Resource Access Control \(CRAC\) CR](#).

Using user interface

1. Open the IBM Fusion UI and go to Content-aware Storage > Vector stores.
2. Select the vector store to modify.
3. Select the Access control tab.
4. In the Search access settings section, select Edit.
5. Use the toggle to enable or disable File permission checking.
6. Click Save changes.

Client application with Content-Aware Storage (CAS)

You are required to provide a client application that uses the CAS search API to use the data ingested by CAS as part of your RAG application. This topic outlines the workflow for querying the CAS database using the exposed API.

Before you begin, ensure the following prerequisites are met for the client application:

- NVIDIA llama-3.1 NIM and GPU support.
- Network connectivity to issue REST APIs to CAS.

The following diagram illustrates the workflow where a user client application runs query REST calls on the CAS database and displays the results in the front end.

The entire workflow is divided into two parts: One part retrieves results from CAS, while the other obtains results from a Large Language Model (LLM).

The Vector database within the CAS namespace is designed to store data ingested from various files. The namespace also includes the query service pod, which features a FAST API (REST API). To retrieve information from the Vector database, there exists an installation of a document processing engine outside the namespace. Document processing is available with [IBM Docling Multimodal](#) services or [NVIDIA NeMo Retriever Extraction](#) microservices. [NVIDIA re-ranking service](#) is an optional search component that can be added to provide more accuracy. Your task involves developing an application (client application), that communicates with this REST API by using the OpenShift® cluster authentication. For more information about the FAST API methods, syntax, description, or to try the APIs, see [Content-Aware Storage \(CAS\) APIs](#).

In addition, you must have a large language model of your choice that is accessible from your application. If you want to use the IBM Watson granite model LLM, then to download and use the different IBM Granite models, see [IBM Granite](#).

When the user of the client application raises a question from its front end, a query REST Call is sent to the query service pod through the FAST API REST call. The query service in turn goes with the query to the document processing engine to get the embedding. This service generates embeddings for the data, enabling the query service to understand and process the request of the user effectively. After the results are fetched, a SQL query is sent with the embedding to the database for top "K" number of Vector results. When the user runs query from the front end, they can specify the value of this "K". For example, `Select, column from table order by, limit by vector, with embedding`. The top "K" results are returned to the client application which in turn sends it to the LLM. While embeddings make the retrieval process efficient, LLMs add a layer of contextual understanding, transforming raw data into meaningful information. Finally, the end results are published on the front end of the client application.

- [Content-Aware Storage \(CAS\) APIs](#)
List of all REST API references for CAS service.
- [Integrating Model Context Protocol \(MCP\) with CAS](#)
Content-Aware Storage (CAS) supports Model Context Protocol (MCP), enabling AI chat applications to access and search vector stores through natural language interactions.
- [Integrating CAS with watsonx Orchestrate by using MCP](#)
Large language models move from experimentation into production. Enterprises build AI agents that require access to real-time business data. watsonx Orchestrate provides conversational AI for workflow automation. Integrating watsonx Orchestrate with enterprise systems such as Content-Aware Storage (CAS) often requires custom integration code for each data source.

List of all REST API references for CAS service.

[/cas/api/v1](#)

For more information about Swagger docs, see <https://<console-ibm-spectrum-fusion-ns.apps.openshifturl>/cas/api/v1/docs#>.

Authentication

For authentication of REST APIs, ensure that you have a valid OpenShift® Container Platform bearer token in the Authorization header:
Retrieve the token:

1. In the OpenShift console, click your profile name and select Copy login command.

2. Log in with your credentials. Then click the Display Token link.
3. Copy the token value available under the Log in with this token section.
Note: For authentication of REST APIs when an external Identity Provider (IDP) is configured, ensure that you have a valid IDP bearer token in the Authorization header.

Swagger documentation

1. In your browser, go to Swagger: **`https://<console-ibm-spectrum-fusion-ns.apps.openshifturl>/cas/api/v1/docs#`**.
The Swagger document specifies the list of resources that are available in the REST API and the operations that can be called on those resources. The Swagger document also specifies the list of parameters for an operation, including the name and type of the parameters and information about acceptable values for those parameters.
2. In the FastAPI page, click Authorize.
3. In the Available authorizations window, enter a value for HTTPBearer.
4. Click Authorize.

Try APIs from Swagger

In your browser, go to Swagger: **`https://<console-ibm-spectrum-fusion-ns.apps.openshifturl>/cas/api/v1/docs#`**.

In Swagger, expand the API and click Try it out.

- **`/vector_stores`**

- Description: It returns a document processor "vector stores" query that you have access to.
- Method: GET
- Query parameters:

Parameter:Type	Description
"after":string	Optional. A cursor for use in pagination. This parameter is not yet implemented.
"before":string	Optional. A cursor for use in pagination. This parameter is not yet implemented.
"limit":int	Optional. A limit on the number of objects to be returned. The default limit is 10.
"order":string	Optional. Sorts order by the vector store ID - asc for ascending order and desc for descending order. Default value is desc .

- Usage: Check Swagger.
- Response: Check Swagger.

- **`/vector_stores/{vector_store_id}/search`**

- Description: Matches the exact words and uses Natural Language Processing (NLP) and machine learning to find results that are semantically relevant. If you do not have access to a specific vector store, the API raises a 403 (Invalid access) error. If file-level security is enabled, semantic search results are restricted to only those files, which the CAS query user is authorized to read in the IBM Storage Scale file system.
- Method: POST
- Path parameter:

Parameter:Type	Description
"vector_store_id":string	Required. Name of a particular document processor that ingested documents from a particular vector store.

- Request body parameters:

Parameter:Type	Description
"query":string	Required. The natural language question that is used by the embedding model to return a list of relevant snippets of text from the ingested documents.
"filters":dict	Optional. A filter to apply based on file attributes. For more information, see Filter parameters .
"max_num_results":int	Optional. The maximum number of results returned. The default value is "10".
"ranking_options":dict	Optional. Ranking options for search default is null: "ranker":str - Optional. The default value is "auto". "score_threshold":float - Optional. The default value is "0". This parameter is not yet implemented.
"rewrite_query":bool	Optional. Whether to rewrite the natural language query for vector search. This parameter is not yet implemented.
"enable_source":boolean	Optional. If true, any source information about the document is returned. Default value is "False".
"enable_content_metadata":boolean	Optional. If true, any metadata about the relevant document is returned. Default value is "False".

- Usage: Check Swagger.
- Response: Check Swagger.

- **`/vector_stores/{vector_store_id}/files/{file_id}/content`**

- Description: It returns all the content (text chunks) for a specific **vector-store** and file by their IDs.
- Method: GET
- Query parameters:

Parameter	Description
enable_source	Optional. When enabled, it returns top-level source file metadata attributes, or null , if not enabled.
enable_content_metadata	Optional. When enabled, it returns content metadata attributes, or null , if not enabled.

- Usage: Check Swagger.
- Response: Check Swagger.

- **`/vector_stores/{vector_store_id}/files`**

- Description: It returns a list of files that are ingested in a specific vector store. If file-level security is enabled, only files that the CAS query user is authorized to access are returned.
- Method: GET
- Path parameter:

Parameter:Type	Description
"vector_store_id":string	Required. The ID of the vector store that the files belong to.

- Query parameters:

Parameter:Type	Description
"filter":string	Optional. Filter files based on attributes. For more information, see Filter parameters .
"limit":int	Optional. Number of files to return. The default value is 20. The maximum value is 1000.
"before":string	Optional. A cursor for use in pagination. It returns files before the file ID (descending by primary key).
"after":string	Optional. A cursor for use in pagination. It returns files after the file ID (ascending by primary key).
"order":string	Optional. Sort order based on ingestion timestamp. Specify asc for ascending order and desc for descending order. The default value is desc .

- Usage: Check Swagger.
- Response: Check Swagger.

Filter parameters

Two types of filters can be used:

- Comparison filter: A filter used to compare a specified attribute key to a defined value using a defined comparison operation.

Parameter	Type	Description
key	str	Required. The key to compare against the value.
type	str	Required. Comparison operators: eq , ne , gt , gte , lt , lte , in , nin The set of valid operators for a comparison filter depends on the key being compared.
value	str, int, float, bool, ISO8601 str	Required. The value to compare against the key, which can be an array for in or nin operators.

- Compound filter: A filter used to combine an array of filters using **and** or **or**.

Parameter	Type	Description
type	str	Required. A type of logical operation: and , or .
filters	array	Required. An array of filters to combine. Items can be Comparison filter or Compound filter.

Supported keys:

Key	Type	Description
file_id	str	The file identifier.
file_size	int, float	The size of the file in bytes.
file_path	str	The full path of the file including the file name.
file_name	str	The full name of the file after the last path delimiter.
file_type	str	The type of source file as determined by the ingester (for example: PDF).
file_created	ISO8601 str	The creation date of the file in ISO8601 format.
file_modified	ISO8601 str	The last modified date of the file in ISO8601 format.
file_status	str	The ingestion status of the file. Valid values: in_progress , completed , failed , cancelled
attributes	str, int, bool	The custom attributes set on the file through IBM Data Cataloging service tags. For more information, see Managing tags .

Supported comparison operators for key types:

Key type	Operators
str	eq , ne , in , nin , contains
int, float	eq , ne , gt , gte , lt , lte , in , nin
ISO8601 str	eq , ne , gt , gte , lt , lte , in , nin
bool	eq , ne

Note: When using the **in** or **nin** operators, the **value** parameter of the comparison must be an array of the appropriate type.

Examples

- Comparison filter:

```
"filters": { "key": "file_name", "type": "eq", "value": "sg248497.pdf" }
```

- Compound filter:

```
"filters": {
  "type": "and",
  "filters": [ { "key": "file_path", "type": "eq", "value": "/gpfs/fs1/gt20" },
               { "key": "file_size", "type": "lt", "value": 28000000 },
               { "key": "file_size", "type": "gt", "value": 24000000 }
            ]
}
```

- Compound filters support two nesting levels:

```
"filters": {
  "type": "or",
  "filters": [ { "key": "file_size", "type": "gt", "value": 2000000 },
               { "type": "and",
                 "filters": [ { "key": "date_created", "type": "gt", "value": "2021-05-01" },
                             { "key": "date_created", "type": "lt", "value": "2021-05-31" }
               ]
             }
            ]
}
```

/api/v1/querysearch

Note: The `/api/v1/querysearch` APIs are deprecated with IBM Fusion 2.12.0 (CAS 1.1.0) release.

Authentication

For authentication of REST APIs, ensure that you have a valid OpenShift Container Platform bearer token in the Authorization header:

Retrieve the token:

1. In the OpenShift console, click your profile name and select Copy login command.
2. Log in with your credentials. Then click the Display Token link.
3. Copy the token value available under the Log in with this token section.

Note: For authentication of REST APIs when an external Identity Provider (IDP) is configured, ensure that you have a valid IDP bearer token in the Authorization header.

Swagger documentation

1. In your browser, go to Swagger: <https://<fusionconsoleurl>/api/v1/querysearch/docs>.

The Swagger document specifies the list of resources that are available in the REST API and the operations that can be called on those resources. The Swagger document also specifies the list of parameters for an operation, including the name and type of the parameters and information about acceptable values for those parameters.

2. In the FastAPI page, click Authorize.
3. In the Available authorizations window, enter a value for HTTPBearer.
4. Click Authorize.

Try APIs from Swagger

In your browser, go to Swagger: <https://<fusionconsoleurl>/api/v1/querysearch/docs>.

In Swagger, expand the API and click Try it out.

- **/tables**
 - Description: It returns a document processor "tables" query that you have access to.
 - Method: GET
 - Usage: Check Swagger.
 - Response: Check Swagger.
- **/semantic_search**
 - Description: Matches the exact words and uses Natural Language Processing (NLP) and machine learning to find results that are semantically relevant. If you do not have access of a specific vector store, the API raises a 403 (Invalid access) error. If file-level security is enabled, semantic search results are restricted to only those files, which the CAS query user is authorized to read in the IBM Storage Scale file system.
 - Method: POST
 - Parameters:

Parameter: Type	Description
"query": string	The natural language question that is used by the embedding model to return a list of relevant snippets of text from the ingested documents.
"table": string	Name of a particular document processor that ingested documents from a specific vector store.
"limit": int	The maximum number of results returned, default is 5.
"enable_source": boolean	If true, any source information about the document is returned.
"enable_content_metadata": boolean	If true, any metadata about the relevant document is returned.
 - Usage: Check Swagger.
 - Response: Check Swagger.

End-user CLI chatbot sample

The CLI-powered chatbot enables a secured, authenticated access to Content-Aware Storage (CAS) through a conversational CLI. It is powered by LLMs such as IBM watsonx Granite, Open AI, NVIDIA NIM, and Ollama. It uses CAS's semantic APIs to deliver efficient, AI-enabled insights, accelerating RAG workflows with improved performance, security, and efficiency.

For more information, follow the reference example in [GitHub](#).

Access Control List (ACL) users control the query search process. The system retrieves user identities from the Identity Provider (such as Keycloak) and validates them against CAS ACL users based on roles and permissions. If validation succeeds, the system issues a token, which the user uses to run the CAS query API.

ABOUT CAS

Content-Aware Storage powers AI applications like RAG with faster insights, lower costs, better performance, stronger security, and simplified operations.

Integrating Model Context Protocol (MCP) with CAS

Content-Aware Storage (CAS) supports Model Context Protocol (MCP), enabling AI chat applications to access and search vector stores through natural language interactions.

Model Context Protocol (MCP)

Model Context Protocol (MCP) is a standardized JSON-RPC 2.0 protocol that allows AI assistants and chat applications to interact with external services. MCP enables AI clients to discover available capabilities and use them through conversational interfaces.

- AI assistants can discover and use CAS vector stores automatically.
- It supports natural language queries for vector search operations.
- It provides both standard and streaming response options.

Available MCP tools

CAS uses two primary tools through the MCP interface for working with vector stores.

list_vector_stores

- Description: It lists all vector stores available in the CAS instance. This tool retrieves the complete inventory of vector stores that can be accessed for search operations.
- Parameters: The parameters (**server_url** and **auth_token**) are needed as input for the CAS server you want to search in.

Parameter	Type	Description
server_url	string	Required. Base URL of the CAS server (for example, <code>https://<console-ibm-spectrum-fusion-ns.apps.openshifturl></code>).
auth_token	string	Required. Authentication token for API access.

- Usage example: An AI assistant calls this tool to discover which vector stores are available before performing searches.

search_vector_stores

- Description: It performs semantic search within a specified vector store. This tool uses vector embeddings to find content similar to the provided query text that returns ranked results based on semantic similarity.
- Parameters:

Parameter	Type	Description
server_url	string	Required. Base URL of the CAS server (for example, <code>https://<console-ibm-spectrum-fusion-ns.apps.openshifturl></code>).
auth_token	string	Required. Authentication token for API access.
vector_store_id	string	Required. ID of the vector store to search.
query	string	Required. Search query text.
limit	integer	Optional. Maximum number of results to return. The default value is '10'.

- Usage example: To find documents about 'machine learning best practices' in a vector store named 'technical_docs', the AI assistant calls this tool with the query text and store ID. The tool returns semantically similar documents that are ranked by relevance score.

get_vector_store_file_content

- Description: It retrieves the complete content of a specific file from a vector store. Use this tool when you need the complete document after finding it through search results. The **file_id** can be obtained from **search_vector_stores** results.
- Parameters:

Parameter	Type	Description
server_url	string	Required. Base URL of the CAS server (for example, <code>https://<console-ibm-spectrum-fusion-ns.apps.openshifturl></code>).
auth_token	string	Required. Authentication token for API access.
vector_store_id	string	Required. ID of the vector store to search.
file_id	string	Required. The ID of the file to fetch content for.

- Usage example: After searching for **storage configuration** and finding relevant results, use this tool with the **file_id** from those results to fetch the complete document content for detailed analysis.
- Example: Standard MCP endpoint

```
curl -k -N -X POST "https://<console-ibm-spectrum-fusion-ns.apps.openshift>/cas/api/v1/mcp" \
-H "Content-Type: application/json" \
-H "Accept: application/json" \
-d '{
  "jsonrpc": "2.0",
  "id": 6,
  "method": "tools/call",
  "params": {
    "name": "get_vector_store_file_content",
    "arguments": {
      "server_url": "https://<console-ibm-spectrum-fusion-ns.apps.openshifturl>",
      "auth_token": "your_auth_token",
      "vector_store_id": "your_store_id",
      "file_id": "5243905"
    }
  }
},'
```

- Example: MCP streamable endpoint

```
curl -k -N -X POST \ https://<console-ibm-spectrum-fusion-ns.apps.openshifturl>/cas/api/v1/mcp-streamable/ \
-H "Content-Type: application/json" \
-H "Accept: application/json, text/event-stream" \
-d '{
  "jsonrpc": "2.0",
  "id": 6,
  "method": "tools/call",
  "params": {
    "name": "get_vector_store_file_content",
    "arguments": {
      "server_url": "https://<console-ibm-spectrum-fusion-ns.apps.openshifturl>",
```

list_vector_store_files

- | Parameter | Type | Description |
|------------------------------|---------|--|
| <code>auth_token</code> | string | Required. Authentication token for API access. |
| <code>vector_store_id</code> | string | Required. ID of the vector store to list files from. |
| <code>filters</code> | object | Optional. Filter files based on attributes. It can be a comparative filter or a compound filter. For more information, see Filter parameters . |
| <code>limit</code> | integer | Optional. Number of files to return. The default value is 20. The maximum value is 1000. |
| <code>before</code> | string | Optional. A cursor for backward pagination. Returns files before the file ID. |
| <code>after</code> | string | Optional. A cursor for forward pagination. Returns files after the file ID. |
| <code>order</code> | string | Optional. Sort order based on ingestion timestamp. Specify asc for ascending order and desc for descending order. The default value is desc . |

- ## Authentication

All MCP tool calls require authentication. Provide the CAS authentication token in the `auth_token` parameter when you call any tool. The token is validated by using the same authentication system as the REST APIs.

MCP endpoints

- **Description:** Streaming MCP endpoint that provides real-time response delivery by using Server-Sent Events (SSE). Use this endpoint when continuous or progressive responses are needed.

- Method: POST
- Content-Type: `application/json`
- Accept: `text/event-stream`

Initialize example:

```
curl -N -X POST \
  https://<console-ibm-spectrum-fusion-ns.apps.openshifturl>/cas/api/v1/mcp-streamable/ \
  -H "Content-Type: application/json" \
  -H "Accept: text/event-stream" \
  -d '{
    "jsonrpc": "2.0",
    "id": 1,
    "method": "initialize",
    "params": {
      "protocolVersion": "2024-11-05",
      "capabilities": {},
      "clientInfo": {
        "name": "test-client",
        "version": "1.0.0"
      }
    }
  }'
```

Call streaming tools:

```
curl -k -N -X POST \
  https://<console-ibm-spectrum-fusion-ns.apps.openshifturl>/cas/api/v1/mcp-streamable/ \
  -H "Content-Type: application/json" \
  -H "Accept: application/json, text/event-stream" \
  -d '{
    "jsonrpc": "2.0",
    "id": 3,
    "method": "tools/call",
    "params": {
      "name": "list_vector_stores",
      "arguments": {
        "server_url": "https://<console-ibm-spectrum-fusion-ns.apps.openshifturl>",
        "auth_token": "your-token-here"
      }
    }
  }'
```

```
curl -N -X POST \
  https://<console-ibm-spectrum-fusion-ns.apps.openshifturl>/cas/api/v1/mcp-streamable/ \
  -H "Content-Type: application/json" \
  -H "Accept: text/event-stream" \
  -d '{
    "jsonrpc": "2.0",
    "id": 4,
    "method": "tools/call",
    "params": {
      "name": "search_vector_stores",
      "arguments": {
        "server_url": "https://<console-ibm-spectrum-fusion-ns.apps.openshifturl>",
        "auth_token": "your_auth_token",
        "vector_store_id": "your_store_id",
        "query": "your search query",
        "limit": 10
      }
    }
  }'
```

Getting started using MCP endpoints in your application

To use MCP with CAS, follow these steps:

1. Obtain the CAS server URL and authentication token.
2. Configure the AI chat client to connect to the MCP endpoint.
The AI assistant discovers the available tools automatically.
3. Begin with using natural language queries that require information from vector stores.

Error handling

MCP follows JSON-RPC 2.0 error conventions. If a request fails, the response includes an error object with a code and message.

Common error codes:

- -32700: Parse error (invalid JSON)
- -32600: Invalid request
- -32601: Method not found
- -32602: Invalid parameters
- -32603: Internal error

Integrating CAS with watsonx Orchestrate by using MCP

Large language models move from experimentation into production. Enterprises build AI agents that require access to real-time business data. watsonx Orchestrate provides conversational AI for workflow automation. Integrating watsonx Orchestrate with enterprise systems such as Content-Aware Storage (CAS) often requires custom integration code for each data source.

Model Context Protocol (MCP) removes this requirement. MCP provides a standardized, conversational interface that allows AI agents to discover and invoke enterprise capabilities without custom integration code. For more information about integrating MCP with CAS, see [Integrating Model Context Protocol \(MCP\) with CAS](#).

The following section explains how MCP enables watsonx Orchestrate to access CAS, describes the technical configuration, and demonstrates the integration through natural language queries.

Integration challenges

Traditional integrations between AI agents and enterprise systems introduce several challenges:

- Each vector database integration requires a custom API client code.
- AI agents cannot discover new capabilities without redeployment.
- Authentication, error handling, and connection management increase development overhead.
- Adding multiple data sources multiplies integration complexity.

Integration with watsonx Orchestrate

Validation of the architecture uses watsonx Orchestrate. The workflow follows three phases:

1. Connect CAS to watsonx Orchestrate by using MCP.
2. Create an AI agent that uses CAS tools.
3. Validate queries through natural language interaction.

Before you begin

Ensure that the following components are available:

- watsonx Orchestrate instance: An active watsonx Orchestrate deployment with CLI access. For more information about setting up this deployment, see [Installing watsonx Orchestrate service](#).
- Model configured in watsonx Orchestrate: A model enabled to run AI agents that query CAS. For more information about adding a model, see [Enabling a specific model](#).
- IBM Fusion instance with CAS deployed: CAS running on OpenShift®. For more information about installing CAS, see [Installing Content-Aware Storage \(CAS\)](#).
- CAS authentication token: Bearer token for CAS API access.
- CAS URL: The IBM Fusion console URL of the cluster. For example: `https://<console-ibm-spectrum-fusion-ns.apps.openshifturl>`
- Network connectivity: Network access from watsonx Orchestrate instance to the CAS server route.

Configuration

1. Set up the watsonx Orchestrate CLI environment.
The watsonx Orchestrate CLI manages MCP servers, toolkits, and agents.

- a. Download and install the watsonx Orchestrate CLI for your operating system. For more information, see https://developer.watson-orchestrate.ibm.com/getting_started/installing.
- b. Verify the installation:

```
orchestrate --version
```

- c. Set up a Python virtual environment (recommended):

```
python3 -m venv orchestrate-env  
source orchestrate-env/bin/activate # On Windows: orchestrate-env\Scripts\activate
```

2. Configure the watsonx Orchestrate environment.

- a. In the watsonx Orchestrate web console, retrieve the watsonx Orchestrate instance URL from Profile Settings. Add and activate the environment:

```
orchestrate env add -n wxo-instance -u <your orchestrate url>
```

```
orchestrate env activate wxo-instance
```

- b. When prompted, enter the watsonx Orchestrate credentials. Credentials can be obtained from the [watsonx Orchestrate documentation](#).

3. Configure the CAS MCP server URL.

- a. To construct the URL, append `/cas/api/v1/mcp-streamable/` to the base CAS URL described in the [Before you begin](#) section. For example:

```
https://console-ibm-spectrum-fusion-ns.apps.<openshift-cluster-domain>/cas/api/v1/mcp-streamable/
```

4. Register the CAS MCP server as a toolkit in watsonx Orchestrate:

```
orchestrate toolkits add \  
--kind mcp \  
--name cas \  
--description "MCP server for CAS vector stores" \  
--url <your-cas-mcp-url> \  
--transport streamable http \  
--tools "search_vector_stores,list_vector_stores,get_vector_store_file_content"
```

This command registers the CAS MCP server and exposes the following tools to watsonx Orchestrate agents:

- `search_vector_stores`
- `list_vector_stores`
- `get_vector_store_file_content`

5. Create and configure the AI agent.

- a. Open the watsonx Orchestrate web console and click Create new agent.

- b. Enter the required details and click Create.

- c. In the Tools section of agent configuration, select Add Tool.

- d. Select tools from the cas toolkit.

- e. Click Add tool and add the following tools:

- `list_vector_stores`
- `search_vector_stores`
- `get_vector_store_file_content`

- f. Click Save.

- g. Click Deploy.

Validation

Verify tool registration

After registering the MCP server, confirm that the CAS tools appear in the agent Tools list.

Verify tool execution

Test the deployed agent by using natural language prompts.

Example prompt:

What vector stores are available in CAS?

Note: When prompted, provide the CAS route URL and bearer token in the chat interface.

Results

The integration connects CAS with watsonx Orchestrate through MCP. AI agents access enterprise vector stores directly by using natural language.

With this configuration, you can:

- Run agentic workflows that retrieve and act on enterprise knowledge.
- Integrate retrieval-augmented generation (RAG) pipelines with CAS vector stores.
- Eliminate custom integration code and reduce operational complexity.

Monitoring

This page provides a comprehensive view of monitoring capabilities, structured into two key sections: monitoring using dashboard in Content-Aware Storage (CAS) user interface and metric collection through Prometheus.

Monitor from CAS dashboard

Go to Content-Aware Storage > Overview page of the IBM Fusion user interface to view the CAS dashboard. It provides an inventory of vector stores and data sources and newly created vector store entries. You can use this information to get insights of system activity.

CAS metrics

CAS provides a set of Prometheus metrics to give you insights on processing time of a batch of documents with respect to the document sizes.

Metric	Description
cas_documents_batch_duration_seconds [label: document_processor_name, event_type]	Overall time taken by CAS to successfully process a batch of new, updated, or deleted documents.
cas_ingest_service_batch_duration_seconds [label: document_processor_name]	Time taken by document processor to successfully process a batch of new or updated documents. This is a subset of the overtime time measured by cas_documents_batch_duration_seconds.
cas_documents_size_bytes_total [label: document_processor_name, event_type]	Total size of all documents in a batch of new, updated, or deleted documents. This metric is published regardless of whether the batch processing is successfully or not. It gives you insights on whether there is any unexpected spike of document size.
cas_document_size_bytes [label: document_processor_name, event_type]	Size of each document. This metric is published regardless of whether the batch processing is successfully or not. It gives you insights on whether there is any unexpected large file.
cas_documents_count [label: file_type, domain, documentProcessor]	Total number of files in the vector store that the specified document processor handles. This metric is published only after the document processor processes at least one file.
cas_documents_size_bytes [label: file_type, domain, documentProcessor]	Total size in bytes of all files present in the vector store that the specified document processor handles. This metric is published only after the document processor processes at least one file.

The following table provides label definitions:

Label	Value
document_processor_name	vector store name
event_type	update: new or updated documents delete: deleted documents

Uninstalling Content-Aware Storage (CAS) service

When you do not need CAS service, uninstall it from IBM Fusion.

About this task

After you run the script, the following high-level steps occur in sequence:

- Uninstalls Apache Kafka service.
- Uninstalls the CloudNativePG (CNPg) service.
- Deletes the CAS namespace.

Procedure

- Log in to your cluster.
- In your browser, go to this URL - https://github.com/IBM/storage-fusion/blob/master/CAS/cas-cleanup/customer_cas_cleanup.sh.
- Download the customer_cas_cleanup.sh file and run the script.

- [Cleaning up Content-Aware Storage \(CAS\) data](#)
You can use CRs to clean the data source.

Cleaning up Content-Aware Storage (CAS) data

You can use CRs to clean the data source.

Clean up the data source

Clean up the data source through CLI

To delete the data source, run the following command:

```
oc delete datasource <datasource-name>
```

Note: After you delete the data source, the respective PV, PVC, Kafka Topic, and Clustered Watch Folder also get deleted.

Clean up the data source through user interface

To clean up the data source through UI, follow these steps:

1. Open the IBM Fusion UI.
2. Go to Content-aware Storage > Data sources.
3. Select the data source that you want to delete.
4. In the ellipsis overflow menu, click Remove.

Cleanup steps for an S3 data source

To clean up an S3 data source, follow these steps:

1. From the data source YAML, get the associated **filesystem-name** and **fileset-name**.
2. Log in to the IBM Storage Scale cluster.
3. Unlink the fileset with the following command:

```
mmunlinkfileset <filesystem-name> <fileset-name>
```

4. Delete the fileset:

```
mmdeletefileset <filesystem-name> <fileset-name>
```

5. Delete the bucket configuration information:

```
mmafmcosskeys <bucket-name>:<fileset-name>-exportmap delete
```

6. Delete the data source.

Clean up the vector store

To delete the vector store, run the following command:

```
oc delete Domain <vector-store-name>
```

Clean up the Document Processor

To delete the Document Processor, run the following command:

```
oc delete DocumentProcessor <document-processor-name>
```

Note: After you delete the Document Processor, the respective deployment, PVC, Service, and Database Table also get deleted.

Troubleshooting issues and known limitations in Content-Aware Storage (CAS)

The common troubleshooting steps and limitations in CAS service.

CAS pods see permission denied when writing to shared PVCs during upgrade

Problem statement

After upgrading CAS from 1.1.4 to 1.1.5, two related failures share a common root cause:

- **docling-serve** RapidOCR filename mismatch (**_infer** vs **_mobile**): After the upgrade, **RapidOcrModel.__init__()** expects model files with a **_mobile** filename suffix, but the stale **huggingface-model-data** PVC contains **_infer**-suffix files from the 1.1.4 download job. A **FileNotFoundError** ends uvicorn startup.
- **vllm-embedding**, **vllm-vision**, and **cast-runtime** permission denied on model-images PVC: After the **cas-ensure-model-data-job** finishes, subsequent pods run as different UIDs and GIDs and cannot write to the shared PVC.

Cause

The **ibm-cas-setuid-setgid-scc** at priority 10 wins SCC admission and sets **fsGroup: RunAsAny**, which suppresses kubelet **fsGroup** injection. This leaves shared PVC mounts owned by **root:root**, and the relevant pods cannot write to those mounts.

When to apply

Apply during an upgrade of CAS from 1.1.4 to 1.1.5.

Resolution

SCC patch and override: Create a copy of `ibm-cas-setuid-setgid-scc` that is identical in all fields except `fsGroup: MustRunAs` (with the namespace GID range) and `priority: 11`. Setting `priority: 11` causes this SCC to beat `ibm-cas-setuid-setgid-scc` during admission. The kubelet then injects the `fsGroup` GID and chowns the volume mount, allowing `vllm` to write to `/models/modules` and `cast-runtime` to write to `/shared`.

1. Create the override SCC:

```
oc apply -f - <<'EOF'
apiVersion: security.openshift.io/v1
kind: SecurityContextConstraints
metadata:
  name: ibm-cas-cast-runtime-mustrunasgroup
allowPrivilegeEscalation: false
allowPrivilegedContainer: false
allowedCapabilities: [SETUID, SETGID]
fsGroup:
  type: MustRunAs
groups: []
users: []
priority: 11
runAsUser:
  type: MustRunAsNonRoot
selinuxContext:
  type: MustRunAs
supplementalGroups:
  type: RunAsAny
volumes: [configMap, emptyDir, persistentVolumeClaim, secret]
EOF
```

2. Create the ClusterRole:

```
oc apply -f - <<'EOF'
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: ibm-cas-cast-runtime-mustrunasgroup-use
rules:
- apiGroups: [security.openshift.io]
  resourceNames: [ibm-cas-cast-runtime-mustrunasgroup]
  resources: [securitycontextconstraints]
  verbs: [use]
EOF
```

3. Bind the ClusterRole to the relevant service accounts:

```
oc apply -f - <<'EOF'
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: ibm-cas-cast-runtime-mustrunasgroup-use
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: ClusterRole
  name: ibm-cas-cast-runtime-mustrunasgroup-use
subjects:
- kind: ServiceAccount
  name: ibm-isf-cas-operator-system
  namespace: ibm-cas
- kind: ServiceAccount
  name: default
  namespace: ibm-cas
EOF
```

4. Delete the affected pods so that they restart under the new SCC:

```
oc delete pod -n ibm-cas -l app.kubernetes.io/component=cast-runtime,app.kubernetes.io/part-of=deucalion-domain
oc delete pod -n ibm-cas -l app.kubernetes.io/component=vllm
```

Important: `priority: 11` is required to beat `ibm-cas-setuid-setgid-scc` (priority 10) during SCC admission. `ibm-cas-cast-runtime-mustrunasgroup` must be bound to both `ibm-isf-cas-operator-system` (`cast-runtime`, `vllm`) and `default` (`cas-ensure-model-data-job`, first writer on the `huggingface-model-data` PVC) so that the injected `fsGroup` GID is consistent across all pods sharing those volumes.

CAS operator reconcile stalls: Missing EventManager NetworkPolicy

Problem statement

The CAS operator logs repeat the following pattern approximately every 60 seconds throughout the entire install and any subsequent reconcile:

```
Event Manager service url: https://<clusterIP>:10666/api/v1/eventmanager/alerts
Error POSTing info request (...): Post "https://<clusterIP>:10666/api/v1/eventmanager/alerts":
context deadline exceeded (Client.Timeout exceeded while awaiting headers)
```

Each timeout adds approximately 60 seconds of dead time to every reconcile cycle, visibly slowing installation and upgrade progress.

Important: This fix is non-recurrent. Apply it once before CAS installation. It persists across installations and upgrades unless `isf-serviceability-operator` reconciles the policy away.

Cause

The `eventmanager-network-policy` in `ibm-spectrum-fusion-ns` has no ingress rule permitting traffic from the `ibm-cas` namespace to port 10666. Every outbound POST from the CAS operator is silently dropped, and the HTTP client blocks until the OS TCP timeout expires.

When to apply

Apply this fix before CAS installation begins. Every reconcile cycle stalls without it.

Re-apply if the symptom returns after an `isf-serviceability-operator` reconcile overwrites the policy.

Resolution

Save the following manifest to a file named `allow-cas-operator-to-eventmanager.yaml` and apply it:

```
apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
  name: allow-cas-operator-to-eventmanager
  namespace: ibm-spectrum-fusion-ns
  labels:
    app.kubernetes.io/managed-by: cas-operator
spec:
  podSelector:
    matchLabels:
      app: isfemdep
  policyTypes:
    - Ingress
  ingress:
    - from:
        - namespaceSelector:
            matchLabels:
              kubernetes.io/metadata.name: ibm-cas
          podSelector:
            matchLabels:
              app.kubernetes.io/component: operator
              app.kubernetes.io/name: cas.isf.ibm.com
      ports:
        - port: 10666
          protocol: TCP
```

```
oc apply -f allow-cas-operator-to-eventmanager.yaml
```

Result

After applying the policy, the CAS operator logs no longer show `context deadline exceeded` for Event Manager POST calls.

Docling, vllm, and cast-runtime pods crash with permission errors: SCC fsGroup override

Problem statement

After a CAS upgrade or on a fresh install, one or more of the following symptoms occur:

- The `docling` pod shows 1/2 `CrashLoopBackOff`. Logs show:

```
FileNotFoundError: .../ch_PP-OCRv4_det_mobile.onnx does not exist
```

A stale `huggingface-model-data` PVC contains `_infer`-suffix model files. CAS 1.1.5 expects `_mobile`-suffix files.

- The `vllm-embedding` or `vllm-vision` pod shows 1/2 `CrashLoopBackOff`. Logs show:

```
PermissionError: [Errno 13] Permission denied: '/models/modules'
```

- The `cast-runtime` pod logs show:

```
Error publishing messages [Errno 13] Permission denied: '/shared/<jobID>'
```

Inspecting the volume mount inside the pod confirms root ownership:

```
$ stat /shared
Access: (0755/drwxr-xr-x)  Uid: (0/root)   Gid: (0/root)
```

Important: This fix is non-recurrent. Apply it once before the affected pods first start. It persists until the SCC or RBAC binding is removed.

Cause

The `ibm-cas-setuid-setgid-scc` is configured with `fsGroup`:

`RunAsAny` at priority 10. When this SCC wins pod admission, the kubelet skips `fsGroup` injection and does not chown volume mounts. PVC mounts remain owned by `root:root`, and pods running as a non-root UID cannot write to them.

When to apply

Apply all steps before the `DocumentProcessor`, `vllm`, and `docling` pods first start. The SCC must exist at pod admission time.

If the affected pods have already started under the wrong SCC, complete all steps and then bounce the pods (step 4).

Resolution

- Create an override SCC at priority 11, which takes precedence over the existing SCC at priority 10:

```
oc apply -f - <<'EOF'
apiVersion: security.openshift.io/v1
kind: SecurityContextConstraints
metadata:
  name: ibm-cas-cast-runtime-mustrunasgroup
allowPrivilegeEscalation: false
allowPrivilegedContainer: false
allowedCapabilities: [SETUID, SETGID]
```

```

fsGroup:
  type: MustRunAs
groups: []
users: []
runAsUser:
  type: MustRunAsNonRoot
seLinuxContext:
  type: MustRunAs
supplementalGroups:
  type: RunAsAny
volumes: [configMap, emptyDir, persistentVolumeClaim, secret]
EOF

```

2. Create a ClusterRole that grants use of the new SCC:

```

oc apply -f - <<'EOF'
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: ibm-cas-cast-runtime-mustrunasgroup-use
rules:
- apiGroups: [security.openshift.io]
  resourceNames: [ibm-cas-cast-runtime-mustrunasgroup]
  resources: [securitycontextconstraints]
  verbs: [use]
EOF

```

3. Bind the ClusterRole to the relevant service accounts:

```

oc apply -f - <<'EOF'
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: ibm-cas-cast-runtime-mustrunasgroup-use
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: ClusterRole
  name: ibm-cas-cast-runtime-mustrunasgroup-use
subjects:
- kind: ServiceAccount
  name: ibm-isf-cas-operator-system
  namespace: ibm-cas
- kind: ServiceAccount
  name: default
  namespace: ibm-cas
EOF

```

4. Bounce the affected pods so that they are re-admitted under the new SCC:

```

# Replace <domain> with your DocumentProcessor domain name (for example, deucalion-domain)
oc delete pod -n ibm-cas \
  -l app.kubernetes.io/component=cast-runtime,app.kubernetes.io/part-of=<domain>
oc delete pod -n ibm-cas -l app.kubernetes.io/component=vllm
oc delete pod -n ibm-cas -l app.kubernetes.io/name=docling

```

Result

After the pods restart, confirm that they are admitted under the new SCC:

```

oc get pod <pod-name> -n ibm-cas \
  -o jsonpath='{.metadata.annotations.openshift\.io/scc}'{"\n"}'
# Expected: ibm-cas-cast-runtime-mustrunasgroup

```

Upgrade stalls: Kafka CR is patched to an unsupported version

Problem statement

After enabling the cache filesystem or triggering any upgrade, the CAS operator logs repeat indefinitely:

```
Kafka not yet ready.
```

Inspecting the Kafka custom resource (CR) shows:

```

oc get kafka kafka -n ibm-cas -o jsonpath='{.status.conditions}'
[{"message": "Unsupported Kafka.spec.kafka.version: 3.9.0. Supported versions are: [4.0.0, 4.1.0]",
  "reason": "UnsupportedKafkaVersionException",
  "status": "True",
  "type": "NotReady"}]

```

Important: This issue is recurrent. Re-apply the fix each time the CAS operator patches the Kafka CR to an unsupported version, that is, on every install re-entry or upgrade that triggers `UpdateKafkaVersion`.

Cause

The CAS operator hardcodes Kafka version 3.9.0 when patching the Kafka CR during upgrades and install re-entry. AMQ Streams 3.1.0-14 supports only Kafka versions 4.0.0 and 4.1.0. As a result, the Kafka CR transitions to a `NotReady` state immediately after the update, and the `IsHealthyKafkaCluster` check never returns `true`.

When to apply

Apply this fix before triggering install re-entry, that is, before applying the `CasInstall` status patch that re-enters the cache filesystem install path. Strimzi requires approximately 30 seconds to reconcile the Kafka CR to `Ready` after this patch.

If the operator has already entered the loop, apply the patch and wait for the next reconcile cycle to proceed.

Resolution

Patch the Kafka CR to set a supported version:

```
oc patch kafka kafka -n ibm-cas --type=merge \
-p '{"spec":{"kafka":{"version":"4.0.0"}}}'
```

Result

Within approximately 30 seconds, the Kafka CR shows **type=Ready, status=True**.

Verify by running the following command:

```
oc get kafka kafka -n ibm-cas \
-o jsonpath='{.status.conditions[?(@.type=="Ready")].status}'{"\n"}'
# Expected: True
```

The operator log stops repeating `Kafka not yet ready` after the next reconcile cycle.

CAS installation fails with CAS Cache Filesystem Failed error

Problem statement

When installing CAS with Local Data Caching for Content Aware Storage (CAS) enabled, the installation stops and eventually fails with a message similar to:

CAS Cache Filesystem Failed

The installation does not progress past the cache filesystem validation stage.

Cause

When Local Data Caching for Content Aware Storage (CAS) is enabled, CAS waits for the IBM Storage Scale cache filesystem (**cache-fs**) to reach a healthy state before continuing the installation.

By default, CAS waits up to 20 minutes for the cache filesystem to become healthy. If the filesystem does not reach a healthy state within this period, the installation is canceled and marked as failed.

This situation can occur when:

- Filesystem creation is taking longer than expected.
- The **cache-fs** filesystem requires additional time to become healthy.

Resolution

If additional time is required for the cache filesystem to become healthy, configure the CAS installation to ignore the filesystem health timeout.

1. Verify the CAS installation resource:

```
oc get casinstall -n ibm-cas
```

2. Patch the CAS installation resource to add the following annotation:

```
oc patch casinstall ibm-cas-service-instance \
-n ibm-cas \
--type merge \
-p '{"metadata":{"annotations":{"ignore-filesystem-health-timeout":"true"}}}'
```

3. Verify that the annotation is applied:

```
oc get casinstall ibm-cas-service-instance \
-n ibm-cas \
-o yaml
```

Result

After you apply the annotation, CAS overrides the default 20-minute cache filesystem health timeout. The installation continues to wait until the IBM Storage Scale cache filesystem becomes healthy, and then proceeds.

Note: This annotation only affects installations that use Local Data Caching for Content Aware Storage (CAS).

Important: Use this workaround only when the cache filesystem is expected to become healthy eventually.

EventManager NetworkPolicy blocks CAS operator alert POSTs

Problem statement

The CAS operator (**ibm-isf-cas-operator-controller-manager**) calls **PostInfo()** and **PostAlert()** from the **isf-common** event client library during every **setInstallationStageAndStatus** reconcile step. These calls POST to `https://<clusterIP>:10666/api/v1/eventmanager/alerts`. As a result, no CAS events are reported in the IBM Fusion UI events section.

Cause

The **eventmanager-network-policy** in **ibm-spectrum-fusion-ns** has no ingress rule permitting traffic from **ibm-cas**. Hence, every outbound POST is silently dropped. The HTTP client also lacks a short timeout, so each POST blocks for the full OS or kernel TCP timeout before returning **context deadline exceeded**.

Resolution

Apply the following custom NetworkPolicy in **ibm-spectrum-fusion-ns** to grant the CAS operator pod ingress to eventmanager on port 10666.

1. Create a YAML file with the following content:

```
apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
  name: allow-cas-operator-to-eventmanager
  namespace: ibm-spectrum-fusion-ns
labels:
```

```

    app.kubernetes.io/managed-by: cas-operator
spec:
  podSelector:
    matchLabels:
      app: isfemdep
  policyTypes:
  - Ingress
  ingress:
  - from:
    - namespaceSelector:
        matchLabels:
          kubernetes.io/metadata.name: ibm-cas
      podSelector:
        matchLabels:
          app.kubernetes.io/component: operator
          app.kubernetes.io/name: cas.isf.ibm.com
  ports:
  - port: 10666
    protocol: TCP

```

2. Apply with the following command:

```
oc apply -f allow-cas-operator-to-eventmanager.yaml
```

Important: This workaround is not durable. The `isf-serviceability-operator` (label `app.kubernetes.io/managed-by: isf-serviceability-operator`) manages `eventmanager-network-policy`, which might reconcile over or conflict with the standalone policy. The custom policy is also not applied automatically on fresh installations.

PVC remains in Pending state

Problem statement

The data source remains in the Connecting state and the associated PersistentVolumeClaim (PVC) stays in the **Pending** state.

The PVC events might contain an error similar to the following:

```

rpc error: code = Internal desc = failed to update comment for fileset [...]
rpc error: code = Internal desc = remote call failed with response
400 Invalid value in 'filesetName'

```

Cause

This issue can occur when the NFS export path that is specified during data source creation is no longer valid or accessible.

Resolution

1. Verify that the configured NFS export path still exists on the NFS server.
2. If the export path is changed:
 - a. Delete the data source that references the outdated NFS export path.
 - b. Obtain the current NFS export path from the NFS server.
 - c. Create a new data source by using the updated NFS export path.

After the data source is re-created with a valid export path, the PVC must progress from the **Pending** state and the data source must eventually transition to the Connected state.

PVC remains in Pending state because the volume cannot be provisioned

Problem statement

The data source remains in the Connecting state and the associated PersistentVolumeClaim (PVC) stays in the **Pending** state.

Review the PVC events:

1. Open the data source PVC.
2. Select the Events tab.
3. Look for messages similar to the following:

```

Waiting for a volume to be created either by the external provisioner 'spectrumscale.csi.ibm.com' or manually by the
system administrator. If volume creation is delayed, please verify that the provisioner is running and correctly
registered.

```

Cause

The prior message indicates that IBM Storage Scale has not yet provisioned the volume that is requested by the PVC.

Possible causes include:

- The IBM Storage Scale cluster is running low on available capacity.
- The IBM Storage Scale cluster is temporarily unable to create new filesets or volumes.
- Volume provisioning is taking longer than expected due to cluster activity or resource constraints.

Resolution

1. Verify that the IBM Storage Scale cluster has sufficient free capacity.
2. If the cluster is full or nearly full, free up storage space and wait for provisioning to resume.
3. Monitor the PVC status and events for updates.
4. Wait for the PVC to transition from **Pending** to **Bound**.

Note: By default, an NFS data source can take up to one hour to transition to the Connected state. If the PVC is still progressing and no provisioning errors are reported, allow sufficient time for the provisioning process to complete before taking corrective action.

After the PVC reaches the **Bound** state, the data source must continue the connection process and eventually transition to the Connected state.

IBM Fusion or Global Data Platform upgrade gets stuck due to ibm-cas/kafka-broker-nodepool eviction

Problem statement

Global Data Platform upgrade gets stuck in between as ibm-cas/kafka-broker-nodepool-0 fails to evict.

Cause #1

The nodepools have anti-affinity configured correctly, but the eviction logic is restrictive. After one pod is evicted, the system does not allow any additional pods to be taken down, which prevents further rescheduling.

Cause #2

IBM Storage Scale includes a Pod Disruption Budget (PDB) for its node pods with a similar restrictiveness to the Kafka pods. Sometimes, a conflict can occur between the Kafka PDB and the IBM Storage Scale PDB. When this happens, the **scale-core** pod might remain in the **Terminating** state, and block the rolling update of a Machine Config Pool (MCP).

Resolution

1. Update Kafka custom resource (CR)

- In the OpenShift® console, go to Installed Operators > Streams for Apache Kafka (ibm-cas ns) > All Instances > Kafka > YAML.
- Locate the **Kafka** section and add:

```
template:
  podDisruptionBudget:
    maxUnavailable: 2
```

- Save and apply the updated **Kafka** CR.

2. If one or more relevant scale-core pods are stuck in **Terminating** state for an extended period, follow these steps:

- Log in to the OpenShift cluster and check the pod status in the **openshift-machine-config-operator** namespace:

```
oc get pods -n openshift-machine-config-operator
```

- Identify the **machine-config-controller** pod (for example: **machine-config-controller-669b794b8f-6p4b1**).

- View the logs to determine where MCP is blocked:

```
oc logs machine-config-controller-669b794b8f-6p4b1 -n openshift-machine-config-operator
```

- If the logs indicate that a pod is blocking MCP, manually evict that pod from the node:

```
oc adm drain compute-1-ru4.racke.mydomain.com --force=true --ignore-daemonsets=true --grace-period=1 --delete-emptydir-data
```

- Delete the **scale-core** pod:

```
kubectl delete pod <scale-core-pod-name> --grace-period=0 --force
```

Strimzi migration from ZooKeeper to KRaft gets stuck at early CAS upgrade stage

Problem statement

The Strimzi cluster operator pod gets stuck in a no-op reconciliation loop. The following **cas-operator** log message reconciles multiple times:

```
2025-10-30T00:49:10Z INFO KRaft migration in progress... requeueing {"controller": "casinstall", "controllerGroup": "cas.isf.ibm.com", "controllerKind": "CasInstall", "CasInstall": {"name": "ibm-cas-service-instance", "namespace": "ibm-cas"}, "namespace": "ibm-cas", "name": "ibm-cas-service-instance", "reconcileID": "07107592-ca70-4d44-9a96-b66fa29f20af"}
```

If the metadata state of the Kafka Custom Resource (CR) is in **KRaftMigration** for a long time, it means that it is stuck:

```
% oc get Kafka
NAME DESIRED KAFKA REPLICAS DESIRED ZK REPLICAS READY METADATA STATE WARNINGS
kafka 3 3 True KRaftMigration
```

amq-streams-cluster-operator logs:

```
2025-10-30 01:03:33 INFO StrimziPodSetController:349 - Reconciliation #632 (watch) StrimziPodSet (ibm-cas/kafka-broker-nodepool): StrimziPodSet will be reconciled

2025-10-30 01:05:35 INFO ClusterOperator:140 - Triggering periodic reconciliation for namespace ibm-cas
2025-10-30 01:05:35 INFO AbstractOperator:266 - Reconciliation #637 (timer) Kafka (ibm-cas/kafka): Kafka kafka will be checked for creation or modification
2025-10-30 01:05:38 INFO AbstractOperator:546 - Reconciliation #637 (timer) Kafka (ibm-cas/kafka): reconciled
```

Resolution

Restart the **amq-streams-cluster-operator** pod. This resumes the migration process.

Errors in CAS runtime pod after Scale upgrade

Problem statement

Data ingestion fails with errors in CAS runtime pod.

Cause #1

The filesystem might be unmounted. This error can be observed in the `cas-runtime` logs as a `NodeNotReadyError`, or a pod is stuck at `Init:0/1` or in a `CrashLoopBackOff` state with a `FailedMount` event.

Resolution

1. Ensure that the filesystem is mounted correctly on all required nodes where Kafka pods and other affected pods are running.
2. To check which nodes the filesystem is mounted on, go to the Scale cluster and run the following command:

```
mmismount all -L
```

This lists all the nodes that filesystem is mounted on.

3. On the OpenShift Container Platform cluster, in the `ibm-spectrum-scale` namespace, identify the corresponding pod.
4. In the `ibm-spectrum-scale` namespace, find a healthy pod that is one where the filesystem is correctly mounted.
5. Run the following command to mount the filesystem on all the necessary pods:

```
mmmount all -a
```

It also resolves any filesystem mount-related errors.

6. Restart all the Kafka pods, `cas-runtime` pod, and `nv-ingest` pods.

Cause #2

The `nv-ingest` job fails.

Resolution

1. Check whether the NV-ingest Redis pod is restarted. It can cause `nv-ingest` job to fail.
2. Restart the pods corresponding to `nv-ingest`.

Cause #3

The Kafka pods fail.

Resolution

1. This issue can be related to the filesystem mount problem described in Cause #1. Follow the resolution steps in Cause #1 if the error is related to filesystem mount.
2. Restart the Kafka pods.

Inaccurate search results using the Docling Multimodal Processing Engine

Problem statement

Intermittent issues are observed where search results from a vector store using Docling Multimodal Processing Engine return random results.

Cause

The vector index becomes corrupted and results in inaccurate search results.

Resolution

To fix the issue, drop and recreate the vector index on the affected vector store by following these steps:

1. Log in to the OpenShift cluster by running the following command through command line:

```
oc login <cluster-url>
```

2. Switch to the `ibm-cas` project:

```
oc project ibm-cas
```

3. Save the database password for later use:

```
oc get secret cluster-parade-app -oyaml -n ibm-cas | yq '.data.password' | base64 -d
```

4. Access the parade database pod:

```
oc exec -it cluster-parade-1 -- psql -U app -d app -h localhost -W
```

Enter the database password retrieved in Step 3.

5. Run the following command to view table details:

```
\d nameOfDomain
```

Locate the index labeled `diskann (vector)`.

Example output:

```
app=> \d red1
```

		Table "public.red1"		
Column	Type	Collation	Nullable	Default
pk	bigint		not null	nextval('red1_pk_seq'::regclass)
fileid	character varying			
text	character varying			

```

vector      | vector(768) |
source      | jsonb       |
content_metadata | jsonb       |
Indexes:
  "redl_pkey" PRIMARY KEY, btree (pk)
  "redl_file_idx" btree (fileid)
  "redl_vector_idx" diskann (vector)

```

6. Drop the `diskann (vector)` index:

```
DROP INDEX nameOfDiskAnnIndex
```

Example:

```
app=> DROP INDEX redl_vector_idx;
DROP INDEX
```

7. Verify the table details and confirm that the vector index no longer appears:

```
\d nameOfTable
```

8. Recreate the vector index with the following command:

```
CREATE INDEX nameOfDomain_vector_idx on public.nameOfDomain USING diskann (vector vector_cosine_ops);
```

Example:

```
app=> CREATE INDEX redl_vector_idx on public.redl USING diskann (vector vector_cosine_ops);
NOTICE: Starting index build with num_neighbors=-1, search_list_size=100, max_alpha=1.2,
storage_layout=SbqCompression.
WARNING: Indexed 96 tuples
CREATE INDEX
```

9. Verify the table details and confirm that the new vector index appears in the list:

```
\d nameOfTable
```

Example:

```
app=> \d redl
```

Column	Type	Table "public.redl"	Collation	Nullable	Default
pk	bigint			not null	nextval('redl_pk_seq'::regclass)
fileid	character varying				
text	character varying				
vector	vector(768)				
source	jsonb				
content_metadata	jsonb				

```

Indexes:
  "redl_pkey" PRIMARY KEY, btree (pk)
  "redl_file_idx" btree (fileid)
  "redl_vector_idx" diskann (vector)

```

Errors in CAS operator after upgrading to CAS v1.0.6

Problem statement

If IBM Data Cataloging is installed, errors can be observed in the CAS operator:

```
~2025-10-02T15:17:35Z ERROR Failed to get DCS Instance~
```

Cause

If IBM Data Cataloging is installed by using Fusion GUI but it is not enabled for filtering, CAS operator repeatedly shows an error when it looks up the IBM Data Cataloging instance. This issue does not happen if you install IBM Data Cataloging through CLI.

Resolution

After you upgrade CAS to version 1.0.6, if IBM Data Cataloging is installed but you do not plan to enable filtering for CAS, follow these steps:

1. Scale down the CAS operator:

```
oc scale deployment ibm-isf-cas-operator-controller-manager --replicas=0 -n ibm-cas
```

2. Patch the `CasInstall` custom resource (CR):

```
oc patch casinstall ibm-cas-service-instance -n ibm-cas --type=merge -p '{"spec":{"enabled_features":{"dcs":{"enable":false,"instance_name":"data-cataloging-service-instance","namespace":"ibm-data-cataloging"}}}}'
```

3. Scale up the CAS operator:

```
oc scale deployment ibm-isf-cas-operator-controller-manager --replicas=1 -n ibm-cas
```

Errors in existing document processor after upgrading to CAS v1.0.6

Problem statement

After upgrading CAS from v1.0.5 to v1.0.6, errors can be observed in ingestion in the document processor logs. If you are running one or more Docling Multimodal pipelines, the following error can be observed in the document processor (`cast-runtime`) pod logs:

```
~2025-10-02T07:05:26Z - xxx - ERROR - xxx - Repo id must be in the form 'repo_name' or 'namespace/repo_name':
'/models/granite-embedding-278m-multilingual'. Use `repo_type` argument if needed.~
```

Cause

With CAS 1.0.6 release, the deployment `spec` for the Docling Multimodal document processors (`cast-runtime`) is changed to mount a PVC with the required LLM models. You need to force the operator to deploy a new deployment for each document processor that is running `docling_multimodal` type pipeline.

Resolution

After you upgrade CAS to version 1.0.6, redeploy all the document processors that are running the `docling_multimodal` type pipeline:

1. Scale down the CAS operator.

```
oc scale deployment ibm-isf-cas-operator-controller-manager --replicas=0 -n ibm-cas
```

2. Identify `DocumentProcessor` CRs that are running the `docling_multimodal` type pipeline.

```
oc get DocumentProcessor -n ibm-cas
```

Alternatively, you can use `jq` to filter by type.

```
oc get documentprocessor -ojson | jq '.items[] | select(.spec.type == "docling_multimodal") | .metadata.name'
```

3. Delete all the deployments associated with those CRs.

```
oc delete deployment <DocumentProcessor CR name> -n ibm-cas
```

4. Scale up the CAS operator.

```
oc scale deployment ibm-isf-cas-operator-controller-manager --replicas=1 -n ibm-cas
```

Data Cataloging `SpectrumDiscover` CR fails to display `SuccessfullyEnabled` status

Problem statement

When you update `CasInstall` Custom Resource (CR) to enable filtering by Data Cataloging, `SpectrumDiscover` CR fails to display `SuccessfullyEnabled` status for `ContentAwareStorage` feature.

Cause

Run the following command and check if `isd-metadata-extender` pod is having any issue to start:

```
oc get pod -n ibm-data-cataloging
```

Resolution

To identify the issue that is preventing the pod to start, run the following command:

```
oc describe pod <isd-metadata-extender pod name>
```

No data ingested after vector store creation with Data Cataloging filtering enabled

Problem statement

Data Cataloging is successfully enabled for filtering. When you create a vector store by using a data source through UI (or a vector store and document processor through CLI), the files that meet the filtering criteria are not ingested into the vector database as expected.

The `isd-metadata-extender` pod logs under the `ibm-data-cataloging` namespace shows the following error:

```
{ "level": "error", "ts": "2025-09-27T06:56:58Z", "caller": "watch/document_processor.go:88", "msg": "Error running scale partial scan", "error": "unexpected status code 404 while running partial scan on connection fs1", "stacktrace": "github.ibm.com/ProjectAbell/dcs-metadata-extender/pkg/watch.TriggerPartialScans\n\t/tmp/app/pkg/watch/document_processor.go:88" }
```

Cause

A connection to the Scale filesystem is not created.

Resolution

1. Go to the Data Cataloging UI and create a connection for the Scale filesystem.
2. Delete the vector store and document processor CR and redeploy them.

No data ingested for any vector store

Problem statement

No indication of data ingestion in logs of CAS runtime pods for any of the corresponding `DocumentProcessor`.

Cause

One possible area to check is the health of `cas-core` pod. Check whether it is up and running with the following command:

```
oc get pod -n ibm-cas
```

Resolution

Restart the `cas-core` pod or determine the issue by running the following command:

```
oc describe pod <cas-core pod name>
```

Error in `query_service` configmap and deployment

Problem statement

When you upgrade CAS from v1.0.3 to v1.0.4, a ConfigMap and some deployment configs must be added to prevent errors in Access Control List (ACL) processing.

Cause

Query service API fails to work when an external Identity Provider (IDP) token is provided.

Resolution

1. Create the following ConfigMap:

```
kind: ConfigMap
apiVersion: v1
metadata:
  name: query-search-config
  namespace: ibm-cas
data:
  use_self_cert: 'false'
```

2. Update the query search deployment:

- a. Set the `readOnlyRootFilesystem` attribute to 'true'.
- b. In the query service deployment's `env` section, add the following entry:

```
- name: ENABLE_FILE_LEVEL_SECURITY
  value: false
```

- c. In the `volumes` section, add the following section:

```
- name: query-search-config
  configMap:
    name: query-search-config
    defaultMode: 420
- name: ibm-cas-cabundle
  configMap:
    name: openshift-service-ca.crt
    items:
      - key: service-ca.crt
        path: service-ca.crt
```

- d. In the `volumeMounts` section, add the following section:

```
- name: "query-search-config"
  readOnly: true
  mountPath: "/etc/config/cm/"
- name: ibm-cas-cabundle
  readOnly: true
  mountPath: /etc/config/cabundle
```

The nv-ingest pod is in imagepullback error

Problem statement

The `nv-ingest` pod is in `imagepullback` error state due to too many requests for `docker.io`.

Cause and resolution

1. **Cause:**

Too many requests for `docker.io`.

Resolution: Authenticate to `docker.io`.

2. **Cause:**

The `nv-ingest` pod is not able to pull the image correctly.

Resolution: Check NVIDIA guide to fix the issue.

CAS ingestion fails

Problem statement

The CAS ingestion fails with the following error in the logs of the `cast-runtime` pods:

```
2025-03-26 22:46:36,725 - ERROR - Error during fetching, retrying...
Error: HTTPSConnectionPool(host='nv-ingest.nv-ingest.svc.cluster.local', port=7670):
Max retries exceeded with url: /v1/fetch_job/ (Caused by SSLError(SSLError(1, '[SSL] record layer failure (_ssl.c:1006)')))
```

Cause

It implies that the `https` NVIDIA NIM service is not available.

Resolution

1. Go to `cast-runtime` deployment.
2. In the value parameter, change `https` to `http`:

```
- name: NVMM_NIM_SERVICE
  value: https://nv-ingest.nv-ingest.svc.cluster.local
```

to

```
- name: NVMM_NIM_SERVICE
  value: http://nv-ingest.nv-ingest.svc.cluster.local
```

Error in semantic_search

Problem statement

In the query search pod, you can get the following errors during a `semantic_search`:

```

ERROR: querysearch/semantic_search failed Connection error.
Traceback (most recent call last):
File "/opt/app-root/lib64/python3.11/site-packages/httpx/_transports/default.py", line 101, in map_httpcore_exceptions
yield

resp = self.pool.handle_request(req)
File "/opt/app-root/lib64/python3.11/site-packages/httpcore/_backends/sync.py", line 154, in start_tls
with map_exceptions(exc_map):
File "/usr/lib64/python3.11/contextlib.py", line 158, in __exit__
self.gen.throw(typ, value, traceback)
File "/opt/app-root/lib64/python3.11/site-packages/httpcore/_exceptions.py", line 14, in map_exceptions
raise to_exc(exc) from exc

```

Cause

It implies that the TLS version of the NVIDIA service is not available.

Resolution

1. Scale down the query-search deployment.
2. In the query-search deployment, change the value of variable:

```

- name: NVMM_EMBED_SERVICE
value: 'https://llama-nemotron-embed-1b-v2.nv-ingest.svc.cluster.local'

```

to

```

- name: NVMM_EMBED_SERVICE
value: 'http://llama-nemotron-embed-1b-v2.nv-ingest.svc.cluster.local'

```

3. If the NVMM Nemo Ranking service is enabled in CAS Install CR, change the following value in the query-search deployment. Change the value of variable:

```

- name: NVMM_NEMO_RANKER_SERVICE
value: 'https://llama-nemotron-rerank-1b-v2.nv-ingest.svc.cluster.local'

```

to

```

- name: NVMM_NEMO_RANKER_SERVICE
value: 'http://llama-nemotron-rerank-1b-v2.nv-ingest.svc.cluster.local'

```

4. Scale the deployment back up to its original number.

Datasource stuck in "Connecting" state error

Problem statement

The create Datasource may get stuck in a "connecting" state due to different reasons. To do a proper diagnostic, check the CAS operator logs to find the error message.

Cause and resolution

The possible causes of this error are as follows:

1. Cause:

Scale CSI user does not have enough privileges for Watcher creation.

```

ERROR RETURNED BY sConn.CreateWatch4Fileset =====>
=====> [EFSSG0012C Permission denied: Your role(s): [csiadmin, containeroperator], required
role(s): [admin, storageadmin, securityadmin]] Unable to enable clustered watch for source
castFS:root

```

Resolution:

Add the Scale CSI user to the Storage Administrator group in Scale as specified [Configuring Scale user to enable watch creation](#).

2. Cause:

Kafka authentication ConfigMap is missing.

```

2025-03-28T18:21:10Z ERROR Reconciler error {"controller": "datasource", "controllerGroup": "cas.isf.ibm.com", "controlle

```

Resolution:

Create the ConfigMap for Kafka authentication.

3. Cause:

Access is denied to static PV that is created by the Datasource. If a functional issue is detected regarding static PV accessibility, it could be related to an access denied error. To validate, access the mount path by using the pod generated by the DocumentProcessor. The pod has the same name as the DocumentProcessor.

```

(app-root) sh-5.1$ cd /gpfs/gpfs3/fileset_sample
bash: cd: /app-root: Permission denied

```

Resolution:

Add a known GID to the Fileset in Scale and add an annotation to the Datasource in CAS as described in [Step 8](#).

Known limitations

- When you open the data source Details page from the IBM Fusion UI, an error message about failing to fetch data source insights might appear. If IBM Data Cataloging is not installed on the cluster, you can ignore this message. The error is relevant only when IBM Data Cataloging is installed.
- When you deploy the `CasInstall` version 1.1.0 with `docling_multimodal` `enabled: true`, the `vllm-vision` pod results in `CrashLoopBackoff` status. The pod and its status can be ignored as the failing pod causes no functional

impact.

- Deploying an S3 data source with a custom SSL certificate is not supported for Filesystem with IBM Storage Scale version 5.2.x.
- When you upgrade CAS from v1.0.5 to v1.0.6, two PVCs are orphaned and must be manually deleted to reclaim storage. To delete these PVCs, run the following commands:

```
oc delete pvc vllm-embedding-pvc
oc delete pvc vllm-vision-pvc
```

- When you create a vector store in the user interface, the `docling_multimodal` pipeline is automatically enabled. To disable it, update the `DocumentProcessor` custom resource (CR) and set the `dataType` of the new vector store to `nvidia_multimodal`.
- Support for CAS on Azure Red Hat® OpenShift (ARO) has additional licensing requirements from Red Hat due to the need to change the maximum number of threads for the pods. For more information, see the Red Hat [knowledge base](#).
- Each vector store must use a unique datasource location, that is, unique Scale path or unique S3 location. CAS currently does not support sharing same datasource location among multiple vector stores.

Software Hub

The Software Hub is a comprehensive platform that simplifies the deployment and management of IBM software solutions, including IBM Software Hub, watsonx.ai and watsonx Orchestrate, on IBM Fusion HCI. It provides a streamlined and automated experience, reducing the complexity and manual effort associated with traditional deployment processes.

The Software Hub is designed to simplify the deployment and management of IBM software solutions on IBM Fusion HCI. The platform automates many of the manual tasks associated with traditional deployment processes, reducing the time and effort required for initial setup and ongoing management.

Important:

- To install services such as Software Hub, watsonx.ai, and watsonx Orchestrate, IBM Software Hub requires containers to run with root privileges. For more information about installing the services, see [Installing Software Hub services](#).
- If you have installed any Software Hub or IBM watsonx services previously and not through the IBM Fusion HCI user interface, and the installation of remaining services is stalled, contact [IBM support](#).

Key features and benefits

- Simplifies the deployment of IBM software solutions, including watsonx.ai and watsonx Orchestrate, on IBM Fusion HCI.
- Automates pre-requisites and configuration for Software Hub, eliminating the need for manual documentation review.
- Provides basic resource pre-checks (CPU, memory, storage) to ensure successful installation.
- Auto-selects storage classes, such as `ibm-spectrum-fusion-cp` or recommended default, for optimal performance.
- Supports the deployment of watsonx.ai, watsonx Orchestrate, and watsonx.data.
- Uses Software Hub 5.4.0, enabling customers to deploy the latest version of Software Hub.
- Initializes the cp-br service in Software Hub, enabling recipe-based backups without additional manual configuration.
- **Prerequisites**
Ensure that you meet all the prerequisites for a successful installation of the Software Hub service.
- **Installing Software Hub services**
Initiate the installation of Software Hub service from the user interface of IBM Fusion.
- **Troubleshooting issues and known limitations in Software Hub**
The common troubleshooting steps and limitations in the Software Hub service.

Prerequisites

Ensure that you meet all the prerequisites for a successful installation of the Software Hub service.

1. One of the following storage services must be available:
 - Fusion Data Foundation
 - Global Data Platform
2. Verify that the required storage classes exist:
 - For Fusion Data Foundation: `ocs-storagecluster-ceph-rbd` and `ocs-storagecluster-cephfs`.
 - For Global Data Platform: `ibm-storage-fusion-cp-sc`.
3. MCG must be set up for installing watsonx Orchestrate. If you are using Fusion Data Foundation, MCG is installed automatically.
4. If you are using Global Data Platform storage class, install MCG separately before installing IBM watsonx OC.
5. If possible, install watsonx.ai and watsonx Orchestrate separately, rather than concurrently. Wait for one service to complete installation successfully before installing the other. For more information, see [Preparing to install IBM watsonx.ai](#) and [Preparing to install watsonx Orchestrate](#).
6. IBM watsonx services stack on IBM Fusion HCI is not supported with AMD GPU cards. It is currently supported with only NVIDIA GPU cards.
7. Ensure that you must install Software Hub service to install the Watsonx services.

Installing Software Hub services

Initiate the installation of Software Hub service from the user interface of IBM Fusion.

Before you begin

Ensure that you meet all the prerequisites for a successful installation of the Software Hub service. For more information, see [Prerequisites](#).

About this task

Use this procedure to install the IBM Software Hub service from the Services page of the IBM Fusion user interface. You can also install the IBM Software Hub service using CLI. For more information about CLI usage, see [Installing the IBM Software Hub command-line interface](#).

Important: The installation procedure for the Software Hub, watsonx.ai, and watsonx Orchestrate services are identical. This topic provides the steps to install the Software Hub service.

Note:

- It is recommended to install the Software Hub before you install the watsonx.ai or watsonx Orchestrate, as it provides the foundational components required for both services.
- Installing watsonx.ai and watsonx Orchestrate automatically installs the Software Hub.
- Red Hat® OpenShift® AI version 2.22 is installed automatically as part of the watsonx.ai and watsonx Orchestrate services. For more information, see [Installing Red Hat OpenShift AI](#).

Procedure

1. Before installing Software Hub, ensure that IBM **Cert Manager** is not installed and that the `ibm-cert-manager` namespace does not exist. If either is present, uninstall IBM **Cert Manager** and delete the namespace.

Note: As part of a fresh installation, the latest version of Red Hat certificate Manager is installed with Software Hub.

2. In the IBM Fusion user interface, go to Services page.
3. In the Available section, click the Software Hub tile.
4. In the Software Hub page, go through the features and capabilities of the service and click Install.

If the pre-check raises a warning, then resolve it at OpenShift level.

The installation starts and a notification appears on the Services page. You can see the progress of the installation in the Services > **Installed** section. After the installation is completed successfully, you can see the status as Healthy. A success notification gets displayed. It disappears automatically after some time.

From the ellipsis menu, you can download logs and view documentation.

5. Validate the installation.
 - Verify the IBM Software Hub installation from the IBM Fusion user interface:
After you enable the IBM Software Hub service, you can view the service version and health status. From the ellipsis menu, you can download logs and view documentation. After you successfully collect the logs, a success notification is displayed. The notification disappears automatically after some time.
 - Verify the IBM Software Hub installation from the OpenShift Container Platform web console:
 - In the OpenShift console, go to Home > Projects.
 - In the Projects page, search and check for the availability of a namespace with string `ibm-software-hub-operator`.
 - Go to Operators > Installed Operators and check for the availability of IBM Software Hub.
 - After you enable the IBM Software Hub service, you can view the service version and health status. From the ellipsis menu, you can download logs and view documentation. After you successfully collect the logs, a success notification is displayed. The notification disappears automatically after some time.

What to do next

1. If a failure occurs, check for pods in the `cpd-instance` and `cpd-operator` namespaces.
2. For post installation instructions, check the following details:
 - For watsonx.ai, see [Post-installation setup for IBM watsonx.ai](#).
 - For watsonx Orchestrate, see [Post-installation setup for watsonx Orchestrate](#).
3. You can access the watsonx dashboard by using the information in `softwarehubmanager` CR in the `ibm-software-hub-operator` namespace.

```
apiVersion: softwarehub.fsh.ibm.com/v1
kind: SoftwarehubManager
metadata:
  labels:
    app.kubernetes.io/managed-by: kustomize
    app.kubernetes.io/name: fsh-ai-operator
  name: ibm-softwarehub-service-instance
```

```

namespace: ibm-software-hub-operator
spec: {}
status:
  cpdServiceEndpoint: 'https://xxxx.ibm.com'
  cpdServiceEndpointSecret: ibm-iam-bindinfo-platform-auth-idp-credentials
  health: Healthy
  healthStatuses:
    - message:
        message: Operators & Operands are healthy
        messageCode: BMYSH0106
        serviceName: SoftwareHub
        status: Healthy
  installStatus:
    messages:
      - message: Installed SoftwareHub installed and healthy
        messageCode: BMYSH0102
    progressPercentage: 100
    retryOnFailure: true
    status: Completed
    installedVersion: 5.4.0
    upgradeStatus: {}

```

After successfully installing Software Hub, you can access the IBM watsonx dashboard by clicking the URL present in field `cpdServiceEndpoint` and use the credentials that are present in secret `ibm-iam-bindinfo-platform-auth-idp-credentials`.
 Note: The secret is present in the `cpd-instance` namespace.

- [Installing watsonx.ai service](#)
Initiate the installation of watsonx.ai service from the user interface of IBM Fusion.
- [Installing watsonx Orchestrate service](#)
Initiate the installation of watsonx Orchestrate service from the user interface of IBM Fusion.

Installing watsonx.ai service

Initiate the installation of watsonx.ai service from the user interface of IBM Fusion.

Before you begin

Ensure that you meet all the prerequisites for a successful installation of the watsonx.ai service. For more information, see [Prerequisites](#).

About this task

Use this procedure to install the watsonx.ai service from the Services page of the IBM Fusion user interface.

Procedure

1. In the IBM Fusion user interface, go to Services page.
2. In the Available section, click the Watsonx.ai tile.
3. In the Watsonx.ai page, go through the features and capabilities of the service and click Install.
 If the pre-check raises a warning, then resolve it at OpenShift® level.
 The installation starts and a notification appears on the Services page. You can see the progress of the installation in the Services > **Installed** section. After the installation is completed successfully, you can see the status as Healthy. A success notification gets displayed. It disappears automatically after some time.
 From the ellipsis menu, you can download logs and view documentation.
4. Validate the installation.
 - Verify the watsonx.ai installation from the IBM Fusion user interface:
 After you enable the watsonx.ai service, you can view the service version and health status. From the ellipsis menu, you can download logs and view documentation. After you successfully collect the logs, a success notification is displayed. The notification disappears automatically after some time.
 - Verify the watsonx.ai installation from the OpenShift Container Platform web console:
 - In the OpenShift console, go to Home > CustomResourceDefinition.
 - In the CustomResourceDefinition page, search and check for the **WatsonxAIManager** CR.
 - After you enable the watsonx.ai service, you can view the service version and health status. From the ellipsis menu, you can download logs and view documentation. After you successfully collect the logs, a success notification is displayed. The notification disappears automatically after some time.

What to do next

1. If a failure occurs, check for pods in the `cpd-instance` and `cpd-operator` namespaces.
2. For post installation instructions, check the following details:
 - For watsonx.ai, see [Post-installation setup for IBM watsonx.ai](#).

Installing watsonx Orchestrate service

Initiate the installation of watsonx Orchestrate service from the user interface of IBM Fusion.

Before you begin

- Ensure that you meet all the prerequisites for a successful installation of the watsonx Orchestrate service. For more information, see [Prerequisites](#).
- For watsonx Orchestrate, a new flag, **EnableGPUPrechecks**, is introduced. By default, this flag is set to **false**, indicating that you are using an external Large Language Model (LLM). In this case, prechecks for the GPU operator and Node Feature Discovery (NFD) operator are not performed. To use an internal LLM, users can set the **EnableGPUPrechecks** flag to **true**, which triggers additional prechecks for the NFD and GPU operators.

About this task

Use this procedure to install the watsonx Orchestrate service from the Services page of the IBM Fusion user interface.

Procedure

1. In the IBM Fusion user interface, go to Services page.
2. In the Available section, click the Watsonx.Orchestrate tile.
3. In the Watsonx.Orchestrate page, go through the features and capabilities of the service and click Install.
If the pre-check raises a warning, then resolve it at OpenShift® level.
The installation starts and a notification appears on the Services page. You can see the progress of the installation in the Services > **Installed** section. After the installation is completed successfully, you can see the status as Healthy. A success notification gets displayed. It disappears automatically after some time.

From the ellipsis menu, you can download logs and view documentation.
4. Validate the installation.
 - Verify the watsonx Orchestrate installation from the IBM Fusion user interface:
After you enable the watsonx Orchestrate service, you can view the service version and health status. From the ellipsis menu, you can download logs and view documentation. After you successfully collect the logs, a success notification is displayed. The notification disappears automatically after some time.
 - Verify the watsonx Orchestrate installation from the OpenShift Container Platform web console:
 - In the OpenShift console, go to Home > CustomResourceDefinition.
 - In the CustomResourceDefinition page, search and check for the **WatsonxOrchestrateManager** CR.
 - After you enable the watsonx Orchestrate service, you can view the service version and health status. From the ellipsis menu, you can download logs and view documentation. After you successfully collect the logs, a success notification is displayed. The notification disappears automatically after some time.

What to do next

1. If a failure occurs, check for pods in the **cpd-instance** and **cpd-operator** namespaces.
2. For post installation instructions, check the following details:
 - For watsonx Orchestrate, see [Post-installation setup for watsonx Orchestrate](#).

Troubleshooting issues and known limitations in Software Hub

The common troubleshooting steps and limitations in the Software Hub service.

Software Hub, IBM watsonx, and watsonx Orchestrate services installation fails due to Podman runtime errors

Problem statement

During the installation of Software Hub, the deployment can fail due to container runtime errors related to Podman. These errors prevent required installation steps from completing.

In the operator logs, the failure appears as follows:

```
Ansible execution failed: exit status 2
```

```
User specified container image: icr.io/cpopen/cpd/olm-utils-v4:5.3.1, but error detected:  
cannot clone: Operation not permitted  
Error: cannot re-exec process
```

```
Attempting pull container image icr.io/cpopen/cpd/olm-utils-v4:5.3.1
```

```
Pulling image output:  
cannot clone: Operation not permitted  
Error: cannot re-exec process
```

```
Command exception: exit status 125  
RunPluginCommand: Execution error: exit status 1
```

Impact

- The Software Hub installation fails during the Ansible execution phase.
- The **olm-utils-v4** container image cannot be pulled or executed.

Root cause

This issue occurs due to insufficient container runtime permissions. A recent change introduced enforces stricter security constraints that prevent Podman from performing required operations.

As a result, containers fail to execute unless elevated privileges are explicitly allowed.

Resolution

To resolve this issue, update the Software Hub ClusterServiceVersion (CSV) to allow the required elevated privileges for Podman.

- Option 1: Update the security context in the CSV
Add the following security context settings:

```
securityContext:
  privileged: true
  allowPrivilegeEscalation: true
```

And:

```
securityContext:
  runAsNonRoot: false
  runAsUser: 0
```

- Option 2: Patch the CSV by using the CLI
Run the following command to apply the required security context settings:

```
oc patch csv ibm-fsh-operator.v1.0.3 \
-n ibm-software-hub-operator \
--type='json' \
-p='[
{
  "op": "add",
  "path": "/spec/install/spec/deployments/0/spec/template/spec/securityContext/runAsUser",
  "value": 0
},
{
  "op": "add",
  "path": "/spec/install/spec/deployments/0/spec/template/spec/securityContext/runAsNonRoot",
  "value": false
},
{
  "op": "add",
  "path": "/spec/install/spec/deployments/0/spec/template/spec/containers/0/securityContext/privileged",
  "value": true
},
{
  "op": "add",
  "path":
"/spec/install/spec/deployments/0/spec/template/spec/containers/0/securityContext/allowPrivilegeEscalation",
  "value": true
}
]'
```

Existing configuration:

```
securityContext:
  capabilities:
    drop:
      - ALL
  privileged: false
  allowPrivilegeEscalation: false
```

New configuration:

```
securityContext:
  privileged: true
  allowPrivilegeEscalation: true
```

Known limitations

- When installing an Inference Foundation Model, such as **llama3-1-8b**, the installation starts but the **watsonxaiifm** operator reconciliation stops at 60%. Do not upgrade to NVIDIA GPU Operator version 25.10. For more information on troubleshooting this issue, see [Watsonx.ai model installation stuck at 60% reconciliation](#). Note: This limitation is not applicable to IBM Software Hub v5.3.x.
- If you upgrade from an older version of OpenShift® Container Platform to version 4.20, IBM Software Hub 5.2.2 is not supported. If you plan to install any Blue Stack services, perform a fresh installation of IBM Fusion 2.12 only on OCP versions up to 4.19.
- In the IBM Fusion user interface, IBM watsonx service tiles showing version 1.0.0, while the installed version is 5.2.2.
- When upgrading Software Hub from version 5.2.2 to 5.3.0, the IBM Fusion user interface might display a **Precheck Failed** status for Watsonx services. This indication is false and does not necessarily signify an actual failure. To confirm the upgrade status, check the status of the **WatsonxAIManager CR ibm-watsonxai-service-instance** or **WatsonxOrchestrateManager ibm-watsonxorchestrate-service-instance**, specifically the **environmentReadiness** section. If all entries in **environmentReadiness**, such as **SoftwareHubHealth**, **NFDCRHealth**, and **GPUClusterPolicyHealth**, report a healthy or ready state with **INFO** messages, the environment is valid. In this case, you can safely upgrade the watsonx services, disregarding the **Precheck Failed** status in the IBM Fusion user interface.

For example:

```
environmentReadiness:
- category: SoftwareHubHealth
  message: Software Hub has been upgraded to latest version.
  messageCode: BMYSH0111
  messageType: INFO
  noRedirection: false
  prechecks:
    - ibm-watsonxorchestrate-service-instance
    skipEnvironmentalCheck: false
- category: NFDCRHealth
  message: NFD CR is in Ready state.
  messageCode: BMYCO0305
```

```
messageType: INFO
noRedirection: false
prechecks:
  - ibm-watsonxorchestrate-service-instance
skipEnvironmentalCheck: false
- category: GPUClusterPolicyHealth
message: GPU ClusterPolicy gpu-cluster-policy is in Ready state.
messageCode: BMYCO0355
messageType: INFO
noRedirection: false
prechecks:
  - ibm-watsonxorchestrate-service-instance
```

Lakehouse-Table [Technology preview]

The Lakehouse-Table service is a Kubernetes-native solution for building and managing lakehouse infrastructure on IBM Fusion. It provides a simplified experience for administrators to provision and manage Data Lakehouse capabilities.

Important:

Lakehouse-Table service is a Technology Preview feature and is subject to Technology Preview support limitations. Technology Preview features are not supported with Red Hat® production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information, see [Technology Preview Features Support Scope](#).

The Lakehouse-Table service enables administrators to create a foundational lakehouse environment, including object storage integration, Iceberg catalog management, and integration with the IBM watsonx.data. This service is the entry point for building a complete data lakehouse experience on IBM Fusion.

Key features and benefits

- It provides a simplified experience for building and managing lakehouse infrastructure.
- It is tightly integrated with IBM watsonx.data, enabling seamless data management and analytics.
- It automates infrastructure provisioning by using operators, reducing manual configuration and minimizing errors.
- It provides a Kubernetes-native experience, enabling administrators to manage lakehouse infrastructure using familiar tools and workflows.
- [Installing Lakehouse-Table service](#)
Initiate the installation of Lakehouse-Table service from the user interface of IBM Fusion.
- [Configuring Lakehouse-Table service](#)
Use the instructions to configure the Lakehouse-Table service by creating an `OpenTableCatalog` resource and verifying its creation.
- [Troubleshooting issues and known limitations in Lakehouse-Table](#)
The common troubleshooting steps and limitations in the Lakehouse-Table service.

Installing Lakehouse-Table service

Initiate the installation of Lakehouse-Table service from the user interface of IBM Fusion.

Before you begin

To ensure a successful installation of the Software Hub service, verify that the following prerequisites are met:

- IBM Fusion is installed and configured.
- The necessary storage classes are available:
 - Block storage (RBD)
 - Filesystem storage (CephFS)
Note: As part of a fresh installation, the latest version of Red Hat® certificate Manager is installed with Software Hub.
 - Object storage (RGW)
- The following table outlines the compatibility matrix for the components involved, including the minimum supported versions.

Table 1. Compatibility Matrix for Components

Component	Minimum supported version
IBM Cloud Paks for Data	5.4
watsonx.data	2.4
Data Lakehouse-Table	1.0.0
Fusion Data Foundation	4.22

Note: The versions listed are the minimum supported versions. Using versions later than those listed is supported unless otherwise noted.

About this task

Use this procedure to install the Lakehouse-Table service from the Services page of the IBM Fusion user interface.

Procedure

1. Before installing Lakehouse-Table, ensure that IBM `Cert Manager` is not installed and that the `ibm-cert-manager` namespace does not exist. If either is present, uninstall IBM `Cert Manager` and delete the namespace.
Note: As part of a fresh installation, the latest version of Red Hat® certificate Manager is installed with Software Hub.
2. In the IBM Fusion user interface, go to Services page.

3. In the Available section, click the Lakehouse-Table tile.
It opens a Lakehouse-Table service page.
4. In the Lakehouse-Table page, go through the features and capabilities of the service and click Install.
It opens a Lakehouse-Table install service page.
The installation starts and a notification appears on the Services page. You can see the progress of the installation in the Services > Installed section. After the installation is completed successfully, you can see the status as Healthy. A success notification gets displayed. It disappears automatically after some time.

From the ellipsis menu, you can download logs and view documentation.

5. Validate the installation.
 - Verify the Lakehouse-Table installation from the IBM Fusion user interface:
After you enable the Lakehouse-Table service, you can view the service version and health status. From the ellipsis menu, you can download logs and view documentation. After you successfully collect the logs, a success notification is displayed. The notification disappears automatically after some time.
 - Verify the Lakehouse-Table installation from the OpenShift® Container Platform web console:
 - In the OpenShift console, go to Home > CustomResourceDefinition.
 - In the CustomResourceDefinition page, search and check for the **LakehouseManager** CR.
Lakehouse-Table service also installs Software Hub in a separate namespace with the **SoftwareHubManager** custom resource named **lakehouse-table-softwarehub**.
 - After you enable the Lakehouse-Table service, you can view the service version and health status. From the ellipsis menu, you can download logs and view documentation. After you successfully collect the logs, a success notification is displayed. The notification disappears automatically after some time.

Configuring Lakehouse-Table service

Use the instructions to configure the Lakehouse-Table service by creating an **OpenTableCatalog** resource and verifying its creation.

Before you begin

Ensure that you meet all the prerequisites before you configure the Lakehouse-Table service.

Configure the global ConfigMap as follows:

Important:

- Before creating catalogs, configure the global ConfigMap for the operator to provide default values. This way, you can create minimal catalog custom resources without duplicating the configuration.
- IBM Fusion automatically populates the global ConfigMap. If necessary, you can update the details.
- Set **CPD_HOST** to the base URL of the IBM Software Hub (formerly Cloud Pak for Data) instance. The operator derives the token endpoint as **{CPD_HOST}/icp4d-api/v1/authorize**.

1. Run the following command to edit the global ConfigMap:

```
oc edit configmap ibm-isf-lakehouse-tables-operator-global-config -n lakehouse-tables-operator-system
```

2. Configure the required settings.

For example:

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: ibm-isf-lakehouse-tables-operator-global-config
  namespace: lakehouse-tables-operator-system
data:
  # RGW Configuration
  RGW_ADMIN_USER_SECRET_NAME: "rook-ceph-object-user-ocs-storagecluster-cephobjectstore-lakehouse-rgw-admin-user"
  RGW_NAMESPACE: "openshift-storage"
  RGW_TLS_DISABLED: "false"
  RGW_TLS_CERT_CONFIGMAP_REF: "openshift-service-ca.crt"
  RGW_TLS_KEY: "service-ca.crt"

  # watsonx.data Configuration
  WATSONX_MODE: "standalone_mds"
  CPD_ROUTE: "https://cpd-lakehouse-table-cpd-instance.apps.f551020.fusion.tadn.ibm.com"
  CPD_HOST: "https://internal-nginx-svc.lakehouse-table-cpd-instance.svc.cluster.local:12443"

  # MDS Configuration
  MDS_URI: "https://ibm-lh-lakehouse-mds-rest-svc.lakehouse-table-cpd-instance.svc.cluster.local:8180/mds/metadata/v1"
  MDS_USERNAME: "cpadmin"
  MDS_PASSWORD_SECRET_NAME: "ibm-iam-bindinfo-platform-auth-idp-credentials"
  MDS_NAMESPACE: "lakehouse-table-cpd-instance"
  MDS_AUTH_INSTANCE_ID: "1787641357575284"
  MDS_TOKEN_TYPE: "Bearer"

  # MDS TLS Configuration
  MDS_TLS_DISABLED: "false"
  MDS_TLS_CERT_SECRET_REF: "ibm-lh-tls-secret"
  MDS_TLS_KEY: "cabundle.crt"
```

Procedure

To create an **OpenTableCatalog** resource, follow these steps:

- a. You can create an **OpenTableCatalog** resource by using either a minimal catalog configuration or an explicit catalog configuration.

Minimal catalog configuration

- i. Create a file named `my-catalog-minimal.yaml` with the following content:

```
apiVersion: lakehouse-tables.isf.ibm.com/v1alpha1
kind: OpenTableCatalog
metadata:
  name: my-iceberg-catalog
  namespace: lakehouse-table-cpd-instance
spec:
  catalog:
    tableFormat: "iceberg"
```

- ii. Run the following command to apply the resource:

```
oc apply -f my-catalog-minimal.yaml
```

Explicit catalog configuration (optional)

If you prefer to specify all values explicitly or override the global configuration, create a file that is named `my-catalog.yaml` with the following content:

```
apiVersion: lakehouse-tables.isf.ibm.com/v1alpha1
kind: OpenTableCatalog
metadata:
  name: my-iceberg-catalog
  namespace: lakehouse-table-cpd-instance
spec:
  objectStore:
    adminUser:
      secretName: rook-ceph-object-user-ocs-rgw-rgw-user
      secretNamespace: openshift-storage
    tls:
      disabled: true
  bucketName: my-data-bucket
  iamResources:
    account:
      accountId: "RGW12345678901234567"
      accountName: "my-data-account"
      rootUserName: "my-account-root"
      userName: "my-data-user"
      roleName: "my-data-role"
      policyName: "my-data-policy"
  catalog:
    catalogName: "my_catalog"
    server:
      lakehouse:
        mdsUri: "https://ibm-lh-lakehouse-mds-rest-svc.lakehouse-table-cpd-instance.svc.cluster.local:8180/mds/metadata/v1"
        userName: "cpadmin"
        passwordSecretRef:
          secretName: "ibm-iam-bindinfo-platform-auth-idp-credentials"
          secretNamespace: "lakehouse-table-cpd-instance"
        cpdHost: "https://cpd-lakehouse-table-cpd-instance.<your-domain>"
      tls:
        disabled: true
    tableFormat: "iceberg"
```

- b. Run the following command to apply the resource:

```
oc apply -f my-catalog.yaml
```

- c. Run the following command to verify that the `OpenTableCatalog` resource is created successfully:

```
oc -n lakehouse-table-cpd-instance get otc my-iceberg-catalog -o jsonpath='{.status}' | jq -r .
```

Example status:

```
{
  "accountId": "RGW63652856098721134",
  "info": {
    "catalogName": "my-iceberg-catalog",
    "catalogStorageBackend": "my-data-bucket",
    "cpdHost": "https://internal-nginx-svc.lakehouse-table-cpd-instance.svc.cluster.local:12443",
    "cpdRoute": "https://cpd-lakehouse-table-cpd-instance.apps.f551020.fusion.tadn.ibm.com",
    "mdsUri": "https://ibm-lh-lakehouse-mds-rest-svc.lakehouse-table-cpd-instance.svc.cluster.local:8180/mds/iceberg",
    "objectStoreEndpoint": "https://rook-ceph-rgw-ocs-storagecluster-cephobjectstore.openshift-storage.svc:443",
    "userName": "<openshift-username>",
    "watsonxMode": "standalone_mds"
  },
  "phase": "Ready"
}
```

The operator creates the following resources:

- S3 bucket: `my-data-bucket`
- IAM account with root user
- IAM user, role, and policy
- Iceberg catalog registered in Lakehouse-Table
- Access grants for the OpenShift requester on the catalog and storage resources in the Access Management Service.

- d. To use the `catalog`, obtain a IBM Software Hub bearer token with the OpenShift® user identity and a IBM Software Hub API key. Set `CPD_HOST` to the IBM Software Hub base URL and follow these steps:

- i. Create a IBM Software Hub API key for the OpenShift user through the IBM Software Hub console or API. Store the API key in a Kubernetes secret:

```
curl -s -X GET "${CPD_HOST}/usermgmt/v1/user/apiKey" \
-H "Accept: application/json" \
-H "Authorization: Bearer ${TOKEN}" \
| jq .
```

```
# Store the API key in a Kubernetes Secret
oc create secret generic lakehouse-catalog-admin-cpd-apikey \
-n lakehouse-catalog-admin \
--from-literal=apiKey=PAT-xxxxxxx-xxxx-xxxx-xxxxxxxxxxxx
```

ii. Run the following command to obtain a bearer token. Replace the placeholder values with the OpenShift username and API key:

```
curl -X POST "${CPD_HOST}/icp4d-api/v1/authorize" \
-H "Content-Type: application/json" \
-d '{"api_key": "<API_KEY>", "username": "<openshift-username>"}' | jq -r '.token'
```

iii. Use the bearer token with the `catalog` resource.

e. Create an additional `OpenTableCatalogUser`, and add the CRD to the configuration.

Minimal CRD (catalog use only)

```
apiVersion: lakehouse-tables.isf.ibm.com/v1alpha1
kind: OpenTableCatalogUser
metadata:
  name: analyst-user
  namespace: cpd-instance
spec:
  resource:
    catalogRef: opentablecatalog-sample
    permission: use
```

Minimal CRD with L3 data policies

```
apiVersion: lakehouse-tables.isf.ibm.com/v1alpha1
kind: OpenTableCatalogUser
metadata:
  name: invoice-user
  namespace: cpd-instance
spec:
  catalogUser:
    userName: invoice-user
  resource:
    catalogRef: opentablecatalog-sample
    permission: use
    dataPolicies:
      - scope: table
        target: sales.invoices
        permissions: ["read"]
```

f. Optional: Run the following command to delete the resource:

```
oc delete otc my-iceberg-catalog -n lakehouse-table-cpd-instance
```

The data is retained even if you delete the resource.

Troubleshooting issues and known limitations in Lakehouse-Table

The common troubleshooting steps and limitations in the Lakehouse-Table service.

Catalog creation fails

Problem statement

The `OpenTableCatalog` resource shows an error in its status, indicating a failure in catalog creation.

Cause

The cause of the failure can be attributed to several factors, including:

- Incorrect RGW admin credentials.
- Network connectivity issues to RGW and `watsonx.data`.
- Invalid TLS certificates if TLS is enabled.
- Detailed error messages available in the operator logs.

Resolution

To resolve the issue, follow these steps:

1. Verify that the RGW admin credentials are correct.
2. Check the network connectivity to RGW and `watsonx.data`.
3. Ensure that the TLS certificates are valid if TLS is enabled.
4. Check the operator logs for detailed error messages to diagnose the issue.

Cannot access catalog from Spark or Trino

Problem statement

Authentication errors occur when querying the catalog from Spark or Trino.

Cause

The cause of the authentication errors can be due to:

- Missing or incorrect bearer token secret.

- Expired bearer token.
- Vended credentials not enabled in the catalog configuration.
- Inaccessibility of the S3 endpoint from the query engine pods.

Resolution

To resolve the issue, follow these steps:

1. Verify that the bearer token secret exists using the command `oc get secret <catalog-name>-fetch-bearer-token`.
2. Check the token expiration and refresh it if necessary.
3. Ensure that vended credentials are enabled in the catalog configuration.
4. Verify that the S3 endpoint is accessible from the query engine pods.

Out-of-Memory (OOM) issues

Problem statement

Exceeding the specified limits in the catalog table configuration can result in OOM issues on IO engines, MDS, and other components.

Symptoms

- OOM errors occur on IO engines, MDS, or other components.
- System performance degrades or becomes unresponsive.

Cause:

The following limits, when exceeded, can cause OOM issues:

- Total artifacts exceeding 900 in a single catalog.
- Total number of schemas exceeding 250.
- Total number of tables exceeding 1250.
- Number of rows exceeding 80,000 (with 5 columns) or 250,000 (with 5 columns) in a table.
- Number of `OpenTableCatalogUser` exceeding 250.
- Number of IO engines (Trino) exceeding 5 with 4G RAM.

Resolution

Follow the steps to resolve the issue:

1. Ensure that the total number of artifacts, schemas, tables, and rows are within the specified limits.
2. Distribute data across multiple catalogs, schemas, or tables to avoid exceeding the specified limits.
3. Limit the number of IO engines (Trino) to 5 or fewer with 4G RAM, or increase the RAM allocation as needed.
4. Regularly monitor system performance and adjust configuration as needed to prevent OOM issues.

Known limitations

- When installing Lakehouse-Table service, the `ibm-cpd-ae-operator` pod may encounter an `ImagePullBackOff` error. As a resolution, run the following command to patch the `ibm-cpd-ae-operator` deployment:

```
oc patch deployment ibm-cpd-ae-operator -n cpd-operator \
--type='json' \
-p='[
  {
    "op": "replace",
    "path": "/spec/template/spec/containers/0/image",
    "value": "cp.stg.icr.io/cp/ibm-cpd-analyticsengine-
operator@sha256:7f9ceed629755a77a4443059fee31b677a3d9f8dcad82336892ee77fd252b83e"
  }
]'
```

watsonx.data (WXD)

The watsonx.data service delivers a complete, enterprise-ready data lakehouse platform in IBM Fusion.

The watsonx.data service (WXD) simplifies data management for analytics and AI workloads by providing a unified platform to store, organize, govern, and query enterprise data.

WXD is a superset of the Lakehouse-Table service in terms of features and capabilities:

Table 1. Comparison between Lakehouse-Table and watsonx.data

Capability	Lakehouse-Table	watsonx.data (WXD)
Apache Iceberg catalog management	Yes	Yes
Object storage integration	Yes	Yes
Kubernetes-native operator deployment	Yes	Yes
Integration with IBM watsonx.data platform	Yes (entry point)	Native
Web-based management UI (WXD-UI)	No	Yes
Query engines (Presto, Spark, and more)	No, only external engine connectivity	Yes, in-house engines
SQL query workspace	No	Yes
Infrastructure topology visualization	No	Yes
Data ingestion	Limited	Full platform

Where Lakehouse-Table focuses on foundational lakehouse infrastructure such as object storage integration, Iceberg catalog management, and operator-based provisioning, WXD delivers the complete watsonx.data experience. It includes the management console, query engines, and end-to-end data lakehouse operations.

Key features and benefits

- Unified lakehouse platform: Store, organize, and analyze structured and unstructured data by using open formats such as Apache Iceberg.
- WXD-UI (watsonx.data console): A rich web interface for provisioning, monitoring, and managing the entire lakehouse environment.
- One-click installation: Deploy WXD from the IBM Fusion Services catalog with operator-based automation, reducing manual configuration and operational complexity.
- In-house query engines: Built-in Presto and Spark engines and related services enable interactive SQL, ETL, and analytics workloads directly on the platform.
- Open and flexible: Engine-agnostic metadata management, support for multiple object storage backends, and open table formats help avoid vendor lock-in.
- Tight IBM Fusion integration: WXD runs on the IBM Fusion-managed OpenShift® platform and can use IBM Fusion storage services (for example, Data Foundation and storage acceleration) for production-grade deployments.
- Scalable architecture: Compute and storage resources scale independently to optimize utilization.

WXD-UI capabilities

After installation, administrators and data engineers access the watsonx.data console (WXD-UI) to manage lakehouse. Key areas of the user interface include:

Home dashboard

- Overview of infrastructure component counts including engines, catalogs, storage, and data sources
- Recent tables, ingestion jobs, saved worksheets, and query history
- Alerts about infrastructure health and active queries
- Quick links to recommended getting started resources

Infrastructure manager

The Infrastructure manager provides a visual topology of the lakehouse environment. Components are organized in layers:

- Engines: Query and compute engines (for example, Presto Java, Presto C++, native Spark, and serverless Spark)
- Catalogs: Metadata catalogs (for example, Apache Iceberg catalogs) connected to engines and storage
- Storage: Object storage registrations (for example, IBM Storage Ceph, Amazon S3, MinIO, and IBM Cloud Object Storage)
- Databases or services: Optional specialty services (for example, vector databases)

By using the Infrastructure manager, administrators can:

- Add and associate engines, catalogs, and storage.
- View component definitions, associations, and access control.
- Scale, pause, resume, and manage the engine lifecycle.
- Switch between graph and list views.

Query workspace

- Run SQL queries against registered catalogs and engines.
- Use built-in benchmark catalogs (for example, TPC-H and TPC-DS) for testing.
- Save worksheets and review query history.

Data and access management

- Register and manage object storage backends.
- Configure catalog-to-engine associations.
- Manage users, roles, and resource-level access policies.
- Monitor ingestion jobs and table maintenance operations.

For more UI details, see [IBM watsonx.data documentation](#).

- [Installing watsonx.data service](#)
Install the watsonx.data service from the IBM Fusion console.

Use the instructions to configure the watsonx.data service by creating an `OpenTableCatalog` resource and verifying its creation.
- [Troubleshooting issues and known limitations in watsonx.data](#)
Common troubleshooting steps, suggested checks, and known limitations for the watsonx.data service.

Installing watsonx.data service

Install the watsonx.data service from the IBM Fusion console.

Before you begin

Ensure that the following prerequisites are met before installing the watsonx.data (WXD) service:

- An IBM Fusion environment with a supported OpenShift® version.
- The required storage classes are available:
 - Block storage (RBD)
 - Filesystem storage (CephFS)
 - Object storage (RGW)
- A valid watsonx.data license. WXD requires a separate watsonx.data entitlement. Contact [IBM Support](#) representative for licensing information.
- Sufficient cluster resources (CPU, memory, and storage) for WXD platform components and optional engines.

- ```
apiVersion: service.ksf.ibm.com/v1

```

- The following table outlines the compatibility matrix for the components involved, including the minimum supported versions:

Table 1. Compatibility matrix for components

Component	Minimum supported version
IBM Cloud Paks for Data	5.4
watsonx.data	2.4
Fusion Data Foundation	4.22

Note: The versions listed are the minimum supported versions. Using versions later than those listed is supported unless otherwise noted.

About this task

Use this procedure to install the watsonx.data service from the Services page in the IBM Fusion console.

Procedure

- Log in to the IBM Fusion console.
- From the left navigation menu, select Services.
- In the Available section, locate the watsonx.data tile.
- Click the tile to open the service details page.
- Review the service description, capabilities, and prerequisites.
- Accept the licensing requirement.
- Click Install.

IBM Fusion uses Red Hat® OpenShift operators to automate deployment, providing a consistent setup that simplifies upgrades and reduces operational complexity.

Results

The installation starts and the progress displays in the Services > Installed section.

What to do next

Verify installation

After the installation completes, follow these steps to verify that the service is running and launch the console:

- Go to Services > Installed.
- Confirm that the watsonx.data tile shows status Running.
- Click the overflow menu and select Launch UI to access the watsonx.data console.

IBM Fusion redirects administrators to the IBM Software Hub UI to access the watsonx.data service.

In the IBM Software Hub UI:

- Go to Services > Instances.
- Locate the watsonx.data service instance.
- Open the watsonx.data service instance.
- Click Open to launch the watsonx.data console UI in a new browser context.

Administrators can then access watsonx.data capabilities such as Infrastructure Manager, Query Workspace, and other WXD functionality.

Tip: If the watsonx.data service instance is not visible, the logged-in user must first be assigned access to the watsonx.data service instance. After the user is granted access, the instance appears under Services > Instances in the IBM Software Hub.

Configuring watsonx.data service

Use the instructions to configure the watsonx.data service by creating an `OpenTableCatalog` resource and verifying its creation.

Before you begin

Ensure that you meet all the prerequisites before you configure the watsonx.data service.

Configure the global ConfigMap as follows:

Important:

- Before creating catalogs, configure the global ConfigMap for the operator to provide default values. This way, you can create minimal catalog custom resources without duplicating the configuration.
- IBM Fusion automatically populates the global ConfigMap. If necessary, you can update the details.

- Set `CPD_HOST` to the base URL of the IBM Software Hub (formerly Cloud Pak for Data) instance. The operator derives the token endpoint as `{CPD_HOST}/icp4d-api/v1/authorize`.

1. Run the following command to edit the global ConfigMap:

```
oc edit configmap ibm-isf-lakehouse-tables-operator-global-config -n lakehouse-tables-operator-system
```

2. Configure the required settings.

For example:

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: ibm-isf-lakehouse-tables-operator-global-config
  namespace: lakehouse-tables-operator-system
data:
  # RGW Configuration
  RGW_ADMIN_USER_SECRET_NAME: "rook-ceph-object-user-ocs-storagecluster-cephobjectstore-lakehouse-rgw-admin-user"
  RGW_NAMESPACE: "openshift-storage"
  RGW_TLS_DISABLED: "false"
  RGW_TLS_CERT_CONFIGMAP_REF: "openshift-service-ca.crt"
  RGW_TLS_KEY: "service-ca.crt"

  # watsonx.data Configuration
  WATSONX_MODE: "full"
  CPD_ROUTE: "https://cpd-lakehouse-table-cpd-instance.apps.f551020.fusion.tadn.ibm.com"
  CPD_HOST: "https://internal-nginx-svc.lakehouse-table-cpd-instance.svc.cluster.local:12443"

  # MDS Configuration
  MDS_URI: "https://cpd-lakehouse-table-cpd-instance.apps.f551020.fusion.tadn.ibm.com/watsonx-data/lakehouse/api/v3"
  MDS_USERNAME: "cpadmin"
  MDS_PASSWORD_SECRET_NAME: "ibm-iam-bindinfo-platform-auth-idp-credentials"
  MDS_NAMESPACE: "lakehouse-table-cpd-instance"
  MDS_AUTH_INSTANCE_ID: "1787641357575284"
  MDS_TOKEN_TYPE: "Bearer"

  # MDS TLS Configuration
  MDS_TLS_DISABLED: "false"
  MDS_TLS_CERT_SECRET_REF: "ibm-lh-tls-secret"
  MDS_TLS_KEY: "cabundle.crt"
```

Procedure

To create an `OpenTableCatalog` resource, follow these steps:

a. You can create an `OpenTableCatalog` resource by using either a minimal catalog configuration or an explicit catalog configuration.

Minimal catalog configuration

i. Create a file named `my-catalog-minimal.yaml` with the following content:

```
apiVersion: lakehouse-tables.isf.ibm.com/v1alpha1
kind: OpenTableCatalog
metadata:
  name: my-iceberg-catalog
  namespace: lakehouse-table-cpd-instance
spec:
  catalog:
    tableFormat: "iceberg"
```

ii. Run the following command to apply the resource:

```
oc apply -f my-catalog-minimal.yaml
```

Explicit catalog configuration (optional)

If you prefer to specify all values explicitly or override the global configuration, create a file that is named `my-catalog.yaml` with the following content:

```
apiVersion: lakehouse-tables.isf.ibm.com/v1alpha1
kind: OpenTableCatalog
metadata:
  name: my-iceberg-catalog
  namespace: lakehouse-table-cpd-instance
spec:
  objectStore:
    adminUser:
      secretName: rook-ceph-object-user-ocs-rgw-rgw-user
      secretNamespace: openshift-storage
    tls:
      disabled: true
  bucketName: my-data-bucket
  iamResources:
    account:
      accountId: "RGW12345678901234567"
      accountName: "my-data-account"
      rootUserName: "my-account-root"
      userName: "my-data-user"
      roleName: "my-data-role"
      policyName: "my-data-policy"
  catalog:
    catalogName: "my_catalog"
  server:
    lakehouse:
      mdsUri: "https://ibm-lh-lakehouse-mds-rest-svc.lakehouse-table-cpd-instance.svc.cluster.local:8180/mds/metadata/v1"
```

```

    userName: "cpadmin"
    passwordSecretRef:
      secretName: "ibm-iam-bindinfo-platform-auth-idp-credentials"
      secretNamespace: "lakehouse-table-cpd-instance"
    cpdHost: "https://cpd-lakehouse-table-cpd-instance.<your-domain>"
    tls:
      disabled: true
    tableFormat: "iceberg"

```

b. Run the following command to apply the resource:

```
oc apply -f my-catalog.yaml
```

c. Run the following command to verify that the `OpenTableCatalog` resource is created successfully:

```
oc -n lakehouse-table-cpd-instance get otc my-iceberg-catalog -o jsonpath='{.status}' | jq -r .
```

Example status:

```

{
  "accountId": "RGW63652856098721134",
  "info": {
    "catalogName": "my-iceberg-catalog",
    "catalogStorageBackend": "my-data-bucket",
    "cpdHost": "https://internal-nginx-svc.lakehouse-table-cpd-instance.svc.cluster.local:12443",
    "cpdRoute": "https://cpd-lakehouse-table-cpd-instance.apps.f551020.fusion.tadn.ibm.com",
    "mdsUri": "https://ibm-lh-lakehouse-mds-rest-svc.lakehouse-table-cpd-instance.svc.cluster.local:8180/mds/iceberg",
    "objectStoreEndpoint": "https://rook-ceph-rgw-ocs-storagecluster-cephobjectstore.openshift-storage.svc:443",
    "userName": "<openshift-username>",
    "watsonxMode": "full"
  },
  "phase": "Ready"
}

```

The operator creates the following resources:

- S3 bucket: `my-data-bucket`
- IAM account with root user
- IAM user, role, and policy
- Iceberg catalog registered in `watsonx.data`
- Access grants for the OpenShift requester on the catalog and storage resources in the Access Management Service.

d. To use the `catalog`, obtain a IBM Software Hub bearer token with the OpenShift® user identity and a IBM Software Hub API key. Set `CPD_HOST` to the IBM Software Hub base URL and follow these steps:

i. Create a IBM Software Hub API key for the OpenShift user through the IBM Software Hub console or API. Store the API key in a Kubernetes secret:

```

curl -s -X GET "${CPD_HOST}/usermgmt/v1/user/apiKey" \
-H "Accept: application/json" \
-H "Authorization: Bearer ${TOKEN}" \
| jq .

# Store the API key in a Kubernetes Secret
oc create secret generic lakehouse-catalog-admin-cpd-apikey \
-n lakehouse-catalog-admin \
--from-literal=apiKey=PAT-xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx

```

ii. Run the following command to obtain a bearer token. Replace the placeholder values with the OpenShift username and API key:

```

curl -X POST "${CPD_HOST}/icp4d-api/v1/authorize" \
-H "Content-Type: application/json" \
-d '{"api_key":"<API_KEY>","username":"<openshift-username>"}' | jq -r '.token'

```

iii. Use the bearer token with the `catalog` resource.

e. Create an additional `OpenTableCatalogUser`, and add the CRD to the configuration.

Minimal CRD (catalog use only)

```

apiVersion: lakehouse-tables.isf.ibm.com/v1alpha1
kind: OpenTableCatalogUser
metadata:
  name: analyst-user
  namespace: cpd-instance
spec:
  resource:
    catalogRef: opentablecatalog-sample
    permission: use

```

Minimal CRD with L3 data policies

```

apiVersion: lakehouse-tables.isf.ibm.com/v1alpha1
kind: OpenTableCatalogUser
metadata:
  name: invoice-user
  namespace: cpd-instance
spec:
  catalogUser:
    userName: invoice-user
  resource:
    catalogRef: opentablecatalog-sample
    permission: use
    dataPolicies:
      - scope: table
        target: sales.invoices
    permissions: ["read"]

```

f. Optional: Run the following command to delete the resource:

```
oc delete otc my-iceberg-catalog -n lakehouse-table-cpd-instance
```

The data is retained even if you delete the resource.

Troubleshooting issues and known limitations in watsonx.data

Common troubleshooting steps, suggested checks, and known limitations for the watsonx.data service.

Diagnostic checks and common symptoms

The following table outlines common symptoms and suggested checks for diagnosing issues with the watsonx.data service:

Table 1. Symptoms and suggested checks for watsonx.data

Symptom	Suggested checks
watsonx.data tile is not in Available state	• Verify that IBM Software Hub is installed. • Confirm that the IBM Fusion catalog sync is complete. • Verify that your account has valid watsonx.data entitlements.
Installation fails or stalls	• Review operator logs in the <code>cpd-operator</code> and <code>cpd-instance</code> namespaces. • Verify that required storage classes exist and are available. • Verify that image pull secrets are configured properly.
Tile does not show Running status	• Check the status of the <code>wxdaddon</code> and <code>lakehouse</code> custom resources. • Review IBM Fusion service health in the console.
Launch UI action fails or times out	• Verify OpenShift® routes, DNS configuration, and IBM Software Hub platform health. • Confirm that the user has the required platform roles and permissions.
Engines do not provision	• Check cluster resources (CPU, memory, and storage) for availability. • Verify license tier entitlements. • Review the engine operator logs for error details.

Known limitations

Engine deployment requires query monitoring to be disabled

To deploy engines from the watsonx.data service, you must disable query monitoring.

To disable query monitoring:

1. Log in to the watsonx.data UI as `cpadmin`.
2. Go to Configurations.
3. Confirm that Query monitoring is set to Disabled.

Spark engine creation requires a volume to be created manually

When you create a Spark engine from the watsonx.data console, the engine provisioning form requires a volume. Create the volume manually in the IBM Software Hub UI before you create the Spark engine.

The volume must use a persistent volume claim (PVC) that is provisioned from a storage class that supports ReadWriteMany (RWX) access mode, such as `ocs-storagecluster-cephfs`.

For more information about provisioning a Spark engine, see [Provisioning a watsonx.data Spark engine](#).

External Spark engine with vended credentials not working

When an external Spark engine uses Iceberg REST or Metadata Service (MDS) vended credentials, the user sometimes gets access denied error. The default Service Manager role alone might not be sufficient for this use case.

Workaround:

Login to IBM Software Hub UI by using `cpadmin` credentials. Complete the following steps to configure the required role and validate the Spark engine:

1. Go to Watsonx.data service instance.
2. Select **ManageAccess**.
3. Change the watsonx.data role to MetastoreAdmin for the required user.
4. Configure Spark to use the MDS or Iceberg REST catalog with vended credentials.
5. Validate the Spark read and write operations.

Note: Do not use static S3 access keys when validating the vended-credential flow.

Important:

The Metastore Admin role enables metastore and vended-credential access but does not provide UI permissions to create, register, or scale engines.

After Spark validation, restore `cpadmin` to Service Manager or Admin before managing engines through the watsonx.data UI.

Recommendation: For long-term use, keep `cpadmin` as Admin or Service Manager for infrastructure management. Use a dedicated user or service ID with the Metastore Admin role for external Spark vended-credential access.

Disaster recovery

Disaster recovery offerings of IBM Fusion HCI.

Disaster recovery (DR) is the ability to recover and continue business-critical applications from natural or human created disasters. It is a component of the overall business continuance strategy of any major organization as designed to preserve the continuity of business operations during major adverse events.

IBM Fusion HCI with Fusion Data Foundation storage offers a resilient disaster recovery solution that protects against regional failures, maintaining predictable data loss and business continuity. For more information, see [Disaster recovery configuration for Fusion Data Foundation](#).

IBM Fusion HCI with Global Data Platform storage offers a robust disaster recovery solution that helps minimize data loss and downtime during critical events. It allows two systems to form a stretched storage layer, enabling seamless failover and failback between clusters. For more information, see [Disaster recovery configuration for Global Data Platform](#).

- [Disaster recovery configuration for Fusion Data Foundation](#)
Disaster recovery offerings of IBM Fusion HCI with Fusion Data Foundation storage.

Disaster recovery configuration for Global Data Platform

Disaster recovery offerings of IBM Fusion HCI with Global Data Platform storage.

IBM Fusion HCI with Global Data Platform storage supports the metropolitan disaster recovery (Metro-DR). It allows two IBM Fusion HCIs to form a stretched storage layer, enabling seamless failover and failback between clusters. For more information, see [Metro-DR configuration for Global Data Platform](#).

Note: In a disaster recovery solution, two clusters must be connected to failover and failback applications. If the cluster recovers after the expiry of the client certificate, clean and set up the connection to rejoin the recovered cluster. For the procedure to rejoin, see [Reconnecting OpenShift Container Platform cluster](#).

Metro-DR configuration for Global Data Platform

Metropolitan disaster recovery (Metro-DR) provides two-way synchronous data replication between IBM Fusion HCI clusters installed at two sites. When a site disaster occurs, applications can be failed over to the second site. Because replication is synchronous, the Metro-DR solution is only available for metropolitan distance data centers with 40-millisecond latency or less.

You can deploy IBM Fusion HCI in data center site 1 and data center site 2, resulting in Red Hat® OpenShift® Container Platform clusters that run at each site. Two clusters are configured such that they share a synchronously replicated storage layer, allowing for data mirroring with zero Recovery Point Objective (RPO) between the two clusters. Both the Red Hat OpenShift clusters can host active workloads at the same time rather than keeping one cluster to be a cold standby. The IBM Fusion HCI storage network is stretched between both Red Hat OpenShift clusters so that data written to one cluster is automatically mirrored to the second cluster. A special tie breaker node is hosted at a third site and is used to determine which cluster is in charge of the data when the network between the two clusters is severed. Configuring a Metro-DR topology requires several network connections to be made between the two clusters and the tie breaker.

Note: In Metro-DR, the terminology scale admin network refers to the OpenShift Container Platform pod network, and scale daemon network refers to the IBM Fusion HCI storage network.

The following picture depicts the connectivity between Site 1 and Site 2.

The Metro-DR setup includes two sets of networks, namely internal storage network and Red Hat OpenShift network. In Metro-DR, the internal storage network of one site must connect to the other site and tiebreaker, that is, externalize your storage network. Similarly, the Red Hat OpenShift network of one site needs to connect to the other site.

OpenShift management network

The Red Hat OpenShift management network provides communication between the two OpenShift clusters, and is used by IBM Fusion HCI to coordinate replication activities, such as determining which applications are mirrored or triggering application failover. Every node in both clusters has an IP address in this network. The

Red Hat OpenShift network across the sites must not be connected over network address translation (NAT). You can decide to have the Red Hat OpenShift network across the sites in the same or different subnet.

IBM Fusion storage network

The IBM Fusion HCI storage network is used for storage communication between nodes. In a Metro-DR configuration, the storage network must be connected between the two clusters to allow data replication. The storage network must also be connected to a tie breaker and the tie-breaker needs connectivity only on the storage network. This allows the tie breaker to choose which cluster is in charge of the data when the two clusters cannot talk to each other. The IBM Fusion HCI Storage network uses the 100G interface of each node and requires a high-bandwidth connection across the sites. The IBM Fusion HCI Storage network between the sites must not be connected through Network Address Translation (NAT). The IBM Fusion HCI storage network for each site must be in a different subnet than the other site and the tiebreaker.

Upgrade and upsize considerations in Metro-DR

As a prerequisite, know these upgrade and upsize considerations before you use Metro-DR.

- When any of the following activities are in progress on either site, do not start another activity from this list on either site:
 - Upgrade
 - Scale out
 - Scale up
 - Node maintenance/replacement or repair
 - Disk maintenance/replacement or repair
 - Unhealthy state of OpenShift® or the storage cluster

For example, when a scale-up operation is in progress, do not trigger an upgrade, and vice versa

- When one site is running a lower version than the other site, do not start any operations on either site in the Metro-DR cluster. For example, if site 1 is running IBM Fusion HCI 2.8.2 and site 2 is running IBM Fusion HCI 2.9.0, do not start any operations on either site until both sites are running the same version.
- Do not perform an upgrade if the storage cluster on either site is in an unhealthy state. Verify that both sites are healthy before you proceed.
- In the following situations, do an upgrade or scale-up operation to make the two sites consistent:

Important: Mismatches in the IBM Fusion HCI version, Global Data Platform version, node count, or disk count between the two sites place the Metro-DR cluster in a Degraded state. Restore the configuration so that both sites match as soon as possible to minimize the risk to data protection. The cluster continues to report a Degraded status and generates warning events until the mismatch is resolved.

- Ensure that the IBM Fusion HCI version is the same on site 1 and site 2.
- Ensure that the Global Data Platform version is the same on site 1 and site 2.
- Ensure that the OpenShift Container Platform version is the same on site 1 and site 2.
- Add nodes when mismatch in the number of nodes between sites exist.
- Add disks when mismatch in the number of disks between sites exist.

Configuring Metro-DR set up

Configure a Metro-DR relationship between two racks by connecting Site 1 and Site 2 through the Topology page and completing the setup wizard.

Before you begin

Before you set up Metro-DR, ensure that all the mentioned prerequisites are met:

- For general Metro-DR prerequisites, see [General Metro-DR prerequisites](#).
- For tiebreaker prerequisites, see [Preparing the tiebreaker](#).
- In disaster recovery, two clusters must be connected to failover and failback applications. If the cluster recovers after the expiry of the client cert, the connection must be cleaned and setup to rejoin the recovered cluster. For the procedure to rejoin, see [Reconnecting OpenShift Container Platform cluster](#).

During the installation planning, you can enable disaster recovery for your rack in either of these methods:

- You have already set up your first rack as Site 1. During the installation of Site 2, connect it to Site 1 in a Metro-DR relationship.
- You already got a standalone rack set up but not designated it as Site 1. During the installation of Site 2, use the connection snippet of Site 1 to establish a Metro-DR relationship between the two racks.

About this task

For more information about Metro-DR, see [Metro-DR configuration for Global Data Platform](#).

Procedure

1. Go to the Topology page of the primary site to see a pictorial representation of the connection between primary site and secondary site.
Example failure statuses for Metro-DR are connection state failed, admin network connectivity failure, Daemon network connectivity failure, stretch cluster addition failure, Minio setup failure, RamenDr failure.
2. Click Connect in the pictorial representation or click Connect tiebreaker.
3. Enter the following tiebreaker details in the Connect tiebreaker window:

IP address

Enter the IP address of the tiebreaker.

User ID

The user id to log in to the tiebreaker

Password

The password for the tiebreaker user.

4. Click Save

The `Tiebreaker connecting` notification message is displayed. After the tiebreaker connects successfully, the Connect tiebreaker changes to Connect cluster. You cannot add more than two clusters.

Note: The sites (clusters) and tiebreaker statuses are as follows:

Healthy

The status of the cluster or tiebreaker is healthy.

Degraded

Whenever a mismatch exists between the two sites.

Failed

When the connectivity is lost between the sites or with tiebreaker.

Running

All clusters and tiebreaker are running.

If you want to edit details of the tiebreaker, do the following steps:

- Go to the Topology page.
- In the pictorial representation, click the tiebreaker.
- Click Edit.
- In the Edit tiebreaker credentials window, update the details of the tiebreaker and click Save.

Enabling and disabling applications for Metro-DR

You must first register your applications for disaster recovery.

Before you begin

The prerequisite for this step is that the Metro-DR setup must be complete.

Procedure

- Go to the Applications page.
Alternatively, you can enroll applications from the Replicated applications page:
- Click the ellipsis overflow menu of your application record and click Manage disaster recovery.
- In the Manage disaster recovery window, select Metro tile and click Save.
Disaster recovery is enabled for the selected application. After you register your applications, you can see a table with a list of applications that are protected by this disaster recovery in the Disaster recovery page.
- To validate, go to the Disaster recovery > Replicated applications page.
- Check whether the enrolled application is available in the Replicated applications page.
If you no longer need disaster recovery for an application, then do the following steps to disable from the Replicated applications page or the Applications page:
 - Scale down the applications before you remove the enrollment.
Otherwise, it leads to inconsistent Ramen CR and Replication error.
 - Search for the application and click the ellipsis overflow menu of the record and click Manage disaster recovery.
 - In the Manage disaster recovery window, select No disaster recovery tile.
 - Click Save.
 - Scale up the applications.

Failover applications from site 1 to site 2

Application failover is the capability of automatically switching over to the secondary site when the primary site becomes unavailable.

Before you begin

Consider the following points before you failover applications:

- If backup policies are applied to the applications on site 1, they continue to run until those policies are removed from the failover application.
- The applications must be enabled for disaster recovery.
- Scale down of an application before initiating planned failover.
- Before unplanned failover of applications to surviving site, do Metro-DR Data Fencing. For the procedure, see [Metro-DR data fencing](#).

About this task

The planned failover must be done from the site where you want the applications to be failed over.

Note: If you plan to failover virtual machines, also see [Disaster recovery for virtual machines](#).

Procedure

1. In the Replicated applications page, click Actions > Failover.
The Failover remote applications window gets displayed. It also indicates the number of applications available for failover. This Failover does a failover for all remote applications.
2. In the Failover remote applications window, select the applications and click Failover.
It creates the Persistent Volumes (PVs) that belong to the applications in the local site. In addition, it creates namespace and application CR on the cluster from where you initiated the failover. After relocation is complete to remote cluster, a success message is displayed on the screen.
3. In the Replicated applications page, check the status of the Primary cluster.
Initially, the status of the Primary cluster for the application is Failing over. After successful completion of the failover, the primary cluster of the given application must be changed to secondary site or partner cluster. After completion, it displays

icon next to the name of the Primary cluster, and a Failover complete notification is displayed. The IBM Fusion HCI prepares the cluster for deployment of the relocated applications.

4. Scale up the applications.

Failback applications from the mirrored site to the original site

In a Metro-DR setup, application failback involves the process of restoring applications and virtual machines back to the original site.

About this task

You failback after a failover operation completes successfully and the primary site is restored from disaster. It helps ensure minimal disruption to the business operations and allows for the gradual migration of workloads back to the original site.

Note: If you plan to failover virtual machines, also see [Disaster recovery for virtual machines](#).

Procedure

1. Log in to the original site of the application.
2. Go to the Replicated applications page.
3. Select one or more applications marked with  symbol and click Failover.
4. Click Actions > Failover.
5. In the Failover remote applications window, select the applications and click Failover.
A success notification is displayed on the screen.

Metro-DR data fencing

Before failover of applications to surviving site, do the following Metro-DR Data Fencing.

About this task

Note: Fencing is needed only in case of unplanned failover.

Procedure

1. Designate two new additional Scale quorum nodes.
2. Add label `scale.spectrum.ibm.com/designation=quorum` for any two worker nodes.

```
oc label node <node> scale.spectrum.ibm.com/designation=quorum
```

For example:

```
oc label node compute-1-ru6.rackae2.mydomain.com scale.spectrum.ibm.com/designation=quorum
node/compute-1-ru6.rackae2.mydomain.com labeled
```

3. Verify the node status.

```
oc get nodes -l scale.spectrum.ibm.com/designation=quorum | grep compute
```

Sample output:

NAME	STATUS	ROLES	AGE	VERSION
compute-1-ru6.rackae2.mydomain.com	Ready	worker	14d	v1.23.17+16bcd69
compute-1-ru7.rackae2.mydomain.com	Ready	worker	14d	v1.23.17+16bcd69

4. Uninstall submariner from site-2 to disrupt admin network connectivity across sites.
Submariner goes down due to unavailability of the other site.
5. Edit `mni` CR and add `uninstall` to `installSubmariner`. When other site comes up, it gets uninstalled. This step avoids network connection to establish between the sites accidentally.

```
oc edit mni metrodr-network
```

Run the following command to check the edited YAML.

```
oc get mni metrodr-network -oyaml -n ibm-spectrum-fusion-ns
```

Example YAML:

```
apiVersion: network.isf.ibm.com/v1
kind: MetroDRNetworkInstall
metadata:
  creationTimestamp: "2023-07-10T06:11:53Z"
  finalizers:
  - metrodrnetworkinstall.network.isf.ibm.com/finalizer
  generation: 6
  name: metrodr-network
  namespace: ibm-spectrum-fusion-ns
  ownerReferences:
  - apiVersion: metrodr.isf.ibm.com/v1
    blockOwnerDeletion: true
    controller: true
    kind: MetroDR
    name: metrodrsite
    uid: b5501ab2-4865-4866-aa78-1ef8ca5199f1
  resourceVersion: "39680914"
  uid: 7a2b39e6-9d21-4f8c-9bc2-4e6ce4139415
spec:
  installSubmariner: uninstall
  vlanAdditionRequeDuration: 2m
```

6. Modify network definition in the network CR on the surviving site.

- a. Take the backup of `networks.operator.openshift.io/cluster`.

```
oc get networks.operator.openshift.io/cluster -oyaml >/tmp/networks.operator.openshift.io_cluster.yaml
```

- b. Edit and remove `daemon-network` entries.

```
oc edit networks.operator.openshift.io/cluster
```

- c. Delete the following route entries pointing to the other site:

```
name: daemon-network
namespace: ibm-spectrum-scale
rawCNIConfig: '{ "cniVersion": "0.3.1", "name": "daemon-network", "type": "bridge",
"bridge": "br3201", "mtu": 9000, "ipam": { "type": "static", "routes": [{ "dst":
"192.168.192.0/18", "gw": "192.168.128.1"}, { "dst": "192.168.192.200/32", "gw":
"192.168.128.1"}]}'
type: Raw
```

- d. Restart the scale pods for the changes to take effect.

Note: Check that the Scale PODs are restarted after this step and make a note.

- e. Do not break route to Tiebreaker.

Run the following commands to validate whether the daemon connectivity to Tie-breaker is available.

```
oc project ibm-spectrum-scale
oc get po
```

Example output:

NAME	READY	STATUS	RESTARTS	AGE
compute-1-ru5	2/2	Running	2	14d
compute-1-ru6	2/2	Running	9 (18h ago)	14d
compute-1-ru7	2/2	Running	9 (18h ago)	14d
control-1-ru2	2/2	Running	2	14d
control-1-ru3	2/2	Running	2	14d
control-1-ru4	2/2	Running	2	14d

```
oc rsh compute-1-ru5 //any Running node)
mmgetstate -a
```

Example output:

Node number	Node name	GPFS state
13	control-1-ru2.daemon.ibm-spectrum-scale.stg.rackae1	unknown
2	control-1-ru3.daemon.ibm-spectrum-scale.stg.rackae1	unknown
3	control-1-ru4.daemon.ibm-spectrum-scale.stg.rackae1	unknown
4	compute-1-ru5.daemon.ibm-spectrum-scale.stg.rackae1	unknown
5	compute-1-ru6.daemon.ibm-spectrum-scale.stg.rackae1	unknown
6	compute-1-ru7.daemon.ibm-spectrum-scale.stg.rackae1	unknown
7	compute-1-ru5.daemon.ibm-spectrum-scale.stg.rackae2	active
8	compute-1-ru6.daemon.ibm-spectrum-scale.stg.rackae2	active
9	compute-1-ru7.daemon.ibm-spectrum-scale.stg.rackae2	active
10	control-1-ru2.daemon.ibm-spectrum-scale.stg.rackae2	active
11	control-1-ru3.daemon.ibm-spectrum-scale.stg.rackae2	active
12	control-1-ru4.daemon.ibm-spectrum-scale.stg.rackae2	active
13	gpfs-tiebreaker	active

```
ping gpfs-tiebreaker
```

Example output:

```
PING gpfs-tiebreaker (192.168.192.200) 56(84) bytes of data.
64 bytes from gpfs-tiebreaker (192.168.192.200): icmp_seq=1 ttl=64 time=0.239 ms
64 bytes from gpfs-tiebreaker (192.168.192.200): icmp_seq=2 ttl=64 time=0.218 ms
```

- f. Click Exit.

7. Check for the presence of static routes on each scale CORE POD. If they are present, then manually remove entry on each scale CORE PODs to immediately break daemon connection to the failed site.

- a. Check route entries on each scale pod

```
oc project ibm-spectrum-scale
oc get po
```

Example output:

NAME	READY	STATUS	RESTARTS	AGE
compute-1-ru5	2/2	Running	2	14d
compute-1-ru6	2/2	Running	9 (18h ago)	14d
compute-1-ru7	2/2	Running	9 (18h ago)	14d
control-1-ru2	2/2	Running	2	14d
control-1-ru3	2/2	Running	2	14d
control-1-ru4	2/2	Running	2	14d

```
oc rsh compute-1-ru5 //any Running node
```

- b. Check existing routes.

```
route -n
```

```
Kernel IP routing table
Destination    Gateway         Genmask         Flags Metric Ref    Use Iface
0.0.0.0        10.135.0.1     0.0.0.0         UG    0      0          0 eth0
10.135.0.0     0.0.0.0        255.255.254.0   U     0      0          0 eth0
192.168.128.0  192.168.192.1 255.255.192.0   UG    0      0          0 net1
192.168.192.0  0.0.0.0        255.255.192.0   U     0      0          0 net1
192.168.192.200 192.168.192.1 255.255.255.255 UGH   0      0          0 net1
```

- c. Delete route with daemon network between two sites.

```
route del -net 192.168.128.0 gw 192.168.192.1 netmask 255.255.192.0
```

- d. Ensure that the route is deleted.

```
route -n
```

Example output:

```
Kernel IP routing table
Destination    Gateway         Genmask         Flags Metric Ref    Use Iface
0.0.0.0        10.135.0.1     0.0.0.0         UG    0      0          0 eth0
10.135.0.0     0.0.0.0        255.255.254.0   U     0      0          0 eth0
192.168.192.0  0.0.0.0        255.255.192.0   U     0      0          0 net1
192.168.192.200 192.168.192.1 255.255.255.255 UGH   0      0          0 net1
```

- e. Click Exit.

- f. Repeat steps from [7.a](#) to [7.d](#) for all the compute nodes.

8. Capture a Scale must-gather for any future reference.
9. Deploy the application on the surviving site.
10. Check whether the application deployment works correctly.
11. Failover applications and wait for its completion.
12. Recover the failed site.
13. Delete failed over VMs on the failed site.
14. Remove the added label `scale.spectrum.ibm.com/designation=quorum` for the two compute nodes.

```
oc get nodes -l scale.spectrum.ibm.com/designation=quorum | grep compute
```

Sample output:

```
NAME                                STATUS ROLES AGE VERSION
compute-1-ru6.rackae2.mydomain.com Ready worker 14d v1.23.17+16bcd69
compute-1-ru7.rackae2.mydomain.com Ready worker 14d v1.23.17+16bcd69
```

Run the command to remove labels added

```
oc label node compute-1-ru6.rackae2.mydomain.com scale.spectrum.ibm.com/designation=
oc label node compute-1-ru7.rackae2.mydomain.com scale.spectrum.ibm.com/designation=
```

15. Verify whether the labels are removed from the compute nodes.

```
oc get nodes -l scale.spectrum.ibm.com/designation=quorum | grep compute
```

16. Scale down deployments and delete VMs of all failed-over applications or VMs on the recovered site:

- a. Check for application deployments under each namespace:

```
oc get deployments --namespace=<namespace>
```

Example command:

```
oc get deployments --namespace=wordpressapp1-ns
```

```
NAME                READY    UP-TO-DATE    AVAILABLE    AGE
Wordpressapp1       0/0      0              0            21h
wordpressapp1-mysql 0/0      0              0            21h
```

- b. Scale down application deployments to 0.

```
oc scale deployments/wordpressapp1 --namespace=wordpressapp1-ns --replicas 0
oc scale deployments/wordpressapp1-mysql --namespace=wordpressapp1-ns --replicas 0
```

- c. Run the following command to delete the VMs.

```
oc delete vm -n myvmnamespace
```

17. Reapply network configurations on the surviving site.

- a. Re-install submariner.

- i. Get the status of Submariner.

```
oc get mni metrodr-network -oyaml -n ibm-spectrum-fusion-ns
```

Sample YAML:

```
apiVersion: network.isf.ibm.com/v1
..
reason: LastReconcileCycleSucceeded
status: "True"
type: Available
networkInstallStatus:
messageCode:
message: Submariner uninstalled successfully.
progressPercentage: 100
```

- ii. Edit Submariner CR.

```
oc edit mni metrodr-network
```

```
Spec:
installSubmariner: install
```

- iii. Check installation status:

```
oc get mni metrodr-network -oyaml -n ibm-spectrum-fusion-ns
```

Output:

```
message: Submariner installation completed successfully
```

- b. Add the following entries as follows:

- i. Run the following `oc` command.

```
oc edit networks.operator.openshift.io/cluster
```

- ii. Copy the `daemon-network` entries (removed with step [6.a](#)) from the backup file.

For example:

```
name: daemon-network
namespace: ibm-spectrum-scale
rawCNIConfig: '{ "cniVersion": "0.3.1", "name": "daemon-network", "type": "bridge",
"bridge": "br3201", "mtu": 9000, "ipam": { "type": "static", "routes": [{ "dst":
"192.168.192.0/18", "gw": "192.168.128.1"}, { "dst": "192.168.192.200/32", "gw":
"192.168.128.1"}]}'
type: Raw
```

- iii. Run the following command to check whether `daemon-network` entries are added correctly.

```
oc get networks.operator.openshift.io/cluster -oyaml
```

- iv. Restart the scale core pods to update the configuration.

- c. Check if the routes are present on scale code pods, else add route entries for each scale pod.

```
oc project ibm-spectrum-scale
oc get po
```

Sample output:

NAME	READY	STATUS	RESTARTS	AGE
compute-1-ru5	2/2	Running	2	14d
compute-1-ru6	2/2	Running	9 (18h ago)	14d
compute-1-ru7	2/2	Running	9 (18h ago)	14d
control-1-ru2	2/2	Running	2	14d
control-1-ru3	2/2	Running	2	14d
control-1-ru4	2/2	Running	2	14d

```
oc rsh compute-1-ru5 //any Running node
```

```
route add -net 192.168.128.0 gw 192.168.192.1 netmask 255.255.192.0
route -n
```

Sample output:

```
Kernel IP routing table
Destination      Gateway         Genmask        Flags Metric Ref    Use Iface
0.0.0.0          10.135.0.1     0.0.0.0        UG    0      0      0 eth0
10.135.0.0       0.0.0.0        255.255.254.0  U      0      0      0 eth0
192.168.128.0    192.168.192.1 255.255.192.0  UG    0      0      0 net1
192.168.192.0    0.0.0.0        255.255.192.0  U      0      0      0 net1
192.168.192.200 192.168.192.1 255.255.255.255 UGH    0      0      0 net1
```

- d. Run the following command to check whether the routes are present.

```
route -n
```

If routes are not present, then add the routes and verify using the following commands.

```
route add -net 192.168.128.0 gw 192.168.192.1 netmask 255.255.192.0
route -n
```

e. Check the scale pod status. The status must be active.

```
oc project ibm-spectrum-scale
oc get po
```

Sample output:

NAME	READY	STATUS	RESTARTS	AGE
compute-1-ru5	2/2	Running	2	14d
compute-1-ru6	2/2	Running	9 (18h ago)	14d
compute-1-ru7	2/2	Running	9 (18h ago)	14d
control-1-ru2	2/2	Running	2	14d
control-1-ru3	2/2	Running	2	14d
control-1-ru4	2/2	Running	2	14d

```
oc rsh compute-1-ru5 //any Running node
mmgetstate -a
```

Sample output:

Node number	Node name	GPFS state
1	control-1-ru2.daemon.ibm-spectrum-scale.stg.rackae1	active
2	control-1-ru3.daemon.ibm-spectrum-scale.stg.rackae1	active
3	control-1-ru4.daemon.ibm-spectrum-scale.stg.rackae1	active
4	compute-1-ru5.daemon.ibm-spectrum-scale.stg.rackae1	active
5	compute-1-ru6.daemon.ibm-spectrum-scale.stg.rackae1	active
6	compute-1-ru7.daemon.ibm-spectrum-scale.stg.rackae1	active
7	compute-1-ru5.daemon.ibm-spectrum-scale.stg.rackae2	active
8	compute-1-ru6.daemon.ibm-spectrum-scale.stg.rackae2	active
9	compute-1-ru7.daemon.ibm-spectrum-scale.stg.rackae2	active
10	control-1-ru2.daemon.ibm-spectrum-scale.stg.rackae2	active
11	control-1-ru3.daemon.ibm-spectrum-scale.stg.rackae2	active
12	control-1-ru4.daemon.ibm-spectrum-scale.stg.rackae2	active
13	gpfs-tiebreaker	active

Metro-DR issues

Use these troubleshooting information to resolve issues when you work with Metro-DR.

Metro-DR failback blockage due to ISO DataVolume

Problem statement

During a Metro-DR failback operation, the process is blocked, and the virtual machine fails to recover. The failback operation remains in a pending state, preventing the successful completion of the disaster recovery process.

Cause

The failback blockage is caused by the handling of the ISO **DataVolume** in the virtualization or Containerized Data Importer (CDI) layer. When an ISO **DataVolume** is attached to a VM, additional temporary Persistent Volume Claims (PVCs) are created during failback and remain in a **Pending** state. This prevents the failover or failback workflow from progressing.

Resolution

When a failback operation is triggered with ISO PVC protection enabled, the workflow might be blocked due to the presence of an ISO **DataVolume**. To resolve this issue, complete the following steps:

1. Delete the additional temporary PVCs created during the failback operation.
2. After deleting the temporary PVCs, the failback workflow can proceed successfully.
3. To avoid potential issues with ISO PVC protection during failback operations, follow these best practices:
 - a. Detach the installation ISO after OS installation.
 - b. Configure the VM to reference the ISO PVC directly using **persistentVolumeClaim**.

For more information about Virtual Machine Disaster Recovery, see [virtual machine disaster recovery](#) documentation.

Metro-DR compute node issue

In a Metro-DR setup, if a compute node is a part of the scale cluster at any site, the Global Data Platform service status may appear as Degraded. To validate the scale health for that site, in the IBM Fusion user interface, go to Storage > Local Storage and check the storage cluster status.

Usable capacity displayed as 0 in the user interface

In Metro-DR setup, the IBM Fusion user interface may display the usable capacity as 0. It is a user interface issue and does not affect the actual capacity or functionality of the setup.

Failback issues

Problem statement

During unplanned failover, some applications can be in a "replication error" state after recovery of the failed site with fencing.

Resolution

- If the application failover is not successful, then check for the `volumeattachments` of the application by using the following command.

```
oc get volumeattachment -n <namespace name> | grep < pvc name of given application>
```

If the `volumeattachments` exist, then try to delete by using the following command.

```
oc delete volumeattachment -n < namespace name>
```

IBM Fusion operator status is pending with errors

Problem statement

The IBM Fusion operator status is pending with the following errors in 2.7.2 version:

- RequirementsNotMet
- `asyncreplications.dataprotection.isf.ibm.com`

Resolution

Apply the following CRD YAML:

```
apiVersion: apiextensions.k8s.io/v1
kind: CustomResourceDefinition
metadata:
  annotations:
    controller-gen.kubebuilder.io/version: v0.8.0
  creationTimestamp: null
  name: asyncreplications.dataprotection.isf.ibm.com
spec:
  group: dataprotection.isf.ibm.com
  names:
    kind: AsyncReplication
    listKind: AsyncReplicationList
    plural: asyncreplications
    singular: asyncreplication
  scope: Namespaced
  versions:
    - name: v1
      schema:
        openAPIV3Schema:
          description: AsyncReplication is the Schema for the asyncreplications API
          properties:
            apiVersion:
              description: 'APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#resources'
              type: string
            kind:
              description: 'Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More info: https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds'
              type: string
            metadata:

```

```
plural: ""
conditions: []
storedVersions: []
```

Global Data Platform upgrade fails in site 1

Problem statement

- Whenever you do the following upgrades on site 1 of the Metro-DR, the "Global Data platform service not active on all the nodes" error message gets displayed:
 - IBM Fusion 2.7.2 to 2.8.0
 - Global Data Platform 5.19.0 to 5.2.0
- When you upgrade IBM Fusion 2.7.2 to 2.8.0, the Global Data Platform upgrade of 5.1.9.0 to 5.2.0.0 of Metro-DR Site 1 gets stuck with error "ECE service not active on all the nodes".

Resolution

Run the following command to patch Scale recovery group with 'Active' condition:

```
oc patch recoverygroup rg201 -n ibm-spectrum-scale --type=merge --subresource status --type='json' -p '[{"op": "add", "path": "/status/conditions/-", "value": { "type": "Active", "status": "True", "message": "The recovery group is active", "reason": "Active", "lastTransitionTime": "'date +%FT%T`Z'" } } ]'
```

Less descriptor disks

Problem statement

The site monitoring checks whether enough descriptor disks are assigned for each site. For multiple RGs per site, only one RG sees the descriptor disks. The other RG servers send `disk_missing` that is interpreted as less descriptor disks.

Resolution

As a resolution, add the `site_fs_desc_fail` event to the "ignore list" to suppress the entire event. Run the command `mmchconfig mmhealth-events-ignore="site_fs_desc_fail" --force` once on the cluster and then run `mmysmoncontrol restart` on the cluster manager node.

Latest tiebreaker version

After the upgrade of tiebreaker to the latest version, Metro-DR CR does not show the latest version. You can ignore this as it is a known issue.

Application removals fail in the local tab of failed site after recovery or reconnect

You can observe this issue only in case of fail over or fail back of applications on the surviving site. You can ignore this issue as the CR status is correct, and further relocation or fail back of these applications happen properly.

Add and Remove DR does not work as expected when a remote site is down

When multiple DR protected applications exist in the local site and the other site goes down, the add and remove operations of disaster recovery takes longer than usual.

Connection setup after OpenShift Container Platform cluster recovery

Problem statement

The OpenShift® Container Platform cluster can have problems and become unusable.

Resolution

After you recover the cluster, rejoin the connections. For the steps to clean the connection and setup the connection between two clusters again, see [Connection setup after OpenShift Container Platform cluster recovery](#).

IBM Fusion HCI installation hangs because of disaster recovery

Resolution

If minio pod does not come up for a long time and the Metro-DR installation gets stuck even after the minio pod goes to the running state, then restart Metro-DR deployment in `ibm-spectrum-fusion-ns` (or your Fusion namespace) to trigger reconciliation.

RamenDR operator crashes after the restoration of a failed site

Resolution

If RamenDR operator crashes after the restoration of a failed site, then apply the following workaround:

- Retrieve `s3CompatibleEndpoint` from `s3StoreProfiles` of the local site.
- Retrieve the secret of local site that is specified in `s3SecretRef` of `s3StoreProfiles`.
- Run the following command from `isf-minio` pod in `ibm-spectrum-fusion-ns` namespace to connect to the local Minio server.

```
mc alias set myminio <s3CompatibleEndpoint retrieved in step 1> <AWS_ACCESS_KEY_ID parameter of secret retrieved in step 1> < AWS_SECRET_ACCESS_KEY parameter of secret retrieved in step 1>
```

- Run the following command to find out all zero-bytes files in Minio store:

```
mc ls myminio --recursive --insecure | grep -i VolumeReplicationGroup | grep 0B
```

- Run the following command to delete the zero-bytes file that is retrieved in step 3:

```
mc rm <path of files retrieved in step 3>
```

6. Restart `ramen-dr-cluster-operator` deployment in the `ibm-spectrum-fusion-ns` namespace.

If the `Volumereplicationgroup`'s `ReplicationState` of the application fail over does not change to secondary after the restoration of a failed site, then do the following workaround steps:

1. Go to Red Hat® OpenShift Container Platform web management console.
2. Go to CustomResourceDefinitions > `volumereplicationgroups.ramendr.openshift.io` instances.
3. Edit YAMLS of selected `Volumereplicationgroups` and change `spec.replicationState = secondary`.
4. Save YAMLS.

Failovers of concurrent applications take a long time after network recovery

Problem statement

During Disaster Recovery scenario, when either of the Metro-DR site is powered Off or network is disconnected.

Resolution

As a resolution, run the following steps before you initiate failover of applications on the surviving site:

1. In Red Hat OpenShift Container Platform console, go to Workloads > ConfigMap.
2. Open the `ramen-dr-cluster-operator-config` configmap in the `ibm-spectrum-fusion-ns` namespace.
3. Add `MaxConcurrentReconcile` parameter in this configmap with value as 50.
4. Save the changes and restart `ramen-dr-cluster-operator` deployment in the `ibm-spectrum-fusion-ns` namespace.

Connection between IBM Storage Scale pods

Problem statement

Unable to ping between IBM Storage Scale pods after you reestablish the network connection between site 1 and site 2.

Workaround:

1. Change in the CR `Spec` of the `installSubmariner` field to `uninstall`.

```
oc edit mni
```

```
Spec:
  installSubmariner: uninstall
```

2. Delete the namespace, if it is not already deleted.
3. Change in the CR `Spec` of the `installSubmariner` field to `install`.

```
oc edit mni
```

```
Spec:
  installSubmariner: install
```

4. If the installation is not successful, then try to install the submariner by using the following manual steps:
 - a. Label the control nodes as gateways on both sites of Metro-DR.

```
oc label node control-0.<domainname> submariner.io/gateway=true
oc label node control-1.<domainname> submariner.io/gateway=true
oc label node control-2.<domainname> submariner.io/gateway=true
```

- b. Login to MetroDR-operator pod.

```
[root@hci-dev1 ~]# oc get po | grep metr
isf-metrodr-operator-controller-manager-bddffd98-dhvgt      2/2      Running    0           13h
[root@hci-dev1 ~]# oc rsh isf-metrodr-operator-controller-manager-bddffd98-dhvgt
```

- c. Deploy the broker for submariner.

```
subctl deploy-broker --operator-debug --kubeconfig=/tmp/site-1-kubeconfig
```

- d. Join to broker.

```
subctl join --kubeconfig=/tmp/site-2-kubeconfig --operator-debug --pod-debug --clusterid=site-2 broker-
info.subm
subctl join --kubeconfig=/tmp/site-1-kubeconfig --operator-debug --pod-debug --clusterid=site-1 broker-
info.subm
```

Disaster recovery connections in installing state for hours

Diagnosis

You might encounter authentication or authorization issues while you connect to the remote cluster. To confirm that the issue is related to authorization, check whether you see the following messages in the Metro-DR pod logs:

- Incorrect token, need to regenerate kubeconfig file
- Unauthorized

Cause

- If Metro-DR instance displays any of the following error messages, then do the following workaround:

```
oc get mdr -oyaml
```

```
"Submariner is not installed"
```

- `oc get mni -oyaml`

```
"Failed to uninstall Submariner"
OR
"Submariner installation failed"
```

- Submariner connectivity might get affected when any of the nodes go to a bad state.
If problems exist in pod connectivity between racks even after all nodes are back in working condition, then do the following workaround.

Resolution

1. Update site 2 password on site 1 and regenerate the kubeconfig file:

- a. Get the site 2 token from site 2 service account:

```
[root@hci-dev1 ~]# oc get sa fusion-admin-controller-manager -oyaml
secrets:
- name: fusion-admin-controller-manager-dockercfg-vmp2m
- name: fusion-admin-controller-manager-token-wj96d
```

```
[root@hci-dev1 ~]# oc get secret fusion-admin-controller-manager-token-wj96d -oyaml
data:
  token: site2Token
```

- b. Update the site 2 token in secret `isf-metrodr-config-secret` on site 1:

```
[root@hci-dev1 ~]# oc edit secret isf-metrodr-config-secret
Data:
  Site2KubePassword: site2Token
```

- c. Log in to the Metro-DR pod on site 1 and delete the incorrect site 2 kubeconfig file:

```
root@hci-dev1 ~]# oc get po | grep metro
isf-metrodr-operator-controller-manager-7fd8c4fbc-wwkc8      2/2      Running      0          13h

[root@hci-dev1 ~]# oc exec -ti isf-metrodr-operator-controller-manager-7fd8c4fbc-wwkc8 -c manager bash
kubectl exec [POD] [COMMAND] is DEPRECATED and will be removed in a future version. Use kubectl exec [POD] --
[COMMAND] instead.
bash-4.4$ ls /tmp/
ks-script-c9hd6mir  ks-script-jrnjxyf4  site-1-kubeconfig  site-2-kubeconfig
bash-4.4$ rm -f /tmp/site-2-kubeconfig
```

2. Update site 1 password on site 2 and regenerate the kubeconfig file:

- a. Get the site 1 token from site 1 service account:

```
[root@hci-dev1 ~]# oc get sa fusion-admin-controller-manager -oyaml
secrets:
- name: fusion-admin-controller-manager-dockercfg-vmp2m
- name: fusion-admin-controller-manager-token-wj96d
```

```
[root@hci-dev1 ~]# oc get secret fusion-admin-controller-manager-token-wj96d -oyaml
data:
  token: site1Token
```

- b. Update the site 1 secret token in `isf-metrodr-config-secret` on site 2:

```
[root@hci-dev1 ~]# oc edit secret isf-metrodr-config-secret
Data:
  Site1KubePassword: site1Token
```

- c. Log in to the Metro-DR pod on site 2 and delete the incorrect site 1 kubeconfig file:

```
root@hci-dev1 ~]# oc get po | grep metro
isf-metrodr-operator-controller-manager-7fd8c4fbc-wwkc8      2/2      Running      0          13h

[root@hci-dev1 ~]# oc exec -ti isf-metrodr-operator-controller-manager-7fd8c4fbc-wwkc8 -c manager bash
kubectl exec [POD] [COMMAND] is DEPRECATED and will be removed in a future version. Use kubectl exec [POD] --
[COMMAND] instead.
bash-4.4$ ls /tmp/
ks-script-c9hd6mir  ks-script-jrnjxyf4  site-1-kubeconfig  site-2-kubeconfig
bash-4.4$ rm -f /tmp/site-1-kubeconfig
```

Issues with more than 3 quorum nodes on a cluster

Problem statement

The following error occurs only when the OpenShift Container Platform contains more than 10 nodes for the initial installation in a Metro-DR:

```
mmchnode: The number of quorum nodes exceeds the maximum (8) allowed.
```

Cause

The Scale works fine when both sites are healthy. As the quorum nodes are not balanced on both sites, when the site that has five quorum nodes goes down, the whole scale cluster goes down.

Resolution

1. Run the following command to get the quorum nodes:

```
oc get nodes -l scale.spectrum.ibm.com/designation=quorum
```

2. Run the following command to remove the label from two non-control nodes:

```
oc label nodes <node_name> scale.spectrum.ibm.com/designation-
```

Metro-DR goes into a critical state after scale up or scale down operation

Problem statement

The Metro-DR pod goes into critical state critical state after scale up or scale down operation.

Resolution

Follow the steps on the sites to resolve this issue:

1. Log in to the OpenShift Container Platform web console.
2. Go to Administration > CustomResourceDefinitions.
3. Click Filesystem CR.
4. Go to YAML tab and copy the specification details.
5. Similarly, check the RecoveryGroup CR and note the available RVGs dedicated for the sites.
For example, rg1 and rg201 for the primary site and rg2 and rg202 for the secondary site.
6. Check the number of NVME disks attached to the storage nodes on both the sites. You can also execute `lsblk` command on the storage nodes to get the NVME disk count.
7. Calculate the Vdisk Size:
 - If there are two disks, then it is 100%
 - If there are four disks, then it is 500%
 - If there are six disks, then it is 33%
 - If there are eight disks, then it is 25%
8. Add the respective entries for the recovery group.
For example, the entry order must be rg1, rg2, rg201 and rg202.
9. Check whether the Vdisk array count for the respective RVG should be half of the disk count. ex. Suppose
For example:
 - If there are two disks, then the Vdisk array should appear only once
 - If there are four disks, then the Vdisk array should appear twice.
10. Ensure to adjust the Vdisk set array for the site RVG and create a set.
11. Add another site RVG entries as it is in the **Filesystem** CR spec.
12. Save the **Filesystem** CR.

Storage configuration failed on the Metro-DR site

Problem statement

Storage configuration on the secondary site is stuck because of the following error in the `isf-storage-operator-controller-manager` pod.

```
ERROR   controllers.scale      Unable to set the values      {"scale": {"name":"storagemanager","namespace":"ibm-spectrum-f
```

Resolution

Follow the steps to create secrets for the service account to resolve this issue:

1. Run the following command to list the service accounts in the `ibm-spectrum-scale-operator` namespace to verify whether the `ibm-spectrum-scale-operator` service account is present.

```
oc get sa -n ibm-spectrum-scale-operator
```

2. Run the following command to list the secrets in the `ibm-spectrum-scale-operator` namespace to verify whether the `ibm-spectrum-scale-operator-token` secret is present.

```
oc get secrets -n ibm-spectrum-scale-operator
```

3. If the secret is not present, then create a file `tokensecret.yaml` with the following content.

```
kind: Secret
apiVersion: v1
metadata:
  name: ibm-spectrum-scale-operator-token-metro
  namespace: ibm-spectrum-scale-operator
  annotations:
    kubernetes.io/service-account.name: ibm-spectrum-scale-operator
data:
  namespace: aWJtLXNwZWNOcnVtLXNjYWx1LW9wZXJhdG9y
  type: kubernetes.io/service-account-token
```

4. Run the following command to apply the `tokensecret.yaml` file in the `ibm-spectrum-scale-operator` namespace.

```
oc apply -f tokensecret.yaml -n ibm-spectrum-scale-operator
```

5. Run the following command to list the secrets again in the `ibm-spectrum-scale-operator` namespace and ensure that the `ibm-spectrum-scale-operator-token` secret is added.

```
oc get secrets -n ibm-spectrum-scale-operator
```

Ramen DR pod goes into a CrashLoopBackOff state

Problem statement

Ramen DR pod is in a `CrashLoopBackOff` goes into a `CrashLoopBackOff` state with the following errors.

```
ERROR controller/controller.go:200 Could not wait for Cache to sync {"controller": "drclusterconfig", "controllerGroup": "rame
ERROR setup cmd/main.go:285 problem running manager {"error": "failed to wait for drclusterconfig caches to sync: timed out wa
```

Cause

This issue might occur due to the `DRClusterConfig` CRD is missing from the cluster.

Diagnosis

To confirm that the issue is related to CRD missing, check whether you see the following message in the Metro-DR pod logs:

- missing drclusterconfigs.ramendr.openshift.io

Resolution

Contact [IBM support](#) to resolve the issue.

Application DR configuration for Metro-DR

For Metro-DR configuration, from the disaster recovery page of IBM Fusion HCI user interface, you can manage disaster recovery for your storage and Kubernetes storage resources. You can use the **VolumeReplicationGroup** (VRG) to manage disaster recovery for all other Kubernetes resources. Enable **kubeObjectProtection** flag to protect all Kubernetes resources in the namespace where VRG is associated. If it is in disabled mode, then only PV metadata is protected.

See the instructions in the sub-sections on how you can setup Application DR, enable DR for an application, failover an application, and disable Application DR.

Application DR

Steps to setup an Application DR, enroll an application, failover applications, and disable applications.

Step 1-setup Application DR

You can setup an Application DR anytime after you set up the Metro-DR and before you enable DR for an application.

1. Set up Metro-DR. For the procedure to setup, see [Configuring Metro-DR set up](#). After Site 1, Site 2, and Tiebreaker are installed, proceed with the next steps.
2. Do the following steps on both Site 1 and Site 2 of Metro-DR:
 - a. If OADP (version that is used by Backup & Restore) operator does not exist, then create a namespace and install it.

Note: The installed OADP must align with the version that is used by Fusion Backup & Restore so that the following issues do not exist:

 - OADP inconsistencies
 - CRD conflicts between Fusion Backup & Restore and Metro-DR
 - i. Go to OperatorHub > Operator Installation.
 - ii. Find OADP, the Red Hat® distribution of Velero.
 - iii. In the Install Operator window, select the default namespace **openshift-adp**. You can also install it in another namespace.
 - iv. Click Install.
 - b. Create **DataProtectionApplication** instance to start the **velero** operator.

```
apiVersion: oadp.openshift.io/v1alpha1
kind: DataProtectionApplication
metadata:
  labels:
    app.kubernetes.io/component: velero
  name: velero
  namespace: openshift-adp
spec:
  backupImages: false
  configuration:
    restic:
      enable: false
    velero:
      defaultPlugins:
        - openshift
        - aws
      noDefaultBackupLocation: true
  podConfig:
    resourceAllocations:
      limits:
        cpu: '1'
        ephemeral_storage: 25Mi
        memory: 1Gi
      requests:
        cpu: 100m
        ephemeral_storage: 25Mi
        memory: 256Mi
  podDnsConfig: {}
```

3. On the site1, do the following steps:
 - a. Obtain the minio secret content.

```
site1_keyid=$(oc extract -n ibm-spectrum-fusion-ns secret/isf-metrodr-minio-site1 --keys=AWS_ACCESS_KEY_ID --to=-);site1_key=$(oc extract -n ibm-spectrum-fusion-ns secret/isf-metrodr-minio-site1 --keys=AWS_SECRET_ACCESS_KEY --to=-);echo "[default]" > cloud-credentials-site1.yaml;echo "aws_access_key_id = ${site1_keyid}" >> cloud-credentials-site1.yaml;echo "aws_secret_access_key = ${site1_key}" >> cloud-credentials-site1.yaml
```

It creates a cloud-credentials-site1.yaml.

- b. Create secret **cloud-credentials-site1** from the file generated in the previous step.

```
oc create secret generic cloud-credentials-site1 --namespace openshift-adp --from-file cloud=./cloud-credentials-site1.yaml
```

- c. Obtain the minio secret for site2.

```
site2_keyid=$(oc extract -n ibm-spectrum-fusion-ns secret/isf-metrodr-minio-site2 --keys=AWS_ACCESS_KEY_ID --
to=);site2_key=$(oc extract -n ibm-spectrum-fusion-ns secret/isf-metrodr-minio-site2 --keys=AWS_SECRET_ACCESS_KEY --
to=);echo "[default]" > cloud-credentials-site2.yaml;echo "aws_access_key_id = ${site2_keyid}" >> cloud-credentials-
site2.yaml;echo "aws_secret_access_key = ${site2_key}" >> cloud-credentials-site2.yaml
```

- d. Create `cloud-credentials-site2` from the file generated in the previous step.

```
oc create secret generic cloud-credentials-site2 --namespace openshift-adp --from-file cloud=./cloud-credentials-
site2.yaml
```

- e. Check whether the cloud credential secrets are created for both the sites. Example output:

```
[root@roadiem9 cpd-cli-linux-EE-13.1.2-89]# oc get secret -n openshift-adp |grep -E "NAME|cloud"
NAME                                TYPE                                DATA    AGE
cloud-credentials-site1             Opaque                              1        57s
cloud-credentials-site2             Opaque                              1        31s
```

4. Repeat the previous step and substeps on site2.
5. On site1, create secret `cloud-credentials-site1` from the file that is generated in step 3.
6. Create secrets in the Velero operator namespace to access S3 storage on both the sites of Metro-DR. The S3 credentials in this secret are in the following Amazon Web Services format:

```
[default]
aws_access_key_id=<AWS_ACCESS_KEY_ID>
aws_secret_access_key=<AWS_SECRET_ACCESS_KEY>
```

7. Access details in the `ibm-spectrum-fusion-ns` (or your Fusion namespace) Velero secret:
 - For Velero secret to access Site 1 S3 storage, see `isf-metrodr-minio-site1` secret.
 - For Velero secret to access Site 2 S3 storage, see `isf-metrodr-minio-site2` secret.
- Example `cloud-credentials-site1` secret content to access the S3 storage of Metro-DR sites:
- Metro-DR Site 1.

```
Key: cloud
Value:
[default]
aws_access_key_id=minio
aws_secret_access_key=04ie0o07x46g0i5
```

- Metro-DR Site 2:

```
Key: cloud
Value:
[default]
aws_access_key_id=minio
aws_secret_access_key=84ie0o09x46g0i8
```

8. Enable `kubeObjectProtection` in `ramen-dr-cluster-operator-config` map of `ibm-spectrum-fusion-ns` namespace:
 - a. To enable `kubeObjectProtection`, set `disabled` to `false` and specify the Velero installation namespace.

```
kubeObjectProtection:
  disabled: false
  veleroNamespaceName: openshift-adp
```

- b. In `S3StoreProfiles` section, for every `S3StoreProfile`, specify the Velero secret details for the corresponding site, including key name and secret name:
- Example for Site 1:

```
veleroNamespaceSecretKeyRef:
  key: cloud
  name: cloud-credentials-site1
```

Example for Site 2:

```
veleroNamespaceSecretKeyRef:
  key: cloud
  name: cloud-credentials-site2
```

- c. From site 1, get the ingress certificate details by using the following command:

```
oc get cm default-ingress-cert -n openshift-config-managed -o jsonpath="{.data.ca-bundle\.crt}"
```

Note: Encode `ingresscertificate` to base64 format.

- d. Repeat the previous step on site 2.
 - e. On site1, edit the ConfigMap `ramen-dr-cluster-operator-config` in namespace `ibm-spectrum-fusion-ns` to add `caCertificates` under `s3StoreProfiles`. Ensure that you add the appropriate `caCertificates` for the S3 profile.
 - f. Repeat the previous step on site 2.
 - g. Configure `ramen-dr-cluster-operator-config` ConfigMap by using the following example:

```
kind: ConfigMap
apiVersion: v1
metadata:
  name: ramen-dr-cluster-operator-config
  namespace: ibm-spectrum-fusion-ns
data:
  ramen_manager_config.yaml: |
    apiVersion: ramendr.openshift.io/v1alpha1
    drClusterOperator: {}
```

```
health:
  healthProbeBindAddress: :8081
kind: RamenConfig
kubeObjectProtection:
  disabled: false
  veleroNamespaceName: openshift-adp
leaderElection:
  leaderElect: true
  leaseDuration: 0s
  renewDeadline: 0s
  resourceLock: ""
  resourceName: dr-cluster.ramendr.openshift.io
  resourceNamespace: ""
  retryPeriod: 0s
metrics:
  bindAddress: 127.0.0.1:9289
ramenControllerType: dr-cluster
s3StoreProfiles:
- s3Bucket: isf-minio-sitel
  s3CompatibleEndpoint: https://isf-minio-ibm-spectrum-fusion-ns.apps.rackag2.mydomain.com
  s3ProfileName: sitel
  s3Region: sitel
  s3SecretRef:
    name: isf-minio-sitel
    namespace: ibm-spectrum-fusion-ns
  veleroNamespaceSecretKeyRef:
    key: cloud
    name: cloud-credentials-sitel
  caCertificates:

TUFBD0hRURWUjBQKjZRUZJvY9UdjdtY1BBS1JVW1VJN1RDMmVmdwpaZWhtTUI4R0EXVWRJd1FZTUJhQUZDNmpGaXJzZdVeXduEc2UTFDWHMjMMVwV
jJNQ
```

```
webhook:
  port: 9443
```

h. Go to Workloads > Pods in the `ibm-spectrum-fusion-ns` namespace on site1 and site2 (or IBM Fusion namespace) and then delete the pod with the prefix `ramen-dr-cluster-operator-` to reflect the Ramen configuration changes.

Step 2-enroll an application

1. Enable DR from IBM Fusion user interface and update `VolumeReplicationGroup` by adding `kubeObjectProtection`. For example:

```
apiVersion: ramendr.openshift.io/v1alpha1
kind: VolumeReplicationGroup
metadata:
  name: shioramen
  namespace: shioramen
spec:
  kubeObjectProtection: {}
  pvcSelector: {}
  replicationState: primary
  s3Profiles:
    - site2
    - site1
  sync: {}
  volSync:
    disabled: true
```

Important: Ensure that all the required parameters are defined in spec section during the VRG creation. If you edit VRG parameters later on, it can lead to an inconsistent behavior. If changes to the VRG are required after creation, then you must recreate the VRG.

2. If the Application is already enrolled by using the UI, then use the following command to patch the existing VRG:

```
kubectl patch -n <namespace> vrg/<namespace> --type json -p' [{"op": "add", "path": "/spec/kubeObjectProtection", "value": {}}]'
```

3. The VRG status must show `ClusterDataProtected` as true. If you see `AnnotationFailed` reason, then go to the PVC and remove the following annotation from it:

```
volumereplicationgroups.ramendr.openshift.io/vr-archived: archiveV1-0
```

Step 3-failover applications

1. Scale down the applications deployment on site1 after the `KubeObjects` are protected.
2. Update the `VolumeReplicationGroup` (VRG) by setting the `replicationState` to `secondary` to initiate the failover on the site1.
3. Delete the PVC on Site1.
4. Create a VRG with `replicationState` set to `primary` and `kubeObjectProtection: {}`, and verify whether the applications deployment starts successfully.

Step 4-disable Application DR

For each application that is DR enabled, disable Metro-DR for that application to clean it up, including deletion of its `VolumeReplicationGroup`.

1. Disable DR for applications from the IBM Fusion HCI. For the procedure to disable, see [Disable disaster recovery point in Backing up your applications topic](#).
2. Update `Ramen` ConfigMap and restart the `Ramen` controller:

```
kubectl -nibm-spectrum-fusion-ns patch cm/ramen-dr-cluster-operator-config --type json -
p' [{"op": "add", "path": "/data/ramen_manager_config.yaml", "value": ""} $(kubectl -nibm-spectrum-fusion-ns get cm/ramen-dr-
cluster-operator-config -ojsonpath='{.data.ramen_manager_config.yaml}' | sed -n '/^kubeObjectProtection:/{:1;n;/^
/b1;p;$!s/$/\n/' | tr -d '\n') "\"]'
sleep 120
kubectl -nibm-spectrum-fusion-ns rollout restart deploy/ramen-dr-cluster-operator; kubectl -nibm-spectrum-fusion-ns rollout
status -w deploy/ramen-dr-cluster-operator
```

Note: Update Ramen ConfigMap, wait for two minutes, and then restart the Ramen controller.

Kubernetes Resource Protection

Kubernetes applications rely on Kubernetes API resources to function within a cluster. For example, deployments can specify the program components of an application, ConfigMap modifies how a user wants to run an application, and custom resources control the overall operation of the application through application operators. Protecting Kubernetes resources against data loss and disasters in an application-independent manner simplifies Kubernetes application development for applications, requiring those backups and restore services.

Selective protection and recovery of Kubernetes resources for disaster recovery

To minimize recovery time, an application can pre-deploy some of its Kubernetes resources on the recovery cluster. Such an application wants a method to avoid duplicate recovery of its Kubernetes resources to ensure the benefits of pre-deployment. Some Kubernetes resources are created dynamically by Kubernetes itself and an application does not need to preserve the history of those resources so that the protection is not needed. Kubernetes events are a prime example of such resources. In the case of events, applications might need a method to prevent protection and recovery. Hence, the RamenDR Recipe custom resource for disaster recovery provides a flexible mechanism to support these examples and has generalized the mechanism for other use cases.

The general technique of selective protection and recovery mechanism is to filter Kubernetes resources by its kind and label. Resources can be selectively protected and recovered by its kind. It uses an include and exclude mechanism that is provided within the VRG. In addition to include and exclude, the standard Kubernetes label selector mechanism is used to protect specific resources.

Kubernetes resource protection and recovery order

Kubernetes applications must be designed to run on a specified system with a desired state, and the desired state is continuously attempted, achieved, and maintained over time. It is up to the application to deal with asynchronous behavior that is required by this set and attempt, achieve, maintain architecture. However, this level of asynchrony cannot be maintained in highly complex applications with stringent user expectations. First, an asynchronous scope breaks the ability of programmers to predict all sequences of events. Second, asynchronous scope can be a source of failed dependencies. It results in back-off retry loops that can violate the application's Recovery Time Objective (RTO). Restoring resources in a prescribed order can avoid both of these problems. So the Ramen VRG provides a mechanism to support capturing and restoring resources in a prescribed order.

An example of Kubernetes resource protection specification

```
apiVersion: ramendr.openshift.io/v1alpha1
kind: Recipe
metadata:
  name: recipe-sample
  namespace: my-app-ns
spec:
  appType: demo-app # required, but not currently used
  - name: volumes
    type: volume
    labelSelector: app=my-app
  - name: config
    backupRef: config
    type: resource
    includedResourceTypes:
      - configmap
      - secret
  - name: deployments
    backupRef: deployments
    type: resource
    includedResourceTypes:
      - deployment
  - name: instance-resources
    backupRef: instance-resources
    type: resource
    excludedResourceTypes:
      - configmap
      - secret
      - deployment
hooks:
  - name: service-hooks
    namespace: my-app-ns
    labelSelector: shouldRunHook=true
    ops:
      - name: pre-backup
        container: main
        command: ["/scripts/pre_backup.sh"] # must exist in 'main' container
        timeout: 1800
      - name: post-restore
        container: main
        command: ["/scripts/post_restore.sh"] # must exist in 'main' container
        timeout: 3600
workflows:
  - name: capture # referenced in VRG
    sequence:
      - group: config
      - group: deployments
      - hook: service-hooks/pre-backup
      - group: instance-resources
  - name: recover # referenced in VRG
    sequence:
      - group: config
      - group: deployments
      - group: instance-resources
      - hook: service-hooks/post-restore
```

VRG sample that uses this Recipe

```
apiVersion: ramendr.openshift.io/v1alpha1
kind: VolumeReplicationGroup
metadata:
  name: vrg-sample
  namespace: my-app-ns # same Namespace as Recipe
spec:
  kubeObjectProtection:
    recipeRef:
      name: recipe-sample
      captureWorkflowName: capture
      recoverWorkflowName: recover
    volumeGroupName: volumes
```

Explanation of the capture and recovery specifications in VRG

The scope of a VRG disaster protection is a single Kubernetes namespace. The VRG protects persistent volumes that are associated with the namespace and optionally protects Kubernetes resources in the namespace. This documentation contains the product previews for protecting Kubernetes resources so does not explain the persistent volume disaster protection.

VRG allows Kubernetes resources to be captured (backed up) and restored as part of disaster recovery. This is achieved through the RamenDR recipe. If a RamenDR recipe specification is not included in VRG, Kubernetes resources are not protected as part of VRG disaster protection.

The RamenDR has two workflows, namely capture and recover. The capture order workflow provides instructions on how to capture a namespace Kubernetes resource. The recover workflow provides instructions on how to recover a namespaces Kubernetes resource after a disaster. This indicates that the order of capture and recovery workflow can be different and need not include the same resources. Each capture and recover workflow contains a list of resource instructions. Each item in the list is acted upon, even if it duplicates the work that is done by other items in the list. So care must be taken to avoid duplication in backup or recover lists so that best RPO and RTO are achieved.

The list items must meet the following requirements:

Note: If the requirements are not met, then the operations of the lists are undefined.

1. The name of each item in the captureOrder list must be unique.
2. The backupName of each item in the recoverOrder list must match a name in the recoverOrder list.
3. A labelSelector in a list item only applies to that item in the list.
4. If a list item contains multiple labelSelectors, then any resource that matches either label selector is operated upon.
5. IncludeClusterResources in a list item apply only to that item in the list.
6. Each list item can contain either an includedResources section or an excludedResources section, but not both.

Disaster recovery configuration for Fusion Data Foundation

Disaster recovery offerings of IBM Fusion HCI with Fusion Data Foundation storage.

Disaster recovery provides the ability to fail over an application from one Red Hat® OpenShift® Container Platform cluster to another. It also allows relocating the same application back to the original primary cluster.

IBM Fusion HCI with Fusion Data Foundation storage supports the regional disaster recovery (Regional-DR) capability that protects applications and virtual machines (VMs) against regional failures and disaster scenarios like data center failures, maintaining predictable data loss and business continuity. For more information, see [Regional-DR configuration for Fusion Data Foundation](#).

Region failure in Regional-DR is expressed by using the terms, **Recovery Point Objective (RPO)** and **Recovery Time Objective (RTO)**.

- **RPO** is a measure of how frequently you take backups or snapshots of persistent data. In practice, the RPO indicates the amount of data that is lost or need to be reentered after an outage.
- **RTO** is the amount of downtime a business can tolerate. The RTO answers the question, “How long can it take for our system to recover after we are notified of a business disruption?”
- [Regional-DR configuration for Fusion Data Foundation](#)
Regional disaster recovery (Regional-DR) ensures business continuity during the unavailability of an IBM Fusion HCI site in a geographical region, accepting some loss of data in a predictable amount.

Regional-DR configuration for Fusion Data Foundation

Regional disaster recovery (Regional-DR) ensures business continuity during the unavailability of an IBM Fusion HCI site in a geographical region, accepting some loss of data in a predictable amount.

IBM Fusion HCI with Fusion Data Foundation storage supports the Regional-DR capability that is built on asynchronous data replication. While Regional-DR uses asynchronous replication with some risk of data loss, it protects business-critical applications on IBM Fusion HCI from region failures.

Regional-DR supports the following site deployment topologies:

- Two standalone single-rack IBM Fusion HCI sites.
- A primary site that uses a two-availability-zone and arbiter node (2AZ and arbiter) topology paired with a secondary standalone single-rack IBM Fusion HCI site, available with Fusion Data Foundation 4.22 or later. In this configuration, the 2AZ and arbiter node deployment provides local high availability across zones at the primary site, and Regional-DR provides cross-site disaster recovery protection across regional distances.

Regional-DR supports the following Fusion Data Foundation storage configurations on IBM Fusion HCI:

- Replica-3 block (RBD) and file (CephFS) storage
- Erasure-coded block (RBD) and file (CephFS) storage, available with Red Hat® OpenShift® Container Platform and Fusion Data Foundation 4.22 or later

To configure Regional-DR, use Red Hat Advanced Cluster Management (RHACM) to set disaster recovery policies on base clusters and Hosted Control Plane clusters deployed across two IBM Fusion HCI sites. To manage them, a hub cluster is required for the RHACM operator. For more information, see [Components required for Regional-DR](#).

- [Components required for Regional-DR](#)

Regional disaster recovery (Regional-DR) relies on RHACM and Fusion Data Foundation components to support workloads and data mobility between clusters deployed across two IBM Fusion HCI sites.

Configure regional disaster recovery (Regional-DR) capability in the IBM Fusion HCI with Fusion Data Foundation to replicate and recover applications and virtual machines (VMs) across clusters.
- [Validating Regional-DR with applications](#)
Regional disaster recovery (Regional-DR) supports disaster recovery of applications deployed on managed clusters regardless of whether the Red Hat Advanced Cluster Management (RHACM) manages the applications or not. It also supports disaster recovery of virtual machines (VMs).
- [Validating disaster recovery](#)
Validate disaster recovery configurations by using the Red Hat OpenShift Data Foundation CLI `odf dr validate` command to verify cluster health, S3 endpoints, and protected applications.
- [Viewing Recovery Point Objective values for disaster recovery enabled applications](#)
Recovery Point Objective (RPO) value is the most recent sync time of persistent data from the cluster where the application is currently active to its peer. This sync time helps determine duration of data lost during failover.
- [Enabling granular disaster recovery for individual or groups of virtual machines in a namespace](#)
You can enable granular disaster recovery (DR) for individual virtual machines (VMs) or VM groups within the same namespace, allowing independent failover and relocation actions.
- [DryRun mode for testing failover \[Technology preview\]](#)
Validate disaster recovery procedures without disrupting production applications by using DryRun mode in Fusion Data Foundation.
- [Monitoring regional disaster recovery relationships and actions by using Topology view](#)
Monitor disaster recovery relationships, failover and relocate operations, and application DR statuses across clusters by using the Topology view.
- [Storage-agnostic disaster recovery for third-party vendors](#)
Ramen integrates with third-party storage providers to deliver disaster recovery between OpenShift clusters.

Components required for Regional-DR

Regional disaster recovery (Regional-DR) relies on RHACM and Fusion Data Foundation components to support workloads and data mobility between clusters deployed across two IBM Fusion HCI sites.

Clusters

The Regional-DR brings the ability to failover applications and virtual machines (VMs) from one cluster to another cluster and then failback the same applications and VMs to the original primary cluster.

The following figure illustrates an example of the Regional-DR configuration for clusters deployed across two IBM Fusion HCI sites:

Figure 1. Illustration of a Regional-DR setup for base clusters

Figure 2. Illustration of a Regional-DR setup for Hosted Control Plane clusters

As shown in the figures [Figure 1](#) and [Figure 2](#), you can have the following clusters in the Regional-DR setup:

Table 1. List of clusters for Regional-DR setup

Cluster	Description
Base cluster	The cluster where Fusion Data Foundation is installed in provider mode and serves storage to Hosted Control Plane clusters. Each IBM Fusion HCI site must have at least one base cluster. Base clusters can be deployed on a standalone single-rack deployment or across a 2AZ and arbiter node topology at the primary site, available with Fusion Data Foundation 4.22 or later.
Hosted Control Plane cluster	The virtualized or bare metal Hosted Control Plane cluster where the Fusion Data Foundation client is installed. You can have multiple virtualized and bare metal Hosted Control Plane clusters at each site. On a 2AZ and arbiter primary site, control plane nodes and etcd members are distributed across both availability zones to provide local high availability. Important: Hosted Control Plane clusters with KubeVirt are not supported due to a known issue. For more information, see ACM-36616 in Known issues .
Hub cluster	An external cluster where the RHACM operator is installed and created outside the IBM Fusion HCI sites. This hub cluster manages base clusters and Hosted Control Plane clusters of both IBM Fusion HCI sites.

Red Hat Advanced Cluster Management for Kubernetes (RHACM) operator

The RHACM operator manages multiple clusters and application lifecycle. Hence, the RHACM hub cluster serves as a control plane in the Regional-DR setup.

RHACM operator is split into two parts:

- **RHACM hub:** Run on the hub cluster or multicluster control plane.
- **Managed clusters:** Imported base and Hosted Control Plane clusters to the hub cluster. The base or Hosted Control Plane cluster from the primary site is called a primary-managed cluster, while the one from the secondary site is called a secondary-managed cluster.

For more information about the RHACM, see About, Welcome to Red Hat Advanced Cluster Management for Kubernetes in [Red Hat® Advanced Cluster Management for Kubernetes](#) product documentation.

Note: Select the appropriate version for your environment and requirements.

OpenShift Multicluster Orchestrator operator

The OpenShift® Multicluster Orchestrator operator orchestrates configuration and peering of the Fusion Data Foundation clusters for the Regional-DR configuration. It needs to be installed on the hub cluster.

Configuring Regional-DR

Configure regional disaster recovery (Regional-DR) capability in the IBM Fusion HCI with Fusion Data Foundation to replicate and recover applications and virtual machines (VMs) across clusters.

Before you begin

- Important: Hosted Control Plane clusters with KubeVirt are not supported due to a known issue. For more information, see [ACM-36616](#) in [Known issues](#).
- If an external Red Hat® Advanced Cluster Management (RHACM) hub cluster is already available, you can use it for the Regional-DR configuration. If you do not have it, install the RHACM operator to create a hub cluster outside the IBM Fusion HCI sites.

For instructions, see the [Install](#) guide in the RHACM documentation set.

If Hosted Control Plane clusters deployed on IBM Fusion HCI sites are upgraded from a previous version and the RHACM operator is already installed on an Hosted Control Plane cluster, migrate the RHACM operator from the Hosted Control Plane cluster to a new cluster. For assistance with migration, contact [IBM support](#).

- It is recommended that the VMs should use the `ocs-storagecluster-ceph-rbd-virtualization` storage class.
- Ensure that the storage class with the same name exists on the secondary-managed cluster.

- To use erasure-coded block (RBD) or file (CephFS) storage with Regional-DR, ensure that the following conditions are met:
 - Fusion Data Foundation 4.22 or later is installed on both IBM Fusion HCI sites.
 - Each single-rack IBM Fusion HCI site has sufficient storage nodes to support the selected erasure coding profile. For more information about supported erasure coding profiles, see [Configuring Fusion Data Foundation in provider mode](#).
 - Both IBM Fusion HCI sites use a matching erasure coding storage configuration.
 - Red Hat OpenShift® Container Platform 4.22 or later is deployed on both sites.
- For a 2AZ and arbiter deployment at the primary site, ensure that Fusion Data Foundation 4.22 or later is installed and that the Hosted Control Plane clusters are deployed with zone-aware node distribution across both availability zones.

Procedure

1. Deploy primary and secondary IBM Fusion HCI sites and configure network reachability between them.
Deploy the appropriate topology for your environment:

Standalone single-rack sites

If only one IBM Fusion HCI site is present, install IBM Fusion HCI at the other site. For installation instructions, see [Installing IBM Fusion HCI](#).

2AZ and arbiter node topology

If the primary site uses a 2AZ and arbiter deployment, deploy the Hosted Control Plane clusters across both availability zones:

- For virtualized Hosted Control Plane clusters on Regional-DR topology, see [Deploying a virtualized Hosted Control Plane cluster on Regional-DR topology](#).
- For bare metal Hosted Control Plane clusters on Regional-DR topology, see [Deploying a Bare Metal Hosted Control Plane cluster on Regional-DR topology](#).

Important: The IBM Fusion HCI version number must be the same across both sites.

2. Open the following ports to ensure that the pods are reachable from other clusters:

Note: In provider mode, host networking is used for MONs and OSD.

- Ceph mon v1: 6789
- Ceph mon v2: 3300
- Ceph OSD: 6800–7300
- Ceph Manager: 9283

3. Optional: Set up an SSL connection between clusters deployed on IBM Fusion HCI sites.

For instructions, see [Establishing an SSL connection between clusters](#).

Note: If a signed and valid set of certificates has been used for the deployment of base or Hosted Control Plane clusters in both IBM Fusion HCI sites, skip this step.

4. Install the Fusion Data Foundation in newly created clusters.

Base clusters

Install Fusion Data Foundation in provider mode. For instructions, see [Installing Fusion Data Foundation](#).

Hosted Control Plane clusters

Install the Fusion Data Foundation client. For instructions, see [Installing Fusion Data Foundation on a Hosted Control Plane cluster](#).

Important: The Fusion Data Foundation version number must be the same on base and Hosted Control Plane clusters deployed across IBM Fusion HCI sites.

5. Import the clusters of primary and secondary IBM Fusion HCI sites to the RHACM hub cluster.

Base clusters

Import base clusters to the RHACM hub. For instructions, see [Cluster management and multicluster engine](#), [multicluster engine operator with Red Hat Advanced Cluster Management](#), [Working with hosted clusters in Red Hat Advanced Cluster Management](#), [Discovering multicluster engine operator hosted clusters in Red Hat Advanced Cluster Management](#) in [Red Hat Advanced Cluster Management for Kubernetes](#) product documentation.

Note: Select the appropriate version for your environment and requirements.

Hosted Control Plane clusters

Discover Hosted Control Plane clusters from the multicluster engine (MCE) operator. For instructions, see [Cluster management and multicluster engine](#), [multicluster engine operator with Red Hat Advanced Cluster Management](#), [Working with hosted clusters in Red Hat Advanced Cluster Management](#), [Discovering multicluster engine operator hosted clusters in Red Hat Advanced Cluster Management](#), [Discovering hosted clusters in Red Hat Advanced Cluster Management for Kubernetes](#) product documentation.

Note: Select the appropriate version for your environment and requirements.

Discovered Hosted Control Plane clusters can be automatically imported into the RHACM hub if the `spec.importAsManagedCluster` field is set to `true`. You need to set this field in the individual discovered cluster's custom resource (CR). For instructions, see [Cluster management and multicluster engine](#), [multicluster engine operator with Red Hat Advanced Cluster Management](#), [Working with hosted clusters in Red Hat Advanced Cluster Management](#), [Automating import for discovered hosted clusters](#), [Configuring settings for automatic import in Red Hat Advanced Cluster Management for Kubernetes](#) product documentation.

Note: Select the appropriate version for your environment and requirements.

6. Connect the managed clusters and service networks by using the Submariner add-on of the RHACM.

Verify that the clusters have non-overlapping Classless Inter-Domain Routings (CIDRs) and cluster private networks. For overlapping CIDRs, enable Globalnet during the Submariner add-on installation to connect clusters.

Run the following command on each managed cluster to verify that the clusters have overlapping CIDRs or non-overlapping CIDRs:

```
oc get networks.config.openshift.io cluster -o json | jq .spec
```

The following example is for clusters with overlapping CIDRs, so the Globalnet needs to be enabled to connect clusters.

Example output for primary-managed cluster:

```
{
  "clusterNetwork": [
    {
      "cidr": "10.5.0.0/16",
      "hostPrefix": 23
    }
  ],
  "externalIP": {
    "policy": {}
  }
}
```

```

    },
    "networkType": "OVNKubernetes",
    "serviceNetwork": [
      "10.15.0.0/16"
    ]
  }
}

```

Example output for secondary-managed cluster:

```

{
  "clusterNetwork": [
    {
      "cidr": "10.5.0.0/16",
      "hostPrefix": 23
    }
  ],
  "externalIP": {
    "policy": {}
  },
  "networkType": "OVNKubernetes",
  "serviceNetwork": [
    "10.15.0.0/16"
  ]
}

```

Additionally, if Submariner and Fusion Data Foundation are already installed on the managed clusters, use the Red Hat OpenShift Data Foundation command-line interface (CLI) tool to get additional information about the managed clusters. This information determines the need for enabling Globalnet during Submariner installation based on the cluster service and private networks. Download the Red Hat OpenShift Data Foundation CLI tool from the [Red Hat Customer Portal](#).

Note: Download the latest Red Hat OpenShift Data Foundation CLI package from the Red Hat Customer Portal. No additional license is required to use the CLI tool. The latest CLI package works with earlier and later versions of Fusion Data Foundation, though newer CLI versions can include additional capabilities.

Run the following command on one of the two managed clusters, where *PeerManagedClusterName(ClusterID)* is the name of the peer Fusion Data Foundation cluster:

```
odf get dr-prereq <PeerManagedClusterName(ClusterID)>
```

If Submariner is installed without Globalnet on managed clusters with overlapping services, the following output appears:

```

Info: Submariner is installed.
Info: Globalnet is required.
Info: Globalnet is not enabled.

```

Note: This requires Submariner to be uninstalled and then reinstalled with Globalnet enabled.

If Submariner is installed with Globalnet on managed clusters with overlapping services, the following output appears:

```

Info: Submariner is installed.
Info: Globalnet is required.
Info: Globalnet is enabled.

```

If Submariner is installed without Globalnet on managed clusters with non-overlapping services, the following output appears:

```

Info: Submariner is installed.
Info: Globalnet is not required.
Info: Globalnet is not enabled.

```

If Submariner is installed with Globalnet on managed clusters with non-overlapping services, the following output appears:

```

Info: Submariner is installed.
Info: Globalnet is not required.
Info: Globalnet is enabled.

```

For more information on Submariner add-ons and Globalnet configuration, see Operations_>Networking_>Submariner multicluster networking and service discovery in [Red Hat Advanced Cluster Management for Kubernetes](#) product documentation.

Note: Select the appropriate version for your environment and requirements.

7. Install the Data Foundation Multicluster Orchestrator operator on the hub cluster.

For instructions, see [Installing Multicluster Orchestrator operator](#).

8. To connect clusters with providerAPIServerServiceType: ClusterIP by using the Submariner add-on do one of the following methods:

If MetalLB is configured and the IP range is provided, do [method 1](#). If MetalLB is not configured and Globalnet was enabled when setting up Submariner, do [method 2](#).

Note: If a proxy is configured on the clusters, ensure that the **No_Proxy** list is configured based on the method that you use.

- If you use [method 1](#) or [method 2](#), add the **api-server-exported-address** to the **No_Proxy** list.
- If you do not use either method, add the service network of the peer managed cluster to the **No_Proxy** list.

Method 1:

If MetalLB is configured and the **ocs-provider-server-load-balancer** service has assigned IP addresses, add the following annotation (key-value pair) to the **StorageCluster** resource on both managed clusters:

- **Key:** **ocs.openshift.io/api-server-exported-address**
- **Value:** Endpoint of the **<LoadBalancer ip>:50051**.

If the **ocs-provider-server-load-balancer** service is in the **Pending** state and has no assigned IP addresses, assign IP addresses to the **LoadBalancer** service. If no IP addresses are available, use [method 2](#).

To fetch the IP address of the **ocs-provider-server-load-balancer** service, run the following command:

```
oc get svc -n openshift-storage -o wide | grep provide
```

Example output:

```
ocs-provider-server-load-balancer   LoadBalancer   172.30.213.146   172.200.88.109   50051:30506/TCP   6d   app=ocsProvid
```

After the annotation is added, the **odf-info configMap** detects this endpoint, which the MCO uses to create the **StorageClusterPeer**.

For example:

```
ocs.openshift.io/api-server-exported-address: '172.200.88.109:50051'
```

- **Method 2:**

If you do not want to use MetalLB and no IP addresses are available, create a service export and use Submariner for cross-cluster communication between the two clusters. Do the following steps:

- Create a **ServiceExport** for the **ocs-provider-server** service.

```
apiVersion: multicloud.x-k8s.io/v1alpha1
kind: ServiceExport
metadata:
  name: ocs-provider-server
  namespace: openshift-storage
```

- Add the following annotation (key-value pair) to the **StorageCluster** resource on both managed clusters:

- **Key:** `ocs.openshift.io/api-server-exported-address`
- **Value:** `<managerClusterName>.ocs-provider-server.openshift-storage.svc.cluster.local:50051`

managedClusterName refers to the name used during cluster import into the hub cluster. For example, if **rackm03** was the name provided, then:

```
ocs.openshift.io/api-server-exported-address: rackm03.ocs-provider-server.openshift-
storage.svc.cluster.local:50051
```

Command example to add the annotation:

```
oc -n openshift-storage annotate storagecluster ocs-storagecluster 'ocs.openshift.io/api-server-exported-
address="173.100.89.108:50051"'
```

Where,

- **openshift-storage:** The namespace where Fusion Data Foundation is installed.
- **ocs-storagecluster:** The storage cluster name.
- **key:** `ocs.openshift.io/api-server-exported-address`
- **value:** `"173.100.89.108:50051"`

Note: Either RHACM, MCE, or Submariner brings the **ServiceExport** CRD. So, you can create the **ServiceExport** after Submariner is installed for the clusters that do not have MCE installed.

After the annotation is added, the **odf-info** configMap detects this endpoint, which the MCO uses to create the **StorageClusterPeer**.

9. Check whether a **KlusterletAddonConfig** resource already exists for both managed clusters on the RHACM hub cluster.

Run the following command on the RHACM hub cluster to verify that **KlusterletAddonConfig** resources exist for both managed clusters:

```
oc get klusterletaddonconfig -A
```

If the **KlusterletAddonConfig** resources for both managed clusters are listed in the output, proceed to the next step. Otherwise, create the missing resource by applying the following YAML configuration:

For example:

```
apiVersion: agent.open-cluster-management.io/v1
kind: KlusterletAddonConfig
metadata:
  name: <rack name>
  namespace: <rack name>
spec:
  clusterName: <rack name>
  clusterNamespace: <rack name>
  clusterLabels:
    name: <rack name>
    cloud: auto-detect
    vendor: auto-detect
  applicationManager:
    enabled: true
  policyController:
    enabled: true
  searchCollector:
    enabled: true
  certPolicyController:
    enabled: true
```

Remember: In the YAML configuration, provide the same cluster name that you get in the output of the following command:

```
oc get managedcluster
```

10. Create a disaster recovery policy (DRPolicy) for the managed clusters.

For instructions, see [Creating a disaster recovery policy on hub cluster](#).

11. Verify whether the Regional-DR is successfully configured.

For instructions, see [Verifying Regional-DR configuration](#).

What to do next

Validate Regional-DR with applications by following the instructions mentioned in [Validating Regional-DR with applications](#).

- [Installing Multicloud Orchestrator operator](#)

Install the Data Foundation Multicloud Orchestrator operator for orchestrating configuration and peering of the Fusion Data Foundation clusters for the Regional-DR configuration.

- [Establishing an SSL connection between clusters](#)

Establish an SSL connection between clusters deployed on IBM Fusion HCI sites so that metadata can be stored on the Multicloud Object Gateway (MCG) bucket of the base clusters by using a secure transport protocol.

- [Creating a disaster recovery policy on hub cluster](#)
The disaster recovery policy (DRPolicy) defines an asynchronous replication schedule with a specified replication interval for the managed clusters. Use this policy to replicate and recover applications across those managed clusters.
- [Disaster recovery protection for cloned and restored RBD volumes](#)
The CephCSI driver does necessary operations on the cloned or restored RADOS Block Device (RBD) volumes to prepare them for disaster recovery protection when you enable the disaster recovery support for restored and cloned PersistentVolumeClaims (PVCs).
- [Verifying Regional-DR configuration](#)
Verify that all required components for regional disaster recovery (Regional-DR) are properly configured and operational.

Installing Multicluster Orchestrator operator

Install the Data Foundation Multicluster Orchestrator operator for orchestrating configuration and peering of the Fusion Data Foundation clusters for the Regional-DR configuration.

Before you begin

- Ensure that you created the following **CatalogSource** manifest on the hub cluster:

```
apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: isf-data-foundation-catalog
  namespace: openshift-marketplace
spec:
  displayName: Data Foundation Catalog
  grpcPodConfig:
    affinity:
      nodeAffinity:
        preferredDuringSchedulingIgnoredDuringExecution:
          - preference:
              matchExpressions:
                - key: gpu.isf.ibm.com
                  operator: DoesNotExist
              weight: 50
    securityContextConfig: restricted
  icon:
    base64data: ""
    mediatype: ""
  image: icr.io/cpopen/isf-data-foundation-catalog:v4.21
  publisher: IBM
  sourceType: grpc
  updateStrategy:
    registryPoll:
      interval: 60m
```

Note: Ensure that the version number you specify in the **image** field of the **CatalogSource** manifest matches the Fusion Data Foundation version installed on the managed cluster.

- Ensure that you are logged in to the Red Hat® OpenShift® Container Platform as an administrator.
- Ensure that **ibm-spectrum-fusion-ns** is selected in the Project field.

Procedure

1. Go to **Ecosystem > Software Catalog** tab.
2. Search for the **Multicluster Orchestrator** operator in the All Items field and select the IBM-provided Multicluster Orchestrator tile.
3. On the Data Foundation Multicluster Orchestrator window, keep all default settings and click **Install**.
Data Foundation Multicluster Orchestrator operator is installed.
Note:
The Data Foundation Multicluster Orchestrator operator also installs the Openshift DR Hub operator on the hub cluster.
4. Verify that the resources of the Data Foundation Multicluster Orchestrator operator are installed in the openshift-operators project and available to all namespaces.
5. Verify that Pods of operators are in the **Running** status.
Note: Check whether the Openshift DR Hub operator is also in the **Running** status.
Run the following command:

```
oc get pods -n openshift-operators
```

Example output:

NAME	READY	STATUS	RESTARTS	AGE
odf-multicluster-console-6845b795b9-blxrn	1/1	Running	0	4d20h
odfmo-controller-manager-f9d9dfb59-jbrsd	1/1	Running	0	4d20h
ramen-hub-operator-6fb887f885-fss4w	2/2	Running	0	4d20h

Establishing an SSL connection between clusters

Establish an SSL connection between clusters deployed on IBM Fusion HCI sites so that metadata can be stored on the Multicloud Object Gateway (MCG) bucket of the base clusters by using a secure transport protocol.

About this task

Here, clusters refer to the base or Hosted Control Plane clusters imported into the hub cluster. For more information, see [List of clusters for Regional-DR setup](#).

If a signed and valid set of certificates has been used for the deployment of base or Hosted Control Plane clusters in IBM Fusion HCI sites, skip this procedure.

Procedure

1. Extract the ingress certificate of the primary-managed cluster and save the output to the `primary.crt` file.

Run the following command:

```
oc get cm default-ingress-cert -n openshift-config-managed -o jsonpath="{['data']['ca-bundle\.crt']}" > primary.crt
```

2. Extract the ingress certificate of the secondary-managed cluster and save the output to the `secondary.crt` file.

Run the following command:

```
oc get cm default-ingress-cert -n openshift-config-managed -o jsonpath="{['data']['ca-bundle\.crt']}" > secondary.crt
```

3. Copy the certificate contents from both managed clusters into a new config map file and save it in the namespace of clusters.

For base clusters, save it in the namespace where the base cluster object is created, such as `openshift-config`. For Hosted Control Plane clusters, save it in the namespace where the `HostedCluster` object is created.

For example, the config map file name is `user-ca-bundle.yaml`.

Note:

- Ensure that the certificate contents are correctly indented after you copy and paste it from the `primary.crt` and `secondary.crt` files.
- Each cluster might have more or fewer than three certificates, as shown in the following example.

An example of a config map file is as follows:

```
apiVersion: v1
data:
  ca-bundle.crt: |
    -----BEGIN CERTIFICATE-----
    <copy contents of cert1 from primary.crt here>
    -----END CERTIFICATE-----

    -----BEGIN CERTIFICATE-----
    <copy contents of cert2 from primary.crt here>
    -----END CERTIFICATE-----

    -----BEGIN CERTIFICATE-----
    <copy contents of cert3 primary.crt here>
    -----END CERTIFICATE-----

    -----BEGIN CERTIFICATE-----
    <copy contents of cert1 from secondary.crt here>
    -----END CERTIFICATE-----

    -----BEGIN CERTIFICATE-----
    <copy contents of cert2 from secondary.crt here>
    -----END CERTIFICATE-----

    -----BEGIN CERTIFICATE-----
    <copy contents of cert3 from secondary.crt here>
    -----END CERTIFICATE-----
kind: ConfigMap
metadata:
  name: user-ca-bundle
  namespace: openshift-config
```

4. Add the name of the newly created config map to the `spec.configuration.proxy.trustedCA` in the `HostedCluster` CR.

Note: This step applies only to Hosted Control Plane clusters.

For example:

```
configuration:
  proxy:
    trustedCA:
      name: user-ca-bundle
```

5. Create the config map on primary-managed cluster, secondary-managed cluster, and hub cluster.

Run the following command:

```
oc create -f user-ca-bundle.yaml
```

Example output:

```
configmap/user-ca-bundle created
```

6. Patch the default proxy resource on primary-managed cluster, secondary-managed cluster, and hub cluster.

Run the following command:

```
oc patch proxy cluster --type=merge --patch='{ "spec": { "trustedCA": { "name": "user-ca-bundle" } } }'
```

Example output:

```
proxy.config.openshift.io/cluster patched
```

Creating a disaster recovery policy on hub cluster

The disaster recovery policy (DRPolicy) defines an asynchronous replication schedule with a specified replication interval for the managed clusters. Use this policy to replicate and recover applications across those managed clusters.

Before you begin

Ensure that primary and secondary-managed clusters are imported to the hub cluster as instructed in [step 5](#) of *Configuring Regional-DR*.

Procedure

1. Log in to the OpenShift® Container Platform web console and select All clusters.
2. From the Data Services menu, select the Disaster recovery tab.
3. On the Overview tab of the Disaster recovery window, click Create a disaster recovery policy or go to the Policies tab and click Create DRPolicy.
4. In the Policy name field, enter a policy name that is not already in use.
5. Select two clusters from the list of managed clusters to associate with this new policy.
The Replication policy field is automatically set with the value **Asynchronous**.
6. Set the time in the Replication interval field.
Important: If you are creating a disaster recovery policy for VM workloads, enable flattening to ensure reliable and supported regional disaster recovery behavior. To enable flattening, follow [step 7](#).
7. Optional: Expand Advanced settings and select the Enable disaster recovery support for restored and cloned PersistentVolumeClaims (For Data Foundation only) checkbox.
For more information on disaster recovery protection for cloned and restored RADOS Block Device (RBD) volumes, see [Disaster recovery protection for cloned and restored RBD volumes](#).
Important: Use this option only with discovered applications and if cloned and restored RADOS Block Device (RBD) volumes are available.
8. Click Create.
9. Optional: For further validation, see [Validating disaster recovery](#).

Disaster recovery protection for cloned and restored RBD volumes

The CephCSI driver does necessary operations on the cloned or restored RADOS Block Device (RBD) volumes to prepare them for disaster recovery protection when you enable the disaster recovery support for restored and cloned PersistentVolumeClaims (PVCs).

Cloned and restored RBD volumes are copy-on-write clones of the corresponding data sources. Such RBD volumes are still linked to the parent volume to optimize space consumption and Ceph cluster performance. To mirror RBD images that have such volumes, the cloned and restored RBD volumes need to be separated from the parent RBD image.

Selecting the Enable disaster recovery support for restored and cloned PersistentVolumeClaims (For Data Foundation only) checkbox while [creating a disaster recovery policy](#) instructs CephCSI driver to do necessary operations on the cloned or restored RBD volumes to prepare them for disaster recovery protection. The necessary operation has the following consequences:

- Space consumption may increase up to the total capacity of all cloned and restored RBD volumes that are protected. Ensure that enough space available in the cluster so that the cluster does not full.
- Resource usage of the Ceph cluster increases.
- The time taken for the operation to complete depends on the number of the RBD volumes, size of each volume, Ceph cluster resource availability, and client IO going on the RBD volume. Therefore, the amount of time that is required for completion of the operation cannot be determined.

Important: This option should only be used with discovered applications. If there are existing disaster recovery protected workloads in the same namespace, disaster recovery protection may need to be disabled and re-enabled with a new DRPolicy created using this advanced option.

Verifying Regional-DR configuration

Verify that all required components for regional disaster recovery (Regional-DR) are properly configured and operational.

Procedure

1. Verify that the DRPolicy is created successfully.
Run this command on the Hub cluster for each of the DRPolicy resources created, where *<drpolicy_name>* is replaced with your unique name.

```
oc get drpolicy <drpolicy_name> -o jsonpath='{.status.conditions[].reason}'
```

Example output: Succeeded

When a DRPolicy is created, along with it, two DRCluster resources are also created. It might take up to 10 minutes for all three resources to be validated and for the status to show as Succeeded.

Note: Editing of **SchedulingInterval**, **ReplicationClassSelector**, **VolumeSnapshotClassSelector** and **DRClusters** field values are not supported in the DRPolicy.

2. Verify the object bucket access from the Hub cluster to both the **Primary-managed cluster** and the **Secondary-managed cluster**.
 - a. Get the names of the DRClusters on the Hub cluster.

```
oc get drclusters
```

Example output:

NAME	AGE
ocp4bos1	4m42s
ocp4bos2	4m42s

- b. Check S3 access to each bucket created on each managed cluster.
Use the DRCluster validation command, where `<drcluster_name>` is replaced with your unique name.
Note: Editing of **Region** and **S3ProfileName** field values are non supported in DRClusters.

```
oc get drcluster <drcluster_name> -o jsonpath='{.status.conditions[2].reason}'{"\n"}'
```

Example output: Succeeded

Note: Ensure to run command for both DRClusters on the Hub cluster.

3. Verify that the IBM Fusion Data Foundation DR Cluster operator installation was successful on the **Primary-managed cluster** and the **Secondary-managed cluster**.

```
oc get csv,pod -n openshift-dr-system
```

Example output:

NAME	READY	STATUS	RESTARTS	AGE	DISPLAY
clusterserviceversion.operators.coreos.com/metalldb-operator.v4.18.0-202505081435					MetalLB Operator
clusterserviceversion.operators.coreos.com/odr-cluster-operator.v4.18.4-rhodf					OpenShift DR Cluster Operator
clusterserviceversion.operators.coreos.com/openshift-gitops-operator.v1.16.0-0.1746014725.p					Red Hat OpenShift GitOps

NAME	READY	STATUS	RESTARTS	AGE
pod/ramen-dr-cluster-operator-5458dbcb5c-jtzgm	2/2	Running	0	15s

You can also verify that IBM Fusion Data Foundation DR Cluster Operator is installed successfully on the **OperatorHub** of each managed cluster.

Note: On the initial run, VolSync operator is installed automatically. VolSync is used to set up volume replication between two clusters to protect CephFs-based PVCs. The replication feature is enabled by default.

4. Verify that the status of the IBM Fusion Data Foundation mirroring **daemon** health on the **Primary managed cluster** and the **Secondary managed cluster**.

```
oc get cephblockpoolradosnamespaces -n openshift-storage -o jsonpath='{range .items[*]}{.status.mirroringStatus.summary}{\n'}}'
```

Example output:

```
{ "daemon_health": "OK", "health": "OK", "image_health": "OK", "states": {} }
```

CAUTION:

It could take up to 10 minutes for the `daemon_health` and `health` to go from Warning to OK. If the status does not become OK eventually, then use the RHACM console to verify that the Submariner connection between managed clusters is still in a healthy state. Do not proceed until all values are OK.

Validating Regional-DR with applications

Regional disaster recovery (Regional-DR) supports disaster recovery of applications deployed on managed clusters regardless of whether the Red Hat® Advanced Cluster Management (RHACM) manages the applications or not. It also supports disaster recovery of virtual machines (VMs).

After successfully configuring Regional-DR on the managed clusters, you can validate the setup by replicating and recovering applications across those clusters.

Applications are categorized as follows:

- **Managed applications:** Workloads deployed and managed through RHACM, such as ApplicationSet-based application. For more information on ApplicationSet-based application, see Application management and GitOps, Applications, Managing applications (Deprecated), Application model and definitions (Deprecated) and ApplicationSet in [Red Hat Advanced Cluster Management for Kubernetes](#) product documentation.
Note: Select the appropriate version for your environment and requirements.
- **Discovered applications:** Workloads deployed directly on one of the managed clusters without using RHACM. Although these applications appear in the RHACM console, their lifecycle (create, edit, delete) is not managed by RHACM.

To validate with VMs, if the VM is configured with a secondary VLAN in the IBM Fusion HCI site, ensure that the same secondary VLAN is configured and a corresponding Network Attachment Definition (NAD) is created on the other site. For the secondary VLAN configuration, see [Provisioning additional networking](#).

Note: Regional-DR now supports leveraging RBD and CephFS volumes using non-default replica-2 storage classes that are managed by Fusion Data Foundation. Support has also been extended to compression-enabled storage classes.

Validate Regional-DR with the following applications:

ApplicationSet-based application

To validate Regional-DR with a Subscription-based application, do as follows:

1. Create a sample ApplicationSet-based application by following the instructions mentioned in [Creating an ApplicationSet-based application](#).
2. Apply the DRPolicy to the sample application by following the instructions mentioned in [Applying DRpolicy to an ApplicationSet-based application](#).
3. Do the failover operation of the sample application between the managed clusters by following the instructions mentioned in [Subscription-based application failover between managed clusters](#).
4. Do the relocate operation of the sample application between the managed clusters by following the instructions mentioned in [Relocating an ApplicationSet-based application between managed clusters](#).

After validation, you can delete the sample application by following the instructions mentioned in [Deleting a sample application](#).

Discovered application

To validate Regional-DR with a discovered application, do as follows:

1. Ensure that all prerequisites mentioned in [Prerequisites for disaster recovery protection of discovered applications](#) are met.
2. Create a sample discovered application by following the instructions mentioned in [Creating a sample discovered application](#).
3. Enroll the DRPolicy to the sample application by following the instructions mentioned in [Enrolling a sample discovered application for disaster recovery protection](#).

4. Do the failover operation of the sample application between the managed clusters by following the instructions mentioned in [Failover disaster recovery_protected discovered application](#).
5. Do the relocate operation of the sample application between the managed clusters by following the instructions mentioned in [Relocate disaster recovery_protected discovered application](#).

While the Backup & Restore service and Regional-DR can be configured for the same application, the Backup & Restore service does not currently recognize the disaster recovery state of an application. Even when a hub and spoke configuration is used between two sites, a failed-over application is treated by the Backup & Restore service as a new application.

As a result:

- The Backup & Restore service continues to attempt scheduled backups for the original application on site 1, which might require manual disabling.
- The failed-over application on site 2 does not inherit Backup & Restore service protection from site 1. The application remains unprotected until a new **PolicyAssignment** custom resource (CR) is created. Backups created for the application on site 2 are independent of the backups created for the same application on site 1.

To configure Backup & Restore service in a Regional-DR configuration, complete the following steps:

1. Enroll the application for both Regional-DR and the Backup & Restore service.
2. Fail over the application from site 1 to site 2.
3. Delete the **PolicyAssignment** CR for the application on site 1 to prevent scheduled backups.
4. Relocate the application from site 2 back to site 1.
5. Create a new **PolicyAssignment** CR for the application on site 1 to resume backups.

After validation, you can delete the sample application by following the instructions mentioned in [Disable disaster recovery for protected applications](#).

Multi-volume consistency for disaster recovery

By default, Fusion Data Foundation disaster recovery (DR) provides crash-consistent multi-volume consistency groups for Regional-DR to be used by applications that are deployed across multiple volumes.

Note: If you have upgraded from a previous Fusion Data Foundation version to 4.21, to enable consistency groups you must disable Regional-DR after the upgrade, and then re-enable Regional-DR.

- [Virtual machine garbage collection automation](#)
Virtual machine garbage collection automation provides an automated mechanism to clean up virtual machine resources on the source cluster during disaster recovery failover or relocation workflows, reducing manual effort and supporting lower recovery time objectives.

Creating an ApplicationSet-based application

Create an ApplicationSet-based application on the Hub cluster using the Argo CD Pull model to test Regional-DR failover and relocate across managed clusters.

Before you begin

- Ensure that the Red Hat® OpenShift® GitOps operator is installed on all three clusters: **Hub cluster**, **Primary managed cluster** and **Secondary managed cluster**. For instructions, see [Installing Red Hat OpenShift GitOps Operator in web console](#).
- On the Hub cluster, ensure that both Primary and Secondary managed clusters are registered to GitOps. For registration instructions, see Application management and GitOps > GitOps > GitOps overview > Registering managed clusters to Red Hat OpenShift GitOps operator in [Red Hat Advanced Cluster Management for Kubernetes](#) product documentation.

Note: Select the appropriate version for your environment and requirements.

Then check if the Placement used by **GitOpsCluster** resource to register both managed clusters, has the tolerations to deal with cluster unavailability. You can verify if the following tolerations are added to the Placement using the command.

```
oc get placement <placement-name> -n openshift-gitops -o yaml.
```

```
tolerations:
- key: cluster.open-cluster-management.io/unreachable
  operator: Exists
- key: cluster.open-cluster-management.io/unavailable
  operator: Exists
```

In case the tolerations are not added, see Application management and GitOps > GitOps > GitOps overview > Configuring application placement tolerations for GitOps in [Red Hat Advanced Cluster Management for Kubernetes](#) product documentation.

Note: Select the appropriate version for your environment and requirements.

- Ensure that you have created the **ClusterRoleBinding** yaml on both the **Primary** and **Secondary managed** clusters. For instruction, see Application management and GitOps > GitOps > Deploying Argo CD with Push and Pull model > Prerequisites in [Red Hat Advanced Cluster Management for Kubernetes](#) product documentation.

Note: Select the appropriate version for your environment and requirements.

Procedure

1. On the Hub cluster, navigate to All Clusters > Applications > Create application.
2. Select type as Argo CD ApplicationSet - Pull model.
3. In General step, enter your Application set name.
4. Select Argo server **openshift-gitops** and Requeue time as **180** seconds.
5. Click Next.

6. In the Repository location for resources section, select Repository type **Git**.
7. Enter the Git repository URL for the sample application, the GitHub Branch, and Path where the resources **busybox** Pod and PVC is created.
 - a. Use the sample application repository as <https://github.com/red-hat-storage/ocm-ramen-samples>.
 - b. Select Revision as **main**.
 - c. Choose one the following Path:
 - **workloads/deployment/odr-regional-rbd** to use RBD Regional-DR.
 - **workloads/deployment/odr-regional-cephfs** to use CephFS Regional-DR.
8. Enter Remote namespace value. (example, busybox-sample) and click Next.
9. Select Sync policy settings and click Next.

You can choose one or more options.
10. Add a label **<name>** with its value set to the managed cluster name.
11. Click Next.
12. Review the setting details and click Submit.

Applying DRpolicy to an ApplicationSet-based application

Apply a disaster recovery policy to an ApplicationSet-based application from the Hub cluster console to enable volume replication and protect the application against cluster failure.

Before you begin

Ensure that both managed clusters referenced in the DRPolicy are reachable. If not, the application is not DR protected until both clusters are online.

Procedure

1. On the Hub cluster, navigate to All Clusters > Applications.
2. Click the Actions menu at the end of application to view the list of available actions.
3. Click Manage disaster recovery.
4. Click Enroll application.
5. Select Policy name and click Next.
6. Select an Application resource and then use PVC label selector to select **PVC label** for the selected resource.

Note: You can select more than one PVC label for the selected application resources.
7. After adding all the application resources, click Next.
8. In the Enroll managed application modal, review the policy configuration details and click Assign. The newly assigned Data policy details are displayed on the Manage disaster recovery modal.
9. Verify that you can view the assigned policy details on the Applications page.
 - a. On the Applications page, navigate to the DR Status column and view the status.

The status can be any of the following:

 - Protecting: Shown during initial DR setup before data synchronization begins
 - Healthy: All volumes and Kubernetes resources are syncing normally
 - Warning: Volumes or Kubernetes resources are syncing slower than usual
 - Critical: Volumes or Kubernetes resources are not syncing
 - Protection Error: An error occurred during application protection setup

You can click the status to view the last synced time for application volumes and the DR policy assigned.

Note: It may take a few minutes for the DR Status to move from Protecting to Healthy after disaster recovery is enabled. The DR status shows Protecting during initial setup, then automatically transition to health-based statuses (Healthy/Warning/Critical) once data synchronization begins.
 - b. Failover and relocate status can be viewed in the DR Status column when initiated. These statuses can be clicked to view more details about the action. DR Status shows either Protecting, Healthy, Warning, or Critical when failover or relocate is not taking place. During failover or relocate operations, the status shows the operation-specific status (FailingOver, Relocating, and so on).
10. In the user interface, verify the volume consistency groups:
 - a. In the Overview tab, at the end of the protected application row from the action menu (⋮), select Manage disaster recovery.
 - b. In the modal, verify Volume group replication is *Enabled*.
 - c. In the same modal, select View volume groups.
 - d. Verify the volume consistency groups have the correct volumes and a *Synced* status.
11. Optional: For Rados block device (RBD), verify **volumereplication**, **volumereplicationgroup**, and **volume group replication** on the primary cluster.

For **volumereplication**:

```
oc get volumereplication -A
```

Example output:

NAMESPACE	NAME	AGE	VOLUMEREPLICATIONCLASS		SOURCEKIND
SOURCENAME			DESIREDSTATE	CURRENTSTATE	
busybox-sample	vr-bc4a166e-13bc-45cd-99f0-8bd516f7ffcc	112s	rbd-volumereplicationclass-1625360775		
VolumeGroupReplication	vgr-07a0050bee1f25720f5cae8d5daa6230-busybox-placement-drpc		primary		Primary

For **volumereplicationgroup**:

```
oc get volumereplicationgroup -A
```

Example output:

NAMESPACE	NAME	DESIREDSTATE	CURRENTSTATE
busybox-sample	busybox-placement-drpc	primary	Primary

For **volume group replication**:

```
oc get volumegroupreplication -A
```

Example output:

NAMESPACE	NAME	DESIREDSTATE	CURRENTSTATE	VOLUMEGROUPREPLICATIONCLASS
VOLUMEGROUPREPLICATIONCONTENT			AGE	
busybox-sample	vgr-07a0050be1f25720f5cae8d5daa6230-1602718344	busybox-placement	drpc	rbd-volumegroupreplicationclass-1625360775-114s
	vgrcontent-bc4a166e-13bc-45cd-99f0-8bd516f7ffcc	primary		Primary

12. Optional: For CephFS, verify **ReplicationGroupSource** and **ReplicationSource** on the Primary cluster.

For **ReplicationGroupSource**:

```
oc get ReplicationGroupSource -A
```

Example output:

NAMESPACE	NAME	LAST SYNC	DURATION	NEXT SYNC
SOURCE				LAST SYNC
START				
busybox-cephfs	busybox-cephfs-bbd241b65b6589782fddaa82636e358d	2026-03-18T11:20:14Z	1m16.462467415s	2026-03-18T11:25:00Z
	{ "matchLabels": { "ramendr.openshift.io/consistency-group": "busybox-cephfs-bbd241b65b6589782fddaa82636e358d" } }			

For **ReplicationSource**:

```
oc get ReplicationSource -A
```

Example output:

NAMESPACE	NAME	SOURCE	LAST SYNC	DURATION	NEXT SYNC
busybox-cephfs	busybox-pvc	vs-busybox-pvc	2026-03-18T11:20:14Z	16.450725976s	

13. Optional: For CephFS, verify **ReplicationGroupDestination** and **ReplicationDestination** on the Secondary cluster.

For **ReplicationGroupDestination**:

```
oc get ReplicationGroupDestination -A
```

Example output:

NAMESPACE	NAME	LAST SYNC	DURATION	LAST SYNC	START
busybox-cephfs	busybox-cephfs-b1f2b5bac27b3d8805437424895d212c	2026-03-18T11:20:15Z	47.700328282s	2026-03-18T11:20:15Z	

For **ReplicationDestination**:

```
oc get ReplicationDestination -A
```

Example output:

NAMESPACE	NAME	LAST SYNC	DURATION	NEXT SYNC
busybox-cephfs	busybox-pvc	2026-03-18T11:20:15Z	47.401909636s	

14. Optional: For further validation, see [Validating disaster recovery](#).

ApplicationSet-based application failover between managed clusters

Fail over an ApplicationSet-based application from a primary managed cluster to a secondary managed cluster to maintain application availability during a disaster or cluster failure.

About this task

Failover is a process that transitions an application from a primary cluster to a secondary cluster in the event of a primary cluster failure. While failover provides the ability for the application to run on the secondary cluster with minimal interruption, making an uninformed failover decision can have adverse consequences, such as complete data loss in the event of unnoticed replication failure from primary to secondary cluster. If a significant amount of time has gone by since the last successful replication, it's best to wait until the failed primary is recovered.

LastGroupSyncTime is a critical metric that reflects the time since the last successful replication occurred for all PVCs associated with an application. In essence, it measures the synchronization health between the primary and secondary clusters. So, prior to initiating a failover from one cluster to another, check for this metric and only initiate the failover if the LastGroupSyncTime is within a reasonable time in the past.

Note: During the course of failover the Ceph-RBD mirror deployment on the failover cluster is scaled down to ensure a clean failover for volumes that are backed by Ceph-RBD as the storage provisioner.

Before you begin

- When primary cluster is in a state other than Ready, check the actual status of the cluster as it might take some time to update.
 - Go to RHACM console, Infrastructure, Clusters, Cluster list tab.
 - Check the status of both the managed clusters individually before performing a failover operation.However, failover operation can still be run when the cluster you are failing over to is in a *Ready* state.
- Run the following command on the Hub Cluster to check if **lastGroupSyncTime** is within an acceptable data loss window, when compared to current time.

```
oc get drpc -o yaml -A | grep lastGroupSyncTime
```

Example output:

```
[...]
lastGroupSyncTime: "2023-07-10T12:40:10Z"
```

About this task

Failover is a process that transitions an application from a primary cluster to a secondary cluster in the event of a primary cluster failure. While failover provides the ability for the application to run on the secondary cluster with minimal interruption, making an uninformed failover decision can have adverse consequences, such as complete data loss in the event of unnoticed replication failure from primary to secondary cluster. If a significant amount of time has gone by since the last successful replication, it's best to wait until the failed primary is recovered.

LastGroupSyncTime is a critical metric that reflects the time since the last successful replication occurred for all PVCs associated with an application. In essence, it measures the synchronization health between the primary and secondary clusters. So, prior to initiating a failover from one cluster to another, check for this metric and only initiate the failover if the **LastGroupSyncTime** is within a reasonable time in the past.

Note: During the course of failover the Ceph-RBD mirror deployment on the failover cluster is scaled down to ensure a clean failover for volumes that are backed by Ceph-RBD as the storage provisioner.

Procedure

1. Failover the protected application using either of the following paths:

- **Option 1:** From the Applications page

On the Hub cluster, navigate to Applications. Click Actions (:) and select Failover application.

- **Option 2:** From the Protected Applications page

On the Hub cluster, navigate to Data Services > Disaster recovery > Protected Applications > Actions (:) > Failover.

2. When the Failover application modal is shown, verify the details that are presented are correct and check the status of the Failover readiness. If the status is *Ready* with a green tick, it indicates that the target cluster is ready for failover to start.

Important:

If there are data inconsistencies caused by synchronization delays, a warning message appears stating **Inconsistent data on target cluster**. This alerts to the possibility of data loss if the failover is initiated. The message is no longer displayed when data synchronization is complete.

3. Click Initiate.

All the system workloads and their available resources are now transferred to the target cluster.

4. In the DR status column, you can view the progress of the failover. The modal shows the progress of the failover as Preparing > Failover > Restoring > Clean up.

5. Verify that the activity status shows as *FailedOver* for the application.

- a. Go to the Applications > Overview tab.

- b. In the Data policy column, click the policy link for the application you applied the policy to.

- c. On the Data Policy popover page, verify that you can see one or more policy names and the ongoing activities associated with the policy in use with the application.

If volume synchronization does not occur after a failover and ApplicationSet-based applications continue running on both clusters, apply the following workaround:

From the hub cluster, delete the **manifestwork** resource that continues to run the ApplicationSet-based applications on the cluster from which the applications were failed over.

For example:

```
oc delete manifestwork -n rackm14 app-busybox-cephfs-1-rackm14-48b8c
```

Relocating an ApplicationSet-based application between managed clusters

Relocate an application to its preferred location when all managed clusters are available.

Before you begin

- When primary cluster is in a state other than Ready, check the actual status of the cluster as it might take some time to update. Relocate can only be performed when both primary and preferred clusters are up and running.
 1. Go to RHACM console > Infrastructure > Clusters > Cluster list tab.
 2. Check the status of both the managed clusters individually before performing a relocate operation.
- Perform relocate when **LastGroupSyncTime** is within the replication interval (for example, 5 minutes) when compared to current time. This is recommended to minimize the Recovery Time Objective (RTO) for any single application.

Run this command on the Hub Cluster:

```
oc get drpc -o yaml -A | grep lastGroupSyncTime
```

Example output:

```
[...]
lastGroupSyncTime: "2023-07-10T12:40:10Z"
```

Compare the output time (UTC) to current time to validate that all **LastGroupSyncTime** values are within their application replication interval. If not, wait to Relocate until this is true for all **LastGroupSyncTime** values.

Procedure

1. Relocate the protected application using either of the following paths:

Option 1: From the Applications page

- a. On the Hub cluster, navigate to All Clusters > Applications.
- b. In the Overview tab, at the end of the application row from the action menu (⋮), select Manage disaster recovery.
- c. Click Relocate.

Option 2: From the Protected Applications page

- On the Hub cluster, navigate to Data Services > Disaster recovery > Protected Applications > Actions (⋮) > Relocate.

2. When the Relocate application modal is shown, select Policy and Target cluster to which the associated application relocates to in case of a disaster.

Important:

If there are data inconsistencies caused by synchronization delays, a warning message appears stating **Inconsistent data on target cluster**. This alerts to the possibility of data loss if the failover is initiated. The message is no longer displayed when data synchronization is complete.

3. Click Initiate.

All the system workloads and their available resources are now transferred to the target cluster.

4. Close the modal window and track the status using the Data policy column on the Applications page.

The status moves from Preparing > Syncing > Restoring > Clean up.

5. Verify that the activity status shows as *Relocated* for the application.

- a. Go to Applications > Overview.

- b. In the Data policy column, click the policy link for the application you applied the policy to.

- c. On the Data Policy popover page, verify that you can see one or more policy names and the relocation status associated with the policy in use with the application.

Deleting a sample application

The sample application **busybox** can be deleted by using the Red Hat® Advanced Cluster Management for Kubernetes (RHACM) console.

Before you begin

Important: When deleting a DR protected application, access to both clusters that belong to the DRPolicy is required. This is to ensure that all protected API resources and resources in the respective S3 stores are cleaned up as part of removing the DR protection. If access to one of the clusters is not healthy, deleting the **DRPlacementControl** resource for the application, on the hub, would remain in the **Deleting** state.

Do not begin deleting a sample application until the failover and relocate testing is completed and the application is ready to be removed from RHACM and the managed clusters.

About this task

Procedure

1. On the **Hub cluster**, navigate to Applications.
2. Search for the sample application to be deleted (for example, **busybox**).
3. Click the Action menu next to the application that you want to delete.
4. Click Delete application.

When the Delete application is selected a new screen appears asking if the application-related resources should also be deleted.

5. Select Remove application related resources to delete the Subscription and PlacementRule.
6. Click Delete.

This deletes the **busybox** application on the Primary-managed cluster (or the cluster that the application was running on).

7. In addition to the resources deleted by using the RHACM console, delete the **DRPlacementControl** if it is not auto-deleted after deleting the **busybox** application.

- a. Log in to the Red Hat OpenShift® web console for the Hub cluster and navigate to Installed Operators for the project **busybox-sample**.

- For ApplicationSet applications, select the project as **openshift-gitops**.

- b. Click OpenShift DR Hub Operator > DRPlacementControl.

- c. Click the Action menu next to the **busybox** application DRPlacementControl that you want to delete.

- d. Click Delete DRPlacementControl.

- e. Click Delete.

Note: This process can be used to delete any application with a **DRPlacementControl** resource.

Subscription-based application failover between managed clusters

Fail over a subscription-based application from a primary managed cluster to a secondary managed cluster to maintain application availability during a disaster or cluster failure.

About this task

Failover is a process that transitions an application from a primary cluster to a secondary cluster in the event of a primary cluster failure. While failover provides the ability for the application to run on the secondary cluster with minimal interruption, making an uninformed failover decision can have adverse consequences, such as complete data loss in the event of unnoticed replication failure from primary to secondary cluster. If a significant amount of time has gone by since the last successful replication, it's best to wait until the failed primary is recovered.

LastGroupSyncTime is a critical metric that reflects the time since the last successful replication occurred for all PVCs associated with an application. In essence, it measures the synchronization health between the primary and secondary clusters. So, prior to initiating a failover from one cluster to another, check for this metric and only initiate the failover if the LastGroupSyncTime is within a reasonable time in the past.

Note: During the course of failover the Ceph-RBD mirror deployment on the failover cluster is scaled down to ensure a clean failover for volumes that are backed by Ceph-RBD as the storage provisioner.

Before you begin

- When primary cluster is in a state other than Ready, check the actual status of the cluster as it might take some time to update.
 - Go to RHACM console > Infrastructure > Clusters > Cluster list tab.
 - Check the status of both the managed clusters individually before performing a failover operation.However, failover operation can still be run when the cluster you are failing over to is in a *Ready* state.
- Run the following command on the Hub Cluster to check if `lastGroupSyncTime` is within an acceptable data loss window, when compared to current time.

```
oc get drpc -o yaml -A | grep lastGroupSyncTime
```

Example output:

```
[...]
lastGroupSyncTime: "2023-07-10T12:40:10Z"
```

About this task

Failover is a process that transitions an application from a primary cluster to a secondary cluster in the event of a primary cluster failure. While failover provides the ability for the application to run on the secondary cluster with minimal interruption, making an uninformed failover decision can have adverse consequences, such as complete data loss in the event of unnoticed replication failure from primary to secondary cluster. If a significant amount of time has gone by since the last successful replication, it's best to wait until the failed primary is recovered.

`LastGroupSyncTime` is a critical metric that reflects the time since the last successful replication occurred for all PVCs associated with an application. In essence, it measures the synchronization health between the primary and secondary clusters. So, prior to initiating a failover from one cluster to another, check for this metric and only initiate the failover if the `LastGroupSyncTime` is within a reasonable time in the past.

Note: During the course of failover the Ceph-RBD mirror deployment on the failover cluster is scaled down to ensure a clean failover for volumes that are backed by Ceph-RBD as the storage provisioner.

Procedure

- Failover the protected application using either of the following paths:

- Option 1:** From the Applications page

On the Hub cluster, navigate to Applications. Click Actions (:) and select Failover application.

- Option 2:** From the Protected Applications page

On the Hub cluster, navigate to Data Services > Disaster recovery > Protected Applications > Actions (:) > Failover.

- After the Failover application popup is shown, select Policy and Target cluster to which the associated application fails over in a disaster.
- Click the Select subscription group dropdown to verify the default selection or modify this setting.
By default, the subscription group that replicates for the application resources is selected.
- Check the status of the Failover readiness.

- If the status is *Ready* with a green tick, it indicates that the target cluster is ready for failover to start. Proceed to step 5.
- If the status is *Unknown* or *Not ready*, then wait until the status changes to *Ready*.

Important:

If there are data inconsistencies caused by synchronization delays, a warning message appears stating **Inconsistent data on target cluster**. This alerts to the possibility of data loss if the failover is initiated. The message is no longer displayed when data synchronization is complete.

- Click Initiate.
All the system workloads and their available resources are now transferred to the target cluster.
- In the DR status column, you can view the progress of the failover. The modal shows the progress of the failover as Preparing > Failover > Restoring > Clean up.
- Verify that the activity status shows as *FailedOver* for the application.
 - Go to the Applications > Overview tab.
 - In the Data policy column, click the policy link for the application you applied the policy to.
 - On the Data Policy popover page, click the View more details link.
 - Verify that you can see one or more policy names and the ongoing activities (Last sync time and Activity status) associated with the policy in use with the application.

Relocating a Subscription-based application between managed clusters

Relocate an application to its preferred location when all managed clusters are available.

Before you begin

- When the primary cluster is in a state other than Ready, check the actual status of the cluster as it might take some time to update. Relocate can be performed only when both primary and preferred clusters are up and running.
 - Go to RHACM console > Infrastructure > Clusters > Cluster list tab.
 - Check the status of both the managed clusters individually before performing a relocate operation.
- Perform relocate when `lastGroupSyncTime` is within the replication interval (for example, 5 minutes) when compared to current time. This is recommended to minimize the Recovery Time Objective (RTO) for any single application.
Run this command on the Hub Cluster:

```
oc get drpc -o yaml -A | grep lastGroupSyncTime
```

Example output:

```
[...]
lastGroupSyncTime: "2023-07-10T12:40:10Z"
```

Compare the output time (UTC) to current time to validate that all `lastGroupSyncTime` values are within their application replication interval. If not, wait to Relocate until this is true for all `lastGroupSyncTime` values.

Procedure

1. Relocate the protected application using either of the following paths:

Option 1: From the Applications page

- a. On the Hub cluster, navigate to All Clusters > Applications.
- b. In the Overview tab, at the end of the application row from the action menu (:), select Manage disaster recovery.
- c. Click Relocate.

Option 2: From the Protected Applications page

- On the Hub cluster, navigate to Data Services > Disaster recovery > Protected Applications > Actions (:) > Relocate.

2. When the Relocate application modal is shown, select Policy and Target cluster to which the associated application relocates to in case of a disaster.
3. By default, the subscription group that deploys the application resources is selected. Click the Select subscription group dropdown to verify the default selection or modify this setting.
4. Check the status of the Relocation readiness.
 - If the status is *Ready* with a green tick, it indicates that the target cluster is ready for failover to start. Proceed to step 5.
 - If the status is *Unknown* or *Not ready*, then wait until the status changes to *Ready*.

Important:

If there are data inconsistencies caused by synchronization delays, a warning message appears stating **Inconsistent data on target cluster**. This alerts to the possibility of data loss if the failover is initiated. The message is no longer displayed when data synchronization is complete.

5. Click Initiate.

All the system workloads and their available resources are now transferred to the target cluster.
6. In the DR status column, you can view the progress of the failover. The modal shows the progress of the failover as Preparing > Syncing > Restoring > Clean up.
7. Verify that the activity status shows as *Relocated* for the application.
 - a. Go to the Applications > Overview tab.
 - b. In the Data policy column, click the policy link for the application you applied the policy to.
 - c. On the Data Policy popover page, click the View more details link.
 - d. Verify that you can see one or more policy names and the ongoing activities (Last sync time and Activity status) associated with the policy in use with the application.

Deleting a sample application

The sample application `busybox` can be deleted by using the Red Hat® Advanced Cluster Management for Kubernetes (RHACM) console.

Before you begin

Important: When deleting a DR protected application, access to both clusters that belong to the DRPolicy is required. This is to ensure that all protected API resources and resources in the respective S3 stores are cleaned up as part of removing the DR protection. If access to one of the clusters is not healthy, deleting the `DRPlacementControl` resource for the application, on the hub, would remain in the `Deleting` state. Do not begin deleting a sample application until the failover and relocate testing is completed and the application is ready to be removed from RHACM and the managed clusters.

About this task

Procedure

1. On the **Hub cluster**, navigate to Applications.
2. Search for the sample application to be deleted (for example, `busybox`).
3. Click the Action menu next to the application that you want to delete.
4. Click Delete application.

When the Delete application is selected a new screen appears asking if the application-related resources should also be deleted.
5. Select Remove application related resources to delete the Subscription and PlacementRule.
6. Click Delete.

This deletes the `busybox` application on the Primary-managed cluster (or the cluster that the application was running on).
7. In addition to the resources deleted by using the RHACM console, delete the `DRPlacementControl` if it is not auto-deleted after deleting the `busybox` application.
 - a. Log in to the Red Hat OpenShift® web console for the Hub cluster and navigate to Installed Operators for the project `busybox-sample`.

For ApplicationSet applications, select the project as `openshift-gitops`.
 - b. Click OpenShift DR Hub Operator > DRPlacementControl.
 - c. Click the Action menu next to the `busybox` application DRPlacementControl that you want to delete.
 - d. Click Delete DRPlacementControl.
 - e. Click Delete.

Note: This process can be used to delete any application with a `DRPlacementControl` resource.

Prerequisites for disaster recovery protection of discovered applications

Complete the setup steps required before you protect discovered applications with disaster recovery, including installing the OADP operator, configuring certificates, and creating the Data Protection Application (DPA) resource.

1. Ensure that all the DR configurations have been installed on the Primary managed cluster and the Secondary managed cluster.
2. Install the OADP 1.4 operator.

Note: Any version before OADP 1.4 does not work for protecting discovered applications.

- a. On the **Primary** and **Secondary managed cluster**, navigate to OperatorHub and use the keyword filter to search for **OADP**.
- b. Click the OADP tile.
- c. Keep all default settings and click Install. Ensure that the operator resources are installed in the **openshift-adp** project.

Note: If OADP 1.4 is installed after DR configuration has been completed then the **ramen-dr-cluster-operator** pods on the **Primary managed cluster** and the **Secondary managed cluster** in namespace **openshift-dr-system** must be restarted (deleted and recreated).

3. [Optional] Add CACertificates to **ramen-hub-operator-config** ConfigMap.

Configure network (SSL) access between the primary and secondary clusters so that metadata can be stored on the alternate cluster in a Multicloud Gateway (MCG) object bucket using a secure transport protocol and in the Hub cluster for verifying access to the object buckets.

Note: If all of your OpenShift® clusters are deployed using a signed and valid set of certificates for your environment then this section can be skipped.

If you are using self-signed certificates, then you have already created a **ConfigMap** named **user-ca-bundle** in the **openshift-config** namespace and added this ConfigMap to the default Proxy cluster resource.

- a. Find the encoded value for the CACertificates.

```
oc get configmap user-ca-bundle -n openshift-config -o jsonpath="{['data']['ca-bundle.crt']}" |base64 -w 0
```

- b. Add this base64 encoded value to the configmap **ramen-hub-operator-config** on the Hub cluster. The following example shows where to add CACertificates.

```
oc edit configmap ramen-hub-operator-config -n openshift-operators

[...]  
  ramenOpsNamespace: openshift-dr-ops  
  s3StoreProfiles:  
  - s3Bucket: odrbucket-36bceb61c09c  
    s3CompatibleEndpoint: https://s3-openshift-storage.apps.hyper3.vmw.ibmfusion.eu  
    s3ProfileName: s3profile-hyper3-ocs-storagecluster  
    s3Region: noobaa  
    s3SecretRef:  
      name: 60f2ea6069e168346d5ad0e0b5faa59bb74946f  
  caCertificates: {input base64 encoded value here}  
  - s3Bucket: odrbucket-36bceb61c09c  
    s3CompatibleEndpoint: https://s3-openshift-storage.apps.hyper4.vmw.ibmfusion.eu  
    s3ProfileName: s3profile-hyper4-ocs-storagecluster  
    s3Region: noobaa  
    s3SecretRef:  
      name: cc237eba032ad5c422fb939684eb633822d7900  
  caCertificates: {input base64 encoded value here}
```

4. Verify that there are DR secrets created in the OADP operator default namespace **openshift-adp** on the **Primary managed cluster** and the **Secondary managed cluster**. The DR secrets that were created when the first DRPolicy was created, is similar to the following secrets. The DR secret name is preceded with the letter **v**.

```
oc get secrets -n openshift-adp
```

NAME	TYPE	DATA	AGE
v60f2ea6069e168346d5ad0e0b5faa59bb74946f	Opaque	1	3d20h
vcc237eba032ad5c422fb939684eb633822d7900	Opaque	1	3d20h

```
[...]
```

Note: There is one DR created secret for each managed cluster in the **openshift-adp** namespace.

5. Verify if the Data Protection Application (DPA) is already installed on each managed cluster in the OADP namespace **openshift-adp**. If not already created then follow the next step to create this resource.

- a. Create the DPA by copying the following YAML definition content to **dpa.yaml**.

```
apiVersion: oadp.openshift.io/v1alpha1  
kind: DataProtectionApplication  
metadata:  
  labels:  
    app.kubernetes.io/component: velero  
  name: velero  
  namespace: openshift-adp  
spec:  
  backupImages: false  
  configuration:  
    nodeAgent:  
      enable: false  
      uploaderType: kopia  
    velero:  
      defaultPlugins:  
        - openshift  
        - aws  
        - kubevirt  
      noDefaultBackupLocation: true
```

- b. Create the DPA resource.

```
oc create -f dpa.yaml -n openshift-adp  
  
dataprotectionapplication.oadp.openshift.io/velero created
```

- c. Verify that the OADP resources are created and are in **Running** state.

```
oc get pods,dpa -n openshift-adp
```

NAME	READY	STATUS	RESTARTS	AGE
pod/openshift-adp-controller-manager-7b64b74fcd-msjbs	1/1	Running	0	5m30s
pod/velero-694b5b8f5c-b4kwg	1/1	Running	0	3m31s

NAME	AGE
dataprotectionapplication.oadp.openshift.io/velero	3m31s

Creating a sample discovered application

To test failover from the **Primary managed cluster** to the **Secondary managed cluster** and relocate for discovered applications, you need a sample application that is installed without using the RHACM create application capability.

Before you begin

Note: Regional-DR now supports leveraging CephRBD volumes using non-default replica-2 storage classes that are managed by Fusion Data Foundation. Support has also been extended to compression-enabled storage classes.

Procedure

1. Log in to the **Primary managed cluster** and clone the sample application repository.

```
git clone https://github.com/red-hat-storage/ocm-ramen-samples.git
```

2. Verify that you are on the **main** branch.

```
cd ~/ocm-ramen-samples
git branch
* main
```

Use the correct directory when creating the sample application based on your scenario, metro or regional. To find your directory:

```
ls workloads/deployment | egrep -v 'cephfs|k8s|base'

odr-metro-rbd
odr-regional-rbd
odr-regional-cephfs
```

3. Create a project named **busybox-discovered** on both the **Primary and Secondary managed clusters**.

```
oc new-project busybox-discovered
```

4. Create the **busybox** application on the **Primary managed cluster**.

This sample application example is for Regional-DR using a block (Ceph RBD) volume. CephFS volumes can be used as well.

```
oc apply -k workloads/deployment/odr-regional-rbd -n busybox-discovered
```

```
persistentvolumeclaim/busybox-pvc created
deployment.apps/busybox created
```

Note:

Fusion Data Foundation disaster recovery solution now extends protection to discovered applications that span across multiple namespaces.

5. Verify that busybox is running in the correct project on the **Primary managed cluster**.

```
oc get pods,pvc,deployment -n busybox-discovered
```

NAME	READY	STATUS	RESTARTS	AGE
pod/busybox-796fccbb95-qmxjf	1/1	Running	0	18s

NAME	STATUS	VOLUME	CAPACITY	ACCESS	MODES
STORAGECLASS	VOLUMEATTRIBUTESCLASS	AGE			
persistentvolumeclaim/busybox-pvc	Bound	pvc-b20e4129-902d-47c7-b962-040ad64130c4	1Gi	RWO	ocs-
storagecluster-ceph-rbd	<unset>	18s			

NAME	READY	UP-TO-DATE	AVAILABLE	AGE
deployment.apps/busybox	1/1	1	1	18

Enrolling a sample discovered application for disaster recovery protection

This section guides you on how to apply an existing DR Policy to a discovered application from the Protected applications tab.

Before you begin

- Ensure that Disaster Recovery has been configured and that at least one DR Policy has been created.

Procedure

1. On RHACM console, navigate to Disaster recovery > Protected applications tab.
2. Click Enroll application to start configuring existing applications for DR protection.
3. Select ACM discovered applications.
4. In the Namespace page, choose the DR cluster which is the name of the **Primary managed cluster** where **busybox** is installed.
5. Select namespace where the application is installed. For example, **busybox-discovered**.
Note: If you have workload spread across multiple namespaces then you can select all of those namespaces to DR protect.
6. Choose a unique Name, for example **busybox-rbd**, for the discovered application and click Next.
7. In the Configuration page, select either Resource label or Recipe.
8. Resource label is used to protect your resources where you can set which resources is included in the kubernetes-object backup and what volume's persistent data is replicated. If you selected Resource label, provide label expressions and PVC label selector. Choose the label **appname=busybox** for both the kubernetes-objects and for the PVC(s).
9. If you selected Recipe, then from the Recipe list select the name of the recipe.
Important: The recipe resource must be created in the application namespace on both managed clusters before enrolling an application for disaster recovery.
10. If you are using a recipe and want to add the recipe's parameters, under Recipe parameters, add the Key and Value (optional), then click Add parameter.
11. Click Next.
12. In the Replication page, select an existing DR Policy and the kubernetes-objects backup interval.
Note: It is recommended to choose the same duration for the PVC data replication and kubernetes-object backup interval (for example, 5 minutes).
13. Click Next.
14. Review the configuration and click Save.

To check the status, run the following command:

```
oc get drpc <project-name>-n openshift-dr-ops -oyaml
```

Note: It may take up to 3–4 minutes for both application volumes (PVCs) and Kubernetes objects to reach a healthy state.
Use the Back button to go back to the screen to correct any issues.

15. Verify that you can view the assigned policy details on the Applications page.

- a. On the Applications page, navigate to the DR Status column and view the status.

The status can be any of the following:

- Protecting: Shown during initial DR setup before data synchronization begins
- Healthy: All volumes and Kubernetes resources are syncing normally
- Warning: Volumes or Kubernetes resources are syncing slower than usual
- Critical: Volumes or Kubernetes resources are not syncing
- Protection Error: An error occurred during application protection setup

You can click the status to view the last synced time for application volumes and the DR policy assigned.

Note: It may take a few minutes for the DR Status to move from Protecting to Healthy after disaster recovery is enabled. The DR status shows Protecting during initial setup, then automatically transition to health-based statuses (Healthy/Warning/Critical) once data synchronization begins.

- b. Failover and relocate status can be viewed in the DR Status column when initiated. These statuses can be clicked to view more details about the action. DR Status shows either Protecting, Healthy, Warning, or Critical when failover or relocate is not taking place. During failover or relocate operations, the status shows the operation-specific status (FailingOver, Relocating, and so on).

16. Verify that the volume consistency groups have been enabled from the Protected applications tab:

- a. Click the arrow next to the DRPC to expand the details.
- b. Click the number under the Volume Consistency groups column to open the modal.
- c. In the Volume consistency groups modal, verify the volume consistency group(s) has the correct volumes and a *Synced* status.

17. View the status of DRPC and VolumeReplicationGroup (VRG).

- a. To see the status of the DRPC, run the following command on the Hub cluster:

```
oc get drpc {drpc_name} -o wide -n openshift-dr-ops
```

The discovered applications store resources such as DRPlacementControl (DRPC) and Placement on the Hub cluster in a new namespace called **openshift-dr-ops**. The DRPC name can be identified by the unique Name configured in prior steps (for example, **busybox-rbd**).

- b. To see the status of the VRG for discovered applications, run the following command on the managed cluster where the busybox application was manually installed.

```
oc get vrg {vrg_name} -n openshift-dr-ops
```

The VRG resource is stored in the namespace **openshift-dr-ops** after a DR Policy is assigned to the discovered application. The VRG name can be identified by the unique Name configured in prior steps (for example, **busybox-rbd**).

18. Optional: For Rados block device (RBD), verify **volumereplication** and **volumegroupreplication** on the primary cluster.

For **volumereplication**:

```
oc get volumereplication -A
```

Example output:

NAMESPACE	NAME	AGE	VOLUMEREPLICATIONCLASS	SOURCEKIND
SOURCENAME	DESIREDSTATE	CURRENTSTATE		
busybox-discovered	vr-f9fc057c-5e95-47cb-b515-b4ee19d4ca8e	109s	rbd-volumereplicationclass-1625360775	
VolumeGroupReplication	vgr-e8b7cca8211a41455790dad707a08c-busybox-rbd	primary	Primary	

For **volumegroupreplication**:

```
oc get volumegroupreplication -A
```

Example output:

NAMESPACE	NAME	VOLUMEGROUPREPLICATIONCLASS		
VOLUMEGROUPREPLICATIONCONTENT	DESIREDSTATE	CURRENTSTATE	AGE	

```

busybox-discovered    vgr-e8b7cca8211a41455790dadc2707a08c-busybox-rbd    rbd-volumegroupreplicationclass-1625360775-
1602718344           vgrcontent-f9fc057c-5e95-47cb-b515-b4ee19d4ca8e    primary    Primary    113s

```

19. Optional: For CephFS, verify `ReplicationGroupSource` and `ReplicationSource` on the Primary cluster.

For `ReplicationGroupSource`:

```
oc get ReplicationGroupSource -A
```

Example output:

NAMESPACE	NAME	LAST SYNC	DURATION	NEXT SYNC
SOURCE	START	LAST SYNC		
busybox-cephfs	busybox-cephfs-bbd241b65b6589782fddaa82636e358d	2026-03-18T11:20:14Z	1m16.462467415s	2026-03-18T11:25:00Z
	{ "matchLabels": { "ramendr.openshift.io/consistency-group": "busybox-cephfs-bbd241b65b6589782fddaa82636e358d" } }			

For `ReplicationSource`:

```
oc get ReplicationSource -A
```

Example output:

NAMESPACE	NAME	SOURCE	LAST SYNC	DURATION	NEXT SYNC
busybox-cephfs	busybox-pvc	vs-busybox-pvc	2026-03-18T11:20:14Z	16.450725976s	

20. Optional: For CephFS, verify `ReplicationGroupDestination` and `ReplicationDestination` on the Secondary cluster.

For `ReplicationGroupDestination`:

```
oc get ReplicationGroupDestination -A
```

Example output:

NAMESPACE	NAME	LAST SYNC	DURATION	LAST SYNC	START
busybox-cephfs	busybox-cephfs-b1f2b5bac27b3d8805437424895d212c	2026-03-18T11:20:15Z	47.700328282s	2026-03-18T11:20:15Z	

For `ReplicationDestination`:

```
oc get ReplicationDestination -A
```

Example output:

NAMESPACE	NAME	LAST SYNC	DURATION	NEXT SYNC
busybox-cephfs	busybox-pvc	2026-03-18T11:20:15Z	47.401909636s	

21. Optional: For further validation, see [Validating disaster recovery](#).

Failover disaster recovery protected discovered application

Fail over a disaster recovery-protected discovered application to the secondary managed cluster and complete the required cleanup on the primary managed cluster.

Before you begin

- Ensure that the application namespace is created in both managed clusters (for example, `busybox-discovered`).
- Never initiate a failover operation of an application when one or both resource types are in a Warning or Critical status.

About this task

This procedure guides you on how to fail over a discovered application that is disaster recovery protected.

Procedure

- In the RHACM console, navigate to Disaster Recovery > Protected applications tab.
- At the end of the application row, click on the Actions menu and choose to initiate Failover.
- In the Failover application modal window, review the status of the application and the target cluster.
Important:
If there are data inconsistencies caused by synchronization delays, a warning message appears stating **Inconsistent data on target cluster**. This alerts to the possibility of data loss if the failover is initiated. The message is no longer displayed when data synchronization is complete.
- Click Initiate.
Important:
If you initiate a failover while either the primary or secondary site is down, the disaster recovery status (DR Status) displays as critical and a warning message appears: Volumes and Kubernetes resources are not syncing. This is expected behavior. After you verify that the persistent volume claims (PVCs), deployments, applications, and virtual machine (VM) instances are running correctly, you can continue to use the applications.
- In the DR status column, you can view the progress of the failover. The modal shows the progress of the failover as Preparing > Failover > Restoring > Clean up.
- Verify that the busybox application is running on the **Secondary managed cluster**.

```
oc get pods,pvc -n busybox-discovered
```

NAME	READY	STATUS	RESTARTS	AGE
pod/busybox-796fccbb95-qmxjf	1/1	Running	0	2m46s

NAME	STATUS	VOLUME	CAPACITY	ACCESS	MODES
STORAGECLASS	VOLUMEATTRIBUTESCLASS	AGE			
persistentvolumeclaim/busybox-pvc	Bound	pvc-b20e4129-902d-47c7-b962-040ad64130c4	1Gi	RWO	ocs-
storagecluster-ceph-rbd	<unset>	2m57s			

NAME	AGE	VOLUMEREPLICATIONCLASS	PVCNAME
DESIREDSTATE	CURRENTSTATE		
volumereplication.replication.storage.openshift.io/busybox-pvc	2m45s	rbd-volumereplicationclass-1625360775	busybox-
pvc primary	Primary		

- Check the progression status of Failover until the result is **WaitOnUserToCleanup**. The DRPC name can be identified by the unique Name configured in prior steps (for example, **busybox-rbd**).

```
oc get drpc {drpc_name} -n openshift-dr-ops -o jsonpath='{.status.progression}{"\n"}'
```

WaitOnUserToCleanup

Important:

If the result does not appear as **WaitOnUserToCleanup** and instead moves to **Completed**, you might encounter the error "Secondary cluster transition failed as PVC is potentially in use by a pod." This indicates that application cleanup was not completed on the primary cluster. In this case, complete the cleanup on the primary cluster to release the PVC. After cleanup, replication resumes automatically. If replication does not resume, perform a relocate operation to move the application to the secondary cluster and continue operations with the last synchronized data.

- Remove the **busybox** application from the Primary managed cluster to complete the *Failover* process.
 - Go to the Protected applications tab. you see a message to remove the application.
 - Go to the cloned repository for **busybox** and run the following commands on the Primary managed cluster where you failed over from. Use the same directory that was used to create the application (for example, **odr-regional-rbd**).

```
cd ~/ocm-ramen-samples/
git branch

* main

oc delete -k workloads/deployment/odr-regional-rbd -n busybox-discovered

persistentvolumeclaim "busybox-pvc" deleted
deployment.apps "busybox" deleted
```

- After deleting the application, navigate to the Protected applications tab and verify that the busybox resources are both in *Healthy* status.

Relocate disaster recovery protected discovered application

Relocate a disaster recovery protected discovered application from a secondary managed cluster to a primary managed cluster by using the Red Hat® Advanced Cluster Management (RHACM) console.

Before you begin

- Ensure that the application namespace is created in both managed clusters (for example, **busybox-discovered**).
- Never initiate a relocate operation of an application when one or both resource types are in a Warning or Critical status.

About this task

This procedure guides you on how to failover a discovered application which is disaster recovery protected.

Procedure

- In the RHACM console, navigate to Disaster Recovery > Protected applications tab.
- At the end of the application row, click on the Actions menu and choose to initiate Relocate.
- In the Relocate application modal window, review the status of the application and the target cluster.

Important:

If there are data inconsistencies caused by synchronization delays, a warning message appears stating **Inconsistent data on target cluster**. This alerts to the possibility of data loss if the failover is initiated. The message is no longer displayed when data synchronization is complete.
- Click Initiate.
- In the DR status column, you can view the progress of the relocation. The progress shows Preparing > Clean up, at which time you need to perform the following clean up activities.
- The DRPC name can be identified by the unique Name configured in prior steps (for example, **busybox-rbd**).

```
oc get drpc {drpc_name} -n openshift-dr-ops -o jsonpath='{.status.progression}{"\n"}'
```

WaitOnUserToCleanup

- Remove the busybox application from the **Secondary managed cluster** before *Relocate* to the **Primary managed cluster** is completed
 - Go to the cloned repository for **busybox** and run the following commands on the Secondary managed cluster where you relocated from. Use the same directory that was used to create the application (for example, **odr-regional-rbd**).

```
cd ~/ocm-ramen-samples/
git branch

* main
```

```
oc delete -k workloads/deployment/odr-regional-rbd -n busybox-discovered
```

```
persistentvolumeclaim "busybox-pvc" deleted
deployment.apps "busybox" deleted
```

- After deleting the application, navigate to the Protected applications tab and verify that the busybox resources are both in *Healthy* status.
- Verify that the busybox application is running on the **Primary managed cluster**.

```
oc get pods,pvc -n busybox-discovered
```

NAME	READY	STATUS	RESTARTS	AGE
pod/busybox-796fccbb95-qmxjf	1/1	Running	0	2m46s

NAME	STATUS	VOLUME	CAPACITY	ACCESS	MODES
STORAGECLASS	VOLUMEATTRIBUTESCLASS	AGE			
persistentvolumeclaim/busybox-pvc	Bound	pvc-b20e4129-902d-47c7-b962-040ad64130c4	1Gi	RWO	ocs-
storagecluster-ceph-rbd	<unset>	2m57s			

NAME	AGE	VOLUMEREPLICATIONCLASS	PVCNAME
DESIREDSTATE CURRENTSTATE			
volumereplication.replication.storage.openshift.io/busybox-pvc	2m45s	rbd-volumereplicationclass-1625360775	busybox-
pvc primary	Primary		

- After the clean up activities are performed, the DR Status column moves from Syncing to Restoring.

Disable disaster recovery for protected applications

This section guides you to disable disaster recovery resources when you want to delete the protected applications or when the application no longer needs to be protected.

Procedure

- Login to the Hub cluster.
- List the **DRPlacementControl** (DRPC) resources. Each DRPC resource was created when the application was assigned a DR policy.

```
oc get drpc -n openshift-dr-ops
```

- Find the **DRPC** that has a name that includes the unique identifier that you chose when assigning a DR policy (for example, **busybox-rbd**) and delete the DRPC.

```
oc delete {drpc_name} -n openshift-dr-ops
```

- List the **Placement** resources. Each Placement resource was created when the application was assigned a DR policy.

```
oc get placements -n openshift-dr-ops
```

- Find the **Placement** that has a name that includes the unique identifier that you chose when assigning a DR policy (for example, **busybox-rbd-placement-1**) and delete the Placement.

```
oc delete placements {placement_name} -n openshift-dr-ops
```

Virtual machine garbage collection automation

Virtual machine garbage collection automation provides an automated mechanism to clean up virtual machine resources on the source cluster during disaster recovery failover or relocation workflows, reducing manual effort and supporting lower recovery time objectives.

Overview

Virtual machine (VM) garbage collection automation provides an automated mechanism to clean up VM resources on the source cluster during Disaster Recovery (DR) failover or relocation workflows. This reduces manual effort and helps users perform DR operations more quickly, supporting lower Recovery Time Objectives (RTO).

Prerequisites

- Virtual machine protection must be enabled through the Fusion Data Foundation Virtualization console.

How it works

During DR failover or relocation, VM resources that are protected and orchestrated by the Fusion Data Foundation Virtualization console are automatically deleted from the source cluster.

This deletion uses Kubernetes' owner-based garbage collection principles, ensuring that associated child resources, such as disks and pods, are also removed cleanly as part of normal Kubernetes garbage collection.

Known risks and limitations

- Automation applies only to VM resources whose protection is managed by the Fusion Data Foundation Virtualization console.

- Other discovered application workload types, including GitOps-managed and other non-VM resources, remain out of scope and require manual cleanup.
- Automation is limited to resources directly owned by the VM lifecycle.

Validating disaster recovery

Validate disaster recovery configurations by using the Red Hat® OpenShift® Data Foundation CLI **odf dr validate** command to verify cluster health, S3 endpoints, and protected applications.

About this task

Note: Starting with Fusion Data Foundation 4.22, you can use the **odf dr validate** command to verify disaster recovery configurations. Use the Red Hat OpenShift Data Foundation CLI **odf dr validate** command to verify disaster recovery (DR) configurations. Follow these steps to configure your environment, validate clusters, and perform application-level validation to ensure system integrity and readiness for DR operations.

Procedure

1. Download the Red Hat OpenShift Data Foundation CLI tool from the [Red Hat Customer Portal](#) to your local machine or bastion host and make it executable.
Note: Download the latest Red Hat OpenShift Data Foundation CLI package from the Red Hat Customer Portal. No additional license is required to use the CLI tool. The latest CLI package works with earlier and later versions of Fusion Data Foundation, though newer CLI versions can include additional capabilities.
2. Create the config.yaml configuration file for the clusters where you run **odf dr validate**:

```
## Clusters configuration.
clusters:
  hub:
    kubeconfig: kubeconfigs/hub.yaml
  passive-hub:
    kubeconfig: ""
  c1:
    kubeconfig: kubeconfigs/cluster1.yaml
  c2:
    kubeconfig: kubeconfigs/cluster2.yaml

## ClusterSet for validate command.
# - Modify to match your Red Hat ACM (RHACM) configuration.
clusterSet: clusterset-with-managed-clusters
```

Note: **clusterSet** must include managed clusters **cluster1** and **cluster2**.

3. Validate the cluster.
The **validate clusters** command validates the DR clusters by gathering cluster-scoped and related DR resources from all clusters, and validates that configured S3 endpoints are accessible and all resources are healthy.
 - a. Run the **validate** command on the hub cluster:

```
odf dr validate clusters -o out-cluster
```

Example of successful validation:

```
* Using config "config.yaml"
* Using report "out-cluster"

. Validate config ...
  ✓ Config validated

Validate clusters ...
  ✓ Gathered data from cluster "hub"
  ✓ Gathered data from cluster "cluster1"
  ✓ Gathered data from cluster "cluster2"
  ✓ Inspected S3 profiles
  ✓ Checked S3 profile "s3profile-cluster1-ocs-storagecluster"
  ✓ Checked S3 profile "s3profile-cluster2-ocs-storagecluster"
  ✓ Clusters validated

✓ Validation completed (91 ok, 0 warning, 0 problem)
```

The command gathers cluster-scoped and DR resources from all clusters, inspects the resources, and stores output files in the specified output directory:

```
tree -L1 out-cluster
out-cluster
├── style.css
├── validate-clusters.data
├── validate-clusters.html
├── validate-clusters.log
└── validate-clusters.yaml
```

4. Review the HTML report in a web browser. Resolve all identified issues before you proceed.
5. Locate the application **DRPlacementControl** (drpc) resource on the hub cluster:

```
oc get drpc -A --kubeconfig kubeconfigs/hub.yaml
```

NAMESPACE	NAME	AGE	PREFERREDCLUSTER	FAILOVERCLUSTER	DESIREDSTATE	CURRENTSTATE
my-drpc-namespce	my-drpc-name	1h	cluster1			Deployed

6. Validate the application.
The **validate application** command validates a specific DR-protected application by collecting its associated namespaces across all clusters, retrieving relevant S3 data, and inspecting the collected resources. The command requires the drpc name and namespace from the step [5](#).

```
odf dr validate application --namespace my-drpc-namespce --name my-drpc-name -o out-my-drpc-name
```

Example of successful validation:

```
★ Using config "config.yaml"
★ Using report "out-my-drpc-name"

Validate config ...
  ✓ Config validated

Validate application ...
  ✓ Inspected application
  ✓ Gathered data from cluster "hub"
  ✓ Gathered data from cluster "cluster1"
  ✓ Gathered data from cluster "cluster2"
  ✓ Inspected S3 profiles
  ✓ Gathered S3 profile "s3profile-cluster1-ocs-storagecluster"
  ✓ Gathered S3 profile "s3profile-cluster2-ocs-storagecluster"
  ✓ Application validated

✓ Validation completed (30 ok, 0 warning, 0 problem)
```

Example of failed validation:

```
★ Using config "config.yaml"
★ Using report "out-my-drpc-name"

Validate config ...
  ✓ Config validated

Validate application ...
  ✓ Inspected application
  ✓ Gathered data from cluster "hub"
  ✓ Gathered data from cluster "cluster1"
  ✓ Gathered data from cluster "cluster2"
  ✓ Inspected S3 profiles
  ✓ Gathered S3 profile "s3profile-cluster1-ocs-storagecluster"
  ✓ Gathered S3 profile "s3profile-cluster2-ocs-storagecluster"
  ✗ Issues found during validation

✗ Validation failed (27 ok, 0 warning, 2 problem)
```

The command gathers related namespaces from all clusters, inspects the resources, and stores output files in the specified output directory:

```
tree -L1 out-my-drpc-name
out-my-drpc-name
├── style.css
├── validate-application.data
├── validate-application.html
├── validate-application.log
└── validate-application.yaml
```

7. Review the HTML report in a web browser. Resolve all identified issues before you proceed.

What to do next

You can use the **odf dr test** command to test the complete disaster recovery flow. For more information, see the [Testing disaster recovery with odf dr command](#) Red Hat knowledgebase article.

- [Reporting disaster recovery validation issues](#)
Create a tarball from validation output directories to report disaster recovery validation issues.

Reporting disaster recovery validation issues

Create a tarball from validation output directories to report disaster recovery validation issues.

About this task

When reporting validation command failures, create a tarball from its output directory and upload it to the case or issue report. If both commands failed, upload a tarball for each.

Procedure

Create a tarball from the output directory:

```
tar czf out-my-drpc-name.tar.gz out-my-drpc-name
```

What to do next

You can use the **odf dr test** command to test the complete disaster recovery flow. For more information, see the [Testing disaster recovery with odf dr command](#) Red Hat® knowledgebase article.

Viewing Recovery Point Objective values for disaster recovery enabled applications

Recovery Point Objective (RPO) value is the most recent sync time of persistent data from the cluster where the application is currently active to its peer. This sync time helps determine duration of data lost during failover.

About this task

You can view the Recovery Point Objective (RPO) value of all the protected volumes for their workload on the Hub cluster.

Note: This RPO value is applicable only for Regional-DR during failover. Relocation ensures there is no data loss during the operation, as all peer clusters are available.

Procedure

1. On the Hub cluster, navigate to Applications > Overview tab.
2. In the Data policy column, click the policy link for the application you applied the policy to.
A Data Policies modal page appears with the number of disaster recovery policies applied to each application along with failover and relocation status.
3. On the Data Policies modal page, click the View more details link.
A detailed **Data Policies** modal page is displayed that shows the policy names and the ongoing activities (Last sync, Activity status) associated with the policy that is applied to the application.

The **Last sync time** reported in the modal page, represents the most recent sync time of all volumes that are DR protected for the application.

Enabling granular disaster recovery for individual or groups of virtual machines in a namespace

You can enable granular disaster recovery (DR) for individual virtual machines (VMs) or VM groups within the same namespace, allowing independent failover and relocation actions.

Prerequisites

- Red Hat® Advanced Cluster Management for Kubernetes (RHACM) version 2.17 is installed.
- Install the OpenShift® Virtualization Operator. For instructions, see [Virtualization > Installing > Installing the OpenShift Virtualization Operator](#) by using the web console in [Red Hat OpenShift Container Platform](#) product documentation.

Key highlights

- **Granular VM Control:**
Each discovered and ACM-managed VM can have its own DR policy, enabling independent DR operations without impacting other VMs in the namespace.
- **Namespace Partitioning:**
Supports multiple DRPCs within a namespace, avoiding the limitations of namespace-level DR protection.
- **Scenarios Supported:**
 - Independent DR for discovered and ACM-managed VMs.
 - Namespace-level DR remains for non-VM applications.
- **Upgrade Considerations:**
 - Existing DRPCs are treated as namespace-level.
 - Users must disable DR before switching to VM-specific protection.
- **Manage disaster recovery of virtual machines from [Virtual Machines page](#)**
Note: Existing UI for namespace-level DR remains unchanged.

Important:

During failover of a CNV discovered application, if the primary managed cluster is down and other CNV applications are running in different namespaces on either of the managed clusters, there have been cases where the VM fails to start on the failover cluster. This issue is due to MAC address conflicts.

To prevent this issue, it is recommended to configure disjoint MAC address ranges for each cluster from the Day 1. For example:

```
oc patch configmap kubemacpool-mac-range-config -n openshift-cnv --type merge -p '{"data": {"RANGE_START": "02:00:00:00:00:00", "RANGE_END": "02:00:FF:FF:FF:FF"}}'
```

```
oc patch configmap kubemacpool-mac-range-config -n openshift-cnv --type merge -p '{"data": {"RANGE_START": "02:01:00:00:00:00", "RANGE_END": "02:01:FF:FF:FF:FF"}}'
```

Then restart the `kubemacpool-mac-controller-manager`.

Command example:

```
oc get pods -n openshift-cnv | grep kubemacpool-mac-controller-manager
```

Example output:

```
kubemacpool-mac-controller-manager-544ff96b4f-dgb7x    2/2    Running    3    30h
```

DryRun mode for testing failover [Technology preview]

Validate disaster recovery procedures without disrupting production applications by using DryRun mode in Fusion Data Foundation.

Important:

This feature is available as a Technology Preview starting with Fusion Data Foundation 4.22. Technology Preview features are provided for evaluation purposes only and are not intended for production use. The functionality, user experience, APIs, and operational characteristics of this feature might change before general availability, or the feature might not be released as a generally available capability. IBM welcomes feedback on this feature during the preview period.

Testing failover, also known as DryRun mode, allows you to validate disaster recovery procedures without disrupting your production application. This feature enables non-destructive failover testing by temporarily promoting the secondary cluster to verify readiness and data consistency while keeping the primary cluster untouched.

Key benefits include the following items:

- Validate disaster recovery procedures without production impact
- Test application recovery on the secondary cluster
- Verify data consistency and application readiness
- Build confidence in your disaster recovery strategy
- Meet compliance requirements for disaster recovery testing

Test failover mechanics

Test failover performs a full application restore on the secondary (test) cluster by using the same mechanics as a real failover. The critical difference is that the primary cluster remains active and unchanged throughout the test:

- **Primary cluster stays active:** Your production application continues running.
- **Secondary becomes temporary primary:** Application is restored on the test cluster.
- **Replication paused:** Data replication is temporarily suspended during the test.
- **Safe cleanup:** Test resources are cleanly removed when you abort the test.
- [DryRun architecture](#)
The DryRun architecture coordinates non-destructive disaster recovery validation between the primary and secondary clusters by using the hub cluster.
- [DryRun usage](#)
DryRun operations allow administrators to start, monitor, validate, abort, and promote non-destructive failover tests between clusters.
- [Understanding RTO and RPO impact in DryRun mode](#)
Review the recovery time objective (RTO) and recovery point objective (RPO) impacts during and after a DryRun test.
- [DryRun best practices](#)
Follow best practices when planning, executing, and finalizing DryRun test failovers in Fusion Data Foundation.

DryRun architecture

The DryRun architecture coordinates non-destructive disaster recovery validation between the primary and secondary clusters by using the hub cluster.

During a test failover, the hub cluster coordinates both the primary cluster (which remains active and untouched) and the secondary cluster (where the test application runs).

DryRun usage

DryRun operations allow administrators to start, monitor, validate, abort, and promote non-destructive failover tests between clusters.

Perform the following procedures to start, monitor, validate, abort, and promote a DryRun test failover.

Note: Run all commands on the hub cluster.

Starting a test failover

Set the `dryRun` field to `true` and the `action` field to `Failover`. The `<secondary-cluster>` variable specifies the cluster you want to test failing over to. You can locate the cluster name in Red Hat® Advanced Cluster Management:

```
oc patch drpc <drpc_name> -n <drpc_namespace> --type merge -p '{
  "spec": {
    "action": "Failover",
    "failoverCluster": "<secondary-cluster>",
```

```
    "dryRun": true
  },
},'
```

Monitoring test progress

Check the DRPC status to monitor test progress:

```
oc get drpc <drpc_name> -n <drpc_namespace> -o yaml
```

Look for the **progression** field in the status:

```
status:
  phase: Failover
  progression: TestingFailover
  conditions:
  - type: Available
    status: "True"
    reason: Success
```

Key progressions during test

The following progression states occur during the test:

```
WaitForStorageMaintenanceActivation
  Prepares the storage environment.
FailingOverToCluster
  Restores the application on the test cluster.
WaitingForResourceRestore
  Waits for resources to reach ready state.
WaitForReadiness
  Verifies application health.
TestingFailover
  Indicates that the test is active and ready for validation.
```

Validating the test

After the progression reaches **TestingFailover**, you can complete the following validation actions:

- Access the application on the secondary cluster.
- Verify that data is current and correct.
- Test application functionality to ensure that all features work as expected.

Aborting a test

To abort the test and return to normal operation, remove the **dryRun** field or set it to **false**, and revert to the previous **action** and **last-app-deployment-cluster** values:

1. Retrieve the last action:

```
LAST_ACTION=$(oc get drpc <drpc_name> -n <drpc_namespace> -o
jsonpath='{.metadata.annotations.drplacementcontrol\.ramendr\.openshift\.io/last-action}')
```

2. Retrieve the last application deployment cluster:

```
LAST_APP_DEPLOYMENT_CLUSTER=$(oc get drpc <drpc_name> -n <drpc_namespace> -o
jsonpath='{.metadata.annotations.drplacementcontrol\.ramendr\.openshift\.io/last-app-deployment-cluster}')
```

3. Determine the action payload:

```
if [ -z "$LAST_ACTION" ]; then
  ACTION_PAYLOAD="null"
else
  ACTION_PAYLOAD="\`$LAST_ACTION\`"
fi
```

4. Determine the failover cluster payload:

```
if [[ "$LAST_ACTION" != "Failover" && "$LAST_ACTION" != "Relocate" ]]; then
  CLUSTER_PAYLOAD="null"
else
  CLUSTER_PAYLOAD="\`$LAST_APP_DEPLOYMENT_CLUSTER\`"
fi
```

5. Revert to the last action and application deployment cluster:

```
oc patch drpc <drpc_name> -n <drpc_namespace> --type merge -p '{
  "spec": {
    "action": "`$ACTION_PAYLOAD`",
    "failoverCluster": "`$CLUSTER_PAYLOAD`",
    "dryRun": false
  }
},'
```

During the abort process, the following events occur:

1. The system verifies that the application is running on the primary cluster.
2. Progression changes to **CleaningUp** for managed applications, and to **WaitOnUserToCleanUp** for discovered applications.

3. Test resources on the secondary cluster are removed.
4. The secondary cluster returns to standby state.
5. Replication resumes from the primary to the secondary cluster.

Promoting test to real failover

If the primary cluster fails during an active test, you can promote the test to a real failover by setting `dryRun` to `false`:

```
oc patch drpc <drpc_name> -n <drpc_namespace> --type merge -p '{
  "spec": {
    "dryRun": false
  }
}'
```

This action converts the test instance into the production application with near-zero RTO because the application is already running on the secondary cluster.

Understanding RTO and RPO impact in DryRun mode

Review the recovery time objective (RTO) and recovery point objective (RPO) impacts during and after a DryRun test.

During an active test

[Table 1](#) describes the RTO and RPO impact during an active DryRun test.

Table 1. RTO and RPO impact during an active test

Metric	Impact	Explanation
RTO	Near-zero if promoted	Application is already running on the secondary cluster.
RPO	Paused protection	Replication is suspended during the test.

After aborting a test

[Table 2](#) describes the RTO and RPO impact after aborting a DryRun test.

Table 2. RTO and RPO impact after aborting a test

Metric	Impact	Explanation
RTO	Normal	Returns to standard failover time.
RPO	Extended during re-sync	Data protection gap until replication completes.

DryRun best practices

Follow best practices when planning, executing, and finalizing DryRun test failovers in Fusion Data Foundation.

Planning

When planning a test failover, follow these best practices:

- **Schedule during maintenance windows:** Minimize risk exposure.
- **Communicate with stakeholders:** Inform teams about the test.
- **Document procedures:** Create runbooks for validation steps.
- **Plan for quick abort:** Have abort commands ready.

Execution

During test execution, follow these best practices:

- **Monitor primary cluster:** Ensure that production remains healthy.
- **Validate thoroughly:** Test all critical application functions.
- **Check data consistency:** Verify data integrity on the test cluster.
- **Time-box the test:** Do not leave tests running indefinitely.
- **Abort promptly:** Complete validation and abort to resume data protection.

Post-test

After completing or aborting the test, follow these best practices:

- **Verify replication resumed:** Check synchronization status after abort.
- **Document findings:** Record any issues or improvements needed.
- **Update runbooks:** Incorporate lessons learned.

Monitoring regional disaster recovery relationships and actions by using Topology view

Monitor disaster recovery relationships, failover and relocate operations, and application DR statuses across clusters by using the Topology view.

Before you begin

- You configured a Regional-DR solution by using Fusion Data Foundation.
- Red Hat® Advanced Cluster Management for Kubernetes (RHACM) is installed, and the clusters are imported successfully.
- You deployed a sample application and applied a **DRPolicy** to the application.
- You logged in to the OpenShift® Container Platform web console with cluster administrator permissions.

About this task

Note: Starting with Fusion Data Foundation 4.22, you can use the Topology view to monitor disaster recovery relationships and operations across clusters. The disaster recovery (DR) Topology view provides a visual, hierarchical representation of disaster recovery relationships across clusters and applications to help you understand DR coverage, health, and dependencies without navigating multiple pages or inspecting configuration details.

Procedure

1. On the RHACM console, go to All clusters > Data Services > Disaster recovery > Topology.
2. Use the search and filter tools on the Topology page to view and monitor disaster recovery details.

Note: Only DR-managed clusters are displayed.

You can monitor the following items:

- **Cluster peer relationships:** View the peering relationships between clusters, which appear with a dotted line around them after you configure a DRPolicy on the Policy page.
- **Failover and relocate operations:** Track the progress and status of active failover and relocate operations.
- **Application groupings:** View disaster recovery workloads grouped by their current DR status on their respective clusters.

Storage-agnostic disaster recovery for third-party vendors

Ramen integrates with third-party storage providers to deliver disaster recovery between OpenShift® clusters.

Note: Starting with Fusion Data Foundation 4.22, Ramen supports storage-agnostic disaster recovery for third-party storage vendors. Traditionally, Ramen workflows are tightly coupled with Fusion Data Foundation and Ceph-backed storage. Through the agnostic disaster recovery framework, Ramen abstracts the underlying storage tier. As long as a third-party storage vendor provides an operator capable of reconciling the **VolumeGroupReplication** custom resources (CRs), Ramen can orchestrate disaster recovery policies, unplanned failovers, and planned relocations identically across any infrastructure.

System architecture

The agnostic disaster recovery framework separates the responsibilities of the control plane (orchestration) from the data plane (replication). Ramen handles the lifecycle of the application workloads and metadata, while the third-party storage operator manages physical data replication and storage-level volume promotion or demotion.

Component breakdown

Red Hat® Advanced Cluster Management for Kubernetes (RHACM)

Acts as the multicluster control plane on the hub cluster. It is responsible for registering managed clusters and deploying or destroying application workloads across sites based on instructions from Ramen.

Fusion Data Foundation console (agnostic disaster recovery path)

A dedicated user interface wizard hosted on the hub cluster. It allows operators to configure disaster recovery policies for non-Fusion Data Foundation storage providers without requiring an active Ceph backend.

Ramen hub controller

Runs on the hub cluster to orchestrate the top-level disaster recovery definitions (**DRPolicy**, **DRCluster**, and **DRPlacementControl**).

Ramen disaster recovery cluster agent

Reconciles **VolumeReplicationGroup** custom resources for the workload and creates **VolumeGroupReplication** custom resources for third-party storage providers to reconcile.

Third-party storage operator

The vendor-supplied storage subsystem controller. For example, IBM Storage Scale Container Native Storage Access (CNSA) for IBM Fusion Access for SAN. It must watch for changes to **VolumeReplicationGroup** custom resources and manipulate the underlying hardware or storage area network layout accordingly.

The VGR API

For an application to be protected, its target **StorageClass** must carry the following explicit offloading directive label:

```
metadata:
  labels:
    ramendr.openshift.io/offloaded: "true"
```

When this label is detected, Ramen stops attempting to replicate data through native Fusion Data Foundation paths and offloads all data-plane management to the external storage subsystem. It relies on two key custom resources to achieve this:

VolumeReplicationGroup (VRG)

A namespace-scoped resource generated on the managed cluster by the Ramen hub controller. There is exactly one VRG per application. The VRG tracks the individual persistent volume claims matching the application workflow and signals whether that specific workload should be primary or secondary.

VolumeGroupReplication (VGR)

A **VolumeReplicationGroup** custom resource created in the application's namespace on the managed clusters to manage disaster recovery at the workload level. However, backend storage replication groups often span beyond a single application, encompassing an entire physical logical unit number, volume group, or file system array.

To accommodate this disparity, the agnostic disaster recovery framework allows the cluster-level **VolumeGroupReplication** (VGR) resource, located in the **openshift-dr-system** namespace, to represent the broader storage replication boundary. Depending on the storage provider's implementation, Ramen can pool concurrent application VRGs using the same **backend_storageid** and interact with a single, global VGR to orchestrate atomic, group-level data orchestration.

For example, when using IBM Fusion Access for SAN, all applications sharing a physical logical unit number contribute to a single global VGR. They transition replication states and fail over together as an atomic unit.

Agnostic architectural constraint

The third-party storage operator must continuously watch the **spec.replicationState** fields of this VGR. The **spec.external: true** flag tells the vendor operator that it is solely responsible for translating this state change into storage fabric actions, such as logical unit number mapping, masking, or re-zoning.

Storage vendor expectations

To natively integrate with Ramen, a third-party vendor operator must satisfy explicit behavioral contracts during core disaster recovery workflows:

Steady-State protection enrollment

The administrator provisions a **VolumeGroupReplicationClass** with labels that align with those on the **StorageClass**, ensuring that the shared global **storageID** and **groupReplicationID** are consistently identified across clusters.

When an application is enrolled for disaster recovery, the Ramen hub pushes a VRG configuration to the primary cluster's agent. The Ramen agent updates the VGR state to **primary** or **secondary**.

Vendor expectation

The storage operator must watch for the VGR custom resource, parse the metadata, and establish synchronous or asynchronous data channels on the hardware layer to start mirroring data writes to the secondary target location.

Monitoring disaster recovery health

This section provides all the necessary configuration and commands for setting up the disaster recovery dashboard that help to monitor the health of your disaster recovery solution.

- [Enable monitoring for disaster recovery](#)
Enable basic monitoring for your disaster recovery setup by adding a cluster-monitoring label to the **openshift-operators** namespace on the Hub cluster.
- [Enabling disaster recovery dashboard on Hub cluster](#)
Enable the disaster recovery dashboard on the Hub cluster by creating a custom metrics allowlist configmap so that RHACM observability collects Fusion Data Foundation metrics from managed clusters.
- [Viewing health status of disaster recovery replication relationships](#)
View the health status of disaster recovery replication relationships from the Hub cluster dashboard to monitor operator health, cluster status, and DR policy details for protected applications.
- [Viewing health status of ApplicationSet-based and Subscription-based applications](#)
Learn how to view the health status of ApplicationSet-based and Subscription-based applications to identify replication delays and troubleshoot issues.
- [Disaster recovery metrics](#)
Ramen disaster recovery metrics, scraped by Prometheus from the hub cluster, provide per-application data on synchronization timestamps, duration, bytes transferred, and workload protection status.
- [Disaster recovery alerts](#)
Reference list of disaster recovery alerts and recording rules for Fusion Data Foundation.

Enable monitoring for disaster recovery

Enable basic monitoring for your disaster recovery setup by adding a cluster-monitoring label to the **openshift-operators** namespace on the Hub cluster.

About this task

Use this procedure to enable basic monitoring for your disaster recovery setup.

Procedure

1. On the Hub cluster, open a terminal window.
2. Add the following label to **openshift-operator** namespace.

```
oc label namespace openshift-operators openshift.io/cluster-monitoring='true'
```

Enabling disaster recovery dashboard on Hub cluster

Enable the disaster recovery dashboard on the Hub cluster by creating a custom metrics allowlist configmap so that RHACM observability collects Fusion Data Foundation metrics from managed clusters.

Before you begin

- Ensure that you have already installed the following:
 - Red Hat® OpenShift® Container Platform 4.18 or higher and have administrator privileges.
 - Data Foundation Multicluster Orchestrator with the console plugin enabled.
 - Red Hat Advanced Cluster Management for Kubernetes (RHACM) 2.12 or higher from Operator Hub. For instructions on how to install, see [Installation and upgrade](#). Install guide in [Red Hat Advanced Cluster Management for Kubernetes](#) product documentation.Note: Select the appropriate version for your environment and requirements.
 - Ensure you have enabled observability on RHACM. See [Operations](#), [Observability](#), [Observability service](#), [Enabling the Observability service](#), [Enabling Observability from the command line interface](#) in [Red Hat Advanced Cluster Management for Kubernetes](#) product documentation.
- Note: Select the appropriate version for your environment and requirements.

Procedure

1. On the Hub cluster, open a terminal window and perform the next steps.
2. Create the configmap file named **observability-metrics-custom-allowlist.yaml**.
You can use the following YAML to list the disaster recovery metrics on Hub cluster.

```
kind: ConfigMap
apiVersion: v1
metadata:
  name: observability-metrics-custom-allowlist
  namespace: open-cluster-management-observability
data:
  metrics_list.yaml: |
    names:
      - ceph_rbd_mirror_snapshot_sync_bytes
      - ceph_rbd_mirror_snapshot_snapshots
    matches:
      - name = "csv_succeeded", exported_namespace="openshift-dr-system", name=~"odr-cluster-operator.*"
      - name = "kube_running_pod_ready", namespace=~"volsync-system|openshift-operators", pod=~"volsync.*"
```

For details, see [Operations](#), [Observability](#), [Observability service](#), [Observability advanced configuration](#), [Adding custom metrics](#) in [Red Hat Advanced Cluster Management for Kubernetes](#) product documentation.

Note: Select the appropriate version for your environment and requirements.
To know more about ramen metrics, see [Disaster recovery metrics](#).

3. In the **open-cluster-management-observability** namespace, run the following command:

```
oc apply -n open-cluster-management-observability -f observability-metrics-custom-allowlist.yaml
```
4. After **observability-metrics-custom-allowlist** yaml is created, RHACM start collecting the listed Fusion Data Foundation metrics from all the managed clusters.
To exclude a specific managed cluster from collecting the observability data, add the following cluster label to the **clusters: observability: disabled**.

Viewing health status of disaster recovery replication relationships

View the health status of disaster recovery replication relationships from the Hub cluster dashboard to monitor operator health, cluster status, and DR policy details for protected applications.

Before you begin

Ensure that you have enabled the disaster recovery dashboard for monitoring. For instructions, see chapter [Enabling disaster recovery dashboard on Hub cluster](#).

Procedure

1. On the Hub cluster, ensure that All Clusters option is selected.
2. Refresh the console to make the DR monitoring dashboard tab accessible.
3. Go to Data Services and click Data policies.
4. On the Overview tab, you can view the health status of the operators, clusters, and applications. Green tick indicates that the operators are running and available.
5. Click Disaster recovery tab to view a list of DR policy details and connected applications.

Viewing health status of ApplicationSet-based and Subscription-based applications

Learn how to view the health status of ApplicationSet-based and Subscription-based applications to identify replication delays and troubleshoot issues.

Procedure

1. On the Hub cluster, go to All Clusters, Applications.
2. In the DR Status column of the application, view the status:

- Healthy: The last group sync time is less than 2X that of the sync interval.
- Warning: The last group sync time is greater than 2X and less than 3X of the sync interval.
- Critical: The last group sync time is greater than 3X of the sync interval.

What to do next

You can also view the application status for virtual machine (VM) based workloads:

- On the Hub cluster, go to All Clusters > Infrastructure > Virtual Machines > Status column.

Disaster recovery metrics

Ramen disaster recovery metrics, scraped by Prometheus from the hub cluster, provide per-application data on synchronization timestamps, duration, bytes transferred, and workload protection status.

These are the ramen metrics that are scrapped by prometheus.

- ramen_last_sync_timestamp_seconds
- ramen_policy_schedule_interval_seconds
- ramen_last_sync_duration_seconds
- ramen_last_sync_data_bytes
- ramen_workload_protection_status

Run these metrics from the Hub cluster where Red Hat® Advanced Cluster Management for Kubernetes (RHACM operator) is installed.

Last synchronization timestamp in seconds

This is the time in seconds which gives the time of the most recent successful synchronization of all PVCs per application.

Metric name

`ramen_last_sync_timestamp_seconds`

Metrics type

Gauge

Labels

- **ObjType**: Type of the object, here its DPPC
- **ObjName**: Name of the object, here it is DRPC-Name
- **ObjNamespace**: DRPC namespace
- **Policynamespace**: Name of the DRPolicy
- **SchedulingInterval**: scheduling interval value from DRPolicy

Metric value

Value is set as Unix seconds which is obtained from `lastGroupSyncTime` from DRPC status.

Policy schedule interval in seconds

This gives the scheduling interval in seconds from DRPolicy.

Metric name

`ramen_policy_schedule_interval_seconds`

Metrics type

Gauge

Labels

- **Policynamespace**: Name of the DRPolicy

Metric value

Set to scheduling interval in seconds which is taken from DRPolicy.

Last synchronization duration in seconds

This represents the longest time taken to sync from the most recent successful synchronization of all PVCs per application.

Metric name

`ramen_last_sync_duration_seconds`

Metrics type

Gauge

Labels

- **obj_type**: Type of the object, here its DPPC
- **obj_name**: Name of the object, here it is DRPC-Name
- **obj_namespace**: DRPC namespace
- **scheduling_interval**: Scheduling interval value from DRPolicy

Metric value

The value is taken from `lastGroupSyncDuration` from DRPC status.

Total bytes transferred from most recent synchronization

This value represents the total bytes transferred from the most recent successful synchronization of all PVCs per application.

Metric name

`ramen_last_sync_data_bytes`

Metrics type

Gauge

Labels

- `obj_type`: Type of the object, here its DPPC
- `obj_name`: Name of the object, here it is DRPC-Name
- `obj_namespace`: DRPC namespace

Metric value

The value is taken from `lastGroupSyncBytes` from DRPC status.

Workload protection status

This value provides the application protection status per application that is DR protected.

Metric name

`ramen_workload_protection_status`

Metrics type

Gauge

Labels

- `obj_type`: Type of the object, here its DPPC
- `obj_name`: Name of the object, here it is DRPC-Name
- `obj_namespace`: DRPC namespace
- `scheduling_interval`: Scheduling interval value from DRPolicy

Metric value

The value is either a "1" or a "0", where "1" indicates application DR protection is healthy and a "0" indicates application protection degraded and potentially unprotected.

Disaster recovery alerts

Reference list of disaster recovery alerts and recording rules for Fusion Data Foundation.

This section provides a list of all supported alerts associated with IBM Fusion Data Foundation within disaster recovery environment.

Recording rules

- Record: `ramen_sync_duration_seconds`

Expression

```
sum by (obj_name, obj_namespace, obj_type, job, policyname) (time() - (ramen_last_sync_timestamp_seconds > 0))
```

Purpose

The time interval between the volume group's last sync time and the time now in seconds.

- Record: `ramen_rpo_difference`

Expression

```
ramen_sync_duration_seconds{job="ramen-hub-operator-metrics-service"} / on(policyname, job) group_left() (ramen_policy_sc
```

Purpose

The difference between the expected sync delay and the actual sync delay taken by the volume replication group.

- Record: `count_persistentvolumeclaim_total`

Expression

```
count(kube_persistentvolumeclaim_info)
```

Purpose

Sum of all PVC from the managed cluster.

Alerts

- Alert: `VolumeSynchronizationDelay`

Impact

Critical

Purpose

Actual sync delay taken by the volume replication group is thrice the expected sync delay.

YAML

```

alert: VolumeSynchronizationDelay
expr: ramen_rpo_difference >= 3
for: 5s
labels:
  severity: critical
annotations:
  description: "The syncing of volumes is exceeding three times the scheduled snapshot interval, or the volumes have
been recently protected. (DRPC: {{ $labels.obj_name }}, Namespace: {{ $labels.obj_namespace }})"
  alert_type: "DisasterRecovery"

```

- Alert: **VolumeSynchronizationDelay**

Impact

Warning

Purpose

Actual sync delay taken by the volume replication group is twice the expected sync delay.

YAML

```

alert: VolumeSynchronizationDelay
expr: ramen_rpo_difference > 2 and ramen_rpo_difference < 3
for: 5s
labels:
  severity: warning
annotations:
  description: "The syncing of volumes is exceeding two times the scheduled snapshot interval, or the volumes have
been recently protected. (DRPC: {{ $labels.obj_name }}, Namespace: {{ $labels.obj_namespace }})"
  alert_type: "DisasterRecovery"

```

- Alert: **WorkloadUnprotected**

Impact

Critical

Purpose

Application protection status is degraded for more than 10 minutes.

YAML

```

alert: WorkloadUnprotected
expr: ramen_workload_protection_status == 0
for: 10m
labels:
  severity: critical
annotations:
  description: "Workload is not protected for disaster recovery (DRPC: {{ $labels.obj_name }}, Namespace: {{
$labels.obj_namespace }})."
  alert_type: "DisasterRecovery"

```

- Alert: **ApplicationCleanupPending**

Note: Starting with Fusion Data Foundation 4.22, the **ApplicationCleanupPending** alert is available.

Impact

Critical

Purpose

Application cleanup is pending manual action. The DR workflow is halted because leftover application resources must be removed before recovery can continue.

YAML

```

- alert: ApplicationCleanupPending
  expr: ramen_progression_state{state="WaitOnUserToCleanUp"} == 1
  for: 15m
  labels:
    severity: critical
  annotations:
    description: "DRPC '{{ $labels.obj_name }}' in namespace '{{ $labels.obj_namespace }}' requires manual cleanup.
Check DRPC status for details."
    alert_type: "DisasterRecovery"

```

Troubleshooting disaster recovery

This troubleshooting section provides guidance or workarounds on how to fix some of the disaster recovery configuration issues.

- [Troubleshooting Regional-DR](#)
Administrators can use this troubleshooting information to understand how to troubleshoot and fix their Regional-DR solution.

rbd-mirror daemon health is in warning state

If the `rbd-mirror` daemon health reports a **warning** state after a network disconnection, the daemon may have a startup issue caused by unreliable connectivity to the secondary cluster.

Problem

There appears to be numerous cases where WARNING gets reported if mirror service `::get_mirror_service_status` calls Ceph monitor to get service status for `rbd-mirror`.

Following a network disconnection, `rbd-mirror` daemon health is in the **warning** state while the connectivity between both the managed clusters is fine.

Resolution

Run the following command in the toolbox and look for `leader:false`

```
rbd mirror pool status --verbose ocs-storagecluster-cephblockpool | grep 'leader:'
```

If you see the following in the output:

Output	Workaround
leader: false	It indicates that there is a daemon startup issue and the most likely root cause could be due to problems reliably connecting to the secondary cluster. Workaround: Move the <code>rbd-mirror</code> pod to a different node by deleting the pod and verify that it has been rescheduled on another node.
leader: true or no output	Contact IBM Support

BZ reference: [\[2118627\]](#)

volsync-rsync-src pod is in error state as it is unable to resolve the destination hostname

If the `volsync-rsync-src` pod enters an error state with an SSH hostname resolution failure, the `submariner-lighthouse-agent` may need to be restarted on both nodes.

Problem

VolSync source pod is unable to resolve the hostname of the VolSync destination pod. The log of the VolSync Pod consistently shows an error message over an extended period of time similar to the following log snippet.

```
oc logs -n busybox-workloads-3-2 volsync-rsync-src-dd-io-pvc-1-p25rz
```

Example output

```
VolSync rsync container version: ACM-0.6.0-ce9a280
Syncing data to volsync-rsync-dst-dd-io-pvc-1.busybox-workloads-3-2.svc.cluster.set.local:22 ...
ssh: Could not resolve hostname volsync-rsync-dst-dd-io-pvc-1.busybox-workloads-3-2.svc.cluster.set.local: Name or service not known
```

Resolution

Restart `submariner-lighthouse-agent` on both nodes.

```
oc delete pod -l app=submariner-lighthouse-agent -n submariner-operator
```

Cleanup and data sync for ApplicationSet workloads remain stuck after older primary managed cluster is recovered post failover

Troubleshoot DR policies that protect all applications in the same namespace.

Problem

ApplicationSet based workload deployments to managed clusters are not garbage collected in cases when the hub cluster fails. It is recovered to a standby hub cluster, while the workload has been failed over to a surviving managed cluster. The cluster that the workload was failed over from, rejoins the new recovered standby hub.

ApplicationSets that are DR protected, with a regional DRPolicy, hence starts firing the `VolumeSynchronizationDelay` alert. Further such DR protected workloads cannot be failed over to the peer cluster or relocated to the peer cluster as data is out of sync between the two clusters.

Resolution

The workaround requires that

openshift-gitops

operators can own the workload resources that are orphaned on the managed cluster that rejoined the hub post a failover of the workload was performed from the new recovered hub. To achieve this the following steps can be taken:

1. Determine the Placement that is in use by the ArgoCD ApplicationSet resource on the hub cluster in the `openshift-gitops` namespace.
2. Inspect the placement label value for the ApplicationSet in this field: `spec.generators.clusterDecisionResource.labelSelector.matchLabels`. This would be the name of the Placement resource `<placement-name>`
3. Ensure that there exists a `PlacemenDecision` for the ApplicationSet referenced `Placement`.

```
oc get placementdecision -n openshift-gitops --selector cluster.open-cluster-management.io/placement=<placement-name>
```

This results in a single `PlacementDecision` that places the workload in the currently desired failover cluster.

4. Create a new `PlacementDecision` for the ApplicationSet pointing to the cluster where it should be cleaned up.

For example:

```
apiVersion: cluster.open-cluster-management.io/v1beta1
kind: PlacementDecision
metadata:
  labels:
    cluster.open-cluster-management.io/decision-group-index: "1" # Typically one higher than the same value in the
existing PlacementDecision determined at step (2)
    cluster.open-cluster-management.io/decision-group-name: ""
    cluster.open-cluster-management.io/placement: cephfs-appset-busybox10-placement
  name: <placemen-name>-decision-<n> # <n> should be one higher than the existing PlacementDecision as determined in
step (2)
  namespace: openshift-gitops
```

5. Update the newly created `PlacementDecision` with a status `subresource`.

```
decision-status.yaml:
status:
  decisions:
    - clusterName: <managedcluster-name-to-clean-up> # This would be the cluster from where the workload was failed
over, NOT the current workload cluster
      reason: FailoverCleanup

oc patch placementdecision -n openshift-gitops <placemen-name>-decision-<n> --patch-file=decision-status.yaml --
subresource=status --type=merge
```

6. Watch and ensure that the Application resource for the ApplicationSet has been placed on the desired cluster.

```
oc get application -n openshift-gitops <applicationset-name>--<managedcluster-name-to-clean-up>
```

In the output, check if the SYNC STATUS shows as `Synced` and the HEALTH STATUS shows as `Healthy`.

7. Delete the `PlacementDecision` that was created in step (3), such that ArgoCD can garbage collect the workload resources on the `<managedcluster-name-to-clean-up>`

```
oc delete placementdecision -n openshift-gitops <placemen-name>-decision-<n>
```

ApplicationSets that are DR protected, with a regional DRPolicy, stops firing the `VolumeSynchronizationDelay` alert.

BZ reference: [\[2268594\]](#)

VM recipe known issues

Lists known VM recipe issues.

`ramendr.openshift.io/k8s-resource-selector` label is not automatically applied when a PVC is added to an already protected workload NS

Problem

When an additional PV or PVC is attached to an already protected VM on Day 2, the newly created PV/PVC is not automatically protected.

Resolution

To ensure the new PV/PVC is protected, manually add the following label on the new PV/PVC:

```
("ramendr.openshift.io/k8s-resource-selector": "<value same as that of base PVC of associated VM>")
```

This label links the new PV/PVC to the existing protected group of resources.

DRPolicy without flattening applied to a cloned volume leads to errors

Problem

Regional-DR currently does not support volumes created from CSI snapshots or clones in protected applications. These volumes rely on a parent volume that isn't replicated.

Resolution

To avoid these issues, use a DRPolicy that flattens PVs before replication if cloning is required.

For more information, see this [knowledgebase article](#).

Disabling disaster recovery for a disaster recovery-enabled application

Learn how to disable disaster recovery for disaster recovery-enabled managed and discovered applications.

- **Disabling disaster recovery for managed applications**
Use this procedure to disable disaster recovery for disaster recovery-managed applications.
- **Disabling disaster recovery for discovered applications**
Use this procedure to disable disaster recovery for disaster recovery-discovered applications.

Disabling disaster recovery for managed applications

Use this procedure to disable disaster recovery for disaster recovery-managed applications.

Procedure

1. In the RHACM console, go to All Clusters > Data Services > Protected applications tab.
2. At the end of the application row, click Actions menu and select Remove disaster recovery.
3. Click Remove.

Results

Your application loses disaster recovery protection, preventing volume synchronization (replication) between clusters.

The application is no longer in the Protected applications tab when the disaster recovery is removed.

Disabling disaster recovery for discovered applications

Use this procedure to disable disaster recovery for disaster recovery-discovered applications.

Procedure

1. In the RHACM console, go to All Clusters > Data Services > Protected applications tab.
2. At the end of the application row, click Actions menu and select Remove disaster recovery.
3. Click Remove.

Results

Your application loses disaster recovery protection, preventing volume synchronization (replication) between clusters.

The application is no longer in the Protected applications tab when the disaster recovery is removed.

Uninstalling disaster recovery from hub and managed clusters

Learn how to uninstall disaster recovery (DR) partially or completely from hub and managed clusters.

You can uninstall Regional-DR in the following ways:

Partial uninstallation

Partial uninstallation involves removing all DR resources and configurations from two or more peer-managed clusters that are defined in a DRPolicy.

Complete uninstallation

Complete uninstallation is a full uninstallation of the DR setup and includes the following steps:

- Remove all DRPolicies and mirrorpeers from all peer clusters.
- Remove the DR operators and associated resources from the hub cluster.

- [Prerequisites for disaster recovery uninstallation](#)
Before uninstalling disaster recovery (DR), first remove disaster recovery protection from all protected applications, both managed and discovered.
- [Uninstalling disaster recovery for peer-managed clusters](#)
Learn how to uninstall disaster recovery (DR) resources for the peer-managed clusters.
- [Uninstalling disaster recovery operators](#)
Learn how to uninstall disaster recovery completely from DR operators.

Prerequisites for disaster recovery uninstallation

Before uninstalling disaster recovery (DR), first remove disaster recovery protection from all protected applications, both managed and discovered.

Before you begin

Ensure that both managed clusters are online and healthy.

Procedure

1. Find all DRPolicies associated with the peer clusters you want to remove DR from using one of the following options:

- **Using the RHACM console:**

- On the hub cluster, go to All Clusters > Data Services > Disaster Recovery > Policies.
- Identify any DRPolicies associated with the peer clusters you want to remove DR from.

- **Using the CLI:**

- Get the names of the peer clusters from the RHACM console. On the hub cluster, go to All Clusters > Infrastructure > Clusters.
- Run the following commands on the hub cluster, replacing the cluster names with the peer clusters found in the [previous step](#):

```
CLUSTER_A="{cluster1_name}"
CLUSTER_B="{cluster2_name}"

oc get drpolicies -o json | jq -r --arg c1 "$CLUSTER_A" --arg c2 "$CLUSTER_B" '.items[] | select((.spec.drClusters | sort) == ([ $c1, $c2 ] | sort)) .metadata.name'
```

- Identify any DRPolicies associated with the peer clusters you want to remove DR from.

2. Find any existing DRPlacementControl (DRPC) resources that are associated with your peer-managed clusters.

Run the following command on the hub cluster for each DRPolicy identified in step 1:

```
DRPOLICY_NAME="{drpolicy_name}"
```

Replace `drpolicy_name` with the DRPolicy.

```
oc get drplacementcontrols -A -o json | jq -r --arg drpc "$DRPOLICY_NAME" \ '.items[] | select(.spec.drPolicyRef.name == $drpc) | "\(.metadata.namespace)/\(.metadata.name) "'
```

3. If any DRPCs are found, remove DR protection from the associated applications.

- a. Remove DR protection from managed applications.

- i. On the hub cluster, go to All Clusters > Applications.
- ii. In the Overview tab, at the end of the protected application row from the action menu (:), select Manage disaster recovery.
- iii. Click Remove disaster recovery.
- iv. Click Confirm remove.

- b. Remove DR protection from discovered applications.

- i. In the RHACM console, go to All Clusters > Data Services > Protected applications tab.
- ii. At the end of the application row, click the action menu (:) and select Remove disaster recovery.
- iii. Click Remove in the next prompt.

4. Run the following command on the hub cluster to find the associated mirrorpeer:

```
export DR_POLICY={drpolicy_name}
```

Replace `drpolicy_name` with one of the DRPolicy names found in step 1.

```
DR_CLUSTERS=$(oc get drpolicy $DR_POLICY -o json | jq -r '.spec.drClusters | sort | join(",")')
```

```
oc get mirrorpeers -A -o json | jq -r --arg dr_clusters "$DR_CLUSTERS" '.items[] | {name: .metadata.name, clusters: (.spec.items | map(.clusterName) | sort | join(",")) } | select(.clusters == $dr_clusters) | .name'
```

Uninstalling disaster recovery for peer-managed clusters

Learn how to uninstall disaster recovery (DR) resources for the peer-managed clusters.

Before you begin

Ensure that the cluster names, DRPolicies, and mirrorpeer are identified as instructed in [Prerequisites for disaster recovery uninstallation](#).

Procedure

1. From the hub cluster, delete DRPolices associated with the peer-managed clusters that are slated for DR removal.

The DRPolicies that are found in step 1 of [Prerequisites for disaster recovery uninstallation](#) needs to be deleted.

Command example:

```
oc delete drpolicy {drpolicy_name1 drpolicy_name2 ...}
```

Replace **drpolicy_name1** with the DRPolicy names that are found in step 2 of [Prerequisites for disaster recovery uninstallation](#) needs to be deleted.

2. From the hub cluster, delete the mirrorpeer that is associated with the peer-managed clusters that are slated for DR removal.
One mirrorpeer per DRPolicy that are found in step 4 of [Prerequisites for disaster recovery uninstallation](#) needs to be deleted.

Command example:

```
oc delete mirrorpeer {mirrorpeer_name}
```

Important: If you are removing DR for specific peer clusters, do not proceed to uninstall DR operators or other shared resources. This concludes the partial DR uninstall process.

Uninstalling disaster recovery operators

Learn how to uninstall disaster recovery completely from DR operators.

Before you begin

If your goal is to completely remove disaster recovery from your OpenShift® environment, ensure that you followed all the steps that are mentioned in [Prerequisites for disaster recovery uninstallation](#) and [Uninstalling disaster recovery for peer-managed clusters](#) to uninstall disaster recovery from every peer-managed cluster.

Procedure

1. On the hub cluster, delete the **subscriptions.operators** and **clusterserviceversion** (csv) for the Data Foundation Multicloud Orchestrator and OpenShift DR Hub Operator.

Command example:

```
oc delete subscriptions.operators.coreos.com -l operators.coreos.com/odr-hub-operator.openshift-operators -n openshift-operators
oc delete subscriptions.operators.coreos.com -l operators.coreos.com/odf-multicloud-orchestrator.openshift-operators -n openshift-operators
oc delete csv -l operators.coreos.com/odr-hub-operator.openshift-operators -n openshift-operators
oc delete csv -l operators.coreos.com/odf-multicloud-orchestrator.openshift-operators -n openshift-operators
```

2. Alternatively, you can delete the Data Foundation Multicloud Orchestrator and OpenShift DR Hub Operator from the RHACM console.
 - a. Go to Operators > Installed Operators.
 - b. Locate the DR Hub Operator.
 - c. Click the action menu (⋮) and select Uninstall Operator.
 - d. Repeat the same steps for the Data Foundation Multicloud Orchestrator.
3. From the hub cluster, delete the **managedclusterview** for each peer cluster.

Command example:

```
oc delete managedclusterview -l multicloud.odf.openshift.io/created-by=odf-multicloud-managedcluster-controller -A
```

4. From the hub cluster, delete the dynamic console plug-in for the Data Foundation Multicloud Orchestrator operator.
- Command example:

```
oc delete consoleplugins.console.openshift.io odf-multicloud-console
```

5. From the hub cluster, delete the configmap **odf-client-info**.
- Command example:

```
oc delete configmap odf-client-info -n openshift-operators
```

6. From the hub cluster, delete the **odf-multicloud-console** service.
- Command example:

```
oc delete service odf-multicloud-console -n openshift-operators
```

Results

All disaster recovery-related operator components and configurations are fully removed from the hub cluster and all managed clusters.

High availability

High availability ensures that system services and data remain accessible with minimal downtime by distributing compute, control, and storage components across independent failure domains.

In the IBM Fusion HCI solution, high availability refers to deployment configurations that maintain continuous operation and data integrity even in the event of major infrastructure failures, such as the loss of a rack, availability zone, or network domain.

The architecture eliminates single points of failure by distributing control-plane nodes, storage replicas, and compute resources across discrete failure domains or availability zones.

The IBM Fusion HCI offers the following multi rack topology to support the high availability for the OpenShift® Container Platform cluster:

2AZ and arbiter node topology

A deployment configuration that spans two availability zones with an additional arbiter node located in a third zone. The arbiter node maintains cluster quorum and allows continued operation in case of a zone or rack failure. This option offers a cost-effective balance between high availability and resource utilization. For more information, see [Two availability zones and arbiter node configuration with Fusion Data Foundation](#).

- **[Two availability zones and arbiter node configuration with Fusion Data Foundation](#)**
Deploy Fusion Data Foundation in a two-availability-zone and arbiter node (2AZ and arbiter node) configuration to maintain data availability across availability zones.

Two availability zones and arbiter node configuration with Fusion Data Foundation

Deploy Fusion Data Foundation in a two-availability-zone and arbiter node (2AZ and arbiter node) configuration to maintain data availability across availability zones.

IBM Fusion HCI supports a 2AZ and arbiter node configuration, in which two racks are deployed across separate availability zones within a region, while an arbiter node (or control node) is deployed in a third zone. This configuration ensures that one zone or rack can remain isolated if a failure occurs in another zone. For more information on the available deployment configurations of IBM Fusion HCI, see [Deployment configurations](#).

In this configuration, you can run a single OpenShift® Container Platform cluster that includes all nodes from both racks and the arbiter node to achieve high availability. The OpenShift Container Platform control plane is formed using the control node of each rack and the arbiter node, which acts as the tie-breaker to maintain cluster quorum.

An example configuration of 2AZ and arbiter node configuration is as follows:

Figure 1. Sample 2AZ and arbiter node configuration

Deploy the Fusion Data Foundation in the cluster, which is stretched across the two racks to provide the storage infrastructure with disaster recovery capabilities. In the event of a disaster, such as one of the two zones being partially or fully unavailable, the application workloads in the cluster continue running, ensuring business continuity.

For Fusion Data Foundation deployment instructions in the 2AZ and arbiter node configuration, see [Installing Fusion Data Foundation in a two availability zones and arbiter node configuration](#).

Hosted Control Plane is supported on the 2AZ and arbiter node topology with Fusion Data Foundation 4.22 or later releases. For deployment instructions, see [Deploying a virtualized Hosted Control Plane cluster on 2AZ and arbiter node topology](#) and [Deploying a Bare Metal Hosted Control Plane cluster on 2AZ and arbiter node topology](#).

- **[Installing Fusion Data Foundation in a two availability zones and arbiter node configuration](#)**
Install and configure Fusion Data Foundation in a two-availability-zone and arbiter node (2AZ and arbiter node) configuration to provide storage resiliency and disaster recovery capabilities.
- **[Installing zone-aware sample application](#)**
Install a zone-aware sample application to validate of resiliency and high availability in the two-availability-zone and arbiter node (2AZ and arbiter node) configuration.
- **[Recovering applications](#)**

Installing Fusion Data Foundation in a two availability zones and arbiter node configuration

Install and configure Fusion Data Foundation in a two-availability-zone and arbiter node (2AZ and arbiter node) configuration to provide storage resiliency and disaster recovery capabilities.

Before you begin

- Complete the network planning and meet all prerequisites mentioned in [Network for two-availability-zone and arbiter node \(2AZ and arbiter node\) configuration](#).
- Install IBM Fusion HCI by following the instructions mentioned in [Installing IBM Fusion HCI](#).
- Use Fusion Data Foundation version 4.19 or higher.
- Use OpenShift® Container Platform version 4.19 or higher.
- Flexible scaling is not supported for the 2AZ and arbiter node deployment.
- To install and configure Fusion Data Foundation offline, see [Mirroring Fusion Data Foundation images](#).

Procedure

1. In the IBM Fusion HCI web console, go to the Services tab and install Fusion Data Foundation.
Note: If the Install button is not available, upgrade OpenShift Container Platform to version 4.21 or higher.
The installation of Fusion Data Foundation completes successfully.
2. Configure the Fusion Data Foundation storage by following the instructions mentioned in [Configuring Fusion Data Foundation in provider mode](#).
Note: After configuring Fusion Data Foundation storage, ensure that you create **NetworkFenceClass** CRs based on the number of storage clusters connected to the OpenShift Container Platform cluster. The **NetworkFenceClass** CRs are necessary for fencing and tainting nodes during non-graceful node shutdown to prevent volume corruption. For instructions, see [Creating a NetworkFenceClass CR](#).
The configuration of Fusion Data Foundation storage completes successfully.
3. Verify that the arbiter configuration details are available in ocs-storagecluster:
 - a. Log in to the OpenShift Container Platform web console and select the required project.
 - b. Go to Storage > Data Foundation > Storage Systems.
 - c. On the StorageSystems page, click the ellipses (:) menu next to ocs-storagecluster, and select Edit Storage System.
 - d. Click YAML tab and check whether the following arbiter configuration details are present:

```
arbiter:
  enable: true
  nodeTopologies:
    arbiterLocation: arbiter
----
replica: 4
```

Results

Fusion Data Foundation storage is successfully deployed in the 2AZ and arbiter node configuration.

What to do next

Validate whether the 2AZ and arbiter node topology is successfully configured by checking resiliency and high availability by following the instructions as follows:

- Install a zone-aware sample application by following the instructions mentioned in [Installing zone-aware sample application](#).
- Recover the sample application by following the instructions mentioned in [Recovering applications](#).

You can also deploy a Hosted Control Plane cluster on this 2AZ and arbiter node topology with Fusion Data Foundation version 4.22 and later releases. For deployment instructions, see [Deploying a virtualized Hosted Control Plane cluster on 2AZ and arbiter node topology](#) and [Deploying a Bare Metal Hosted Control Plane cluster on 2AZ and arbiter node topology](#).

Installing zone-aware sample application

Install a zone-aware sample application to validate of resiliency and high availability in the two-availability-zone and arbiter node (2AZ and arbiter node) configuration.

About this task

Install a zone-aware sample application in the stretched OpenShift® Container Platform cluster to validate of resiliency and high availability in the 2AZ and arbiter node configuration.

Important: With latency between the data zones, one can expect to see performance degradation compared to an OpenShift Container Platform cluster with low latency between nodes and zones (for example, all nodes in the same location). How much the performance gets degraded, depends on the latency between the zones and on the application behavior that uses the storage (such as heavy write traffic). Ensure that you test the critical applications with stretch cluster configuration to ensure sufficient application performance for the required service levels.

A ReadWriteMany (rwx) Persistent Volume Claim (PVC) is created by using the `ocs-storagecluster-cephfs` storage class. Multiple pods use the newly created rwx PVC at the same time. The application that is used in the example here is called File Uploader.

This topic demonstrates how an application is spread across topology zones so that it is still available when there is a site outage.

Note: This demonstration is possible since this application shares the same rwx volume for storing files. It works for persistent data access as well because Fusion Data Foundation is configured as a stretched cluster with zone awareness and high availability.

Procedure

1. Create a new project.

```
oc new-project my-shared-storage
```

Note: Ensure that there is an image registry available before creating the PHP application `file-uploader`.

2. Deploy the example PHP application called `file-uploader`.

```
oc new-app openshift/php:latest-https://github.com/christianh814/openshift-php-upload-demo --name=file-uploader
```

Example Output:

```
--> Found image e3f98ea (7 days old) in image stream "openshift/php" under tag "latest" for "openshift/php:latest"

    Apache 2.4 with PHP 8.3
    -----
    PHP 8.3 available as container is a base platform for building and running various PHP 8.3 applications and
    frameworks. PHP is an HTML-embedded scripting language. PHP attempts to make it easy for developers to write dynamically
    generated web pages. PHP also offers built-in database integration for several commercial and non-commercial database
    management systems, so writing a database-enabled webpage with PHP is fairly simple. The most common use of PHP coding is
    probably as a replacement for CGI scripts.

    Tags: builder, php, php83, php-83

    * A source build using source code from https://github.com/christianh814/openshift-php-upload-demo will be created
    * The resulting image will be pushed to image stream tag "file-uploader:latest"
    * Use 'oc start-build' to trigger a new build

--> Creating resources ...
    imagestream.image.openshift.io "file-uploader" created
    buildconfig.build.openshift.io "file-uploader" created
    deployment.apps "file-uploader" created
    service "file-uploader" created
--> Success
    Build scheduled, use 'oc logs -f buildconfig/file-uploader' to track its progress.
    Application is not exposed. You can expose services to the outside world by executing one or more of the commands
    below:
    'oc expose service/file-uploader'
    Run 'oc status' to view your app.
```

3. View the build log and wait until the application is deployed.

```
oc logs -f bc/file-uploader -n my-shared-storage
```

Example Output:

```
Cloning "https://github.com/christianh814/openshift-php-upload-demo" ...

Push successful

```

The command prompt returns out of the tail mode once you see **Push successful**.

Note: The new-app command deploys the application directly from the Git repository and does not use the Red Hat® OpenShift template, hence Red Hat OpenShift route resource is not created by default. You need to create the route manually.

What to do next

- [Scaling the application after installation](#)
- [Scaling the application after installation](#)
Scale the application to four replicas and attach a ReadWriteMany PVC to make the application zone-aware and available across both data zones.
- [Modifying deployment to be zone-aware](#)
Modify an application deployment to use topology spread constraints so that pods are distributed across availability zones and remain available during a single zone failure.

Scaling the application after installation

Scale the application to four replicas and attach a ReadWriteMany PVC to make the application zone-aware and available across both data zones.

Procedure

1. Scale the application to four replicas and expose its services to make the application zone-aware and available.

```

oc expose svc/file-uploader -n my-shared-storage

oc scale --replicas=4 deploy/file-uploader -n my-shared-storage

oc get pods -o wide -n my-shared-storage

```

You should have four file-uploader pods in a few minutes. Repeat the previous command until there are 4 file-uploader pods in the **Running** status.

2. Create a PVC and attach it into an application.

```

oc set volume deploy/file-uploader --add --name=my-shared-storage \
-t pvc --claim-mode=ReadWriteMany --claim-size=10Gi \
--claim-name=my-shared-storage --claim-class=ocs-storagecluster-cephfs \
--mount-path=/opt/app-root/src/uploaded \
-n my-shared-storage

```

This command:

- Creates a PVC.
- Updates the application deployment to include a volume definition.
- Updates the application deployment to attach a volume mount into the specified mount-path.
- Creates a new deployment with the four application pods.

3. Check the result of adding the volume.

```
oc get pvc -n my-shared-storage
```

Example Output:

NAME	STATUS	VOLUME	CAPACITY	ACCESS MODES	STORAGECLASS
AGE					
my-shared-storage cephfs 52s	Bound	pvc-5402cc8a-e874-4d7e-af76-1eb05bd2e7c7	10Gi	RWX	ocs-storagecluster-

Notice the **ACCESS MODE** is set to **rwX**.

```
deployment.apps/file-uploader scaled
```

Scaling up to **four** pods

```
oc scale deployment file-uploader --replicas=4 -n my-shared-storage
```

Example output:

```
deployment.apps/file-uploader scaled
```

3. Verify that the four pods are spread across the four nodes in datacenter1 and datacenter2 zones.

```
oc get pods -o wide -n my-shared-storage | egrep '^file-uploader' | grep -v build | awk '{print $7}' | sort | uniq -c
```

Example output:

```
1 perf1-mz8bt-worker-d2hdm
1 perf1-mz8bt-worker-k68rv
1 perf1-mz8bt-worker-ntkp8
1 perf1-mz8bt-worker-qpswr
```

Search for the zone labels used.

```
oc get nodes -L topology.kubernetes.io/zone | grep datacenter | grep -v master
```

Example output:

perf1-mz8bt-worker-d2hdm	Ready	worker	35d	v1.20.0+5fbfd19	datacenter1
perf1-mz8bt-worker-k68rv	Ready	worker	35d	v1.20.0+5fbfd19	datacenter1
perf1-mz8bt-worker-ntkp8	Ready	worker	35d	v1.20.0+5fbfd19	datacenter2
perf1-mz8bt-worker-qpswr	Ready	worker	35d	v1.20.0+5fbfd19	datacenter2

4. Use the file-uploader web application by using your browser to upload new files.
- a. Find the route that is created.

```
oc get route file-uploader -n my-shared-storage -o jsonpath --template="http://{.spec.host}{'\n'}"
```

Example Output:

```
http://file-uploader-my-shared-storage.apps.cluster-ocs4-abdf.ocs4-abdf.sandbox744.opentlc.com
```

- b. Point your browser to the web application by using the route in the previous step.
The web application lists all the uploaded files and offers the ability to upload new ones and download the existing data.
- c. Select an arbitrary file from your local computer and upload it to the application.
- Click Choose file to select an arbitrary file.
 - Click Upload.
- d. Click List uploaded files to see the list of all currently uploaded files.

Note: The OpenShift Container Platform image registry, ingress routing, and monitoring services are not zone-aware.

Recovering applications

Understand the recovery methods for applications and storage in a two-availability-zone and arbiter node (2AZ and arbiter node) configuration to ensure resiliency and high availability.

How the application is designed determines how soon it becomes available again on the active zone.

There are different methods of recovery for applications and their storage depending on the site outage. The recovery time depends on the application architecture.

- [Understanding zone failure](#)
Zone failure occurs when all nodes in a data zone lose communication with the second zone. Recovery succeeds only when communication between zones is fully disconnected.
- [Recovering zone-aware HA applications with rwx storage](#)
Zone-aware HA applications using ReadWriteMany CephFS volumes experience pod termination in the failed zone and may require a node restart if pods enter CrashLoopBackOff during recovery.
- [Recovering HA applications with rwx storage](#)
If all application replicas using ReadWriteMany storage are in the failed zone, the application takes 6–8 minutes to recover on the active zone after the pod eviction timeout expires.
- [Recovering applications with RWO storage](#)
Applications using ReadWriteAfter storage have pods that become stuck in **Terminating** status after a zone failure and require manual intervention such as powering off the node to recover.
- [Recovering StatefulSet pods](#)
StatefulSet pods behave like pods with ReadWriteAfter volumes during a zone failure and must be force-deleted with the node powered off to reschedule on the active zone.
- [Fencing and tainting nodes to prevent volume corruption during non-graceful node shutdown](#)
Fence and taint nodes to protect storage volumes from corruption during unexpected or non-graceful node shutdown.

Understanding zone failure

Zone failure occurs when all nodes in a data zone lose communication with the second zone. Recovery succeeds only when communication between zones is fully disconnected.

In this section, zone failure is considered as a failure where all OpenShift® Container Platform, master and worker nodes in a zone are no longer communicating with the resources in the second data zone (for example, powered down nodes). If communication between the data zones is still partially working (intermittently up or down), the cluster, storage, and network admins should disconnect the communication path between the data zones for recovery to succeed.

Important: Before installing the sample application, power off the OpenShift Container Platform nodes (at least the nodes with Fusion Data Foundation devices) to test the failure of a data zone to validate that your file-uploader application is available, and you can upload new files.

Note: To prevent volume corruption during non-graceful node shutdown, follow the steps in [Fencing and tainting nodes to prevent volume corruption during non-graceful node shutdown](#).

Recovering zone-aware HA applications with rwx storage

Zone-aware HA applications using ReadWriteMany CephFS volumes experience pod termination in the failed zone and may require a node restart if pods enter CrashLoopBackOff during recovery.

Applications that are deployed with `topologyKey: topology.kubernetes.io/zone`, have one or more replicas that are scheduled in each data zone, and are using shared storage, that is, ReadWriteMany (rwx) CephFS volume, terminate themselves in the failed zone after few minutes and new pods are rolled in and stuck in pending state until the zones are recovered.

An example of this type of application is detailed in the [Installing zone-aware sample application](#) section.

Important: During zone recovery if application pods go into CrashLoopBackOff (CLBO) state with permission denied error while mounting the CephFS volume, then restart the nodes where the pods are scheduled. Wait for some time and then check whether the pods are running again.

Note: To prevent volume corruption during non-graceful node shutdown, follow the steps in [Fencing and tainting nodes to prevent volume corruption during non-graceful node shutdown](#).

Recovering HA applications with rwx storage

If all application replicas using ReadWriteMany storage are in the failed zone, the application takes 6–8 minutes to recover on the active zone after the pod eviction timeout expires.

Applications that are using `topologyKey: kubernetes.io/hostname` or no topology configuration, have no protection against all the application replicas being in the same zone.

Note: This can happen even with `podAntiAffinity` and `topologyKey: kubernetes.io/hostname` in the **Pod** spec because this anti-affinity rule is host-based and not zone-based.

If this happens and all replicas are located in the zone that fails, the application that uses ReadWriteMany (rwx) storage takes 6-8 minutes to recover on the active zone. This pause is for the OpenShift® Container Platform nodes in the failed zone to become **NotReady** (60 seconds) and then for the default pod eviction timeout to expire (300 seconds).

Important: To prevent volume corruption during non-graceful node shutdown, follow the steps in [Fencing and tainting nodes to prevent volume corruption during non-graceful node shutdown](#).

Recovering applications with RWO storage

Applications using ReadWriteAfter storage have pods that become stuck in **Terminating** status after a zone failure and require manual intervention such as powering off the node to recover.

Applications that use ReadWriteAfter (RWO) storage have a known behavior that is described in this [Kubernetes issue](#). Because of this issue, if there is a data zone failure, any application pods in that zone mounting RWO volumes (for example, `cephrbd` based volumes) are stuck with **Terminating** status after 6-8 minutes and is not re-created on the active zone without manual intervention.

To prevent volume corruption during non-graceful node shutdown, follow the steps in [Fencing and tainting nodes to prevent volume corruption during non-graceful node shutdown](#).

Recovering StatefulSet pods

StatefulSet pods behave like pods with ReadWriteAfter volumes during a zone failure and must be force-deleted with the node powered off to reschedule on the active zone.

Pods that are part of a StatefulSet have a similar issue as pods mounting ReadWriteAfter (RWO) volumes. More information is referenced in the Kubernetes resource [StatefulSet considerations](#).

To prevent volume corruption during non-graceful node shutdown, follow the steps in [Fencing and tainting nodes to prevent volume corruption during non-graceful node shutdown](#).

Fencing and tainting nodes to prevent volume corruption during non-graceful node shutdown

Fence and taint nodes to protect storage volumes from corruption during unexpected or non-graceful node shutdown.

Before you begin

Ensure that the **NetworkFenceClass** CRs are created in the cluster based on the number of storage clusters connected to the OpenShift® Container Platform cluster. For instructions, see [Creating a NetworkFenceClass CR](#).

Procedure

1. Create a **NetworkFence** CR to fence the IP addresses of storage nodes that are down.

- a. Get the node name that needs to be fenced.

Command example:

```
oc get node
```

- b. Get the **csiaddonsnode** object corresponding to the node found in step [1.a](#).

Command example:

```
oc get csiaddonsnode -n openshift-storage |grep -i <nodename> |grep -i daemonset
```

- c. Get the IP address from the **csiaddonsnode** object found in step [1.b](#).

Command example:

```
oc get csiaddonsnode -n openshift-storage \
compute-2-ru5.f091004.fusion.tadn.ibm.com-openshift-storage-daemonset-openshift-storage.rbd.csi.ceph.com-nodeplugin-
csi-addons \
-o jsonpath='{.status.networkFenceClientStatus}'
[{"ClientDetails": [{"cidrs": ["10.48.120.82/32"], "id": "04a26bdf-1e5b-4d09-b052-871c5e32f960"}], "networkFenceClassName": "odf-networkfenceclass"}, {"ClientDetails": [{"cidrs": ["10.48.120.82/32"], "id": "04a26bdf-1e5b-4d09-b052-871c5e32f960"}], "networkFenceClassName": "ocs-storagecluster-ceph-rbd-networkfenceclass"}]
```

Replace **<csi-addons-name>** with the **csiaddonsnode** object found in step [1.b](#).

- d. Create the **NetworkFence** CR for the CIDR used in step [1.c](#) with the OpenShift node name for easy identification.

For example:

```
apiVersion: csiaddons.openshift.io/v1alpha1
kind: NetworkFence
metadata:
  name: <openshift-node-name>
spec:
  cidrs:
  - 10.244.0.1/32
  driver: openshift-storage.rbd.csi.ceph.com
  fenceState: Fenced
  parameters:
    clusterID: openshift-storage
  secret:
    name: rook-csi-rbd-provisioner
    namespace: openshift-storage
```

- **parameters.clusterID**: Specifies the cluster id. Fetch it from the **parameters.clusterID** field in the **ocs-storagecluster-ceph-rbd** StorageClass.
- **secret.name**: Specifies the name of the secret that is required for network fencing. Fetch it from the **parameters.csi.storage.k8s.io/provisioner-secret-name** field in the **ocs-storagecluster-ceph-rbd** StorageClass.
- **secret.namespace**: Specifies the namespace in which the secret is located. Fetch it from the **parameters.csi.storage.k8s.io/provisioner-secret-namespace** field in the **ocs-storagecluster-ceph-rbd** StorageClass.

- e. Verify that network fencing is done successfully.

Command example:

```
oc get networkfence
```

Example output:

NAME	DRIVER	CIDRS	FENCESTATE	AGE	RESULT
<openshift-node-name>	openshift-storage.rbd.csi.ceph.com	["10.244.0.1/32"]	Fenced	42h	Succeeded

2. Add taint for the nodes that are down.

Command example:

```
oc patch node <node-name> --type='merge' -p '{"spec":{"taints":[{"key":"node.kubernetes.io/out-of-service","value":"nodeshutdown","effect":"NoExecute"}]}'
```

3. Monitor application relocation to surviving nodes.
4. Repeat step [1](#), [2](#), and [3](#) for all nodes that are down.
5. After the nodes are back online, do as follows:

Note: Repeat the following steps for all nodes.

- a. Change the state of **NetworkFence** to **Unfenced** in the CR.

Command example:

```
oc patch networkfence <network-fence-object-name> -p '{"spec":{"fenceState":"Unfenced"}}' --type=merge
```

- b. Verify that the network unfencing is done successfully.

Command example:

```
oc get networkfence
```

Example output:

NAME	DRIVER	CIDRS	FENCESTATE	AGE	RESULT
<openshift-node-name>	openshift-storage.rbd.csi.ceph.com	["10.244.0.1/32"]	unfenced	42h	Succeeded

c. Untaint the node.

Command example:

```
oc adm taint nodes <node-name> node.kubernetes.io/out-of-service=nodeshutdown:NoExecute-
```

Multi-cluster IBM Fusion HCI using Hosted Control Plane

Create a Hosted Control Plane with Red Hat® Red Hat OpenShift Virtualization clusters or Bare Metal clusters (both internal and external) on IBM Fusion HCI.

To know more about internal and external, see [Choose your configuration](#).

Important: Hosted Control Plane is supported only with Fusion Data Foundation as primary storage.

For these clusters, the control plane components are hosted on a IBM Fusion HCI management cluster, and the compute nodes are provisioned as virtual machines or Bare Metal servers. A hosted control plane refers to a solution that offers a decoupled management plane where you can install and run the core control plane components on a IBM Fusion HCI. Instead of running control plane components on a dedicated physical or virtual machine, you can use the hosted control plane feature to run these components as lightweight pods on the IBM Fusion HCI cluster. You can host the control plane components, API server, etcd, and control manager, separately from the compute nodes.

The IBM Fusion HCI can now host multiple IBM Fusion clusters. You can create clusters that match your specific workload needs, and clusters can be created and deleted on demand. IBM Fusion HCI supports Hosted Control Plane clusters using OpenShift® virtualization and Bare Metal nodes (both internal and external).

Benefits of hosted control plane:

- Cost efficiency
The reduction in the number of nodes makes clusters more cost-effective:
 - You do not need control nodes per cluster.
 - Reduced number of Bare Metal nodes needed for clusters.
 - Red Hat Red Hat OpenShift Virtualization VMs can be used as compute nodes. The control pods on a hosting cluster allows for the two variants: Red Hat Red Hat OpenShift Virtualization and Bare Metal.
- Ability to provide Cluster on demand
You can delete clusters when they are no longer needed. The resources are freed up for new provisioning.

For more information and benefits of the Hosted Control Plane, see [Red Hat documentation](#).

OpenShift Virtualization Hosted Control Plane clusters

IBM Fusion HCI supports hosted control plane in the configurations of virtual clusters and Bare Metal clusters. The virtual clusters are virtualized VMs as nodes within the IBM Fusion HCI.

For more information about the deployment, see [Deployment of virtualized clusters with Fusion Data Foundation](#).

Bare Metal Hosted Control Plane clusters

For bare metal clusters, an IBM Fusion HCI admin can provision on demand OpenShift clusters on Bare Metal IBM Fusion HCI, and support is available for both internal and external. Though the control plane is hosted in a similar manner as virtualized clusters, the compute nodes are deployed on physical servers.

Hosted Control Plane Bare Metal internal servers in a rack

Using servers inside the IBM Fusion HCI rack, you can set up workloads to run on your Bare Metal Hosted Control Plane cluster using a GPU node. For example, watsonx.ai is a workload.

The IBM Fusion HCI rack houses all the servers required for the system, with some serving as OpenShift hosts. A Hosted Control Plane Bare Metal cluster is created using a subset of these servers, which takes on the workload of a GPU node. By converting three control servers into control pods on this hosted cluster, you save three control servers. The following diagram illustrates this managed topology:

Hosted Control Plane Bare Metal external servers

External servers outside of the IBM Fusion HCI cluster can be used to create Bare Metal Hosted Control Plane clusters with Fusion data services. Here, bring your own Bare Metal hosts and turn them into nodes. The control planes of this Hosted Control Plane cluster are hosted in the IBM Fusion HCI management cluster. You can create more Bare Metal compute nodes out of your stock of x86 servers.

On the IBM Fusion HCI rack, you can set up your own host cluster. The external rack you bring can be used for OpenShift clusters, where a Hosted Control Plane Bare Metal cluster is created. Meanwhile, the control pods operate on the IBM Fusion HCI cluster, enabling you to make the most of your existing hardware resources. The following diagram illustrates this external topology:

For more information about the deployment, see [Deployment of Bare Metal clusters with Fusion Data Foundation](#).

Benefits of IBM Fusion in Hosted Control Plane

- Provision OpenShift Container Platform clusters with services like Fusion Data Foundation, Backup & Restore, IBM Data Cataloging, and disaster recovery. You can add labels during the time of hosted cluster creation so that you need not log in to your cluster to install the services. For an overview on each of the Fusion services, see [Fusion services](#).
Note: You can also add service label later based on your need. Only Data Foundation Backup & Restore can be done through labeling.
- Support is available for Provider and consumer mode in Fusion Data Foundation. In the provider mode, you run a storage cluster locally that can serve multiple mode clusters. The provider mode is similar to an external Fusion Data Foundation configuration. It acts as the provider and base storage on the host cluster. You can provision new clusters within a internal rack and use storage from the central provider cluster. Here, the provider and consumer are in a hosted control plane relationship.
- Data services are automatically cleaned up upon the deletion of Hosted Control Plane clusters.
- Single dashboard for managing Backup & Restore and storage.
- Manage logs and events of multiple clusters.
- Provide dynamic storage for applications in Hosted Control Plane clusters.

- Disaster recovery is available for applications on Hosted Control Plane clusters.
- Provide Backup & Restore for applications in Hosted Control Plane clusters.
- With IBM Fusion HCI, you can order GPU nodes and install them in your rack so that you can run a dedicated cluster for your AI workloads.
- Support for deployment of IBM Cloud Pak for Integration and IBM Software Hub on Hosted Control Plane.
- [Interoperability matrix](#)
Supported MCE versions and compatible Hosted Control Plane OpenShift Container Platform versions vary by hub cluster version. Use this matrix to determine which MCE versions and Hosted Control Plane OpenShift Container Platform versions are supported for your hub cluster OpenShift Container Platform version.
- [Hosted Control Plane sizing on IBM Fusion](#)
Plan and size your Hosted Control Plane on IBM Fusion to ensure optimal performance, scalability, and resilience.
- [Prerequisites for Hosted Control Plane clusters](#)
The prerequisites before you create virtualized or Bare Metal Hosted Control Plane clusters.
- [Deployment of virtualized clusters with Fusion Data Foundation](#)
Create virtualized (Hosted Control Plane) clusters with the Fusion Data Foundation as storage type.
- [Deployment of Bare Metal clusters with Fusion Data Foundation](#)
Create Bare Metal hosted clusters with Fusion Data Foundation as the storage type. It supports both Hosted Control Plane Bare Metal internal servers in a rack and Hosted Control Plane Bare Metal external servers.
- [Installation of data services on a Hosted Control Plane cluster](#)
Provision Hosted Control Plane clusters with services like Fusion Data Foundation, Global Data Platform remote mount, and Backup & Restore.
- [Backup and restore of the Hosted Control Plane cluster](#)
You can backup and restore your Hosted Control Plane cluster.
- [Cleaning up of a Hosted Control Plane cluster](#)
If you no longer need a hosted cluster, use this procedure to remove it.
- [Troubleshooting issues and known limitations in Hosted Control Plane cluster](#)
Use this troubleshooting information to resolve known issues with hosted control planes clusters, including installation, cleanup, backup, and storage problems.

Interoperability matrix

Supported MCE versions and compatible Hosted Control Plane OpenShift® Container Platform versions vary by hub cluster version. Use this matrix to determine which MCE versions and Hosted Control Plane OpenShift Container Platform versions are supported for your hub cluster OpenShift Container Platform version.

Run the following command to retrieve the list of supported OpenShift Container Platform versions for an Hosted Control Plane cluster with the installed MCE version.

```
oc get configmap supported-versions -n hypershift -o yaml
```

Table 1. Supported MCE and Hosted Control Plane cluster OpenShift Container Platform versions based on hub cluster OpenShift Container Platform version

OpenShift Container Platform version on hub cluster	MCE version	OpenShift Container Platform version on Hosted Control Plane cluster
4.18	2.8	4.16 to 4.18
	2.9	4.17 to 4.19
	2.10	4.18 to 4.20
4.19	2.10	4.18 to 4.20
	2.11	4.17 to 4.19
4.20	2.10	4.18 to 4.20
	2.11	4.18 to 4.20
4.21	2.11	4.19 to 4.21
	2.17	4.19 to 4.21
4.22	2.17	4.20 to 4.22

***- only virtualized Hosted Control Plane is supported, and not Bare Metal Hosted Control Plane.

Table 2. Red Hat Advanced Cluster Management (ACM) deployment and Hosted Control Plane configuration guidance by topology

Topology	Disaster recovery	Disaster recovery type	MCE	Internal ACM	External ACM	Hosted Control Plane configuration
Standalone	False	Not applicable	Required	Optional	Not Required	Single zone
Standalone	True	Regional disaster recovery	Required	Not Allowed	Required	Single zone
2AZ and Arbiter	False	Not applicable	Required	Optional	Not Required	Multi zone
2AZ and Arbiter	True	Metro disaster recovery	Required	Not Allowed	Required	Single zone
2AZ and Arbiter	True	Regional disaster recovery	Required	Not Allowed	Required	Multi zone
3AZ	False	Not applicable	Required	Optional	Not Required	Multi zone
3AZ	True	Regional disaster recovery	Required	Not Allowed	Required	Multi zone

Hosted Control Plane sizing on IBM Fusion

Plan and size your Hosted Control Plane on IBM Fusion to ensure optimal performance, scalability, and resilience.

When planning the sizing of a Hosted Control Plane on IBM Fusion, several factors must be carefully evaluated to ensure optimal performance, scalability, and resilience. This topic provides guidance on the key considerations and formulas to help you estimate the required infrastructure for Hosted Control Plane deployments.

Key considerations

Control and compute node specification

The resource allocation for control nodes and compute nodes (vCPUs, memory, and storage) directly impacts the stability and responsiveness of the hosted clusters. However, control nodes vCPUs and memory are not considered as available capacity for Hosted Control Plane in this sizing guide. Storage from control nodes is considered.

Number of Hosted Control Plane clusters

The total count of Hosted Control Plane clusters to be deployed determines the aggregate resource requirement. Each additional cluster adds to CPU, memory, and storage usage and LVM storage.

vCPU allocation

Proper sizing of vCPUs is essential for workload execution, cluster operations, and ensuring smooth control plane performance. Over or under provisioning can affect latency and throughput.

Memory requirements

Adequate memory allocation is critical for API responsiveness, workload scheduling, and supporting large-scale workloads across clusters.

Storage capacity and drive count

Persistent, ephemeral, and LVM storage must be considered. This ensures sufficient capacity for workloads, logs, and cluster metadata.

OpenShift® reserve

A portion of system resources must be reserved for OpenShift to maintain cluster operations, monitoring, and system services.

High availability

To prevent downtime, HA considerations should include replication of control plane components, redundant nodes, and reserved resources to handle failures seamlessly.

Pod capacity per node

Each OpenShift node supports a maximum number of pods, which defines its pod density. Proper planning of the required number of Hosted Control Plane clusters must account for this limitation to ensure that workloads are evenly distributed and performance is maintained.

Queries Per Second (QPS) limits

Hosted control plane sizing is about control-plane load and workloads that cause heavy API activity, etcd activity, or both.

- For the first 1000 QPS, 11.9 vCPU and 13.6 memory are used.
- As the load increases by 1000 QPS, the hosted control plane resource utilization increases by 9 vCPUs and 2.5 GB memory.

IBM Fusion resource consumption

Fusion resource usage includes:

Fusion base

Resources required for IBM Fusion services. IBM Fusion services run on both control and compute nodes. However, for sizing purposes, we consider only compute node resource consumption.

Fusion Data Foundation

Resources consumed based on the number of nodes and the number of drives per node participating in storage.

Note: Fusion Data Foundation is considering only of compute nodes that participate in Fusion Data Foundation cluster.

Backup & Restore

Additional resources are required to support backup and restore operations.

For guidelines and formulas to estimate infrastructure requirements, incorporating system overhead and high availability considerations. See [Planning Hosted Control Plane deployments on IBM Fusion](#).

- [Planning Hosted Control Plane deployments on IBM Fusion](#)

When planning Hosted Control Plane deployments on IBM Fusion, accurate sizing is essential to ensure performance, scalability, and resilience. Since Hosted Control Plane clusters rely on shared infrastructure, understanding how vCPU, memory, storage, and OpenShift® platform reserves are consumed becomes critical for effective capacity planning.

Planning Hosted Control Plane deployments on IBM Fusion

When planning Hosted Control Plane deployments on IBM Fusion, accurate sizing is essential to ensure performance, scalability, and resilience. Since Hosted Control Plane clusters rely on shared infrastructure, understanding how vCPU, memory, storage, and OpenShift® platform reserves are consumed becomes critical for effective capacity planning.

Examples of Hosted Control Plane sizing:

Guidelines and formulas

The following guidelines and formulas provide a structured approach to estimate infrastructure requirements, incorporating system overhead and high availability considerations. These estimates serve as a baseline for right-sizing clusters.

Understanding Hosted Control Plane sizing requirements

To estimate infrastructure requirements for Hosted Control Plane deployments, consider the following factors:

- Number of Hosted Control Plane clusters
 - HCP size (same or different sizes with distinct vCPU, memory, and storage requirements)
 - Control node and compute node configuration
- For example:
- Control node: 32 core, 512 GiB, 4 disks x 3.2 TiB, and 500 pod limit
 - Compute node: 64 core, 1024 GiB, 4 disks x 3.2 TiB, 1 LVM disk x 1-2 TiB, and 500 pod limit

Calculating Hosted Control Plane resource requirements

Use the following formulas to calculate Hosted Control Plane resource requirements:

Note:

- When sizing a KubeVirt based Hosted Control Plane cluster, consider the following resource consumption guidelines.
- For Bare Metal Hosted Control Plane clusters, Hosted Control Plane data plane resources are provided directly by the Bare Metal nodes and do not require additional sizing considerations.
- vCPU requirement** - total required vCPUs = (vCPUs per node × node count) / overcommit_ratio
Parameters:
 - vCPUs per node** - vCPUs required per Hosted Control Plane cluster node.
 - node count** - number of nodes in the Hosted Control Plane cluster.
 - overcommit_ratio** - factor to consider when you overcommit vCPU resources.
- Memory requirement** - total required memory (GiB) = memory per node × node count
Parameters:
 - memory per node** - memory required per Hosted Control Plane cluster node.
 - node count** - number of nodes in the HCP cluster.
- Storage requirement** - total required storage (GiB) = storage per node × node count
Parameters:
 - storage per node** - storage required per Hosted Control Plane cluster node.
 - node count** - number of nodes in the Hosted Control Plane cluster.

Examples for Hosted Control Plane specification and infrastructure resources

Hosted Control Plane specification overview

Hosted Control Plane specification	Description
KubeVirt	Each Hosted Control Plane node requires 4 vCPUs, 8 GiB of memory, and 32 GiB of storage (root disk) + minimum control plane resources.
Bare Metal	Minimum control plane resources.

Infrastructure resource overview

Infrastructure resources	Description
Control nodes	32 cores and 512 GiB of memory
Compute nodes	64 cores and 1024 GiB of memory
Storage per node	4 disks x 3.2 TiB

Examples for KubeVirt Hosted Control Plane cluster

For 10 KubeVirt Hosted Control Plane clusters with 3 nodes:

Hosted Control Plane control plane component (runs on the host cluster):

Component	Formula	Calculation
vCPU	Number of Hosted Control Plane clusters × vCPU per Hosted Control Plane control plane	10 × 11 vCPUs = 110 vCPUs
Memory	Number of Hosted Control Plane clusters × memory per Hosted Control Plane control plane	10 × 19 GiB = 190 GiB
Pods	Number of Hosted Control Plane clusters × pods per Hosted Control Plane control plane	10 × 78 = 780 pods

Hosted Control Plane data plane component (worker VMs capacity for OpenShift Container Platform ingress or console):

Component	Formula	Calculation
vCPU	Number of Hosted Control Plane clusters × number of nodes per Hosted Control Plane cluster × vCPU per Hosted Control Plane data plane	10 × 3 × 4 vCPUs = 120 vCPUs
Memory	Number of Hosted Control Plane clusters × number of nodes per Hosted Control Plane cluster × memory per Hosted Control Plane data plane	10 × 3 × 8 GiB = 240 GiB
Storage	Number of Hosted Control Plane clusters × number of nodes per Hosted Control Plane cluster × storage per Hosted Control Plane data plane	10 × 3 × 32 GiB = 960 GiB

Hosted Control Plane LVM storage

Component	Formula	Calculation
Storage	Number of Hosted Control Plane clusters × LVM storage per Hosted Control Plane cluster	10 × 24 GiB = 240 GiB

Net resources needed for 10 virtual Hosted Control Plane clusters (prior to overhead consideration)

Component	Formula	Calculation
Total CPUs	vCPUs per Hosted Control Plane control plane + vCPUs per Hosted Control Plane data plane	110 + 120 = 230 vCPUs
Total memory	Memory per Hosted Control Plane control plane + memory per Hosted Control Plane data plane	190 + 240 = 430 GiB
Total Storage	Storage (Fusion Data Foundation) per Hosted Control Plane control plane + storage (Fusion Data Foundation) per Hosted Control Plane data plane	960 GiB (Fusion Data Foundation storage)
	Storage (LVM) per Hosted Control Plane control plane + storage (LVM) per Hosted Control Plane data plane	240 GiB (LVM storage)
Component (IBM Fusion HCI)		Values
Overcommit ratio (vCPU)		2:1
High availability reserve (both vCPU and memory)		10%
Hosted Control Plane Hub QPS (pods based limit)		Minimum 78 pods per Hosted Control Plane - control plane
Hosted Control Plane Hub QPS (load based limit)		Additional for first, 1000 QPS, 11.9 vCPU and 13.6 GiB memory As the load increases by 1000 QPS, the hosted control plane resource utilization increases by 9 vCPUs and 2.5 GB memory.

Component (IBM Fusion HCI)	Values
IBM Fusion base (on managed or hub cluster)	Control: 2 vCPU, 7 GiB memory Compute: 2 vCPU, 7 GiB memory Storage: 0.5GiB
Backup & Restore (on managed or hub cluster)	Compute: 4.46 vCPU, 17.78 GiB and 3.35 GiB Storage
Fusion Data Foundation (on managed or hub cluster)	Compute: 13 + (number of drives x 2) vCPU Compute: 26 + (number of drives x 5) GiB Storage: 50.5 GiB
OpenShift reserve	Start with 0.06 CPU for a 1-core system For each extra core, add 0.012 CPU

Net resources needed for 10 virtual Hosted Control Plane clusters (post overhead consideration)

Table 1.

Metric	Formula	Calculation	Result
vCPU (demand)	Total Hosted Control Plane vCPU + IBM Fusion base + Backup & Restore Hub + FDF hub vCPU + OpenShift reserve vCPU	$230 + 2 + 4.46 + (13 + 2 \times 4) + 11.9$	269.36 vCPU
Physical cores to provision (after 2:1 overcommit & 10% HA)	$(\text{vCPU demand}) \div (2 \times (1 - \text{HA}\%))$	$269.36 \div (2 \times 0.9)$	149.64 physical cores
Memory (demand)	Total Hosted Control Plane memory + IBM Fusion base + Backup & Restore Hub + FDF hub memory + OpenShift reserve memory	$430 + 7 + 17.78 + 46 + 13.6$	514.38 GiB
Memory to provision (after 10% HA)	$(\text{Memory demand}) \div (1 - \text{HA}\%)$	$(\text{Memory demand}) \div 0.9$	571.53 GiB
Fusion Data Foundation storage	Total Hosted Control Plane Fusion Data Foundation storage + IBM Fusion base Fusion Data Foundation + Fusion Data Foundation hub storage + Backup & Restore hub storage	$960 + 0.5 + 50.5 + 3.35$	1014.35 GiB
LVM or other storage	Total Hosted Control Plane LVM storage	240	240 GiB
Storage total	Total storage (Fusion Data Foundation and LVM storage combined)	Fusion Data Foundation (1014.35 GiB) + LVM (240 GiB)	1254.35 GiB
Hosted Control Plane control pods	Total Hosted Control Plane pods	$78 \text{ pods} \times 10 \text{ clusters}$	780 pods

Approximate resources required:

Component	Requirement (after HA & overcommit)	Per node capacity	Nodes needed
Physical cores	149.64 cores	Compute: 64 cores	2 compute nodes
Memory	571.53 GiB	Compute: 1024 GiB	1 compute node
Fusion Data Foundation storage (considering 3-way replica for Fusion Data Foundation)	Fusion Data Foundation 1014.35 GiB Fusion Data Foundation (3x) = 3043.05 GiB	1 node = 12.8 TiB (13,107 GiB)	0 compute node (3 control node disks are sufficient)
LVM storage	240 GiB	1TiB	3 compute nodes (for high availability)
HCP control pods	780 pods	500 pods	2 compute nodes
Control plane (HA minimum)	-	Control node = 32 cores, 512 GiB	3 control nodes

Examples for Bare Metal Hosted Control Plane cluster

Hosted Control Plane control plane component

Component	Formula	Calculation
vCPU	Number of Hosted Control Plane clusters x vCPU per Hosted Control Plane control plane	$3 \times 11 \text{ vCPUs} = 33 \text{ vCPUs}$
Memory	Number of Hosted Control Plane clusters x memory per Hosted Control Plane control plane	$3 \times 19 \text{ GiB} = 57 \text{ GiB}$
Pods	Number of Hosted Control Plane clusters x pods per Hosted Control Plane control plane	$3 \times 78 = 234 \text{ pods}$

Hosted Control Plane LVM storage

Component	Formula	Calculation
Storage	Number of Hosted Control Plane clusters x LVM storage per Hosted Control Plane cluster	$3 \times 24 \text{ GiB} = 72 \text{ GiB}$

Net resources needed for 3 Bare Metal Hosted Control Plane clusters (prior to overhead consideration)

Component	Formula	Calculation
Total CPUs	vCPUs per Hosted Control Plane control plane	33 vCPUs
Total memory	Memory per Hosted Control Plane control plane	57 GiB
Total storage	Storage (LVM) per Hosted Control Plane control plane	240 GiB (LVM storage)
Component (IBM Fusion HCI)	Values	
Overcommit ratio (vCPU)	1:2	
High availability reserve (both vCPU and memory)	10%	

Component (IBM Fusion HCI)	Values
Hosted Control Plane Hub QPS (pods based limit)	Minimum 78 pods per Hosted Control Plane - control plane
Hosted Control Plane Hub QPS (load based limit)	For first, 1000 QPS, 11.9 vCPU and 13.6 GiB memory As the load increases by 1000 QPS, the hosted control plane resource utilization increases by 9 vCPUs and 2.5 GB memory.
IBM Fusion base	Control: 2 vCPU, 7 GiB memory Compute: 2 vCPU, 7 GiB memory Storage: 0.5GiB
Backup & Restore (IBM Fusion HCI)	Compute: 4.46 vCPU, 17.78 GiB and 3.35 GiB Storage
Fusion Data Foundation	Compute: 13 + (number of drives x 2) vCPU Compute: 26 + (number of drives x 5) GiB Storage: 50.5 GiB
OpenShift reserve	Start with 0.06 CPU for a 1-core system For each extra core, add 0.012 CPU

Net resources needed for 3 Bare Metal Hosted Control Plane clusters (post overhead consideration)

Table 2.

Metric	Formula	Calculation	Result
vCPU (demand)	Total Hosted Control Plane vCPU + IBM Fusion base + Backup & Restore Hub + FDF hub vCPU + OpenShift reserve vCPU	$33 + 2 + 4.46 + (13 + 2 \times 4) + 11.9$	72.36 vCPU
Physical vCPU cores to provision (after 1:2 overcommit & 10% HA)	$(\text{vCPU demand}) \div (2 \times (1 - \text{HA}\%))$	$(\text{vCPU demand}) \div (2 \times 0.9)$	40.2 physical cores
Memory (demand)	Total Hosted Control Plane memory + IBM Fusion base + Backup & Restore Hub + FDF hub memory + OpenShift reserve memory	$57 + 7 + 17.78 + 46 + 13.6$	141.38 GiB
Memory to provision (after 10% HA)	$(\text{Memory demand}) \div (1 - \text{HA}\%)$	$(\text{Memory demand}) \div 0.9$	157.08 GiB
Fusion Data Foundation storage	Total Hosted Control Plane Fusion Data Foundation storage + IBM Fusion base Fusion Data Foundation + Fusion Data Foundation hub storage + Backup & Restore hub storage	NA	NA
LVM or other storage	Total Hosted Control Plane LVM storage	72	72 GiB
Storage total	Total storage (Fusion Data Foundation and LVM storage combined)	72 GiB LVM	240 GiB
Hosted Control Plane control pods	Total Hosted Control Plane pods	$78 \text{ pods} \times 3 \text{ clusters}$	234 pods

Approximate resources required:

Component	Requirement	Per node capacity	Nodes needed
vCPU (physical cores)	40.2 cores	Compute: 64 cores	1 compute node
Memory	157.08 GiB	Compute: 1024 GiB	1 compute node
Total storage (LVM)	72 GiB	Per node = 12.8 TiB $\approx$ 13,107.20 GiB	3 compute nodes (for high availability)
HCP control pods	234 pods (78 x 3 clusters)	500 pods	1 compute node
Control plane (HA minimum)	-	Control node = 32 cores, 512 GiB	3 control nodes

Prerequisites for Hosted Control Plane clusters

The prerequisites before you create virtualized or Bare Metal Hosted Control Plane clusters.

Before you begin

- The single or multi-rack installation of IBM Fusion HCI with a minimum of three compute nodes.
- The version of OpenShift® Container Platform must be 4.16 or higher.
- Install and configure Fusion Data Foundation provider mode storage type on the hub cluster.
- If you plan to install Backup & Restore service, ensure that 12 GiB memory is available post the installation.
- Verify that you have all the necessary LVM drives before you initiate LVM configuration on the hub cluster. For more information about LVM drives, see [Dedicated drives for LVM filesystems](#).
- Ensure that the following ports are open on the hub cluster to deploy Hosted Control Plane clusters and support management and data traffic:

Table 1. Ports required for Fusion Data Foundation server and client

Type	Protocol	Ports	Description
Custom TCP	TCP	6789	Ceph Monitor
		3300	Ceph Monitor
		6800-7300	Ceph OSD, MGR, MDS
		9283	Ceph MGR Prometheus Exporter
		31659	API Server

Procedure

- From the Red Hat® Operator Catalog, install MetalLB 4.16 or higher.

Add the MetalLB Operator to your cluster so that when a service of type **LoadBalancer** is added to the cluster, MetalLB can add a fault-tolerant external IP address for the service. For the procedure to install and validate MetalLB, see <https://docs.openshift.com/>. Go to your specific version of OpenShift Container Platform and check MetalLB details.

Note: When you set up the load balancer, other applications can also get the advertised addresses. You must have enough addresses for any workloads on this cluster and created OpenShift Container Platform clusters.

2. Create MetalLB CR based on the following example:

```
apiVersion: metallb.io/v1beta1
kind: MetalLB
metadata:
  name: metallb
  namespace: metallb-system
```

3. Create an IP address pool.

Note:

- Reserve a set of unused IPs on the same CIDR as the Bare Metal network of the IBM Fusion HCI cluster for MetalLB. The MetalLB serves these IPs to any load-balancer service that is installed on the cluster and not just the Hosted Control Plane.
- When planning IP addresses, consider the number of Hosted Control Plane to be created and allocate additional IPs for load balancer services. Reserve three IP addresses for Fusion Data Foundation storage load balancer services. If other workloads use load balancers, factor those requirements into your IP address planning to ensure sufficient addresses are available.

Example:

```
apiVersion: metallb.io/v1beta1
kind: IPAddressPool
metadata:
  name: metallb
  namespace: metallb-system
spec:
  addresses:
  - 9.9.0.51-9.9.0.70
```

Note: When you set up the load balancer, other applications can also get the advertised addresses. You must have enough addresses for any workloads on this cluster and created OpenShift Container Platform clusters.

4. Create **L2Advertisement** based on the following example:

```
apiVersion: metallb.io/v1beta1
kind: L2Advertisement
metadata:
  name: l2advertisement
  namespace: metallb-system
spec:
  ipAddressPools:
  - metallb
```

5. Run the following command to patch ingress:

Note: This requirement is only for virtualized Hosted Control Plane clusters.

```
oc patch ingresscontroller -n openshift-ingress-operator default --type=json -p '[{"op": "add", "path": "/spec/routeAdmission", "value": {"wildcardPolicy": "WildcardsAllowed"}}]'
```

6. Install Multi Cluster Engine for Kubernetes operator.

7. Create a Multi Cluster Engine CR instance based on the following example:

```
apiVersion: multicluster.openshift.io/v1
kind: MultiClusterEngine
metadata:
  name: multiclusterengine
spec:
  targetNamespace: multicluster-engine
```

Change the parameter values according to your environment.

8. Wait until the Multi Cluster Hub instance is created, available, and in Running state.

The Multi Cluster Engine instance must be available.

Run the following command to check whether the Multi Cluster Engine instance is available.

```
$ oc get multiclusterengine
```

Example output:

```
$ oc get multiclusterengine
NAME STATUS AGE
multiclusterengine Available 170m
```

9. Download hosted control plane CLI from OpenShift Container Platform console:

- a. Go to the Command Line Tools page.

- b. From the Hosted Control Plane - Hosted Control Plane Command Line Interface (CLI) section, download the CLI tar and extract from archive based on your platform.

Note: In MCE, you can use the user interface instead of CLI. However, the CLI gives more options than the user interface.

10. On the hub cluster, configure LVM by using the local drives for the etcd pods of hosted clusters. To ensure optimal etcd performance, LVM must be set up with three dedicated LVM drives across three compute or compute-storage nodes.

Note: Use the **lvms-hcp-etcd** StorageClass.

For more information about dedicated drives for LVM filesystems, see [Dedicated drives for LVM filesystems](#).

11. Increase the maximum number of pods per node from the default value of 250 to 500. For the procedure to update the value, see [Managing the maximum number of pods per node](#).

12. For Hosted Control Plane deployments, ensure the following on the hub cluster:

- A valid pull secret must exist in the namespace where the Hosted Control Plane cluster is defined (the namespace containing the **HostedCluster** resource).

- The `HostedCluster` CR must include a reference to this pull secret through the `pullSecret` field.
For example:
Note: Credentials in pull-secret must include username, password and auth.

```
pullSecret:
  name: <hosted_cluster_name>-pull-secret
```

What to do next

1. Create the hosted control plane clusters. For the procedure to create, see [Creating a virtualized Hosted Control Plane cluster](#).
 2. Deploy virtualized or bare metal clusters. For the procedure to install the hosted cluster, see [Prerequisites for Hosted Control Plane clusters](#) or [Installing Backup & Restore on the hosted cluster](#).
- **Dedicated drives for LVM filesystems**
You need dedicated drives for Logical Volume Manager (LVM) filesystems to host control planes. The NVMe drives must be allocated to IBM Fusion HCI with Fusion Data Foundation storage.

Dedicated drives for LVM filesystems

You need dedicated drives for Logical Volume Manager (LVM) filesystems to host control planes. The NVMe drives must be allocated to IBM Fusion HCI with Fusion Data Foundation storage.

Key considerations for dedicated drives for LVM filesystems:

- **Ordering guidance:**
 - You can order these LVM drives of 1.6 TB and add them to a new rack configuration or MES to a pre-ordered rack. By default, when it comes in a new rack, the LVM drive is placed in bay 9.
 - If your earlier IBM Fusion HCI order did not include LVM drives, you can submit a MES order to add them.
 - The MES kit delivers NVMe drives that must be placed in bay 9 of each control plane node, with a maximum of one drive per node.
- **Rack placement guidance for stand-alone and multi-rack:**
 - If you select the LVM drives option, it is not possible to add more than 9 NVMe drives to storage nodes in the rack. Racks that have 10 NVMe drives in each of the storage nodes are not supported.
 - **In high-availability (HA) multi-rack system**, drives must be distributed across one control plane node per rack, spanning three racks, to ensure resiliency.
 - The LVM drives for hosted control plane must be placed on control nodes, not on compute nodes or GPU nodes.
 - When you place them in each of the three control plane nodes, IBM Fusion HCI automatically detects the presence of the control plane drives and configures them for LVM.
- **LVM drive placement for 2AZ and arbiter node topology:**
When you deploy a Hosted Control Plane cluster on a 2AZ and arbiter node topology, place one LVM NVMe drive on each of the three control nodes (AZ1, AZ2, and the arbiter node) instead of on compute nodes. This placement ensures that etcd persistent volumes are available on every control node for proper etcd distribution across zones.
 - Place one LVM drive in bay 9 of each control node, including the arbiter node.
 - Do not place LVM drives for HCP on compute nodes in a 2AZ and arbiter node deployment.
 - The IBM Fusion HCI storage operator automatically applies the `isf.ibm.com/lvm-node` label to control nodes that have an LVM drive installed.

Deployment of virtualized clusters with Fusion Data Foundation

Create virtualized (Hosted Control Plane) clusters with the Fusion Data Foundation as storage type.

- **Planning and prerequisites for virtualized Hosted Control Plane clusters**
The prerequisites before you create OpenShift® Virtualization Hosted Control Plane clusters.
- **Configuring network for Hosted Control Plane**
This topic describes the steps to configure NAD, NIC, and IP for Hosted Control Plane.
- **Creating a virtualized Hosted Control Plane cluster**
Create an OpenShift virtualization Hosted Control Plane cluster.
- **Deploying virtualized Hosted Control Plane cluster in disconnected environment**
A disconnected environment deployment operates without internet access. You can deploy Hosted Control Plane (HCP) in a disconnected environment on the virtualized infrastructure.
- **Deploying a virtualized Hosted Control Plane cluster on 2AZ and arbiter node topology**
Create virtualized Hosted Control Plane clusters with Fusion Data Foundation as the storage type in a two-availability-zone and arbiter node (2AZ and arbiter) multirack topology.
- **Deploying a virtualized Hosted Control Plane cluster on 3AZ topology**
Create virtualized Hosted Control Plane clusters with Fusion Data Foundation as the storage type in a three-availability-zone (3AZ) rack topology.
- **Deploying a virtualized Hosted Control Plane cluster on Regional-DR topology**
Create virtualized Hosted Control Plane clusters with Fusion Data Foundation as the storage type in a Regional-DR topology.

Planning and prerequisites for virtualized Hosted Control Plane clusters

The prerequisites before you create OpenShift® Virtualization Hosted Control Plane clusters.

- From the Red Hat® Operator Catalog, deploy Red Hat OpenShift Virtualization. Use the latest version available in your Red Hat operator catalog as the version is driven by underlying the OpenShift Container Platform version. For more information about the supported versions, see [Interoperability matrix](#).

It is a software component of OpenShift Container Platform to run and manage virtual machine workloads alongside container workloads. For the procedure to install OpenShift Virtualization, see [OpenShift virtualization on IBM Fusion HCI](#). To validate the installation, see [Red Hat Documentation](#).

- Create hyperconverged CR based on the following example:

```
apiVersion: hco.kubevirt.io/v1beta1
kind: HyperConverged
metadata:
  name: kubevirt-hyperconverged
  namespace: openshift-cnv
spec: {}
```

- Wait for five to ten minutes for the CR status to be available and the OpenShift Container Platform console to refresh and show up a new Virtualization menu.

Configuring network for Hosted Control Plane

This topic describes the steps to configure NAD, NIC, and IP for Hosted Control Plane.

You must have a set of free available IPs, and based on the number of Hosted Control Plane clusters, plan to create in the rack. No DHCP or DNS is required.

Follow the steps to configure NAD, NIC, and IP for Hosted Control Plane:

1. On the Hub cluster, add a daemon-network NAD to the cluster namespace:
 - a. Run the following command to edit a network operator.

```
oc edit networks.operator.openshift.io
```

- b. Add the following object to `spec.additionalNetwork` and save.

```
name: daemon-network
namespace: <name of cluster namespace> // example namespace : clusters-hcp414-rc4-8
rawCNIConfig: '{ "cniVersion": "0.3.1", "name": "daemon-network", "type": "bridge",
  "bridge": "br3201", "ipam": {} }'
```

- c. Run the following command to verify the NAD is created in the required namespace.

```
oc get network-attachment-definition -A
```

- d. Ensure that the output must have an entry for added namespace.

2. Use any one of the following two methods to add NIC to the VMs.

- a. Using GUI

- i. Go to Hub cluster.
- ii. Go to virtual machines and click a machine.
- iii. Go to network interfaces, click add network interface.
- iv. Select model as e1000e, network as daemon-network, and type as bridge.
- v. Click save.
- vi. Restart the VM for the NIC to get added.

- b. Edit the YAML

- i. Run the following command to edit the YAML file of the VM.

```
oc edit VM <vm-name> -n <vm-namespace>
```

- ii. Add the following specifications under the specified hierarchy.

```
spec:
  template:
    spec:
      interfaces:
        bridge: {}
        macAddress: <needs to be generated if required, else skip the line>
        model: e1000e
        name: <any name of format nic-rising-minnow>
      networks:
        multus:
          networkName: daemon-network
          name: nic-rising-minno
```

- iii. Restart the VM.

3. Log in to the respective cluster and follow the steps to create a NAD inside the hosted cluster:

- a. Run the following command to edit a network operator.

```
oc edit networks.operator.openshift.io
```

- b. Add the following object to `spec.additionalNetwork` and save.

```
name: daemon-network
namespace: ibm-spectrum-scale
rawCNIConfig: '{ "cniVersion": "0.3.1", "name": "daemon-network", "type": "ipvlan",
  "mode": "12", "master": "enp2s0", "ipam": {} }'
```

```
type: Raw
```

Creating a virtualized Hosted Control Plane cluster

Before you begin

- On a six node IBM Fusion HCI, you must create only a maximum of five Hosted Control Plane clusters. On a larger configuration rack having ten or more nodes, you must create a maximum of ten Hosted Control Plane clusters. Go through the sizing guidelines. See [Hosted control plane sizing guidance](#).
- The IBM Fusion HCI with the Multi-Cluster Engine version 2.7 or higher supports hosted clusters, which run on OpenShift version 4.16. For more information about the supported versions, see [Interoperability matrix](#). The upgrade of OpenShift Container Platform is supported on Hosted Control Plane clusters. For creating a hosted cluster with KubeVirt platform by using CLI, see [Red Hat® Documentation](#).
- Ensure you meet the following prerequisites:
 - [Prerequisites for Hosted Control Plane clusters](#)
 - [Planning and prerequisites for virtualized Hosted Control Plane clusters](#)

About this task

If the virtual cluster is not created or has issues, see [Troubleshooting hosted control planes](#).

Procedure

1. Log in to OpenShift Container Platform console, and go to Multi Cluster Engine (MCE) view.
2. Go to Infrastructure > Clusters.
3. In the Cluster list tab, click Create cluster.
4. Select Red Hat OpenShift Virtualization as your infrastructure provider.
5. In the Control plane type, select Hosted. A Create cluster wizard page gets displayed.
6. In the Create cluster wizard, enter your cluster details:
 - a. In the Cluster details wizard page, enter your cluster details.

Important:

- If the base cluster is FIPS-enabled, set `spec.fips: true` in the `HostedCluster` CR when creating the Hosted Control Plane cluster by enabling the YAML view.
- Add the following tolerations in the specification of the `HostedCluster` CR when creating the Hosted Control Plane cluster by enabling the YAML view:

```
tolerations:
- effect: NoSchedule
  key: node-role.kubernetes.io/control-plane
  operator: Exists
- effect: NoSchedule
  key: node-role.kubernetes.io/master
  operator: Exists
```

Release image

Select your OpenShift version. For more information about the supported versions, see [Interoperability matrix](#).

Note: No multi arch images must be used while provisioning Hosted Control Plane clusters.

If your deployment uses a proxy, add the following proxy configuration to the `spec.configuration` section of the `HostedCluster` CR by enabling the YAML view:

```
spec:
  configuration:
    proxy: # Proxy configuration
      httpProxy: <http-proxy>
      httpsProxy: <https-proxy>
      noProxy: <comma-separated list of domains to bypass proxy>
      trustedCA:
        name: <trusted-ca-secret> # leave empty if no custom CA is used
```

The proxy configuration requires the following fields:

httpProxy

The HTTP proxy URL.

httpsProxy

The HTTPS proxy URL.

noProxy

Comma-separated list of domains that must not be routed through the proxy. Ensure the following are included:

- Existing value of the `noProxy` parameter in the proxy CR on the hub cluster
- `localhost` and `127.0.0.1`
- Cluster subdomain (for example, `isfdelace.mydomain.com`)
- Cluster base domain (for example, `.mydomain.com`)
- Service URL extension: `.svc`
- Service network and cluster network of the hub cluster
- Service network and cluster network of the Hosted Control Plane cluster
- First IP of the Hosted Control Plane service network
- MetalLB IP range

trustedCA.name

Name of the trusted CA secret. Leave empty if no custom certificate is used on the proxy server.

To retrieve the existing proxy configuration values, run the following command on the hub cluster:

```
oc get proxy cluster -o yaml
```

To retrieve the cluster network and service network values of the hub cluster, run:

```
oc get network cluster -o yaml
```

Additional labels

Enter `isf.ibm.com/fusion-base=`, `isf.ibm.com/fusion-fdf=`, and `isf.ibm.com/fusion-backup=` labels to install IBM Fusion, Fusion Data Foundation, and Backup & Restore service on the newly created cluster.

Pull secret

A pull secret is required for the creation of a Hosted Control Plane cluster. Include the `cp.icr.io` for the Fusion services.

- Click Next to go to the Node pools page of the wizard.
- In the Node pools page, enter the location and size of the nodes.
- Click Next to go to the Review and create page of the wizard.
- In the Review and create page, go through the details and click Create.

Alternatively, use the following command line example to create a Hosted Control Plane for OpenShift Virtualization by using the KubeVirt platform type.

Note: Ensure you check the following points before you proceed:

- Ensure you export the variables used in the example with their right values.
- Also, check whether you have the latest Hosted Control Plane Command Line interface (CLI). If you do not have the latest version, go to Red Hat OpenShift Container Platform console and download the latest version from Command line tools page.

```
# Set environment variables
export CLUSTER_NAME=example
export PULL_SECRET="$HOME/pull-secret"
export MEM="6Gi"
export CPU="2"
export WORKER_COUNT="2"

hcp create cluster kubevirt \
  --name $CLUSTER_NAME \
  --node-pool-replicas $WORKER_COUNT \
  --pull-secret $PULL_SECRET \
  --memory $MEM \
  --cores $CPU \
  --etcd-storage-class lvms-hcp-etcd \
  --infra-availability-policy HighlyAvailable \
  --root-volume-storage-class ocs-storagecluster-ceph-rbd-virtualization \
  --root-volume-volume-mode Block \
  --root-volume-access-modes ReadWriteMany
```

Run the following command to get a list of available parameters:

```
hcp create cluster kubevirt --help
```

7. To validate the clusters, do the following steps:

- Log in to the OpenShift Container Platform console of the hub, and go to multi cluster view.
- Go to Infrastructure > Clusters.
- From the Clusters list, click a hosted cluster name link to view the details.

Note: Hosted Control Plane cluster creation can take more than 30 minutes.

What to do next

- Install the IBM Fusion base on the Hosted Control Plane cluster. For instructions, see [Installing the IBM Fusion base](#).
- Install the Fusion Data Foundation storage client on the Hosted Control Plane cluster. For instructions, see [Installing Fusion Data Foundation on a Hosted Control Plane cluster](#).

Deploying virtualized Hosted Control Plane cluster in disconnected environment

A disconnected environment deployment operates without internet access. You can deploy Hosted Control Plane (HCP) in a disconnected environment on the virtualized infrastructure.

For the procedure to deploy virtualized Hosted Control Plane cluster in disconnected network, see [Red Hat® documentation](#).

Important: While you follow the Red Hat documentation, take note of the following steps that must be done differently:

- The pull secret for the Hosted Control Plane in its namespace must only reference the host. Do not include the repository path.
- When you create the virtualized Hosted Control Plane cluster CR, remove OIDC service.
- If the base cluster is FIPS-enabled, set `spec.fips: true` in the `HostedCluster` CR when creating the Hosted Control Plane cluster by enabling the YAML view.
- Add the following tolerations in the specification of the `HostedCluster` CR when creating the Hosted Control Plane cluster by enabling the YAML view:

```
tolerations:
- effect: NoSchedule
  key: node-role.kubernetes.io/control-plane
  operator: Exists
- effect: NoSchedule
  key: node-role.kubernetes.io/master
  operator: Exists
```

Examples of CRs and CMs created while deploying virtualized Hosted Control Plane:

- Create two namespaces: `clusters` and `clusters-hosted-cluster-name`.
For example, `clusters-disconnected1`

```
apiVersion: v1
kind: Namespace
```

```

metadata:
  creationTimestamp: null
  name: clusters-disconnected1
spec: {}
status: {}

```

```

apiVersion: v1
kind: Namespace
metadata:
  creationTimestamp: null
  name: clusters
spec: {}
status: {}

```

2. Copy the registry CA cert and create a configmap in the `clusters` namespace.

```

kind: ConfigMap
apiVersion: v1
metadata:
  name: user-ca-bundle
  namespace: clusters
data:
  ca-bundle.crt: |
    // Registry1 CA
    -----BEGIN CERTIFICATE-----
    -----END CERTIFICATE-----

    // Registry2 CA
    -----BEGIN CERTIFICATE-----
    -----END CERTIFICATE-----

    // Registry3 CA
    -----BEGIN CERTIFICATE-----
    -----END CERTIFICATE-----

```

3. Create a pull secret in the `clusters` namespace.

```

kind: Secret
apiVersion: v1
metadata:
  name: <disconnected-secret>
  namespace: clusters
data:
  .dockerconfigjson: <xxxxxxx>
type: kubernetes.io/dockerconfigjson

```

4. Create a `hostedcluster` CR in the `clusters` namespace.

```

apiVersion: hypershift.openshift.io/v1beta1
kind: HostedCluster
metadata:
  name: <disconnected1>
  namespace: clusters
spec:
  fips: <true/false>
  release:
    image: $TARGET_PATH/openshift/release-images:4.18.20-x86_64
  dns:
    baseDomain: xyz.com
    controllerAvailabilityPolicy: HighlyAvailable
  etcd:
    managed:
      storage:
        persistentVolume:
          size: 8Gi
          storageClassName: lvms-hcp-etcd
          type: PersistentVolume
        managementType: Managed
    infrastructureAvailabilityPolicy: HighlyAvailable
  platform:
    kubvirt:
      baseDomainPassthrough: true
      type: KubeVirt
  additionalTrustBundle:
    name: user-ca-bundle
  networking:
    clusterNetwork:
      - cidr: 10.132.0.0/14
    networkType: OVNKubernetes
    serviceNetwork:
      - cidr: 172.31.0.0/16
  pullSecret:
    name: <disconnected-secret>
  configuration:
    operatorhub:
      disableAllDefaultSources: true
  capabilities: {}
  sshKey:
    name: ''
  autoscaling: {}
  imageContentSources:
    - mirrors:
      - $TARGET_PATH/openshift/release
      source: quay.io/openshift-release-dev/ocp-v4.0-art-dev
    - mirrors:

```

```

- $TARGET_PATH/redhat
  source: registry.redhat.io/redhat
- mirrors:
- $TARGET_PATH/rhel9
  source: registry.redhat.io/rhel9
- mirrors:
- $TARGET_PATH/rhel8
  source: registry.redhat.io/rhel8
- mirrors:
- $TARGET_PATH/openshift/release-images
  source: quay.io/openshift-release-dev/ocp-release
- mirrors:
- $TARGET_PATH/openshift4
  source: registry.redhat.io/openshift4
- mirrors:
- $TARGET_PATH/multicluster-engine
  source: registry.redhat.io/multicluster-engine
olmCatalogPlacement: management
services:
- service: APIServer
  servicePublishingStrategy:
    type: LoadBalancer
- service: Ignition
  servicePublishingStrategy:
    type: Route
- service: Konnectivity
  servicePublishingStrategy:
    type: Route
- service: OAuthServer
  servicePublishingStrategy:
    type: Route

```

Important: While you follow the Red Hat documentation, take note of the following steps that must be done differently:

- The pull secret for the Hosted Control Plane in its namespace must only reference the host. Do not include the repository path.
- When you create the virtualized Hosted Control Plane cluster CR, remove OIDC service.

```

- service: OIDC
  servicePublishingStrategy:
    type: Route

```

- If the base cluster is FIPS-enabled, set `spec.fips: true` in the `HostedCluster` CR when creating the Hosted Control Plane cluster by enabling the YAML view.
- Add the following tolerations in the specification of the `HostedCluster` CR when creating the Hosted Control Plane cluster by enabling the YAML view:

```

tolerations:
- effect: NoSchedule
  key: node-role.kubernetes.io/control-plane
  operator: Exists
- effect: NoSchedule
  key: node-role.kubernetes.io/master
  operator: Exists

```

- Create a `NodePool` CR in the `clusters` namespace.

```

apiVersion: hypershift.openshift.io/v1beta1
kind: NodePool
metadata:
  name: <disconnected1>
  namespace: clusters
spec:
  arch: amd64
  clusterName: <disconnected1>
  management:
    autoRepair: false
    upgradeType: Replace
  nodeDrainTimeout: 0s
  nodeVolumeDetachTimeout: 0s
  platform:
    kubevirt:
      attachDefaultNetwork: true
    compute:
      cores: 2
      memory: 6Gi
      networkInterfaceMultiqueue: Enable
    rootVolume:
      persistent:
        size: 32Gi
        storageClass: ocs-storagecluster-ceph-rbd-virtualization
        type: Persistent
      type: KubeVirt
  release:
    image: $TARGET_PATH/openshift/release-images:4.18.20-x86_64
  replicas: 2

```

Note:

- Specify the cluster name and release image.
- Specify the number of replicas along with configuration such as cores, memory and so on.

Deploying a virtualized Hosted Control Plane cluster on 2AZ and arbiter node topology

Create virtualized Hosted Control Plane clusters with Fusion Data Foundation as the storage type in a two-availability-zone and arbiter node (2AZ and arbiter) multitrack topology.

Before you begin

Before you begin, complete the following prerequisites:

- Complete all prerequisites for deploying Hosted Control Plane. For the full prerequisites checklist, see [Prerequisites for Hosted Control Plane clusters](#) and [Planning and prerequisites for virtualized Hosted Control Plane clusters](#).
- For offline Hosted Control Plane deployments, ensure that mirroring is in place. For more information, see [Deploying virtualized Hosted Control Plane cluster in disconnected environment](#).
- Each control node has one dedicated LVM NVMe drive. The drive must be in bay 9 of the control node. For more information about LVM drive requirements, see [Dedicated drives for LVM filesystems](#).

Procedure

1. Retrieve the zone labels from one control node per zone and from the arbiter node.
IBM Fusion HCI labels nodes with availability zones during installation. You need the zone label values when specifying `nodeLabels` and `nodeSelector` in the `NodePool` CRs.

```
oc get nodes -l node-role.kubernetes.io/master -o custom-  
columns='NODE:.metadata.name,ZONE:.metadata.labels.topology\.kubernetes\.io/zone'
```

For example:

NODE	ZONE
control-1-ru2.<mycluster.com>	AZ1
control-1-ru3.<mycluster.com>	AZ2
control-1-ru4.<mycluster.com>	arbiter

Each control node shows its zone value: `AZ1`, `AZ2`, or `arbiter`. Note the zone values for `AZ1` and `AZ2`. Do not use the `arbiter` zone when you create `NodePools`.

2. Create the `clusters` and `clusters-<cluster-name>` namespaces.

```
apiVersion: v1  
kind: Namespace  
metadata:  
  creationTimestamp: null  
  name: clusters-<cluster-name>  
spec: {}  
status: {}  
---  
apiVersion: v1  
kind: Namespace  
metadata:  
  creationTimestamp: null  
  name: clusters  
spec: {}  
status: {}
```

3. Create the pull secret and SSH key in the `clusters` namespace.

```
kind: Secret  
apiVersion: v1  
metadata:  
  name: hcp-pull-secret  
  namespace: clusters  
data:  
  .dockerconfigjson: xxxxxxxx  
type: kubernetes.io/dockerconfigjson  
---  
apiVersion: v1  
kind: Secret  
metadata:  
  name: hcp-sshkey  
  namespace: clusters  
data:  
  id_rsa.pub: xxxxxxxx  
type: Opaque
```

4. Optional: For offline (air-gapped) deployments, create the `user-ca-bundle` ConfigMap in the `clusters` namespace with the registry CA root certificate.

```
apiVersion: v1  
kind: ConfigMap  
metadata:  
  name: user-ca-bundle  
  namespace: clusters  
data:  
  ca-bundle.crt: |  
    -----BEGIN CERTIFICATE-----  
    -----END CERTIFICATE-----
```

5. Create the `HostedCluster` CR with tolerations.

The tolerations enable the Hosted Control Plane pods, including etcd, to be scheduled on control plane nodes. Use the following example YAML to create the `HostedCluster` CR.

Note: `imageContentSources` is required for offline (air-gapped) deployments. Remove `OIDC` from services and the `additionalTrustBundle` field for online deployments.

```
apiVersion: hypershift.openshift.io/v1beta1  
kind: HostedCluster
```

```

metadata:
  name: <cluster-name>
  namespace: clusters
spec:
  fips: <true/false> # true only if base rack is FIPS enabled
  release:
    image: <release-image> # example: quay.io/openshift-release-dev/ocp-release:4.22.1-x86_64
  dns:
    baseDomain: <base-domain> # example: apps.base-domain
    controllerAvailabilityPolicy: HighlyAvailable
    infrastructureAvailabilityPolicy: HighlyAvailable
  etcd:
    managed:
      storage:
        persistentVolume:
          size: 8Gi
          storageClassName: lvms-hcp-etcd
          type: PersistentVolume
        managementType: Managed
  platform:
    kubevirt:
      baseDomainPassthrough: true
      type: KubeVirt
  additionalTrustBundle:
    name: user-ca-bundle # needed only for offline HCP deployment
  networking:
    clusterNetwork:
      - cidr: 10.132.0.0/14
    networkType: OVNKubernetes
    serviceNetwork:
      - cidr: 172.31.0.0/16
  pullSecret:
    name: <pull-secret-name> # name of the pull secret created above, example: hcp-pull-secret
  tolerations:
    - effect: NoSchedule
      key: node-role.kubernetes.io/master
      operator: Exists
    - effect: NoSchedule
      key: node-role.kubernetes.io/control-plane
      operator: Exists
  configuration:
    operatorhub:
      disableAllDefaultSources: <true> # set to true for offline/air-gapped deployments
  capabilities: {}
  sshKey:
    name: <ssh-key-secret-name> # name of the SSH key secret created above, example: hcp-sshkey
  autoscaling: {}
  # imageContentSources is needed to add mirroring in case of offline HCP deployment
  imageContentSources:
    - mirrors:
        - $TARGET_PATH/openshift/release
        source: quay.io/openshift-release-dev/ocp-v4.0-art-dev
    - mirrors:
        - $TARGET_PATH/redhat
        source: registry.redhat.io/redhat
    - mirrors:
        - $TARGET_PATH/rhel9
        source: registry.redhat.io/rhel9
    - mirrors:
        - $TARGET_PATH/rhel8
        source: registry.redhat.io/rhel8
    - mirrors:
        - $TARGET_PATH/openshift/release-images
        source: quay.io/openshift-release-dev/ocp-release
    - mirrors:
        - $TARGET_PATH/openshift4
        source: registry.redhat.io/openshift4
    - mirrors:
        - $TARGET_PATH/multicloud-engine
        source: registry.redhat.io/multicloud-engine
  olmCatalogPlacement: management
  services:
    - service: APIServer
      servicePublishingStrategy:
        type: LoadBalancer
    - service: Ignition
      servicePublishingStrategy:
        type: Route
    - service: Konnectivity
      servicePublishingStrategy:
        type: Route
    - service: OAuthServer
      servicePublishingStrategy:
        type: Route
    # Remove the OIDC entry for offline HCP deployments
    - service: OIDC
      servicePublishingStrategy:
        type: Route

```

If your deployment uses a proxy, add the following proxy configuration to the `spec.configuration` section of the `HostedCluster` CR:

```

spec:
  configuration:
    proxy: # Proxy configuration
      httpProxy: <http-proxy>
      httpsProxy: <https-proxy>

```

```
noProxy: <comma-separated list of domains to bypass proxy>
trustedCA:
  name: <trusted-ca-secret> # leave empty if no custom CA is used
```

The proxy configuration requires the following fields:

httpProxy

The HTTP proxy URL.

httpsProxy

The HTTPS proxy URL.

noProxy

Comma-separated list of domains that must not be routed through the proxy. Ensure the following are included:

- Existing value of the **noProxy** parameter in the proxy CR on the hub cluster
- **localhost** and **127.0.0.1**
- Cluster subdomain (for example, **isfdelace.mydomain.com**)
- Cluster base domain (for example, **.mydomain.com**)
- Service URL extension: **.svc**
- Service network and cluster network of the hub cluster
- Service network and cluster network of the Hosted Control Plane cluster
- First IP of the Hosted Control Plane service network
- MetalLB IP range

trustedCA.name

Name of the trusted CA secret. Leave empty if no custom certificate is used on the proxy server.

To retrieve the existing proxy configuration values, run the following command on the hub cluster:

```
oc get proxy cluster -o yaml
```

To retrieve the cluster network and service network values of the hub cluster, run:

```
oc get network cluster -o yaml
```

The **HostedCluster** CR is created. The Hosted Control Plane pods and etcd instances begin scheduling on the control nodes.

6. Create a separate **NodePool** CR for each availability zone (AZ1 and AZ2).

Do not create a NodePool for the arbiter zone. This ensures that guest cluster nodes inherit the availability zone from the host cluster, and that router deployments are distributed across VMs on nodes from different availability zones.

Use the zone values retrieved in step 1 for the **nodeLabels** and **nodeSelector** fields.

NodePool for AZ1

```
apiVersion: hypershift.openshift.io/v1beta1
kind: NodePool
metadata:
  name: <nodepool-name> # example: <cluster-name>-np-az1
  namespace: clusters
spec:
  arch: amd64
  nodeLabels:
    topology.kubernetes.io/zone: <zone-name> # example: AZ1
  clusterName: <hcp-cluster-name> # cluster name given in the HostedCluster CR
  replicas: <number-of-nodes> # example, 3
  management:
    autoRepair: false
    upgradeType: Replace
    nodeDrainTimeout: 0s
    nodeVolumeDetachTimeout: 0s
  platform:
    kubevirt:
      nodeSelector:
        topology.kubernetes.io/zone: <zone-name> # example: AZ1
      attachDefaultNetwork: true
      compute:
        cores: 2
        memory: 6Gi
      networkInterfaceMultiqueue: Enable
      rootVolume:
        persistent:
          size: 32Gi
          storageClass: ocs-storagecluster-ceph-rbd-virtualization
          type: Persistent
      type: KubeVirt
      release:
        image: <release-image>
```

NodePool for AZ2

```
apiVersion: hypershift.openshift.io/v1beta1
kind: NodePool
metadata:
  name: <nodepool-name> # example: <cluster-name>-np-az2
  namespace: clusters
spec:
  arch: amd64
  nodeLabels:
    topology.kubernetes.io/zone: <zone-name> # example: AZ2
  clusterName: <hcp-cluster-name> # cluster name given in the HostedCluster CR
  replicas: <number-of-nodes> # example, 3
  management:
    autoRepair: false
    upgradeType: Replace
    nodeDrainTimeout: 0s
```

```
nodeVolumeDetachTimeout: 0s
platform:
  kubevirt:
    nodeSelector:
      topology.kubernetes.io/zone: <zone-name>    # example: AZ2
    attachDefaultNetwork: true
    compute:
      cores: 2
      memory: 6Gi
      networkInterfaceMultiqueue: Enable
    rootVolume:
      persistent:
        size: 32Gi
        storageClass: ocs-storagecluster-ceph-rbd-virtualization
        type: Persistent
      type: KubeVirt
    release:
      image: <release-image>
```

Guest cluster worker nodes inherit the zone labels from their respective NodePools. Router pods are distributed across VMs on nodes from AZ1 and AZ2.

7. Verify that one etcd pod is scheduled on each control node across AZ1, AZ2, and the arbiter zone.

```
oc get pods -n clusters-<cluster-name> -l app=etcd -o wide
```

Expected output:

etcd-0	1/1	Running	control-1-ru3	AZ2
etcd-1	1/1	Running	control-1-ru2	AZ1
etcd-2	1/1	Running	control-1-ru4	arbiter

Three etcd pods appear, each running on a different control node in AZ1, AZ2, and the arbiter zone.

8. Verify that critical control plane pods are distributed across availability zones.

```
oc get pods -n clusters-<cluster-name> -o wide
```

Pods are distributed across AZ1, AZ2, and the arbiter zone.

9. Verify that VMs are scheduled on nodes that correspond to the zones specified in their respective NodePools.

```
oc get vmi -n clusters-<cluster-name> -o wide
```

VMs from `<cluster-name>-np-az1` are running on AZ1 nodes, and VMs from `<cluster-name>-np-az2` are running on AZ2 nodes.

Results

The virtualized Hosted Control Plane cluster is deployed on the 2AZ and arbiter topology. The etcd cluster is distributed one instance per control node across AZ1, AZ2, and the arbiter zone. The cluster remains operational during a single AZ failure.

What to do next

Complete the following tasks after the hosted cluster is available:

1. Install the IBM Fusion base on the hosted cluster. For instructions, see [Installing the IBM Fusion base](#).
2. Install the Fusion Data Foundation storage client on the hosted cluster. For instructions, see [Installing Fusion Data Foundation on a Hosted Control Plane cluster](#).

Deploying a virtualized Hosted Control Plane cluster on 3AZ topology

Create virtualized Hosted Control Plane clusters with Fusion Data Foundation as the storage type in a three-availability-zone (3AZ) rack topology.

Before you begin

Before you begin, complete the following prerequisites:

- Complete all prerequisites for deploying Hosted Control Plane. For the full prerequisites checklist, see [Prerequisites for Hosted Control Plane clusters](#) and [Planning and prerequisites for virtualized Hosted Control Plane clusters](#).
- For offline Hosted Control Plane deployments, ensure that mirroring is in place. For more information, see [Deploying virtualized Hosted Control Plane cluster in disconnected environment](#).
- Each control node has one dedicated LVM NVMe drive. The drive must be in bay 9 of the control node. For more information about LVM drive requirements, see [Dedicated drives for LVM filesystems](#).

Procedure

1. Retrieve the zone labels from one control node per zone.

IBM Fusion HCI labels nodes with availability zones during installation. You need the zone label values when specifying `nodeLabels` and `nodeSelector` in the `NodePool` CRs. In a 3AZ topology, all three zones are full availability zones. Create a NodePool for each zone.

```
oc get nodes -l node-role.kubernetes.io/master -o custom-columns='NODE:.metadata.name,ZONE:.metadata.labels.topology\.kubernetes\.io/zone'
```

For example:

NODE	ZONE
control-1-ru2.<mycluster.com>	AZ1

```
control-1-ru3.<mycluster.com>    AZ2
control-1-ru4.<mycluster.com>    AZ3
```

Each control node shows its zone value: **AZ1**, **AZ2**, or **AZ3**. Note the zone value for each control node.

2. Create the **clusters** and **clusters-*<cluster-name>*** namespaces.

```
apiVersion: v1
kind: Namespace
metadata:
  creationTimestamp: null
  name: clusters-<cluster-name>
spec: {}
status: {}
---
```

```
apiVersion: v1
kind: Namespace
metadata:
  creationTimestamp: null
  name: clusters
spec: {}
status: {}
```

3. Create the pull secret and SSH key in the **clusters** namespace.

```
kind: Secret
apiVersion: v1
metadata:
  name: hcp-pull-secret
  namespace: clusters
data:
  .dockerconfigjson: xxxxxxxx
  type: kubernetes.io/dockerconfigjson
---
```

```
apiVersion: v1
kind: Secret
metadata:
  name: hcp-sshkey
  namespace: clusters
data:
  id_rsa.pub: xxxxxxxx
type: Opaque
```

4. Optional: For offline (air-gapped) deployments, create the **user-ca-bundle** ConfigMap in the **clusters** namespace with the registry CA root certificate.

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: user-ca-bundle
  namespace: clusters
data:
  ca-bundle.crt: |
    -----BEGIN CERTIFICATE-----
    -----END CERTIFICATE-----
```

5. Create the **HostedCluster** CR with tolerations.

The tolerations enable the Hosted Control Plane pods, including etcd, to be scheduled on control plane nodes. Use the following example YAML to create the **HostedCluster** CR.

Note: **imageContentSources** is required for offline (air-gapped) deployments. Remove **OIDC** from services and the **additionalTrustBundle** field for online deployments.

```
apiVersion: hypershift.openshift.io/v1beta1
kind: HostedCluster
metadata:
  name: <cluster-name>
  namespace: clusters
spec:
  fips: <true/false>          # true only if base rack is FIPS enabled
  release:
    image: <release-image>    # example: quay.io/openshift-release-dev/ocp-release:4.22.1-x86_64
  dns:
    baseDomain: <base-domain> # example: apps.base-domain
    controllerAvailabilityPolicy: HighlyAvailable
    infrastructureAvailabilityPolicy: HighlyAvailable
  etcd:
    managed:
      storage:
        persistentVolume:
          size: 8Gi
          storageClassName: lvms-hcp-etcd
          type: PersistentVolume
        managementType: Managed
  platform:
    kubevirt:
      baseDomainPassthrough: true
      type: KubeVirt
  additionalTrustBundle:
    name: user-ca-bundle      # needed only for offline HCP deployment
  networking:
    clusterNetwork:
      - cidr: 10.132.0.0/14
    networkType: OVNKubernetes
    serviceNetwork:
      - cidr: 172.31.0.0/16
  pullSecret:
```

```

    name: <pull-secret-name> # name of the pull secret created above, example: hcp-pull-secret
tolerations:
  - effect: NoSchedule
    key: node-role.kubernetes.io/master

```

If your deployment uses a proxy, add the following proxy configuration to the `spec.configuration` section of the `HostedCluster` CR:

```

spec:
  configuration:
    proxy: # Proxy configuration
      httpProxy: <http-proxy>
      httpsProxy: <https-proxy>
      noProxy: <comma-separated list of domains to bypass proxy>
      trustedCA:
        name: <trusted-ca-secret> # leave empty if no custom CA is used

```

The proxy configuration requires the following fields:

httpProxy

The HTTP proxy URL.

httpsProxy

The HTTPS proxy URL.

noProxy

Comma-separated list of domains that must not be routed through the proxy. Ensure the following are included:

- Existing value of the `noProxy` parameter in the proxy CR on the hub cluster
- `localhost` and `127.0.0.1`
- Cluster subdomain (for example, `isfdelace.mydomain.com`)
- Cluster base domain (for example, `.mydomain.com`)
- Service URL extension: `.svc`
- Service network and cluster network of the hub cluster
- Service network and cluster network of the Hosted Control Plane cluster
- First IP of the Hosted Control Plane service network
- MetalLB IP range

trustedCA.name

Name of the trusted CA secret. Leave empty if no custom certificate is used on the proxy server.

To retrieve the existing proxy configuration values, run the following command on the hub cluster:

```
oc get proxy cluster -o yaml
```

To retrieve the cluster network and service network values of the hub cluster, run:

```
oc get network cluster -o yaml
```

The `HostedCluster` CR is created. The Hosted Control Plane pods and etcd instances begin scheduling on the control nodes.

6. Create a separate `NodePool` CR for each of the three availability zones (AZ1, AZ2, and AZ3).

In a 3AZ topology, all three zones are full availability zones. Creating a `NodePool` for each zone ensures that guest cluster nodes inherit the availability zone from the host cluster, and that router deployments are distributed across VMs on nodes from all three availability zones.

Use the zone values retrieved in step 1 for the `nodeLabels` and `nodeSelector` fields.

NodePool for AZ1

```
apiVersion: hypershift.openshift.io/v1beta1
kind: NodePool
metadata:
  name: <nodepool-name> # example: <cluster-name>-np-az1
  namespace: clusters
spec:
  arch: amd64
  nodeLabels:
    topology.kubernetes.io/zone: <zone-name> # example: AZ1
  clusterName: <hcp-cluster-name> # cluster name given in the HostedCluster CR
  replicas: <number-of-nodes> # example, 3
  management:
    autoRepair: false
    upgradeType: Replace
    nodeDrainTimeout: 0s
    nodeVolumeDetachTimeout: 0s
  platform:
    kubevirt:
      nodeSelector:
        topology.kubernetes.io/zone: <zone-name> # example: AZ1
      attachDefaultNetwork: true
      compute:
        cores: 2
        memory: 6Gi
      networkInterfaceMultiqueue: Enable
      rootVolume:
        persistent:
          size: 32Gi
          storageClass: ocs-storagecluster-ceph-rbd-virtualization
          type: Persistent
        type: KubeVirt
      release:
        image: <release-image>
```

NodePool for AZ2

```
apiVersion: hypershift.openshift.io/v1beta1
kind: NodePool
metadata:
  name: <nodepool-name> # example: <cluster-name>-np-az2
  namespace: clusters
spec:
  arch: amd64
  nodeLabels:
    topology.kubernetes.io/zone: <zone-name> # example: AZ2
  clusterName: <hcp-cluster-name> # cluster name given in the HostedCluster CR
  replicas: <number-of-nodes> # example, 3
  management:
    autoRepair: false
    upgradeType: Replace
    nodeDrainTimeout: 0s
    nodeVolumeDetachTimeout: 0s
  platform:
    kubevirt:
      nodeSelector:
        topology.kubernetes.io/zone: <zone-name> # example: AZ2
      attachDefaultNetwork: true
      compute:
        cores: 2
        memory: 6Gi
      networkInterfaceMultiqueue: Enable
      rootVolume:
        persistent:
          size: 32Gi
          storageClass: ocs-storagecluster-ceph-rbd-virtualization
          type: Persistent
        type: KubeVirt
      release:
        image: <release-image>
```

NodePool for AZ3

```
apiVersion: hypershift.openshift.io/v1beta1
kind: NodePool
metadata:
  name: <nodepool-name> # example: <cluster-name>-np-az3
  namespace: clusters
spec:
  arch: amd64
  nodeLabels:
    topology.kubernetes.io/zone: <zone-name> # example: AZ3
  clusterName: <hcp-cluster-name> # cluster name given in the HostedCluster CR
  replicas: <number-of-nodes> # example, 3
  management:
```

```

    autoRepair: false
    upgradeType: Replace
    nodeDrainTimeout: 0s
    nodeVolumeDetachTimeout: 0s
    platform:
      kubevirt:
        nodeSelector:
          topology.kubernetes.io/zone: <zone-name> # example: AZ3
        attachDefaultNetwork: true
        compute:
          cores: 2
          memory: 6Gi
        networkInterfaceMultiqueue: Enable
        rootVolume:
          persistent:
            size: 32Gi
            storageClass: ocs-storagecluster-ceph-rbd-virtualization
            type: Persistent
        type: KubeVirt
      release:
        image: <release-image>

```

Guest cluster worker nodes inherit the zone labels from their respective NodePools. Router pods are distributed across VMs on nodes from AZ1, AZ2, and AZ3.

7. Verify that one etcd pod is scheduled on each control node across AZ1, AZ2, and AZ3.

```
oc get pods -n clusters-<cluster-name> -l app=etcd -o wide
```

Expected output:

etcd-0	1/1	Running	control-1-ru3	AZ2
etcd-1	1/1	Running	control-1-ru2	AZ1
etcd-2	1/1	Running	control-1-ru4	AZ3

Three etcd pods appear, each running on a different control node in AZ1, AZ2, and AZ3.

8. Verify that critical control plane pods are distributed across all three availability zones.

```
oc get pods -n clusters-<cluster-name> -o wide
```

Pods are distributed across AZ1, AZ2, and AZ3.

9. Verify that VMs are scheduled on nodes that correspond to the zones specified in their respective NodePools.

```
oc get vmi -n clusters-<cluster-name> -o wide
```

VMs from <cluster-name>-np-az1 are running on AZ1 nodes, VMs from <cluster-name>-np-az2 are running on AZ2 nodes, and VMs from <cluster-name>-np-az3 are running on AZ3 nodes.

Results

The virtualized Hosted Control Plane cluster is deployed on the 3AZ topology. The etcd cluster is distributed one instance per control node across AZ1, AZ2, and AZ3. The cluster remains operational during a single AZ failure.

What to do next

Complete the following tasks after the hosted cluster is available:

1. Install the IBM Fusion base on the hosted cluster. For instructions, see [Installing the IBM Fusion base](#).
2. Install the Fusion Data Foundation storage client on the hosted cluster. For instructions, see [Installing Fusion Data Foundation on a Hosted Control Plane cluster](#).

Deploying a virtualized Hosted Control Plane cluster on Regional-DR topology

Create virtualized Hosted Control Plane clusters with Fusion Data Foundation as the storage type in a Regional-DR topology.

Before you begin

Before you begin, complete the following prerequisites:

- Complete all prerequisites for deploying Hosted Control Plane. For the full prerequisites checklist, see [Prerequisites for Hosted Control Plane clusters](#) and [Planning and prerequisites for virtualized Hosted Control Plane clusters](#).
- For offline Hosted Control Plane deployments, ensure that mirroring is in place. For more information, see [Deploying virtualized Hosted Control Plane cluster in disconnected environment](#).
- Each control node has one dedicated LVM NVMe drive. The drive must be in bay 9 of the control node. For more information about LVM drive requirements, see [Dedicated drives for LVM filesystems](#).
- Familiarize yourself with the Hosted Control Plane cluster requirements and components for Regional-DR. For more information, see [Components required for Regional-DR](#).

Procedure

Follow the procedure in [Deploying a virtualized Hosted Control Plane cluster on 2AZ and arbiter node topology](#) to deploy the virtualized Hosted Control Plane cluster.

What to do next

Deployment of Bare Metal clusters with Fusion Data Foundation

Create Bare Metal hosted clusters with Fusion Data Foundation as the storage type. It supports both Hosted Control Plane Bare Metal internal servers in a rack and Hosted Control Plane Bare Metal external servers.

The following are the high-level steps to create a Bare Metal Hosted Control Plane cluster:

Note: Ensure you meet all the prerequisites before you deploy:

- [Prerequisites for Hosted Control Plane clusters](#)
 - [Planning and prerequisites for Bare Metal Hosted Control Plane](#)
1. Plan for the Bare Metal Hosted Control Plane
 2. Create the Infrastructure Environment.
 3. Import the hosts by using Multi Cluster Engine (MCE):
 - a. Create the NMStateConfig for each host.
 - b. Download the **discovery.iso**.
 - c. Boot the host with the **discovery.iso**.
 - d. Accept host into MCE inventory.
 4. Create the Hosted Control Plane cluster.
 5. Configuring ingress for newly created Bare Metal hosted cluster.
- [Planning and prerequisites for Bare Metal Hosted Control Plane](#)
As a prerequisite, gather networking information of the hosting cluster. Define and apply DHCP and DNS information, and configure host inventory settings.
 - [Deploying Bare Metal Hosted Control Plane cluster in disconnected environment](#)
A disconnected environment deployment operates without internet access. You can deploy Hosted Control Plane (HCP) in a disconnected environment on Bare Metal infrastructure.
 - [Deploying a Bare Metal Hosted Control Plane cluster on 2AZ and arbiter node topology](#)
Create Bare Metal Hosted Control Plane clusters with Fusion Data Foundation as the storage type in a two-availability-zone and arbiter node (2AZ and arbiter) multirack topology.
 - [Deploying a Bare Metal Hosted Control Plane cluster on 3AZ topology](#)
Create Bare Metal Hosted Control Plane clusters with Fusion Data Foundation as the storage type in a three-availability-zone (3AZ) rack topology.
 - [Deploying a Bare Metal Hosted Control Plane cluster on Regional-DR topology](#)
Create Bare Metal Hosted Control Plane clusters with Fusion Data Foundation as the storage type in a Regional-DR topology.
 - [Configuring ingress for Bare Metal Hosted cluster](#)
After you deploy the Bare Metal clusters with Fusion Data Foundation, you must configure the ingress for you to view the changes in the user interface.
 - [Booting up the Bare Metal Hosted Control Plane nodes through CLI](#)
Use the steps to boot the Dell and Lenovo nodes from the service node for Bare Metal Hosted Control Plane.
 - [Expanding the Hosted Control Plane Bare Metal cluster](#)
Add a new host to the existing Bare Metal Hosted Control Plane cluster.
 - [Removing a node from the Hosted Control Plane Bare Metal cluster](#)
Remove a node from your Bare Metal Hosted Control Plane cluster when the node is no longer needed or must be replaced.

Planning and prerequisites for Bare Metal Hosted Control Plane

As a prerequisite, gather networking information of the hosting cluster. Define and apply DHCP and DNS information, and configure host inventory settings.

Plan for the Bare Metal Hosted Control Plane:

1. Choose your configuration.
2. Gather networking information about IBM Fusion HCI hosting cluster.
3. Define the new networking information.
4. Apply the networking information to the DNS and DHCP in your environment

Choose your configuration

There are two configurations of Bare Metal Hosted Control Plane cluster.

Internal

In the internal Bare Metal Hosted Control Plane, the servers that are used in the cluster are within the IBM Fusion HCI. When the servers are internal to the IBM Fusion HCI, most of the network information required is collected and present in the Custom Resources of the IBM Fusion HCI.

External

In external Bare Metal Hosted Control Plane, the servers used in the cluster are external to the IBM Fusion HCI. For external servers, you must gather the network information from your lab network administrator.

Connecting your external servers to IBM Fusion HCI:

External servers must be connected to the IBM Fusion HCI through a switch to allow connectivity. These servers can then be imported into Multi Cluster Engine (MCE) as part of a Host Inventory. For instructions to import and its usage in a Hosted Control Plane, see [Deploying Bare Metal clusters with Fusion Data Foundation](#).

Networking prerequisites

Step 1: Gather network information

The networking information consists of the entries that the network administrator needs to add to the network. You need the following information about the host cluster:

Keep the following data ready to use when you create a cluster and **nmstate** config for each node.

Cluster wide information:

Note: The cluster name, sub domain, and domain are all for one hosted cluster. Create them for each of your hosted clusters.

Details	Description	Example values
Base Domain	Cluster base domain you want to use for Hosted Control Plane cluster to be created	mydomain.com
Cluster name	Cluster name you want to use for HCP cluster to be created.	fusion-bm
Sub Domain	This is always <cluster name>.<base domain>	fusion-bm.mydomain.com

Individual nodes in the cluster:

Entry	Description	Example values
BMC address	This is value of field named ipv6ULA or ipv4 in the kickstart CM. You can use ipv6ULA or ipv4.	Example for ipv6ULA - fd9c:316d:179e:c0de:a94:efff:fe:2ec1 Example value for ipv4 - 170.254.2.9
IMM USER/Password	To get this value, search for secretName field in the kickstart config . Inside that secret, search for defaultUserName and defaultUserPasswrd fields for IMM user and Password respectively.	
Bare metal primary interface IP	Unused IP that you plan to use for Bare Metal host in Hosted Control Plane cluster	172.17.x.y
Macaddress	It is available in the kickstart config networkInterfaces , the bond0 macAddress. You need both Bare Metal Primary and secondary interface Mac addresses. You can find the macaddress in the slot section that includes the first macaddress. This guidance is for internal HCI managed nodes. Consult your network administrator for external bare metal nodes	
Gateway IP	Run the following command to get this from one of HCI nodes: <pre>ip r grep default grep br-ex awk '{print \$3}'</pre> If the Hosted Control Plane nodes use the same gateway server as the base HCI cluster. Otherwise, get it from the network administrator. It is only needed when you use the static IP assignment for nodes in Hosted Control Plane cluster. For DHCP managed nodes, this field is not needed.	172.17.x.1
MTU	This can be 9000 or 1500 based on base HCI rack Bare metal MTU used during installation. Find this value from field mtuCount in secret userconfig-secret in namespace ibm-spectrum-fusion-ns .	9000
Bare metal Primary interface's first port's Mac address	This is the value of primary macaddress in kickstart config map for a given node where the interfaceType is baremetal.	08:c0:eb:d4:16:4e
Bare metal Primary interface's second port's Mac address	This is the value of secondary macaddress in kickstart config map for given node where interfaceType is baremetal.	08:c0:eb:d4:16:4f
Bare metal Primary interface's Mac address	This is value of field networkInterfaces -> macAddress in kickstart config map for a given node where the interfaceType is baremetal.	08:c0:eb:d4:16:4e
Bare metal Primary interface's (bond0) first port/interface name	This is value of field networkInterfaces -> interfaceLeg1 in kickstart config map for a given node, where interfaceType is baremetal.	ens3f0np0
Bare metal Primary interface's (bond0) second port/interface name	This is value of field networkInterfaces -> interfaceLeg2 in kickstart config map for given node, where interfaceType is baremetal.	

Example servers external to IBM Fusion HCI:

Server	BMC address of external Bare Metal node	HCP Cluster name	BMC address	Switch bond0 info	mac Address	Type
sr650immru22 tc11-m04-ru22.mydomain.com	fd8c:215d:178e:c0de:3a68:ddff:fe57:2e95	extbarehcp01m04	1.23.45.178	ens1f0np0 b8:3f:d2:3c:6d:60 ens1f1np1 b8:3f:d2:3c:6d:61	b8:3f:d2:3c:6d:60	External

Example servers internal to IBM Fusion HCI:

Server	macaddress Example	HCP Cluster name	BMC address	BMC address	Type/ Label
compute-1-ru8	1070FDB8DF72	fusion-bm	1.23.45.163	fd8c:215d:178e:c0de:a94:efff:fed:e7e1	Compute

DHCP update for the cluster:

Note: This section is needed only when you plan to use DHCP to manage IP and hostname assignment for nodes in Hosted Control Plane. If you use static IP assignment, then skip this section.

You need DHCP only if you want to manage your server IPs using the DHCP for hosted clusters.

To ensure that the individual servers have an IP address that can be contacted by the Hosted Control Plane cluster, make an entry for each host that links its macaddress to an IP address that can be contacted by the IBM Fusion HCI cluster. The macaddress can be found on the back of each physical server.

Example:

Server	macaddress	IP address
compute-1-ru8.fusion-bm.mydomain.com	10:70:FD:B8:DF:72	172.17.x.y

DNS update for Cluster:

Note: Add DNS entry of every host user who wants to create Bare Metal Hosted Control Plane cluster.

The DNS update table entries for each Hosted Control Plane cluster that links a lab provided Server IP address to the `*.apps.NameofCluster.FQDN`. This IP address is used to create a load balancer on the Hosted Control Plane cluster to allow ingress to that cluster.

Load balancer IP	Entry for DNS	FQDN Host	Ingress Type	HCP Clustername	Domain name
1.23.45.910	*.apps.barehcp01m04.mydomain.com	compute-1-ru8.fusion-bm.mydomain.com	loadbalancer	fusion-bm	mydomain.com
Server name	Entry for DNS	IP address			
compute-1-ru8	compute-1-ru8.fusion-bm.mydomain.com	172.17.x.y			

Step 2: Apply the networking information to the DNS and DHCP in your environment

After you gather hosting cluster information, apply the following in your environment (lab network environment):

- DHCP update
- DNS update for host

Multi Cluster Engine (MCE)

Step 1: Configure Host Inventory Settings

After the initial setup, configure the host inventory settings. For more information about the host inventory settings, see [Red Hat® documentation](#).

Step 2: Create project in host IBM Fusion OpenShift Container Platform cluster for host inventory for Hosted Control Plane cluster to be created

From the OpenShift Container Platform console of IBM Fusion, create a project designated for the host inventory along with other necessary resources to support the Hosted Control Plane cluster.

You can use any name. In this example, cluster name is used for simple identification.

Step 3: Create your infrastructure environment

The next step is to create an infrastructure environment in MCE or using the Hosted Control Plane CLI. This infrastructure environment contains the list of Bare Metal hosts that you can select to create a Bare Metal Hosted Control Plane.

Note: Create one infrastructure environment per hosted control plane cluster. Each Hosted Control Plane can only add hosts from a single infrastructure.

1. In the MCE user interface, go to Infrastructure > Host Inventory.
2. Select Create infrastructure environment.
3. On the Create infrastructure environment page, enter the following details:

Name

Name of the infrastructure. No specific name is required.

Network type

Select Static IP, Bridges, and Bonds.

Location

Location of hosts

Labels

Optional value.

Pull Secret

The pull secret must include the following:

- cloud.openshift.com
- cp.icr.io
- quay.io
- registry.connect.redhat.com
- registry.redhat.io

SSH public key

Generate a private/public ssh key pair from bastion host and specify public key in ssh field. It is optional but recommended.

Step 4: Import the hosts by using MCE

With the infrastructure environment created, the next steps are to boot individual servers with an ISO to import them into the host inventory.

Step 4.1: Create the NMStateConfig for each host

The **NMStateConfig** allows the server to be recognized by the IBM Fusion HCI cluster. For additional information, see [Red Hat documentation](#).

The NMStateConfig varies based on whether static IP assignment or DHCP IP assignment is used. For a fresh IBM Fusion HCI 2.10 installation or an upgrade from 2.9 to 2.10 with the network migration script applied, use the new NMStateConfig. If IBM Fusion HCI is upgraded from version 2.9 to 2.10 without applying the network migration script, retain the old NMStateConfig configuration.

Static IP

New **NMStateConfig** for static IP assignment:

```
apiVersion: agent-install.openshift.io/v1beta1
kind: NMStateConfig
metadata:
  labels:
    infraenvs.agent-install.openshift.io: <same as infra name>
  name: <any unique name for host within infra for example fusion-bm-ru8>
  namespace: <same namespace as used for infra>
spec:
  config:
    dns-resolver:
      config:
        server:
          - <DNS server IP>
    interfaces:
      - ipv6:
          enabled: false
          link-aggregation:
            mode: 802.3ad
```

```

    options:
      lacp_rate: '1'

        base-iface: bond0
        id: <VLAN ID of type OpenShift Customer VLAN present on the cluster>
    routes:
      config:
        - destination: 0.0.0.0/0
          next-hop-address: <Gateway IP>
          next-hop-interface: <bond name followed by VLAN ID of type OpenShift Customer VLAN present on the cluster
for example bond0.VLAN_ID>
    interfaces:
      - macAddress: <Bare metal Primary interface's first port's Mac address>
        name: Bare metal Primary interface's first port/interface name>
      - macAddress: <Bare metal Primary interface's second port's Mac address>
        name: Bare metal Primary interface's second port/interface name>

```

Old NMStateConfig for static IP Assignment:

```

apiVersion: agent-install.openshift.io/v1beta1
kind: NMStateConfig
metadata:
  labels:
    infraenvs.agent-install.openshift.io: <same as infra name>
  name: <any unique name for host within infra for example fusion-bm-ru8>
  namespace: <same namespace as used for infra>
spec:
  config:
    dns-resolver:
      config:
        server:
          - <DNS server IP>
    interfaces:
      - ipv4:
          address:
            - ip: <Bare metal primary interface IP>
              prefix-length: 24
            dhcp: false
            enabled: true
          ipv6:
            enabled: false
          link-aggregation:
            mode: 802.3ad
            options:
              lacp_rate: '1'
              miimon: '140'
              xmit_hash_policy: '1'
          ports:
            - <Bare metal Primary interface's first port/interface name>
            - <Bare metal Primary interface's second port/interface name>
          mac-address: <Bare metal Primary interface's first port's Mac address>
          mtu: <MTU value>
          name: bond0
          state: up
          type: bond
        routes:
          config:
            - destination: 0.0.0.0/0
              next-hop-address: <Gateway IP>
              next-hop-interface: bond0
        interfaces:
          - macAddress: <Bare metal Primary interface's first port's Mac address>
            name: <Bare metal Primary interface's first port/interface name>
          - macAddress: <Bare metal Primary interface's second port's Mac address>
            name: <Bare metal Primary interface's second port/interface name>

```

DHCP

New NMStateConfig for DHCP IP assignment:

```

apiVersion: agent-install.openshift.io/v1beta1
kind: NMStateConfig
metadata:
  labels:

```

```

    infraenvs.agent-install.openshift.io: <same as infra name>
    name: <any unique name for host within infra for example fusion-bm-ru8>
    namespace: <same namespace as used for infra>
spec:
  config:
    interfaces:
      - ipv6:
          enabled: false
        link-aggregation:
          mode: 802.3ad
        options:
          lacp_rate: "1"
          miimon: "140"
          xmit_hash_policy: "1"
        ports:
          - <Bare metal Primary interface's first port/interface name>
          - <Bare metal Primary interface's second port/interface name>
        mac-address: <Bare metal Primary interface's first port's Mac address>
        mtu: <MTU value>
        name: bond0
        state: up
        type: bond
      - ipv4:
          dhcp: true
          enabled: true
        ipv6:
          enabled: false
        name: <bond name followed by VLAN ID of type OpenShift Customer VLAN present on the cluster. For example
bond0.VLAN_ID>
        state: up
        type: vlan
        vlan:
          base-iface: bond0
          id: <VLAN ID of type OpenShift Customer VLAN present on the cluster>
        interfaces:
          - macAddress: <Bare metal Primary interface's first port's Mac address>
            name: <Bare metal Primary interface's first port/interface name>
          - macAddress: <Bare metal Primary interface's second port's Mac address>
            name: <Bare metal Primary interface's second port/interface name>

```

Old NMStateConfig:

```

apiVersion: agent-install.openshift.io/v1beta1
kind: NMStateConfig
metadata:
  labels:
    infraenvs.agent-install.openshift.io: <same as infra name>
    name: <any unique name for host within infra for example fusion-bm-ru8>
    namespace: <same namespace as used for infra>
spec:
  config:
    interfaces:
      - ipv4:
          dhcp: true
          enabled: true
        ipv6:
          enabled: false
        link-aggregation:
          mode: 802.3ad
        options:
          lacp_rate: "1"
          miimon: "140"
          xmit_hash_policy: "1"
        ports:
          - <Bare metal Primary interface's first port/interface name>
          - <Bare metal Primary interface's second port/interface name>
        mac-address: <Bare metal Primary interface's first port's Mac address>
        mtu: <MTU value>
        name: bond0
        state: up
        type: bond
      interfaces:
        - macAddress: <Bare metal Primary interface's first port's Mac address>
          name: <Bare metal Primary interface's first port/interface name>
        - macAddress: <Bare metal Primary interface's second port's Mac address>
          name: <Bare metal Primary interface's second port/interface name>

```

The **NMStateConfig** is dependent on the network environment and must be created in consultation with your network administrators.

Enter the following fields in the **NMStateConfig.yaml**:

Note: These fields within the **NMStateConfig** are unique per host.

Field	Description
name	Unique name for each node.
namespace	Namespace is the infraenv namespace.
labels	infraenvs.agent-install.openshift.io: infraNamespace . The infraNamespace must match the name of the infraenvironment into which the host is imported.
ports	The correct ports can be found in the kickstart config CR. The kickstart config for the particular node to be imported to MCE. Within the kickstart config , there is a section "NetworkInterfaces". Within this section, the interfaceName with "baremetal" has the name of the two interfaces interfaceLeg1 and interfaceLeg2. The values under interfaceLeg1 and interfaceLeg2 are the ports. This guidance is for internal. Consult your network administrator for external.
ipaddress	It is the ipv4 address for that node or server.

Field	Description
interfaces > port: macaddress: and port: macaddress:	You can find these values in the <code>kickstart config</code> CR. Each port is an entry from the ports. The <code>macaddress</code> is for that port. The <code>macaddress</code> can be <code>kickstart config</code> for the node by looking for the <code>networkType port: baremetal</code>. Map that <code>macaddress</code> to the <code>networkCards: -slot-#</code>. There is one matching <code>macaddress</code> and one new one, use those in the <code>NMStateConfig.yaml</code>. Important: change any letters to lower case. Example: <pre>ens1f0np1: macaddress: macaddress can be found in the kickstart config for the node under networkCards: slot-1: macaddress:</pre> This guidance is for internal. Consult your network administrator for external.

NMState information is sourced from the switch. For unmanaged servers, you must manually provide the required values.

After the `NMStateConfig.yaml` is created for a server, it must be added to IBM Fusion HCI cluster using the following commands:

1. Go to the `infraenvnamespace` namespace.

```
oc project infraenvnamespace
```

2. Apply the YAML.

```
oc apply -f nmstate.yaml
```

Step 4.2: Download the discovery.iso

Use the `wget` command to download the `discovery.iso` to the service node or another jumpbox.

Note: Keep this ISO secure as you can use this to add a server to the cluster with sensitive information.

To get the retrieval command do the following:

1. Log into the hub IBM Fusion HCI cluster.
2. In the MCE section, go to Infrastructure > Host inventory.
3. In the infrastructure environment, select the infrastructure you intend to import the host into and select that infrastructure environment.
4. Select Add Hosts > With Discovery ISO. There exists either a URL or a `wget` command. Use the command or URL to transfer the ISO to your jumpbox.

Step 4.3: Boot the host with the discovery.iso

This task requires you to log into the IMM, mount the ISO image, and reboot the server.

Note: For internal, go through the steps in this section. For external, go through the [Red Hat documentation](#).

Mount the ISO on to the server through the IMM:

1. Get the IPv6 or IPv4 from kickstart config for that server.
2. Log in to the IMM.
3. To get this value, search for `secretName` field in the `kickstart config`. Inside that secret, search for `defaultUserName` and `defaultUserPasswrld` fields for IMM user and Password respectively.
4. Select Remote Console tab.
5. In the Remote Console tab, select Launch remote console and Media.
6. In the Media page, go to the Mount media from Client Browser section.
7. Select the discovery.iso image and mount it.
8. Select one virtual media to boot on the next restart.
9. Select the mounted discovery.iso and restart immediately.
10. Close windows and monitor that the remote console is showing the reboot.

Step 5: Accept the host into the MCE Inventory

After the server gets restarted with discovery.iso, accept the host into the host inventory.

1. In the MCE user interface, go to Infrastructure > Host inventory.
2. From the table, select the infrastructure environment where the host got imported.
Note: In the hosts table, you can see the approve host after the server gets booted up completely. It can take 10-15 minutes. Verify the server before you accept. If the server name is not recognizable, then look at the details to confirm. You can change the host name but ensure it is unique.
3. Accept the host into the inventory.

(Optional) Step 6: Labeling hosts

After you accept the hosts, add labels to them through the Agent CR. It can be useful to identify a specific cluster or nodepool.

To add the label, do the following steps:

1. Log into the OpenShift console.
2. Go to Administration > CustomResourceDefinitions.
3. Search for Agent of type `agent-install-openshift.io`.
4. In the instances, find the agent to modify the label.
5. Edit the label of the agent to add a new label.

Run the following command to label the agent:

```
oc -n <hosted-cluster-namespace> label agent <agent-name> inventory.agent-install.openshift.io/<label-key>=<label-value>
```

For example, If there exists an agent `0176c90f-1111-78cf-1dc6-8d987fe794b2` under namespace `fusion-bm`, then run the following command to apply the label:

```
oc -n fusion-bm label agent 0176c90f-1111-78cf-1dc6-8d987fe794b2 inventory.agent-install.openshift.io/hcp=hcp1
```

Deploying Bare Metal clusters with Fusion Data Foundation

You can create a Hosted Control Plane cluster by using Bare Metal hosts either through the OpenShift® Console or the Hosted Control Plane CLI.

Before you begin

- Ensure you meet the following prerequisites:
 - [Prerequisites for Hosted Control Plane clusters](#)
 - [Planning and prerequisites for Bare Metal Hosted Control Plane](#)

Procedure

1. Go to Multi Cluster Engine (MCE) user interface.
2. Go to Infrastructure > Clusters > Create cluster.
3. Select Host Inventory and then Hosted.
4. Enter the credentials.
 - The credentials should include the following:
 - cloud.openshift.com
 - cp.icr.io
 - quay.io
 - registry.connect.redhat.com
 - registry.redhat.io
5. Enter Cluster name.
 - Important: It is crucial that the cluster name is the same name used in the network planning. Do not use a name that does not have an alias entry. The cluster is a part of the base domain. For example, **mydomain.com**. Controller and Infrastructure availability are environment dependent.
 - Though the recommendation is to have 3 nodes for a resilient cluster, you can have a single node Hosted Control Plane cluster.
6. Enter Namespace. It is the namespace of the infrastructure environment of the hosts.
7. Enter Labels. These are the labels found on hosts in this particular infrastructure environment. To ensure certain hosts are in a particular cluster, use the labels. Otherwise, a random host from that infrastructure environment gets chosen.
8. Enter the Networking type.
 - The value is environment dependent, but you can choose LoadBalancer type for resilience. The SSH public key must be the same that you used during host import.
9. Open the YAML and add the following in the **spec** section: Hosted Control Plane cluster to use the specially created Local Volume Storage for Hosted Control Plane

```
spec:
  etcd:
    managed:
      storage:
        persistentVolume:
          size: 8Gi
          storageClassName: lvms-hcp-etcd
          type: PersistentVolume
        managementType: Managed
```

It causes the Hosted Control Plane cluster to use the Local Volume Storage created for it.

Important:

- If the base cluster is FIPS-enabled, set `spec.fips: true` in the **HostedCluster** CR when creating the Hosted Control Plane cluster by enabling the YAML view.
- Add the following tolerations in the specification of the **HostedCluster** CR when creating the Hosted Control Plane cluster by enabling the YAML view:

```
tolerations:
- effect: NoSchedule
  key: node-role.kubernetes.io/control-plane
  operator: Exists
- effect: NoSchedule
  key: node-role.kubernetes.io/master
  operator: Exists
```

- If your deployment uses a proxy, add the following proxy configuration to the **spec.configuration** section of the **HostedCluster** CR by enabling the YAML view:

```
spec:
  configuration:
    proxy: # Proxy configuration
      httpProxy: <http-proxy>
      httpsProxy: <https-proxy>
      noProxy: <comma-separated list of domains to bypass proxy>
      trustedCA:
        name: <trusted-ca-secret> # leave empty if no custom CA is used
```

The proxy configuration requires the following fields:

httpProxy

The HTTP proxy URL.

httpsProxy

The HTTPS proxy URL.

noProxy

Comma-separated list of domains that must not be routed through the proxy. Ensure the following are included:

- Existing value of the **noProxy** parameter in the proxy CR on the hub cluster
- **localhost** and **127.0.0.1**
- Cluster subdomain (for example, **isfdelace.mydomain.com**)
- Cluster base domain (for example, **.mydomain.com**)
- Service URL extension: **.svc**
- Service network and cluster network of the hub cluster
- Service network and cluster network of the Hosted Control Plane cluster
- First IP of the Hosted Control Plane service network
- MetalLB IP range

trustedCA.name

Name of the trusted CA secret. Leave empty if no custom certificate is used on the proxy server.

To retrieve the existing proxy configuration values, run the following command on the hub cluster:

```
oc get proxy cluster -o yaml
```

To retrieve the cluster network and service network values of the hub cluster, run:

```
oc get network cluster -o yaml
```

10. Click Create.

The cluster creation starts and it can take up to half an hour. After the nodepool hosts are in the ready state, add the load balancer for the console to be available.

What to do next

After you deploy the Bare Metal clusters with Fusion Data Foundation, configure the ingress to view the changes in the user interface. For more information about the steps to configure ingress, see [Configuring ingress for Bare Metal Hosted cluster](#).

For more information about how to deploy and manage virtual machines on Bare Metal clusters, see [Managing virtual machines on Bare Metal Hosted Control Plane cluster](#).

Deploying Bare Metal Hosted Control Plane cluster in disconnected environment

A disconnected environment deployment operates without internet access. You can deploy Hosted Control Plane (HCP) in a disconnected environment on Bare Metal infrastructure.

For the procedure to deploy Bare Metal Hosted Control Plane cluster in disconnected network, see [Red Hat® documentation](#).

Important: While you follow the Red Hat documentation, take note of the following two steps that must be done differently:

1. Log in from the service node as KNI user to run the commands.
2. The pull secret for Hosted Control Plane in its namespace must reference the host only, without including the repository path.
3. Skip *Deploying a registry for hosted control planes in a disconnected environment* procedure. See [Red Hat documentation](#).
4. If it is a IBM Fusion HCI deployment with a service node, there is no need to set up a new web server. You can use the existing web server on the service node instead of setting up a new one as follows:
 - a. Create a new directory at `/var/www/html/hcp/images`.
 - b. Copy the extracted files into this new directory.
 - c. The web server on the service node runs on port 8118.

However, if the deployment is IBM Fusion SDS, a web server needs to be set up manually.

5. Due to a failure in the extraction of ISO from the private image, the ISO is sourced from `Quay.io` and manually copied to the service node.
6. When you create the hosted cluster CR, remove OI DC service.

```
- service: OI DC
  servicePublishingStrategy:
    type: Route
```

7. Skip *Creating bare metal hosts for the hosted cluster* procedure. See [Red Hat documentation](#).

Important: To add hosts using discovery ISO, follow the steps [4](#) and [5](#) mentioned in the [Planning and prerequisites for Bare Metal Hosted Control Plane](#).

8. When creating an infrastructure environment to configure host inventory, select the following network types: Static, Bond, and Bridge.
9. After the Bare Metal cluster deployment is complete, follow the steps to enable changes to be reflected in the Bare Metal Hosted Control Plane user interface:
 - a. To configure ingress, allow access to the Bare Metal Hosted Control Plane user interface and ensure that your Bare Metal cluster is accessible. For more information about setting up ingress, see [Configuring ingress for Bare Metal Hosted cluster](#).
 - b. Before proceeding with the ingress setup, ensure that the **Red Hat Catalog Source** is deployed in the Bare Metal Hosted Control Plane cluster. This catalog source should include the **MetalLB operator**.
10. If the base cluster is FIPS-enabled, set `spec.fips: true` in the `HostedCluster` CR when creating the Hosted Control Plane cluster by enabling the YAML view.
11. For a 3-node or compact IBM Fusion HCI environment, add the following tolerations in the specification of the `HostedCluster` CR when creating the Hosted Control Plane cluster by enabling the YAML view:

```
tolerations:
- effect: NoSchedule
  key: node-role.kubernetes.io/control-plane
  operator: Exists
- effect: NoSchedule
  key: node-role.kubernetes.io/master
  operator: Exists
```

Examples of CRs and CMs created:

Configuring AgentServiceConfig resources

1. Create a configmap named `custom-registries` in the `multicluster-engine` namespace.

```
kind: ConfigMap
apiVersion: v1
metadata:
  name: custom-registries
  namespace: multicluster-engine
data:
  <registry_name>..<port>: |
    -----BEGIN CERTIFICATE-----
    -----END CERTIFICATE-----
  <registry_name>..<port>: |
    -----BEGIN CERTIFICATE-----
```

```

-----END CERTIFICATE-----
<registry_name>..<port>: |
-----BEGIN CERTIFICATE-----
-----END CERTIFICATE-----
registries.conf: |
unqualified-search-registries = ["registry.access.redhat.com", "docker.io"]
short-name-mode = ""
[[registry]]
  prefix = ""
  location = "quay.io/openshift-release-dev/ocp-v4.0-art-dev"
  mirror-by-digest-only = true
  [[registry.mirror]]
    location = "${TARGET_PATH}/openshift/release"

[[registry]]
  prefix = ""
  location = "quay.io/openshift-release-dev/ocp-release"
  mirror-by-digest-only = true
  [[registry.mirror]]
    location = "${TARGET_PATH}/openshift/release-images"

[[registry]]
  prefix = ""
  location = "registry.redhat.io/multicluster-engine"
  mirror-by-digest-only = true
  [[registry.mirror]]
    location = "${TARGET_PATH}/multicluster-engine"

[[registry]]
  prefix = ""
  location = "registry.redhat.io/openshift4"
  mirror-by-digest-only = true
  [[registry.mirror]]
    location = "${TARGET_PATH}/openshift4"

[[registry]]
  prefix = ""
  location = "registry.redhat.io/rhel9"
  mirror-by-digest-only = true
  [[registry.mirror]]
    location = "${TARGET_PATH}/rhel9"

[[registry]]
  prefix = ""
  location = "registry.redhat.io/rhel8"
  mirror-by-digest-only = true
  [[registry.mirror]]
    location = "${TARGET_PATH}/rhel8"

[[registry]]
  prefix = ""
  location = "registry.redhat.io/redhat"
  mirror-by-digest-only = true
  [[registry.mirror]]
    location = "${TARGET_PATH}/redhat"

```

Note:

- Replace `<registry_name>..<port>` with the actual registry name and port.
- Provide the CA root certificate and intermediate certificate of the registry.
- The `unqualified-search-registries` is mandatory.
- Mirrors list can be found in the workspace folder created when mirroring OpenShift® Container Platform and multi-cluster engine or **metalLB** images.

2. Create an `AgentServiceConfig` resource named `agent`.

```

apiVersion: agent-install.openshift.io/v1beta1
kind: AgentServiceConfig
metadata:
  name: agent
spec:
  databaseStorage:
    accessModes:
      - ReadWriteOnce
    resources:
      requests:
        storage: 200Gi
    storageClassName: ocs-storagecluster-ceph-rbd
  filesystemStorage:
    accessModes:
      - ReadWriteOnce
    resources:
      requests:
        storage: 200Gi
    storageClassName: ocs-storagecluster-ceph-rbd
  imageStorage:
    accessModes:
      - ReadWriteOnce
    resources:
      requests:
        storage: 100Gi
  mirrorRegistryRef:
    name: custom-registries
  osImages:
    - cpuArchitecture: x86_64
      openshiftVersion: 4.18.20
      rootFSUrl: 'http://172.20.x.y:8118/hcp/images/rhcos-418.94.202501221327-0-live-rootfs.x86_64.img'

```

```
url: 'http://172.20.x.y:8118/hcp/images/rhcos-418.94.202501221327-0-live.x86_64.iso'
version: 418.94.202501221327-0
```

Note:

- Specify the configmap name created earlier in the `multicluster-engine` namespace under `mirrorRegistryRef`.
- Add one entry for each OpenShift Container Platform version you wish to deploy hosted cluster with under `osImages`.
- The `rootFSUrl` and `url` are links to files extracted earlier and hosted on a web server.
- The `version` is the core OS version of the downloaded ISO.

Configuring TLS certificates for a disconnected installation of Hosted Control Plane

Create a configmap named `registry-config` in the `openshift-config` namespace.

```
kind: ConfigMap
apiVersion: v1
metadata:
  name: registry-config
  namespace: openshift-config
data:
  <registry_name>..<port>: |
    -----BEGIN CERTIFICATE-----
    -----END CERTIFICATE-----
  <registry_name>..<port>: |
    -----BEGIN CERTIFICATE-----
    -----END CERTIFICATE-----
  <registry_name>..<port>: |
    -----BEGIN CERTIFICATE-----
    -----END CERTIFICATE-----
```

Note:

- Replace `<registry_name>..<port>` with the actual registry name and port.
- Provide the CA root certificate and intermediate certificate of the registry.

Creating a hostedcluster on Bare Metal

1. Create two namespaces: `fusion-bm` and `fusion-bm-fusion-bm`.

```
apiVersion: v1
kind: Namespace
metadata:
  name: fusion-bm-fusion-bm
spec: {}

apiVersion: v1
kind: Namespace
metadata:
  name: fusion-bm
spec: {}
```

2. Create a configmap named `user-ca-bundle` in the `fusion-bm` namespace.

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: user-ca-bundle
  namespace: fusion-bm
data:
  ca-bundle.crt: |
    -----BEGIN CERTIFICATE-----
    -----END CERTIFICATE-----
```

Note: Provide the registry CA root certificate.

3. Create a secret named `fusion-bm-pull-secret` and `sshkey-cluster-fusion-bm` in the `fusion-bm` namespace.

```
apiVersion: v1
kind: Secret
metadata:
  name: fusion-bm-pull-secret
  namespace: fusion-bm
data:
  .dockerconfigjson: xxxxxxxxx
type: kubernetes.io/dockerconfigjson
---
apiVersion: v1
kind: Secret
metadata:
  name: sshkey-cluster-fusion-bm
  namespace: fusion-bm
data:
  id_rsa.pub: xxxxxxxxx
type: Opaque
```

4. Create a role named `capi-provider-role` in the `fusion-bm-fusion-bm` namespace.

```
apiVersion: rbac.authorization.k8s.io/v1
kind: Role
metadata:
  name: capi-provider-role
  namespace: fusion-bm-fusion-bm
rules:
```

```

- verbs:
  - '*'
  apiGroups:
  - agent-install.openshift.io
  resources:
  - agents

```

5. Create a `hostedcluster` CR named `fusion-bm` in the `fusion-bm` namespace.

```

apiVersion: hypershift.openshift.io/v1beta1
kind: HostedCluster
metadata:
  name: fusion-bm
  namespace: fusion-bm
spec:
  fips: true/false
  release:
    image: $TARGET_PATH/openshift/release-images:4.18.20-x86_64
  dns:
    baseDomain: xyz.com
  controllerAvailabilityPolicy: HighlyAvailable
  etcd:
    managed:
      storage:
        persistentVolume:
          size: 8Gi
          storageClassName: lvms-hcp-etcd
          type: PersistentVolume
        managementType: Managed
  infrastructureAvailabilityPolicy: HighlyAvailable
  platform:
    agent:
      agentNamespace: fusion-bm-fusion-bm
      type: Agent
  additionalTrustBundle:
    name: user-ca-bundle
  networking:
    clusterNetwork:
      - cidr: 10.132.0.0/14
    networkType: OVNKubernetes
    serviceNetwork:
      - cidr: 172.31.0.0/16
  pullSecret:
    name: fusion-bm-pull-secret
  configuration:
    operatorhub:
      disableAllDefaultSources: true
  capabilities: {}
  sshKey:
    name: sshkey-cluster-fusion-bm
  autoscaling: {}
  imageContentSources:
    - mirrors:
      - $TARGET_PATH/openshift/release
      source: quay.io/openshift-release-dev/ocp-v4.0-art-dev
    - mirrors:
      - $TARGET_PATH/redhat
      source: registry.redhat.io/redhat
    - mirrors:
      - $TARGET_PATH/redhat
      source: registry.redhat.io/redhat
    - mirrors:
      - $TARGET_PATH/openshift4
      source: registry.redhat.io/openshift4
    - mirrors:
      - $TARGET_PATH/multicluster-engine
      source: registry.redhat.io/multicluster-engine
    ...
  olmCatalogPlacement: management
  services:
    - service: APIServer
      servicePublishingStrategy:
        type: LoadBalancer
    - service: OAuthServer
      servicePublishingStrategy:
        type: Route
    - service: Ignition
      servicePublishingStrategy:
        type: Route
    - service: Konnectivity
      servicePublishingStrategy:
        type: Route

```

Note:

- Specify the configmap name created earlier in the `fusion-bm` namespace under `additionalTrustBundle`.
- Specify the secret name created earlier in the `fusion-bm` namespace under `pullSecret` and `sshKey`.
- Specify the image content sources and mirrors.

6. Wait for the `hostedcluster` CR to get created and the API to become available.

7. Create a `NodePool` CR named `fusion-bm-np` in the `fusion-bm` namespace.

```

apiVersion: hypershift.openshift.io/v1beta1
kind: NodePool
metadata:
  name: fusion-bm-np
  namespace: fusion-bm

```

```
spec:
  arch: amd64
  clusterName: fusion-bm
  management:
    autoRepair: false
    replace:
      rollingUpdate:
        maxSurge: 1
        maxUnavailable: 0
      strategy: RollingUpdate
    upgradeType: InPlace
    nodeDrainTimeout: 0s
  platform:
    agent:
      agentLabelSelector:
        matchLabels:
          inventory.agent-install.openshift.io/hcp: fusion-bm
      type: Agent
  release:
    image: '$TARGET_PATH/openshift/release-images:4.18.20-x86_64'
    replicas: 3
```

Note:

- Specify the cluster name and release image.
- Specify the number of replicas.

Create a host inventory

1. Create a secret named `pullsecret-fusion-bm` in the `fusion-bm-fusion-bm` namespace.

```
apiVersion: v1
kind: Secret
metadata:
  name: pullsecret-fusion-bm
  namespace: fusion-bm-fusion-bm
data:
  .dockerconfigjson: xxxxxxxx
type: kubernetes.io/dockerconfigjson
```

2. Create an `InfraEnv` CR named `fusion-bm` in the `fusion-bm-fusion-bm` namespace.

```
apiVersion: agent-install.openshift.io/v1beta1
kind: InfraEnv
metadata:
  name: fusion-bm
  namespace: fusion-bm-fusion-bm
  labels:
    agentclusterinstalls.extensions.hive.openshift.io/location: us
    networkType: static
spec:
  agentLabels:
    agentclusterinstalls.extensions.hive.openshift.io/location: us
  imageType: minimal-iso
  mirrorRegistryRef:
    name: custom-registries
    namespace: multicluster-engine
  ipxeScriptType: DiscoveryImageAlways
  cpuArchitecture: x86_64
  sshAuthorizedKey: xxxxxxxx
  pullSecretRef:
    name: pullsecret-fusion-bm
  nmStateConfigLabelSelector:
    matchLabels:
      infraenvs.agent-install.openshift.io: fusion-bm
```

Note:

- Specify the mirror registry reference and namespace.
- Specify the image type and CPU architecture.
- Specify the SSH authorized key and pull secret reference.

Deploying a Bare Metal Hosted Control Plane cluster on 2AZ and arbiter node topology

Create Bare Metal Hosted Control Plane clusters with Fusion Data Foundation as the storage type in a two-availability-zone and arbiter node (2AZ and arbiter) multirack topology.

Before you begin

Before you begin, complete the following prerequisites:

- Complete all prerequisites for deploying Hosted Control Plane. For the full prerequisites checklist, see [Prerequisites for Hosted Control Plane clusters](#) and [Planning and prerequisites for Bare Metal Hosted Control Plane](#).
- For offline Hosted Control Plane deployments, ensure that mirroring is in place. For more information, see [Deploying Bare Metal Hosted Control Plane cluster in disconnected environment](#).

- Each control node has one dedicated LVM NVMe drive. The drive must be in bay 9 of the control node. For more information about LVM drive requirements, see [Dedicated drives for LVM filesystems](#).

Before you create the Bare Metal Hosted Control Plane cluster, set up the hosted inventory and complete the node addition process for your deployment type:

- Online deployment:** Create the hosted inventory and complete the node addition process for online Bare Metal Hosted Control Plane. For instructions, see [Planning and prerequisites for Bare Metal Hosted Control Plane](#).
- Disconnected deployment:** Create the hosted inventory and complete the node addition process for offline Bare Metal Hosted Control Plane. For instructions, see [Deploying Bare Metal Hosted Control Plane cluster in disconnected environment](#).

Procedure

- Retrieve the zone labels from one control node per zone and from the arbiter node.

IBM Fusion HCI labels nodes with availability zones during installation. You need the zone label values when specifying `nodeLabels` and `agentLabelSelector` in the `NodePool` CRs.

```
oc get nodes -l node-role.kubernetes.io/master -o custom-
columns='NODE:.metadata.name,ZONE:.metadata.labels.topology\.kubernetes\.io/zone'
```

For example:

```
NODE                                ZONE
control-1-ru2.<mycluster.com>       AZ1
control-1-ru3.<mycluster.com>       AZ2
control-1-ru4.<mycluster.com>       arbiter
```

Each control node shows its zone value: **AZ1**, **AZ2**, or **arbiter**. Note the zone values for AZ1 and AZ2. Do not use the **arbiter** zone when you create NodePools.

- Create the cluster namespaces.

For Bare Metal Hosted Control Plane, the cluster namespace matches the cluster name.

```
apiVersion: v1
kind: Namespace
metadata:
  creationTimestamp: null
  name: <cluster_namespace-cluster-name> #example, <fusion-bm>
spec: {}
status: {}
---
apiVersion: v1
kind: Namespace
metadata:
  creationTimestamp: null
  name: <cluster-name> #example, <fusion-bm>
spec: {}
status: {}
```

- Create the pull secret and SSH key in the cluster namespace.

```
kind: Secret
apiVersion: v1
metadata:
  name: hcp-pull-secret
  namespace: <hosted-cluster-namespace> #example, <fusion-bm>
data:
  .dockerconfigjson: xxxxxxxx
  type: kubernetes.io/dockerconfigjson
---
apiVersion: v1
kind: Secret
metadata:
  name: hcp-sshkey
  namespace: <hosted-cluster-namespace> #example, <fusion-bm>
data:
  id_rsa.pub: xxxxxxxx
type: Opaque
```

- Optional: For offline (air-gapped) deployments, create the `user-ca-bundle` ConfigMap in the cluster namespace with the registry CA root certificate.

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: user-ca-bundle
  namespace: <hosted-cluster-namespace> #example, <fusion-bm>
data:
  ca-bundle.crt: |
    -----BEGIN CERTIFICATE-----
    -----END CERTIFICATE-----
```

- Create the `HostedCluster` CR with tolerations.

The tolerations enable the Hosted Control Plane pods, including etcd, to be scheduled on control plane nodes. Use the following example YAML to create the `HostedCluster` CR.

Note: `imageContentSources` is required for offline (air-gapped) deployments. Remove `OIDC` from services and the `additionalTrustBundle` field for online deployments.

```
apiVersion: hypershift.openshift.io/v1beta1
kind: HostedCluster
metadata:
  name: <cluster-name>
  namespace: <cluster-name> # for bare metal HCP, the namespace matches the cluster name
spec:
```

```

fips: <true/false> # true only if base rack is FIPS enabled
release:
  image: <release-image> # example: quay.io/openshift-release-dev/ocp-release:4.22.1-x86_64
dns:
  baseDomain: <base-domain> # example: fusion.tadn.ibm.com
controllerAvailabilityPolicy: HighlyAvailable
infrastructureAvailabilityPolicy: HighlyAvailable
etcd:
  managed:
    storage:
      persistentVolume:
        size: 8Gi
        storageClassName: lvms-hcp-etcd
        type: PersistentVolume
      managementType: Managed
platform:
  type: Agent
agent:
  agentNamespace: <cluster-name>-<cluster-name> # InfraEnv/Agent namespace; example: fusion-bm-fusion-bm
pullSecret:
  name: <pull-secret-name> # name of the pull secret created above, example: fusion-bm-pull-secret
tolerations:
- effect: NoSchedule
  key: node-role.kubernetes.io/master
  operator: Exists
- effect: NoSchedule
  key: node-role.kubernetes.io/control-plane
  operator: Exists
sshKey:
  name: <ssh-key-secret-name> # name of the SSH key secret created above, example: sshkey-cluster-fusion-bm
additionalTrustBundle:
  name: user-ca-bundle # needed only for offline HCP deployment
networking:
  clusterNetwork:
    - cidr: 10.132.0.0/14
  serviceNetwork:
    - cidr: 172.31.0.0/16
  networkType: OVNKubernetes
configuration:
  operatorhub:
    disableAllDefaultSources: <true> # set to true for offline/air-gapped deployments
  capabilities: {}
olmCatalogPlacement: management
# imageContentSources is needed to add mirroring in case of offline HCP deployment
imageContentSources:
- mirrors:
  - $TARGET_PATH/openshift/release
  source: quay.io/openshift-release-dev/ocp-v4.0-art-dev
- mirrors:
  - $TARGET_PATH/redhat
  source: registry.redhat.io/redhat
- mirrors:
  - $TARGET_PATH/rhel9
  source: registry.redhat.io/rhel9
- mirrors:
  - $TARGET_PATH/rhel8
  source: registry.redhat.io/rhel8
- mirrors:
  - $TARGET_PATH/openshift/release-images
  source: quay.io/openshift-release-dev/ocp-release
- mirrors:
  - $TARGET_PATH/openshift4
  source: registry.redhat.io/openshift4
- mirrors:
  - $TARGET_PATH/multicluster-engine
  source: registry.redhat.io/multicluster-engine
services:
- service: APIServer
  servicePublishingStrategy:
    type: LoadBalancer
- service: Ignition
  servicePublishingStrategy:
    type: Route
- service: Konnectivity
  servicePublishingStrategy:
    type: Route
- service: OAuthServer
  servicePublishingStrategy:
    type: Route
# Remove the OIDC entry for offline HCP deployments
- service: OIDC
  servicePublishingStrategy:
    type: Route

```

If your deployment uses a proxy, add the following proxy configuration to the `spec.configuration` section of the `HostedCluster` CR:

```

spec:
  configuration:
    proxy: # Proxy configuration
      httpProxy: <http-proxy>
      httpsProxy: <https-proxy>
      noProxy: <comma-separated list of domains to bypass proxy>
      trustedCA:
        name: <trusted-ca-secret> # leave empty if no custom CA is used

```

The proxy configuration requires the following fields:

httpProxy

The HTTP proxy URL.

httpsProxy

The HTTPS proxy URL.

noProxy

Comma-separated list of domains that must not be routed through the proxy. Ensure the following are included:

- Existing value of the **noProxy** parameter in the proxy CR on the hub cluster
- **localhost** and **127.0.0.1**
- Cluster subdomain (for example, **isfdelace.mydomain.com**)
- Cluster base domain (for example, **.mydomain.com**)
- Service URL extension: **.svc**
- Service network and cluster network of the hub cluster
- Service network and cluster network of the Hosted Control Plane cluster
- First IP of the Hosted Control Plane service network
- MetalLB IP range

trustedCA.name

Name of the trusted CA secret. Leave empty if no custom certificate is used on the proxy server.

To retrieve the existing proxy configuration values, run the following command on the hub cluster:

```
oc get proxy cluster -o yaml
```

To retrieve the cluster network and service network values of the hub cluster, run:

```
oc get network cluster -o yaml
```

The **HostedCluster** CR is created. The Hosted Control Plane pods and etcd instances begin scheduling on the control nodes.

6. Create a separate **NodePool** CR for each availability zone (AZ1 and AZ2).

Do not create a **NodePool** for the arbiter zone. This ensures that Hosted Control Plane cluster nodes inherit the availability zone from the host cluster, and that router deployments are distributed across Bare Metal hosts on nodes from different availability zones.

Use the zone values retrieved in step [1](#) for the **nodeLabels** and **agentLabelSelector** fields.

NodePool for AZ1

```
apiVersion: hypershift.openshift.io/v1beta1
kind: NodePool
metadata:
  name: <nodepool-name> # example: <cluster-name>-np-az1
  namespace: <cluster-name> # must match the HostedCluster namespace
spec:
  arch: amd64
  nodeLabels:
    topology.kubernetes.io/zone: <zone-name> # example: AZ1
  clusterName: <hcp-cluster-name> # cluster name given in the HostedCluster CR
  replicas: <number-of-nodes> # example, 3
  management:
    autoRepair: false
    replace:
      rollingUpdate:
        maxSurge: 1
        maxUnavailable: 0
      strategy: RollingUpdate
    upgradeType: InPlace
  nodeDrainTimeout: 0s
  platform:
    type: Agent
    agent:
      agentLabelSelector:
        matchLabels:
          inventory.agent-install.openshift.io/hcp: <hcp-cluster-name> # must match the HostedCluster name
          topology.kubernetes.io/zone: <zone-name> # example: AZ1
  release:
    image: <release-image>
```

NodePool for AZ2

```
apiVersion: hypershift.openshift.io/v1beta1
kind: NodePool
metadata:
  name: <nodepool-name> # example: <cluster-name>-np-az2
  namespace: <cluster-name> # must match the HostedCluster namespace
spec:
  arch: amd64
  nodeLabels:
    topology.kubernetes.io/zone: <zone-name> # example: AZ2
  clusterName: <hcp-cluster-name> # cluster name given in the HostedCluster CR
  replicas: <number-of-nodes> # example, 3
  management:
    autoRepair: false
    replace:
      rollingUpdate:
        maxSurge: 1
        maxUnavailable: 0
      strategy: RollingUpdate
    upgradeType: InPlace
  nodeDrainTimeout: 0s
  platform:
    type: Agent
    agent:
```

```

agentLabelSelector:
  matchLabels:
    inventory.agent-install.openshift.io/hcp: <hcp-cluster-name> # must match the HostedCluster name
    topology.kubernetes.io/zone: <zone-name> # example: AZ2
  release:
    image: <release-image>

```

Hosted Control Plane cluster nodes inherit the zone labels from their respective NodePools. Router pods are distributed across Bare Metal hosts on nodes from AZ1 and AZ2.

7. Apply the required labels to each Agent CR.

The labels defined in the NodePool `agentLabelSelector.matchLabels` must be applied directly to the corresponding Agent CRs. The HyperShift operator matches Agents to NodePools based on these labels. A Bare Metal host is not added to the Hosted Control Plane cluster until its Agent CR carries both the required labels.

Apply the following labels to each Agent, replacing the namespace, agent name, and values as appropriate:

```

# Label with the HCP cluster name
oc -n <hosted-cluster-namespace> label agent <agent-name> \
    inventory.agent-install.openshift.io/hcp=<hcp-cluster-name>

# Label with the availability zone
oc -n <hosted-cluster-namespace> label agent <agent-name> \
    topology.kubernetes.io/zone=<zone-name>

```

For example:

```

oc -n fusion-bm label agent 0176c90f-1111-78cf-1dc6-8d987fe794b2 \
    inventory.agent-install.openshift.io/hcp=fusion-bm

oc -n fusion-bm label agent 0176c90f-1111-78cf-1dc6-8d987fe794b2 \
    topology.kubernetes.io/zone=AZ1

```

Note: Repeat this step for each agent. Use the correct zone label (**AZ1** or **AZ2**) that matches the NodePool the agent is assigned to. Do not label any agent with the **arbiter** zone.

Each Agent CR carries the labels required for the HyperShift operator to assign the host to the correct NodePool.

8. Verify that one etcd pod is scheduled on each control node across AZ1, AZ2, and the arbiter zone.

```
oc get pods -n <cluster-name>-<cluster-name> -l app=etcd -o wide
```

Expected output:

```

etcd-0    1/1    Running    control-1-ru3    AZ2
etcd-1    1/1    Running    control-1-ru2    AZ1
etcd-2    1/1    Running    control-1-ru4    arbiter

```

Three etcd pods appear, each running on a different control node in AZ1, AZ2, and the arbiter zone.

9. Verify that critical control plane pods are distributed across availability zones.

```
oc get pods -n <cluster-name>-<cluster-name> -o wide
```

Pods are distributed across AZ1, AZ2, and the arbiter zone.

10. Verify that bare metal Agents are bound to the correct NodePools.

```
oc get agents -n <cluster-name>-<cluster-name> -o wide
```

Agents from `<cluster-name>-np-az1` are running on AZ1 bare metal hosts, and Agents from `<cluster-name>-np-az2` are running on AZ2 bare metal hosts.

Results

The Bare Metal Hosted Control Plane cluster is deployed on the 2AZ and arbiter topology. The etcd cluster is distributed one instance per control node across AZ1, AZ2, and the arbiter zone. The cluster remains operational during a single AZ failure.

What to do next

Complete the following tasks after the hosted cluster is available:

1. Configure ingress for the bare metal hosted cluster. For instructions, see [Configuring ingress for Bare Metal Hosted cluster](#).
2. Install the IBM Fusion base on the hosted cluster. For instructions, see [Installing the IBM Fusion base](#).
3. Install the Fusion Data Foundation storage client on the hosted cluster. For instructions, see [Installing Fusion Data Foundation on a Hosted Control Plane cluster](#).

Deploying a Bare Metal Hosted Control Plane cluster on 3AZ topology

Create Bare Metal Hosted Control Plane clusters with Fusion Data Foundation as the storage type in a three-availability-zone (3AZ) rack topology.

Before you begin

Before you begin, complete the following prerequisites:

- Complete all prerequisites for deploying Hosted Control Plane. For the full prerequisites checklist, see [Prerequisites for Hosted Control Plane clusters](#) and [Planning and prerequisites for Bare Metal Hosted Control Plane](#).
- For offline Hosted Control Plane deployments, ensure that mirroring is in place. For more information, see [Deploying Bare Metal Hosted Control Plane cluster in disconnected environment](#).

- Each control node has one dedicated LVM NVMe drive. The drive must be in bay 9 of the control node. For more information about LVM drive requirements, see [Dedicated drives for LVM filesystems](#).

Before you create the Bare Metal Hosted Control Plane cluster, set up the hosted inventory and complete the node addition process for your deployment type:

- Online deployment:** Create the hosted inventory and complete the node addition process for online Bare Metal Hosted Control Plane. For instructions, see [Planning and prerequisites for Bare Metal Hosted Control Plane](#).
- Disconnected deployment:** Create the hosted inventory and complete the node addition process for offline Bare Metal Hosted Control Plane. For instructions, see [Deploying Bare Metal Hosted Control Plane cluster in disconnected environment](#).

Procedure

- Retrieve the zone labels from one control node per zone.

IBM Fusion HCI labels nodes with availability zones during installation. You need the zone label values when specifying `nodeLabels` and `agentLabelSelector` in the `NodePool` CRs. In a 3AZ topology, all three zones are full availability zones. Create a `NodePool` for each zone.

```
oc get nodes -l node-role.kubernetes.io/master -o custom-
columns='NODE:.metadata.name,ZONE:.metadata.labels.topology\.kubernetes\.io/zone'
```

For example:

```
NODE                                ZONE
control-1-ru2.<mycluster.com>       AZ1
control-1-ru3.<mycluster.com>       AZ2
control-1-ru4.<mycluster.com>       AZ3
```

Each control node shows its zone value: **AZ1**, **AZ2**, or **AZ3**. Note the zone value for each control node.

- Create the cluster namespaces.

For Bare Metal Hosted Control Plane, the cluster namespace matches the cluster name.

```
apiVersion: v1
kind: Namespace
metadata:
  creationTimestamp: null
  name: <cluster_namespace-cluster-name>          #example, <fusion-bm>
spec: {}
status: {}
---
apiVersion: v1
kind: Namespace
metadata:
  creationTimestamp: null
  name: <cluster-name>                            #example, <fusion-bm>
spec: {}
status: {}
```

- Create the pull secret and SSH key in the cluster namespace.

```
kind: Secret
apiVersion: v1
metadata:
  name: hcp-pull-secret
  namespace: <hosted-cluster-namespace>          #example, <fusion-bm>
data:
  .dockerconfigjson: xxxxxxxx
  type: kubernetes.io/dockerconfigjson
---
apiVersion: v1
kind: Secret
metadata:
  name: hcp-sshkey
  namespace: <hosted-cluster-namespace>          #example, <fusion-bm>
data:
  id_rsa.pub: xxxxxxxx
type: Opaque
```

- Optional: For offline (air-gapped) deployments, create the `user-ca-bundle` ConfigMap in the cluster namespace with the registry CA root certificate.

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: user-ca-bundle
  namespace: <hosted-cluster-namespace>          #example, <fusion-bm>
data:
  ca-bundle.crt: |
    -----BEGIN CERTIFICATE-----
    -----END CERTIFICATE-----
```

- Create the `HostedCluster` CR with tolerations.

The tolerations enable the Hosted Control Plane pods, including etcd, to be scheduled on control plane nodes. Use the following example YAML to create the `HostedCluster` CR.

Note: `imageContentSources` is required for offline (air-gapped) deployments. Remove `OIDC` from services and the `additionalTrustBundle` field for online deployments.

```
apiVersion: hypershift.openshift.io/v1beta1
kind: HostedCluster
metadata:
  name: <cluster-name>
  namespace: <cluster-name> # for bare metal HCP, the namespace matches the cluster name
spec:
```

```

fips: <true/false> # true only if base rack is FIPS enabled
release:
  image: <release-image> # example: quay.io/openshift-release-dev/ocp-release:4.22.1-x86_64

    servicePublishingStrategy:
      type: Route

```

If your deployment uses a proxy, add the following proxy configuration to the `spec.configuration` section of the `HostedCluster` CR:

```

spec:
  configuration:
    proxy: # Proxy configuration
      httpProxy: <http-proxy>
      httpsProxy: <https-proxy>
      noProxy: <comma-separated list of domains to bypass proxy>
      trustedCA:
        name: <trusted-ca-secret> # leave empty if no custom CA is used

```

The proxy configuration requires the following fields:

httpProxy

The HTTP proxy URL.

httpsProxy

The HTTPS proxy URL.

noProxy

Comma-separated list of domains that must not be routed through the proxy. Ensure the following are included:

- Existing value of the **noProxy** parameter in the proxy CR on the hub cluster
- **localhost** and **127.0.0.1**
- Cluster subdomain (for example, **isfdelace.mydomain.com**)
- Cluster base domain (for example, **.mydomain.com**)
- Service URL extension: **.svc**
- Service network and cluster network of the hub cluster
- Service network and cluster network of the Hosted Control Plane cluster
- First IP of the Hosted Control Plane service network
- MetalLB IP range

trustedCA.name

Name of the trusted CA secret. Leave empty if no custom certificate is used on the proxy server.

To retrieve the existing proxy configuration values, run the following command on the hub cluster:

```
oc get proxy cluster -o yaml
```

To retrieve the cluster network and service network values of the hub cluster, run:

```
oc get network cluster -o yaml
```

The **HostedCluster** CR is created. The Hosted Control Plane pods and etcd instances begin scheduling on the control nodes.

6. Create a separate **NodePool** CR for each of the three availability zones (AZ1, AZ2, and AZ3).

In a 3AZ topology, all three zones are full availability zones. Creating a NodePool for each zone ensures that Hosted Control Plane cluster nodes inherit the availability zone from the host cluster, and that router deployments are distributed across Bare Metal hosts on nodes from all three availability zones.

Use the zone values retrieved in step [1](#) for the **nodeLabels** and **agentLabelSelector** fields.

NodePool for AZ1

```
apiVersion: hypershift.openshift.io/v1beta1
kind: NodePool
metadata:
  name: <nodepool-name> # example: <cluster-name>-np-az1
  namespace: <cluster-name> # must match the HostedCluster namespace
spec:
  arch: amd64
  nodeLabels:
    topology.kubernetes.io/zone: <zone-name> # example: AZ1
  clusterName: <hcp-cluster-name> # cluster name given in the HostedCluster CR
  replicas: <number-of-nodes> # example, 3
  management:
    autoRepair: false
    replace:
      rollingUpdate:
        maxSurge: 1
        maxUnavailable: 0
      strategy: RollingUpdate
    upgradeType: InPlace
  nodeDrainTimeout: 0s
  platform:
    type: Agent
    agent:
      agentLabelSelector:
        matchLabels:
          inventory.agent-install.openshift.io/hcp: <hcp-cluster-name> # must match the HostedCluster name
          topology.kubernetes.io/zone: <zone-name> # example: AZ1
  release:
    image: <release-image>
```

NodePool for AZ2

```
apiVersion: hypershift.openshift.io/v1beta1
kind: NodePool
metadata:
  name: <nodepool-name> # example: <cluster-name>-np-az2
  namespace: <cluster-name> # must match the HostedCluster namespace
spec:
  arch: amd64
  nodeLabels:
    topology.kubernetes.io/zone: <zone-name> # example: AZ2
  clusterName: <hcp-cluster-name> # cluster name given in the HostedCluster CR
  replicas: <number-of-nodes> # example, 3
  management:
    autoRepair: false
    replace:
      rollingUpdate:
        maxSurge: 1
        maxUnavailable: 0
      strategy: RollingUpdate
    upgradeType: InPlace
  nodeDrainTimeout: 0s
  platform:
    type: Agent
    agent:
```

```

    agentLabelSelector:
      matchLabels:
        inventory.agent-install.openshift.io/hcp: <hcp-cluster-name> # must match the HostedCluster name
        topology.kubernetes.io/zone: <zone-name> # example: AZ2
  release:
    image: <release-image>

```

NodePool for AZ3

```

apiVersion: hypershift.openshift.io/v1beta1
kind: NodePool
metadata:
  name: <nodepool-name> # example: <cluster-name>-np-az3
  namespace: <cluster-name> # must match the HostedCluster namespace
spec:
  arch: amd64
  nodeLabels:
    topology.kubernetes.io/zone: <zone-name> # example: AZ3
  clusterName: <hcp-cluster-name> # cluster name given in the HostedCluster CR
  replicas: <number-of-nodes> # example, 3
  management:
    autoRepair: false
    replace:
      rollingUpdate:
        maxSurge: 1
        maxUnavailable: 0
      strategy: RollingUpdate
    upgradeType: InPlace
    nodeDrainTimeout: 0s
  platform:
    type: Agent
    agent:
      agentLabelSelector:
        matchLabels:
          inventory.agent-install.openshift.io/hcp: <hcp-cluster-name> # must match the HostedCluster name
          topology.kubernetes.io/zone: <zone-name> # example: AZ3
  release:
    image: <release-image>

```

Hosted Control Plane cluster nodes inherit the zone labels from their respective NodePools. Router pods are distributed across Bare Metal hosts on nodes from AZ1, AZ2, and AZ3.

7. Apply the required labels to each Agent CR.

The labels defined in the NodePool `agentLabelSelector.matchLabels` must be applied directly to the corresponding Agent CRs. The HyperShift operator matches Agents to NodePools based on these labels. A Bare Metal host is not added to the Hosted Control Plane cluster until its Agent CR carries both the required labels.

Apply the following labels to each Agent, replacing the namespace, agent name, and values as appropriate:

```

# Label with the HCP cluster name
oc -n <hosted-cluster-namespace> label agent <agent-name> \
    inventory.agent-install.openshift.io/hcp=<hcp-cluster-name>

# Label with the availability zone
oc -n <hosted-cluster-namespace> label agent <agent-name> \
    topology.kubernetes.io/zone=<zone-name>

```

For example:

```

oc -n fusion-bm label agent 0176c90f-1111-78cf-1dc6-8d987fe794b2 \
    inventory.agent-install.openshift.io/hcp=fusion-bm

oc -n fusion-bm label agent 0176c90f-1111-78cf-1dc6-8d987fe794b2 \
    topology.kubernetes.io/zone=AZ1

```

Note: Repeat this step for each agent. Use the correct zone label (**AZ1**, **AZ2**, or **AZ3**) that matches the NodePool the agent is assigned to. Each Agent CR carries the labels required for the HyperShift operator to assign the host to the correct NodePool.

8. Verify that one etcd pod is scheduled on each control node across AZ1, AZ2, and AZ3.

```
oc get pods -n <cluster-name>-<cluster-name> -l app=etcd -o wide
```

Expected output:

```

etcd-0   1/1   Running   control-1-ru3   AZ2
etcd-1   1/1   Running   control-1-ru2   AZ1
etcd-2   1/1   Running   control-1-ru4   AZ3

```

Three etcd pods appear, each running on a different control node in AZ1, AZ2, and AZ3.

9. Verify that critical control plane pods are distributed across all three availability zones.

```
oc get pods -n <cluster-name>-<cluster-name> -o wide
```

Pods are distributed across AZ1, AZ2, and AZ3.

10. Verify that Bare Metal Agents are bound to the correct NodePools.

```
oc get agents -n <cluster-name>-<cluster-name> -o wide
```

Agents from `<cluster-name>-np-az1` are running on AZ1 Bare Metal hosts, Agents from `<cluster-name>-np-az2` are running on AZ2 Bare Metal hosts, and Agents from `<cluster-name>-np-az3` are running on AZ3 Bare Metal hosts.

Results

The Bare Metal Hosted Control Plane cluster is deployed on the 3AZ topology. The etcd cluster is distributed one instance per control node across AZ1, AZ2, and AZ3. The cluster remains operational during a single AZ failure.

What to do next

Complete the following tasks after the hosted cluster is available:

1. Configure ingress for the bare metal hosted cluster. For instructions, see [Configuring ingress for Bare Metal Hosted cluster](#).
2. Install the IBM Fusion base on the hosted cluster. For instructions, see [Installing the IBM Fusion base](#).
3. Install the Fusion Data Foundation storage client on the hosted cluster. For instructions, see [Installing Fusion Data Foundation on a Hosted Control Plane cluster](#).

Deploying a Bare Metal Hosted Control Plane cluster on Regional-DR topology

Create Bare Metal Hosted Control Plane clusters with Fusion Data Foundation as the storage type in a Regional-DR topology.

Before you begin

Before you begin, complete the following prerequisites:

- Complete all prerequisites for deploying Hosted Control Plane. For the full prerequisites checklist, see [Prerequisites for Hosted Control Plane clusters](#) and [Planning and prerequisites for Bare Metal Hosted Control Plane](#).
- For offline Hosted Control Plane deployments, ensure that mirroring is in place. For more information, see [Deploying Bare Metal Hosted Control Plane cluster in disconnected environment](#).
- Each control node has one dedicated LVM NVMe drive. The drive must be in bay 9 of the control node. For more information about LVM drive requirements, see [Dedicated drives for LVM filesystems](#).
- Familiarize yourself with the Hosted Control Plane cluster requirements and components for Regional-DR. For more information, see [Components required for Regional-DR](#).

Before you create the Bare Metal Hosted Control Plane cluster, set up the hosted inventory and complete the node addition process for your deployment type:

- **Online deployment:** Create the hosted inventory and complete the node addition process for online Bare Metal Hosted Control Plane. For instructions, see [Planning and prerequisites for Bare Metal Hosted Control Plane](#).
- **Disconnected deployment:** Create the hosted inventory and complete the node addition process for offline Bare Metal Hosted Control Plane. For instructions, see [Deploying Bare Metal Hosted Control Plane cluster in disconnected environment](#).

Procedure

Follow the procedure in [Deploying a Bare Metal Hosted Control Plane cluster on 2AZ and arbiter node topology](#) to deploy the Bare Metal Hosted Control Plane cluster.

What to do next

After you deploy the Bare Metal Hosted Control Plane cluster, configure Regional-DR between the clusters. For instructions, see [Configuring Regional-DR](#).

Configuring ingress for Bare Metal Hosted cluster

After you deploy the Bare Metal clusters with Fusion Data Foundation, you must configure the ingress for you to view the changes in the user interface.

Before you begin

You must have deployed the Bare Metal cluster successfully. For more information about the deployment procedure, see [Deploying Bare Metal clusters with Fusion Data Foundation](#).

Procedure

1. If you choose LoadBalancer networking type, then add a load balancer to the newly created Hosted Control Plane cluster.
You need the load balancer to gain external access to the Hosted Control Plane cluster. Using a load balancer allows the nodes to be resilient as opposed to the nodeport approach. The load balancer gets added to the newly created Hosted Control Plane cluster, and not the IBM Fusion HCI hub cluster. To access the new Hosted Control Plane cluster, download the kubeconfig. Steps to download the kubeconfig:
 - a. Log in to the IBM Fusion HCI hub OpenShift console.
 - b. Go to the ACM user interface and select Infrastructure > Clusters.
 - c. In the clusters list, select the newly created Hosted Control Plane cluster.
 - d. In the Cluster nodepools section, click Download kubeconfig. It downloads the kubeconfig for the cluster.After the kubeconfig is available, use the OC commands to create YAMLs on the new Hosted Control Plane cluster.

Important: In disconnected Hosted Control Plane deployment, before proceeding with the ingress setup, ensure that the **Red Hat® Catalog Source** is deployed in the Bare Metal Hosted Control Plane cluster. This catalog source should include the MetalLB operator.

2. Create MetalLB operator.
 - a. Create a new YAML file.
Example YAML:

```
apiVersion: v1
kind: Namespace
```

```

metadata:
  name: metallb
  labels:
    openshift.io/cluster-monitoring: "true"
  annotations:
    workload.openshift.io/allowed: management
---
apiVersion: operators.coreos.com/v1
kind: OperatorGroup
metadata:
  name: metallb-operator-operatorgroup
  namespace: metallb
---
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: metallb-operator
  namespace: metallb
spec:
  channel: "stable"
  name: metallb-operator
  source: redhat-operators
  sourceNamespace: openshift-marketplace

```

b. Apply the YAML:

```
oc --kubeconfig=kubeconfig.yaml apply -f metallb-operator-config.yaml
```

c. Wait for all the pods to be up and running. Run the following command to confirm:

```
oc --kubeconfig=kubeconfig.yaml get pods -n metallb
```

3. Create an instance of MetalLB.

a. Create a new file metallb-instance-config.yaml.

Example:

```

apiVersion: metallb.io/v1beta1
kind: MetalLB
metadata:
  name: metallb
  namespace: metallb

```

b. Apply the file:

```
oc --kubeconfig=kubeconfig.yaml apply -f metallb-instance-config.yaml
```

c. Wait for the pods to be up and running

```
oc --kubeconfig=kubeconfig.yaml get pods -n metallb
```

4. Create an IPAddressPool and L2Advertisement.

a. Create an IPAddressPool named

ipaddresspool-l2advertisement-config.yaml.

Example:

```

apiVersion: metallb.io/v1beta1
kind: IPAddressPool
metadata:
  name: ippool
  namespace: metallb
spec:
  protocol: layer2
  autoAssign: false
  addresses:
    - 1.23.45.678-1.23.45.678
---
apiVersion: metallb.io/v1beta1
kind: L2Advertisement
metadata:
  name: l2-advertisement
  namespace: metallb
spec:
  ipAddressPools:
    - ippool

```

The name of the IPAddressPool must match the one in the L2Advertisement.

The addresses must be the IPAddress in the DNS that is the *.apps.NAMEofCluster in the DNS network table set up by the network administrator.

b. Apply the ipaddresspool-l2advertisement-config.yaml.

```
oc --kubeconfig=kubeconfig.yaml apply -f ipaddresspool-l2advertisement-config.yaml
```

5. Create a service for the loadbalancer.

a. Create metallb-loadbalancer-service.yaml.

Note: The address-pool must match the name of the addresspool in previous step.

Example:

```

kind: Service
apiVersion: v1
metadata:
  annotations:
    metallb.universe.tf/address-pool: ippool

```

```

name: metallb-ingress
namespace: openshift-ingress
spec:
  ports:
    - name: http
      protocol: TCP
      port: 80
      targetPort: 80
    - name: https
      protocol: TCP
      port: 443
      targetPort: 443
  selector:
    ingresscontroller.operator.openshift.io/deployment-ingresscontroller: default
  type: LoadBalancer

```

b. Apply the load balancer service YAML.

```
oc --kubeconfig=kubeconfig.yaml apply -f metallb-loadbalancer-service.yaml
```

c. Monitor the Cluster Operator console for issues:

```
oc --kubeconfig=kubeconfig.yaml get co
```

Booting up the Bare Metal Hosted Control Plane nodes through CLI

Use the steps to boot the Dell and Lenovo nodes from the service node for Bare Metal Hosted Control Plane.

Before you begin

Ensure that you met the following prerequisites:

1. Log in to the service node as **kni** user.
2. Collect the BMC addresses, username, and passwords for all target nodes. For procedure, see [Planning and prerequisites for Bare Metal Hosted Control Plane](#).
3. Download and host the discovery ISO as follows:
 - a. Get the discovery ISO download URL from the MCE user interface.
 - b. Download the ISO on the bastion node, then transfer it to the service node under the directory.

```

mkdir /var/www/html/discovery-isos
# move the ISO to:
mv discovery.iso /var/www/html/discovery-isos

```

Note: By default, the service node runs an **http** web server on port **8118**.

- c. Access URL for the ISO using only service node provisioning IP. Run the following command to get the provisioning IP.

```
ip -4 -o addr show dev provisioning | awk '{print $4}' | cut -d/ -f1
```

Example output:

```
169.253.1.67
```

Example URL to access the discovery ISO:

```
http://169.253.1.67:8118/discovery-isos/discovery.iso
```

- d. Use node-specific tools for configuration:
 - For Dell nodes, use **racadm**
 - For Lenovo nodes, use **onecli** and **ipmitool**.

Note: These tools are available on the service node.

Procedure

1. Note: The **racadm** command is preinstalled and included in the systems path. You can run it directly from the command line.

Use the following steps to boot the Dell nodes:

- a. Run the following command to enable the iDRAC web server interface (HTTP or HTTPS).

```
racadm -r <BMC_NODE_IP> -u <BMC_NODE_USERNAME> -p <BMC_NODE_PASSWORD> --nocertwarn set iDRAC.Webserver.Enable 1
```

Example output:

```

[Key=iDRAC.Embedded.1#WebServer.1]
Object value modified successfully

```

- b. Run the following command to set the HTTP port for the iDRAC web interface to port 80.

```
racadm -r <BMC_NODE_IP> -u <BMC_NODE_USERNAME> -p <BMC_NODE_PASSWORD> --nocertwarn set iDRAC.Webserver.HttpPort 80
```

Example output:

```

[Key=iDRAC.Embedded.1#WebServer.1]
Object value modified successfully

```

- c. Run the following command to set the HTTPs port for the iDRAC web interface to port 443.

```
racadm -r <BMC_NODE_IP> -u <BMC_NODE_USERNAME> -p <BMC_NODE_PASSWORD> --nocertwarn set iDRAC.Webserver.HttpPort 443
```

Example output:

```
[Key=iDRAC.Embedded.1#WebServer.1]
Object value modified successfully
```

- d. Run the following command to power off the node.

```
racadm -r <BMC_NODE_IP> -u <BMC_NODE_USERNAME> -p <BMC_NODE_PASSWORD> --nocertwarn serveraction powerdown
```

Example output:

```
Server is already powered OFF.
```

- e. Run the following command to set the boot order of the node to virtual CD or DVD.

```
racadm -r <BMC_NODE_IP> -u <BMC_NODE_USERNAME> -p <BMC_NODE_PASSWORD> --nocertwarn set iDRAC.ServerBoot.FirstBootDevice VCD-DVD
```

Example output:

```
[Key=iDRAC.Embedded.1#ServerBoot.1]
Object value modified successfully
```

- f. Run the following command to unmount the ISO image if it is already mounted on the node.

```
racadm -r <BMC_NODE_IP> -u <BMC_NODE_USERNAME> -p <BMC_NODE_PASSWORD> --nocertwarn remoteimage -d
```

Example output:

```
Disable Remote File Started. Please check status using -s
option to know Remote File Share is ENABLED or DISABLED.
```

- g. Run the following command to check the status of ISO image unmount.

```
racadm -r <BMC_NODE_IP> -u <BMC_NODE_USERNAME> -p <BMC_NODE_PASSWORD> --nocertwarn remoteimage -s
```

Example output:

```
Remote File Share is Disabled
UserName
Password
ShareName
```

- h. Run the following command to mount the downloaded discovery ISO image and host it on the service node web server.

```
racadm -r <BMC_NODE_IP> -u <BMC_NODE_USERNAME> -p <BMC_NODE_PASSWORD> --nocertwarn remoteimage -c -l
http://169.253.1.67:8118/discovery-isos/discovery.iso
```

Example output:

```
Remote Image is now Configured
```

- i. Run the following command to check the status of the ISO image that is mounted on node.

```
racadm -r <BMC_NODE_IP> -u <BMC_NODE_USERNAME> -p <BMC_NODE_PASSWORD> --nocertwarn remoteimage -s
```

Example output:

```
Remote File Share is Enabled
UserName
Password
ShareName http://169.253.1.67:8118/discovery-isos/discovery.iso
```

- j. Run the following command to power on the node to boot it with the mounted ISO image.

```
racadm -r <BMC_NODE_IP> -u <BMC_NODE_USERNAME> -p <BMC_NODE_PASSWORD> --nocertwarn serveraction powerup
```

Example output:

```
Server power operation initiated successfully
```

- k. Repeat the same steps for all other nodes that you want to add to the hosted cluster.

2. Use the following steps to boot the Lenovo nodes:

- a. Run the following command to power off the node.

```
ipmitool -I lanplus -H <BMC_NODE_IP> -U <BMC_USERNAME> -P <BMC_PASSWORD> power off
```

- b. Run the following command to set the boot order of the node to CD or DVD.

```
export LC_ALL=en_US;export LC_TYPE=en_US;sudo -E /home/kni/isfconfig/onecli/onecli config set BootOrder.BootOrder
"CD/DVD Rom=Network=USB Storage=Hard Disk" -N --bmc <BMC_USERNAME>:<BMC_PASSWORD>@[<BMC_NODE_IP>]
```

Example output:

```
Lenovo XClarity Essentials OneCLI lxce_onecli02f-3.1.0
```

```
(C) Lenovo 2013-2020 All Rights Reserved
```

```
OneCLI License Agreement and OneCLI Legal Information can be found at the following location:
```

```
"/root/onecli/Lic"
```

```
Invoking SET command ...
```

```
Connected to BMC at IP address <BMC_NODE_IP> by IPMI
```

```
BootOrder.BootOrder=CD/DVD Rom=Network=USB Storage=Hard Disk
```

Succeed.

- c. Run the following command to set the node boot mode to UEFI.

```
export LC_ALL=en_US;export LC_TYPE=en_US;sudo -E /home/kni/isfconfig/onecli/onecli config set
BootModes.SystemBootMode "UEFI Mode" -N --bmc <BMC_USERNAME>:<BMC_PASSWORD>@[<BMC_NODE_IP>]
```

Example output:

```
Lenovo XClarity Essentials OneCLI lxce_onecli02f-3.1.0

(C) Lenovo 2013-2020 All Rights Reserved

OneCLI License Agreement and OneCLI Legal Information can be found at the following location:

    "/root/onecli/Lic"

Invoking SET command ...

Connected to BMC at IP address <BMC_NODE_IP> by IPMI

BootModes.SystemBootMode=UEFI Mode

Configure successfully, please reboot system.

Succeed.
```

- d. Run the following command to mount the ISO image.

```
echo | sudo -E /home/kni/isfconfig/onecli/rdmount -d /var/www/html/discovery-isos/discovery.iso -s <BMC_NODE_IP> -l
<BMC_USERNAME> -p <BMC_PASSWORD>
```

Example output:

```
Extracting...

Executing...

drivePath: /var/www/html/discovery-isos/discovery.iso

spName: <BMC_NODE_IP>

loginName: USERID

password: *****

No existing remote disk used on the target BMC.

/var/www/html/discovery-isos/discovery.iso is an ISO file.

Starting to determine BMC type

XCC found: XCC

XCC found so will try HTTP with password authentication.

Version: 4.0.0.3 AVMP

Remote device list updated.

Mapping /var/www/html/discovery-isos/discovery.iso to Remote Device[0] as Read Only. Success.

Succeed mapping. Wait for notify on status.

Remote device list updated.

Remote device list updated.

Mount 0: /var/www/html/discovery-isos/discovery.iso as type 105

Succeed in mounting.

return code: 0
```

- e. Run the following command to power up the node.

```
ipmitool -I lanplus -H <BMC_NODE_IP> -U <BMC_NODE_USERID> -P <BMC_PASSWORD> power on
```

- f. Run the following command to verify the power state of the node.

```
ipmitool -I lanplus -H <BMC_NODE_IP> -U <BMC_NODE_USERID> -P <BMC_PASSWORD> power state
```

- g. Repeat the same steps for all other nodes that you want to add to the hosted cluster.

Expanding the Hosted Control Plane Bare Metal cluster

Add a new host to the exiting Bare Metal Hosted Control Plane cluster.

About this task

After a new Bare Metal host is available in the infrastructure > Nodes > Discovered nodes tab, you can optionally choose to add node to the Hosted Control Plane Bare Metal cluster.

Procedure

1. Create **nmstate** config for new node following **nmstate** YAML template.
For more information about **nmstate**, see [Create the NMStateConfig for each host](#).
2. Add this new host in the host inventory and boot from the discovery ISO. In MCE, approve the host in the host inventory.
For more information about these steps, see [Download the discovery.iso](#) and [Boot the host with the discovery.iso](#).
Wait for sometime for the host to be available in MCE. After you approve, it changes to available state. For more information about the steps to accept, see [Accept the host into the MCE Inventory](#).
3. Go to Infrastructure > Clusters > <Your Bare Metal HCP Cluster Name>.
4. Expand Cluster nodepools section and click the ellipsis menu of the node pool.
5. Increase the value of Number of hosts based on the number of new hosts that you plan to add. For example, if you have two nodes in the cluster and want to expand it by one more, then the value of Number of hosts is 3.
6. Click Update.
It initiates the addition of a new node to an existing cluster and completes within a few minutes.

Removing a node from the Hosted Control Plane Bare Metal cluster

Remove a node from your Bare Metal Hosted Control Plane cluster when the node is no longer needed or must be replaced.

Before you begin

Before you remove a node, ensure that the cluster has sufficient capacity to accommodate the workloads that are running on the node you intend to remove.

Procedure

1. Identify the cluster and the target node that you want to remove.
2. Log in to the hosted cluster from the terminal.
3. Mark the node as **unschedulable** to prevent new workloads from being scheduled on it.

```
oc adm cordon <node-name>
```
4. Evacuate the workloads from the node.

```
oc adm drain <node-name> --ignore-daemonsets --delete-emptydir-data
```
5. Confirm that the cluster is healthy before you proceed with node removal.
 - a. Run the following command to check that all cluster operators are available.

```
oc get co
```
 - b. Verify that the OpenShift® API is accessible.
 - c. Verify that the Red Hat® OpenShift Container Platform Web Console is accessible.
6. In the Red Hat OpenShift Container Platform Web Console, click the ellipsis menu for the node and select Remove from cluster.
7. On the Remove host from cluster? page, click Remove from cluster.
8. Monitor the node status until the node is available.
 - a. Confirm that the node status changes to Returning to the infrastructure environment.
 - b. Confirm that the status updates to Rebooting while returning to infrastructure environment.
 - c. Wait for the process to complete until the node becomes available.
 - d. After the node is available, click the ellipsis menu and select Remove host.
9. Verify the node status.
 - a. Go to the Discovered tab in the IBM Fusion HCI user interface.
 - b. Confirm that the node is listed.
10. Verify the cluster health.
 - a. Run the following command to check that all cluster operators are available.

```
oc get co
```
 - b. Verify that the OpenShift API is accessible.
 - c. Verify that the Red Hat OpenShift Container Platform Web Console is accessible.

What to do next

To add the node back to the cluster with the correct **nmstate** and interface values, follow the steps in [Expanding your Hosted Control Plane Bare Metal cluster](#).

Installation of data services on a Hosted Control Plane cluster

Provision Hosted Control Plane clusters with services like Fusion Data Foundation, Global Data Platform remote mount, and Backup & Restore.

- [Prerequisites for data services on a Hosted Control Plane cluster](#)
Before you install data services on a Hosted Control Plane cluster, verify that the hosted cluster is available and meets the requirements for Fusion Data Foundation, Global Data Platform remote mount, and Backup & Restore.
- [Installing the IBM Fusion base](#)
Procedure to install the IBM Fusion base on a Hosted Control Plane cluster.
- [Installing Fusion Data Foundation on a Hosted Control Plane cluster](#)
Install the Fusion Data Foundation client as the storage type for the hosted cluster.
- [Updating the storage quota of a Hosted Control Plane cluster](#)
Update the allotted storage quota of the Fusion Data Foundation client on a Hosted Control Plane cluster to meet the storage requirement of the application workloads.
- [Installing Global Data Platform remote mount on the hosted cluster](#)
From the IBM Fusion HCI hub cluster, install Global Data Platform remote mount on the hosted cluster so that applications can provision storage from a remote-mounted filesystem. It you can use a label-based approach for configuration of IBM Storage Scale CNSA cluster, similar to existing services.
- [Installing Backup & Restore on the hosted cluster](#)
From the IBM Fusion HCI hub cluster, install Backup & Restore on the hosted cluster with Fusion Data Foundation as the storage type.

Prerequisites for data services on a Hosted Control Plane cluster

Before you install data services on a Hosted Control Plane cluster, verify that the hosted cluster is available and meets the requirements for Fusion Data Foundation, Global Data Platform remote mount, and Backup & Restore.

About this task

For offline Hosted Control Plane deployments, complete the following prerequisites before you install data services on the hosted cluster.

Procedure

1. Mirror the required images to your enterprise registry and apply the **ImageDigestMirrorSet** (IDMS) on both the IBM Fusion HCI cluster and in the **HostedCluster** custom resource.
 - a. Mirror IBM Fusion images to your enterprise registry. For the procedure, see *Mirroring IBM Fusion images* in [IBM Fusion](#) documentation set.
 - b. Mirror Backup & Restore images to your enterprise registry. For the procedure, see *Mirroring Backup & Restore images* in [IBM Fusion](#) documentation set..
 - c. After mirroring is complete, apply the generated IDMS in the following locations:
 - IBM Fusion HCI cluster
Apply the IDMS on the hub cluster so that the IBM Fusion HCI nodes can pull images from the enterprise registry. Apply the IDMS generated from the following sources:
 - IBM Fusion
 - Fusion Data Foundation
 - Backup & Restore
 - HostedCluster** custom resource
Add the mirror entries to the **imageContentSources** field of the **HostedCluster** custom resource so that the Hosted Control Plane guest cluster nodes can pull images from the enterprise registry. Apply the IDMS from the following sources:
 - IBM Fusion HCI
 - IBM Fusion
 - Fusion Data Foundation
 - Backup & Restore
2. Deploy the generated IBM Fusion catalog source on the IBM Fusion HCI cluster.
After mirroring IBM Fusion images, deploy the generated catalog source on the IBM Fusion HCI cluster.
3. Deploy the **redhat-operators** catalog source in the Hosted Control Plane guest cluster.
This catalog source is required for the external operator dependencies that data services rely on, including:
 - MetallB
Provides bare metal load balancer support for the Hosted Control Plane cluster.
 - OADP (OpenShift® API for Data Protection)
Required for backup and restore operations.

Installing the IBM Fusion base

Procedure to install the IBM Fusion base on a Hosted Control Plane cluster.

About this task

Note: If you plan to use IBM Maximo® in Hosted Control Plane with IBM Fusion, log in to the Hosted Control Plane cluster and deploy Fusion operator.
For the procedure to install IBM Fusion on Bare Metal, see [Installing IBM Fusion HCI](#).

- Install Backup & Restore Spoke. See [Backup & Restore spoke](#)

Procedure

1. Log in to the OpenShift® Container Platform web console of the IBM Fusion HCI hub, and select All clusters.
 2. Go to Infrastructure > Clusters.
The Clusters page is displayed, and the Cluster list tab is open by default.
 3. Go through the list of the associated clusters and their details.
 4. You can click the name value link of the cluster to view more information.
In the cluster details page, the Overview tab is open by default.
 5. In the Overview tab page, edit the Labels to include `isf.ibm.com/fusion-base`, and click Save.
- Alternatively, you can edit the label by using the `oc` commands:

- a. Log in to the hub cluster.

```
oc login to the hub cluster
```

- b. Add label `isf.ibm.com/fusion-base` to the hosted control plan clusters on hub to auto install IBM Fusion consumer cluster:

```
oc label managedcluster <consumer_cluster_name> isf.ibm.com/fusion-base=''
```

Installing Fusion Data Foundation on a Hosted Control Plane cluster

Install the Fusion Data Foundation client as the storage type for the hosted cluster.

Before you begin

- Ensure that the `isf.ibm.com/fusion-base` label is present on the hosted cluster. If the label is not present, install IBM Fusion on the hosted cluster. For more information about the steps to install the IBM Fusion base, see [Installing the IBM Fusion base](#).
- Ensure that [prerequisites for Hosted Control Plane clusters](#) are met.

Remember: Fusion Data Foundation is supported on hosted clusters running OpenShift® Container Platform versions N, N-1, N-2, N-3, and N-4, where N is the OpenShift Container Platform version on the hub cluster.

About this task

During the installation of the Fusion Data Foundation client, you can set a storage quota to limit its storage usage.

If the storage quota not assigned during installation, then the storage quota defaults to unlimited for Fusion Data Foundation versions 4.17 and higher.

After the storage quota is set, you cannot reduce it later. Therefore, it is recommended to allocate required storage quota for Fusion Data Foundation clients during the installation of the hosted clusters to ensure the better storage management. For more information about how to set the quota value, see [step 4](#).

Procedure

1. Log in to the OpenShift Container Platform web console and select All clusters.
2. From the Infrastructure menu, select the Clusters tab.
The Cluster list page appears.
3. In the Cluster list tab, click the ellipsis menu of the required cluster and select Edit labels.
The Edit labels window appears.
4. To allocate a specific storage quota for the Fusion Data Foundation client, do one of the following methods before adding the `isf.ibm.com/fusion-fdf` label:
Important: If you skip this step and proceed to [step 5](#), the storage quota is set to unlimited by default for this Fusion Data Foundation client (if version is 4.17 or higher). Also, the `isf.ibm.com/fusion-fdf-quota` label appears on the Labels field.

- **By modifying the Labels field of the hosted cluster:**

- Add the `isf.ibm.com/fusion-fdf-quota=<value>` label specifying the required storage quota.

Remember: The storage quota value must match the pattern `<integer-value><Gi/Ti>`, such as 10Gi, 10Ti, or so on. Otherwise, an error message appears on the screen.

For example:

```
isf.ibm.com/fusion-fdf-quota=300Gi
```

Alternatively, if you can add the `isf.ibm.com/fusion-fdf-quota=<value>` label from the hub cluster by using the following `oc` command:

```
oc label managedcluster <consumer_cluster_name> isf.ibm.com/fusion-fdf-quota='300Gi'
```

- Click Save.

- **By modifying the configmap of the hub cluster:**

- Go to the hub cluster.
- Select the IBM Fusion namespace from the Project list.

For example, `ibm-spectrum-fusion-ns` namespace.

- Go to Workloads > ConfigMaps.
- Select the `fusion-addon-config` configmap and go to the YAML tab.
- Add the `default-fdf-storage-quota: <value>` parameter and click Save.

Remember: The storage quota value must match the pattern `<integer-value><Gi/Ti>`, such as 10Gi, 10Ti, or so on. Otherwise, an error message appears on the screen.

For example:

```
default-fdf-storage-quota: 200Gi
```

Important: This storage quota value is set as a default storage quota for all the hosted clusters associated with this hub cluster whenever you add the `isf.ibm.com/fusion-fdf` label. To override it, add the `isf.ibm.com/fusion-fdf-quota=<value>` label with the required value before adding the `isf.ibm.com/fusion-fdf` label.

- Go back to the All clusters > Infrastructure > Clusters.

The Cluster list page appears.

- Click the ellipsis menu of the required cluster and select Edit labels.

The Edit labels window appears.

5. In the Edit labels window, add the `isf.ibm.com/fusion-fdf` label and click Save.

Alternatively, if you can add the `isf.ibm.com/fusion-fdf` label from the hub cluster by using the following `oc` command:

```
oc label managedcluster <consumer_cluster_name> isf.ibm.com/fusion-fdf=''
```

The Fusion Data Foundation service starts to install automatically, and it might take 5–10 minutes to complete the installation.

Note: A notification appears after the successful installation.

6. Verify whether the Fusion Data Foundation client installation is complete and healthy as follows.

- a. Go to the IBM Fusion user interface of the hosted cluster and open the Services tab.

Ensure that the Fusion Data Foundation service status is healthy.

- b. On the Storage tab, check that the storage status shows as normal and the connection status shows as connected for the local storage.

- c. Go to the hub cluster in the OpenShift Container Platform web console and select the Storage Consumers tab under the Storage menu.

The Storage Consumers tab displays installed storage consumers with the allotted storage quota.

To increase the storage quota, see [Updating the storage quota of a Hosted Control Plane cluster](#).

If you face any issues during the installation of the Fusion Data Foundation client, see [Troubleshooting issues and known limitations in Hosted Control Plane cluster](#).

What to do next

To backup applications on the hosted cluster, see [Backup & Restore of applications in Hosted Control Plane clusters](#).

Updating the storage quota of a Hosted Control Plane cluster

Update the allotted storage quota of the Fusion Data Foundation client on a Hosted Control Plane cluster to meet the storage requirement of the application workloads.

Before you begin

Points to remember before starting this procedure:

- You can only increase the storage quota from a defined value to a higher limited value, such as from 90Gi to 100Gi, 100Gi to 200Gi, 9Gi to 1Ti, and so on.
- You cannot increase the storage quota from a defined value to unlimited.
- You cannot decrease the storage quota.
- You cannot modify the storage quota from unlimited to any specific value, as this action is considered a decrease.
- When you set the storage quota, it sets limits on the total storage consumption across the cluster. Therefore, while updating the storage quota, ensure that:
 - The value meets the storage requirements for all application workloads in the cluster.
 - The value meets the storage requirements of all PersistentVolumeClaims (PVCs), regardless of their state within the cluster.

About this task

Use this procedure if you have configured the storage quota for Fusion Data Foundation clients during their installation on hosted clusters and now need to increase it. For more information on storage quota configuration, see [Installing Fusion Data Foundation on a Hosted Control Plane cluster](#).

Whenever the storage consumption of a Fusion Data Foundation client exceeds 80% of its quota limit, you might face issues in creating new applications on the cluster.

You can verify the usage by checking the Storage quota utilization field on the Storage Consumers tab in the OpenShift® Container Platform web console.

If the client's storage consumption exceeds 80% of the quota, a warning icon appears next to the value of the Storage quota utilization field along with the StorageQuotaUtilizationThresholdReached alert. In such cases, increase the client's storage quota to clear the alert.

Note: To see the details of the StorageQuotaUtilizationThresholdReached alert, go to Notifications > Other Alerts.

Procedure

1. Log in to the OpenShift Container Platform web console and select All clusters.

2. Go to Infrastructure > Clusters.

The Cluster list tab appears on the screen.

3. Click the ellipsis menu of the required cluster and select Edit labels.

The Edit labels window appears on the screen.

4. Update the `isf.ibm.com/fusion-fdf-quota=<value>` with the required value.

Remember: The storage quota value must match the pattern `<integer-value><Gi/Ti>`, such as 10Gi, 10Ti, or so on. Otherwise, an error message appears on the screen.

For example:

Old storage quota value:

```
isf.ibm.com/fusion-fdf-quota=100Gi
```

New storage quota value:

```
isf.ibm.com/fusion-fdf-quota=1Ti
```

5. Click Save.
6. Verify that the Storage Consumers tab displays the updated storage quota for the client as follows.
 - a. Go to the hub cluster in the OpenShift Container Platform web console.
 - b. Select the Storage Consumers tab under the Storage menu.
 - c. Check whether the Storage quota field displays the updated storage quota and the value of the Storage quota utilization field is below 80%.

Results

The Storage Consumers tab displays the updated storage quota for the relevant storage client.

Installing Global Data Platform remote mount on the hosted cluster

From the IBM Fusion HCI hub cluster, install Global Data Platform remote mount on the hosted cluster so that applications can provision storage from a remote-mounted filesystem. It you can use a label-based approach for configuration of IBM Storage Scale CNSA cluster, similar to existing services.

Before you begin

- Install IBM Fusion consumer. The label `isf.ibm.com/fusion-base` is required before you add the Global Data Platform remote mount label.
- Meet all the prerequisites for the hosted cluster. See [Prerequisites for Hosted Control Plane clusters](#).

About this task

Note: Global Data Platform remote mount on Hosted Control Plane clusters is supported only on Bare Metal Hosted Control Plane clusters.

You can have a Data Foundation client alongside the CNSA remote service. The Backup & Restore service can be installed with remote-mounted filesystems and it can protect workloads using storage from remote-mounted filesystems.

Procedure

1. Log in to the OpenShift® Container Platform web console of the IBM Fusion consumer cluster.
2. Go to Operators > Installed operators.
3. Check whether the IBM Fusion consumer mode cluster is installed.
The Status changes from Installing to Succeeded.
4. On the hub cluster, go back to the cluster details > Overview tab page and edit the Labels to include `isf.ibm.com/fusion-gdp-rm`, and click Save.
Alternatively, you can edit the label from the hub cluster by using the following `oc` command:
Add label `isf.ibm.com/fusion-gdp-rm` to the hosted control plan clusters on hub to auto install IBM Fusion consumer cluster:

```
oc label managedcluster <consumer_cluster_name> isf.ibm.com/fusion-gdp-rm=''
```
5. Go to the IBM Fusion consumer cluster user interface and open the Services page.
The Global Data Platform remote mount starts to install automatically. If it does not, then refresh and wait for five to ten minutes.
6. Wait for the Global Data Platform remote mount installation to complete.
A notification is displayed confirming the success of the installation.
7. To backup applications on your hosted plan cluster, see [Backup & Restore of applications in Hosted Control Plane clusters](#).

Installing Backup & Restore on the hosted cluster

From the IBM Fusion HCI hub cluster, install Backup & Restore on the hosted cluster with Fusion Data Foundation as the storage type.

Before you begin

- Install IBM Fusion consumer and Fusion Data Foundation storage type.
- The label `isf.ibm.com/fusion-base` is required before you add `fusion-backup` label.
- If a specific storageclass is to be used during Backup & Restore installation, then do the following:
 1. Go to the OpenShift® Console on the Hub cluster.
Note: Changes made in `fusion-addon-config` ConfigMap is applicable to all Hosted Control Planes deployed on the Hub cluster.
 2. In the IBM Fusion namespace, locate the `fusion-addon-config` configmap.
 3. Add an entry:

```
backup-storage-class-name: "NameOfStorageClass"
```

To provide the custom storage class, update the followings fields:

```
data:
  clusters: |
    <cluster-name>: |
      "fusion-install-namespace": "ibm-spectrum-fusion-ns"
      "backup-storage-class-name": "<custom-storageclass-name>"
```

Example YAML:

```

apiVersion: v1
kind: ConfigMap
metadata:
  name: fusion-addon-config
  namespace: ibm-spectrum-fusion-ns
data:
  sds-catalog-source-image: <sds-image>
  storage-quota-min-supported-version: "v4.17"
  clusters: |
    cluster1: |
      "fusion-install-namespace": "ibm-spectrum-fusion-ns"
      "backup-storage-class-name": "ocs-storagecluster-ceph-rbd"
      "backup-restore-spoke-ns": "ibm-backup-restore"
    cluster2: |
      "fusion-install-namespace": "custom-ns"
      "backup-storage-class-name": "ocs-storagecluster-ceph-rbd"
      "backup-restore-spoke-ns": "ibm-backup-restore"

```

Note: If the storage class name is not filled, the Backup & Restore installation makes use of the default storage class on the hosted cluster, prioritizing a storage class with a volume snapshot class. The default values are same as that of the hub cluster values.

Procedure

1. Log in to the OpenShift Container Platform web console of the IBM Fusion HCI hub, and select All clusters.
2. Go to Infrastructure > Clusters.
The Clusters page is displayed and the Cluster list tab is open by default.
3. Go through the list of the associated clusters and their details.
4. You can click the name value link of the cluster to view more information.
In the cluster details page, the Overview tab is open by default.
5. In the Overview tab page, edit the Labels to include `isf.ibm.com/fusion-backup`, and click Save.
Use the default storage class that got created as a part of the Data Foundation for Backup & Restore.
Use the Backup & Restore to protect your applications but not the entire cluster.

Backup and restore of the Hosted Control Plane cluster

You can backup and restore your Hosted Control Plane cluster.

Red Hat® provides instructions for backing up and restoring the `etcd` database for Hosted Control Plane. For more information about this process, see [Red Hat Documentation](#) on Kubevirt platform.

- [Backup & Restore of applications in Hosted Control Plane clusters](#)
Using the Backup & Restore service, you can backup and restore your applications on Hosted Control Plane clusters.

Backup & Restore of applications in Hosted Control Plane clusters

Using the Backup & Restore service, you can backup and restore your applications on Hosted Control Plane clusters.

Backup and restore your applications on Hosted Control Plane clusters. Here, IBM Fusion HCI hub cluster is where you install the Backup & Restore hub service and Backup & Restore spoke is installed on the hosted cluster. For the steps to backup and restore, see [Backup & Restore overview](#).

Cleaning up of a Hosted Control Plane cluster

If you no longer need a hosted cluster, use this procedure to remove it.

Before you begin

- Get the cluster ID:
 1. Go to the Red Hat® OpenShift® console of the hosted cluster.
 2. Go to Home, > Overview and copy the Cluster ID from the Details section.
- Take a backup of the applications that you want to protect.
- Before you remove the Fusion Data Foundation service, ensure all workloads are stopped: delete the associated PVCs and clean up the storage namespace linked to it.

About this task

If the hosted cluster does not clean up after you remove the base or services label, then give it some time for the changes to take effect. If it still does not clean up, then see [Troubleshooting issues and known limitations in Hosted Control Plane cluster](#).

Procedure

1. On the hub cluster, go back to the hosted cluster details > Overview tab page and edit the Labels to remove `isf.ibm.com/fusion-backup`, and click Save.
2. Remove all the workloads that use Fusion Data Foundation storage classes.
Important: Fusion Data Foundation cannot be uninstalled if PVCs or VolumeSnapshots exist on the hosted cluster.

3. Edit the Labels again to remove `isf.ibm.com/fusion-fdf`, and click Save.
Remember: Removing the `isf.ibm.com/fusion-fdf` label also removes the `isf.ibm.com/fusion-fdf-quota=<value>` label, if available.
4. Do the following steps to verify the removal of the Data Foundation storage:
 - a. Go to the user interface of the IBM Fusion hosted cluster.
 - b. Confirm that the Data Foundation menu option is no longer available.
 - c. Go to the Services tab and check whether the Data Foundation service tile is available in the Get started section.
 - d. Go to the Red Hat OpenShift console of the hosted cluster and go to Storage > StorageClasses and verify whether all Data Foundation storage classes are removed.
 - e. Go to the Storage Clients tab and verify whether the storage client is removed.
Note: Removing the storage client may take up to 5 minutes.
5. To clean up the Global Data Platform remote mount, complete the following steps:
 - a. Delete all applications and PVCs that use storage classes provided by Global Data Platform remote mount.
Important: Global Data Platform remote mount cannot be uninstalled if applications and PVCs exist on the hosted cluster.
 - b. Remove the `isf.ibm.com/fusion-gdp-rm` label from the Hosted Control Plane cluster that you want to delete.
6. Delete the hosted cluster.
 - a. Log in to the OpenShift Container Platform web console of the IBM Fusion HCI hub, and select All clusters.
 - b. Go to Infrastructure > Clusters.
The Clusters page is displayed and the Cluster list tab is open by default.
 - c. Click the name value link of the cluster to view more information.
In the cluster details page, the Overview tab is open by default.
Alternatively, you can also select the Destroy clusters from the ellipses overflow menu of the cluster.
 - d. In the Actions menu, select Destroy clusters to remove the cluster.
 - e. In the Permanently destroy clusters window, go through details.
 - f. Enter the name of the cluster in the Confirm by typing "<cluster name>" below.
 - g. Click Destroy.
The cluster is removed and its components are deleted. The related namespace is also automatically deleted.
7. To verify the deletion of the hosted cluster, do the following steps:
 - a. Log in to the OpenShift Container Platform web console of the IBM Fusion HCI hub, and select All clusters.
 - b. Go to Infrastructure > Clusters.
The Clusters page is displayed and the Cluster list tab is open by default.
 - c. Go through the list of the associated clusters and confirm that the Cluster ID of the deleted hosted cluster does not exist.
8. Remove the Backup & Restore connection.
For the procedure to remove connections, see [Disabling the connection](#).

Troubleshooting issues and known limitations in Hosted Control Plane cluster

Use this troubleshooting information to resolve known issues with hosted control planes clusters, including installation, cleanup, backup, and storage problems.

Collecting must-gather data to troubleshoot Hosted Control Plane clusters

When you troubleshoot an issue with a Hosted Control Plane cluster, you can gather diagnostic information by running the **must-gather** command. For more information, see [Troubleshooting hosted control planes](#) in the Red Hat® OpenShift® Container Platform documentation.

Unable to delete internal and external bare metal Hosted Control Plane clusters using HCP CLI of Red Hat

Problem statement

When you use the HCP CLI, the hosted cluster does not get deleted. The cluster remains in a "destroying" state for over an hour.

Resolution

Check the pods logs of the hypershift namespace for error messages

PVCs on Hosted Control Plane clusters are stuck in terminating state

If PVCs on the Hosted Control Plane clusters are stuck in terminating state, then do the following steps for all applications that have PVCs associated to Fusion Data Foundation storage.

1. Scale down deployment of the PVC application to 0.
2. Delete application.
3. Check the PVC status to confirm whether it is deleted.
Note: Remove all PVCs from the applications before you remove the Fusion Data Foundation label.
4. Check whether the Fusion Data Foundation client on the Hosted Control Plane cluster is deleted.

Issues in hosted cluster clean up

Issues in Fusion base cleanup

If the hosted cluster does not clean up after you remove the base label (`isf.ibm.com/fusion-base`), then give it some time for the changes to take effect. If it still does not clean up, follow these steps to understand the cause of the issue:

1. Log in to the hosted cluster.
2. Go to pods in the `open-cluster-management-agent-addon` namespace.
3. Get the terminal access to the `fusion-cleanup-agent` pod.
4. Run the following **cleanup** script:

```
bash /scripts/sds/sds-cleanup.sh
```

5. If the script stuck at any resource deletion, remove the finalizer from that resource.

Issues in Fusion Data Foundation service clean up

Before you begin:

- Before you proceed with Fusion Data Foundation deletion, stop the backup service and clean up the associated PVCs.
- If Fusion Data Foundation sizes are large and workloads are running continuously, such as Cloud Pak or Watsonx, then do the following steps:
 1. Scale the pods down to zero.
 2. Stop the application.
 3. Delete the associated PVCs.

If the Fusion Data Foundation service does not clean up after you remove its label (`isf.ibm.com/fusion-fdf`), then give it some time for the changes to take effect. If it still does not clean up, follow these steps to understand the cause of the issue:

1. Log in to the hosted cluster.
2. Go to pods in the `open-cluster-management-agent-addon` namespace.
3. Get the terminal access to the `fusion-odf-cleanup-agent` pod.
4. Run the following **cleanup** script:

```
bash /scripts/odf/delete-fusion-odf.sh
```

5. If the script stuck at any resource deletion, remove the finalizer from that resource.

Issues in Backup & Restore service clean up

If the Backup & Restore service does not clean up after you remove its label (`isf.ibm.com/fusion-backup`), then give it some time for the changes to take effect. If it still does not clean up, follow these steps to understand the cause of the issue:

1. Log in to the hosted cluster.
2. Go to pods in the `open-cluster-management-agent-addon` namespace.
3. Get the terminal access to the `fusion-bnr-cleanup-agent` pod.
4. Run the following **cleanup** script:

```
bash /scripts/backup-restore/uninstall-backup-restore.sh
```

5. If the script stuck at any resource deletion, remove the finalizer from that resource.

Pull image issue occurs during the installation of IBM Fusion in a hosted cluster

Problem statement

If a pull image issue occurs, ensure that the pull-secret for `cp.icr.io` is available to the Hosted Control Plane cluster.

Resolution

To check and update the pull-secret, do the following steps:

1. On the IBM Fusion HCI hub cluster, go to Administration > CustomResourceDefinition and search for `HostedCluster`.
2. Look for the instance that corresponds with the Hosted Control Plane cluster and open it in YAML view.
3. Search for `pullSecret` and note down the name of the secret.
4. In the clusters namespace, search for that secret and open it in edit mode.
5. Check to see whether the correct value of `cp.icr.io` is available. If not, modify the secret with the right value.
It can take a while to propagate. You may even have to approve the changes from the Compute > Nodes page of the Hosted Control Plane cluster.

It is recommended to install a Hosted Control Plane cluster with the following credentials:

- `cloud.openshift.com`
- `cp.icr.io`
- `quay.io`
- `registry.connect.redhat.com`
- `registry.redhat.io`

Issues in installation of IBM Fusion in a hosted cluster

Resolution

1. Check the status of `manifestwork fusion-install` in `clusternamespace` of the hub cluster:

```
oc login to the hub
oc get manifestwork fusion-install -n <spoke_cluster_name> -o yaml
```

2. If no error exists in the status of the `manifestwork`, check the status of IBM Fusion installation in the spoke cluster:

```
oc login to the spoke
oc get csv -n ibm-spectrum-fusion-ns
```

Issues in the installation of Fusion Data Foundation in the hosted cluster

Resolution

As a resolution, check the status of `manifestwork odfclient-install` in `clusternamespace` in the hub cluster:

```
oc login to the hub
oc get manifestwork odfclient-install -n <spoke_cluster_name> -o yaml
```

Backup issues in Hosted Control Plane with Fusion Data Foundation

Problem statement

Concurrent backups fail during a Velero snapshot with the following error message:

```
The operation has timed out because Velero has failed to report status.  
However, the backup phase is updated as 'DataTransferfailed.'
```

The timeout for Velero to pickup request is set to 30 minutes in the transaction manager.

Resolution

To resolve the issue, increase it to 60 minutes.

Hosted Control Plane cluster does not get created because of unavailability of IP addresses

Resolution

Check whether the installed load balancer has sufficient IP addresses for the Hosted Control Plane cluster. Check the `IPAddressPool` object for the IP range. Run the following command to check whether an IP is available:

```
oc get svc -A | grep LoadBalancer
```

Known issues and limitations

- During the installation or upgrade of the Hosted Control Plane, you might encounter an issue where the `control-plane-operator` pods restart continuously and increase in number in the `clusters-<hcp_name>` namespaces on the host cluster.
 - The use of the AMD GPU operator is currently not supported with Hosted Control Plane. Internal nodes with AMD GPUs can be installed into the hub cluster. Stand alone clusters with AMD GPUs can be managed by the multi-cluster engine. In case of external servers, you can run AMD GPUs only on the hub cluster and not on the Hosted Control Plane.
Note: This is a limitation of AMD/RH, and not that of IBM Fusion.
 - Random "image pull" failure can occur on the Hosted Control Plane due to secrets.
 - Sometimes, the hosted cluster status goes in offline mode after deletion. Contact IBM Support to resolve the issue.
 - The `hcp destroy` command can cause the hosted cluster to get stuck indefinitely during cleanup. Contact IBM Support to resolve the issue.
 - The YAML tab view on the OpenShift Container Platform console is not working as expected during the installation of the multi cluster engine operator.
 - The hosted clusters expect the `storageprofile` of the used storage class, but it is not available during cluster creation.
 - The following issues occur whenever you remove the disks and place them back in the rack:
 - Disks are not reflected in the node.
 - LVM cluster and Data Foundation go into a degraded state.
- As a resolution, restart the affected node.

Red Hat Red Hat OpenShift Virtualization

IBM Fusion enables the coexistence of containers and VMs, with Red Hat OpenShift Virtualization allowing VMs to be managed as Kubernetes resources. Beyond VM hosting, Fusion and Red Hat OpenShift Virtualization offer virtual machine mobility, backup and restore, and additional capabilities to ensure high availability and disaster recovery.

- [Overview](#)
The Red Hat OpenShift provides a platform for running virtual machines and container workloads side by side. It relieves you of maintaining separate infrastructure, platforms, tools, skills, and teams for virtual machines and containers. It also enables virtual machines to be managed with the same modern practices that are used for containers.
- [Red Hat Red Hat OpenShift Virtualization Sizing on IBM Fusion](#)
Sizing in Red Hat Red Hat OpenShift Virtualization is to arrive at the optimal configuration of the infrastructure resources to efficiently accommodate the number and types of virtual machines (VMs) you plan to deploy.
- [Setting storage for virtual machines](#)
Virtual machines use block storage and file storage.
- [Deploying Red Hat Red Hat OpenShift Virtualization Operator](#)
Procedure to deploy the Red Hat Red Hat OpenShift Virtualization Operator.
- [Managing virtual machines on Bare Metal Hosted Control Plane cluster](#)
In a Bare Metal Hosted Control Plane cluster, you create, delete, manage, clone, and monitor virtual machines.
- [Migrating VMs to Red Hat OpenShift Virtualization](#)
To move from traditional VM-based infrastructure to a Kubernetes-native environment, migrate virtual machines (VMs) to Red Hat OpenShift Virtualization (OSV), which integrates VMs and containers within the same platform.
- [Backup and restore of virtual machines](#)
IBM Fusion protects virtual machines from data loss and corruption by backing up the virtual machines regularly. The virtual machines can then be restored from a previous backup.
- [Creating a virtual machine by using Clone PVC](#)
A clone is an exact duplicate of an existing storage volume that can be used like any standard volume. You create a clone to capture a point-in-time snapshot of the data.
- [Disaster recovery for virtual machines](#)
Disaster Recovery of virtual machines involves creating regular backups, maintaining up-to-date replicas, and implementing robust failover mechanisms. Implementing failover mechanisms ensures high availability and minimizes potential data loss, reducing downtime, and ensuring long-term resilience against disasters.

Overview

The Red Hat® OpenShift® provides a platform for running virtual machines and container workloads side by side. It relieves you of maintaining separate infrastructure, platforms, tools, skills, and teams for virtual machines and containers. It also enables virtual machines to be managed with the same modern practices that are used for containers.

IBM Fusion provides high-performance infrastructure, storage, encryption at rest, and resiliency to run virtual machines on Red Hat OpenShift.

The RWX (ReadWriteMany) mode is crucial because it enables Live Migration for virtual machines in Red Hat OpenShift. With RWX block storage support, virtual machines can seamlessly move between nodes within the OpenShift cluster during Live Migration while maintaining the performance benefits of the block storage.

IBM Fusion HCI provides the infrastructure to run Red Hat OpenShift on Bare Metal- x86 compute workers, a high-speed network, and storage. The appliance is designed with redundancy in mind, allowing for servers, switches, and drives to fail without impacting virtual machines that run in the cluster. IBM Fusion HCI uses an IPI installation of Red Hat OpenShift, which enables the cluster to run without an external load balancer.

Virtual machine resiliency can be provided in the following ways:

- High availability is achieved by using three-way replication to mirror data across availability zones. It allows workloads to continue to run even when storage infrastructure fails.
- RWX storage enables Live Migration, which allows virtual machines to be moved between nodes in the cluster.
- Backup capabilities protect virtual machines from data loss or corruption, enabling them to be restored to an earlier point in time. You can restore the virtual machines to an alternative cluster to recover from a complete cluster failure or practice recovery.

Red Hat Red Hat OpenShift Virtualization Sizing on IBM Fusion

Sizing in Red Hat® Red Hat OpenShift Virtualization is to arrive at the optimal configuration of the infrastructure resources to efficiently accommodate the number and types of virtual machines (VMs) you plan to deploy.

With proper sizing, your infrastructure can efficiently manage the expected workload, allowing you to allocate the right resources to optimize both performance and cost.

Sizing considerations

Some of the factors that influence the sizing of virtual machines on IBM Fusion are as follows:

CPU

The number of vCPUs depend on the computational demands of your VMs. VMs that run resource-intensive applications or multiple workloads require more vCPUs to perform efficiently.

Memory

Memory allocation is crucial for VMs to run smoothly and must be sized according to the specific workload requirements of each VM. Applications that perform data-intensive operations or handle large in-memory datasets require more memory to maintain optimal performance.

Storage

The storage depends on the volume of data that each VM is expected to handle. It includes the storage for operating systems, application data, and any additional storage for backups or high-availability configurations.

Networking

While not directly affecting the number of VMs, network bandwidth and latency are crucial for the performance of VMs, especially in environments with high data transfer rates or low-latency requirements.

Workload Characteristics

The type of applications and their resource usage patterns significantly impact the sizing considerations. For example, CPU-bound, memory-bound, I/O-bound.

Redundancy and High Availability

Configurations for redundancy and high availability (HA) may require additional resources, such as extra storage or memory, to help ensure that VMs can failover without service interruption.

Extra capacity considerations

When you plan your sizing, consider the capacities that are needed for CoreOS, OpenShift® Container Platform, and IBM Fusion HCI to ensure that your VMs have access to the necessary resources.

Go through the following resource requirements for the various components:

OpenShift Container Platform

[OpenShift Container Platform Resource Requirements](#)

Data Foundation

<https://ibm.com/docs/en/fusion-software/2.10.0?topic=foundation-planning-fusion-data-deployment>

Before you allocate resources to VMs, subtract these overhead values from your total available resources.

- [Sizing calculator](#)
Use the following formulas to provide an estimated infrastructure for VM deployments. Considering the overhead and high availability, these estimates offer a close approximation for effective resource planning.

Sizing calculator

Use the following formulas to provide an estimated infrastructure for VM deployments. Considering the overhead and high availability, these estimates offer a close approximation for effective resource planning.

Expected input

Number of VMs

Total number of virtual machines planned.

VM Types

Are the VMs of the same type or different types with distinct vCPU, Memory, and Storage requirements?

Formulas

- CPU Capacity:** The following formula calculates the total vCPU capacity that is available for VMs. Subtract the overhead for control plane and other necessary services:

$Total\ Available\ (vCPUs) = (vCPUs_per_node \times node_count - control_plane_requirements - overhead) \times (1 - ha_reserve_percent) \times (overcommit_ratio)$

Parameter	Description
vCPUs_per_node	The number of vCPUs per compute node. For example, with 64 cores and 2 threads per core, you would have 128 vCPUs per node.
node_count	The number of compute nodes.
control_plane_requirements	CPU is reserved for control plane functions.
overhead	Overhead for management services. For example, Data Foundation in IBM Fusion.
ha_reserve_percent	Percentage of capacity reserved for high availability.
overcommit_ratio	Factor to consider when you overcommit CPU resources. For example, 4:1.

- Memory Capacity:** Similarly, the memory capacity calculation accounts for the overhead and reserves for high availability:

$Total\ Available\ Memory\ (GiB) = (total_node_memory \times node_count - control_plane_requirements - overhead) \times (1 - ha_reserve_percent)$

Parameter	Description
total_node_memory	Total physical memory per compute node.
control_plane_requirements	Memory reserved for control plane operations.
overhead	Overhead for management services. For example, Data Foundation in IBM Fusion.
node_count	Number of compute nodes.
ha_reserve_percent	Percentage of memory reserved for high availability.

- Storage Capacity:** Storage capacity is calculated after accounting for the overhead needed for management and other services:

$Total\ Available\ Storage\ (TiB) = total_storage_capacity - storage_overhead$

Parameter	Description
total_storage_capacity	Total storage capacity available.
storage_overhead	Overhead for management services and storage redundancy.

Example

Table with example VM specification:

VM specification	Description
50 VMs of Type 1	Each VM requires 2 vCPUs, 8 GiB of memory, and 100 GiB of storage.
20 VMs of Type 2	Each VM requires 4 vCPUs, 16 GiB of memory, and 200 GiB of storage.

Table with example infrastructure Resources (Before Overhead and HA)

Infrastructure Resources (Before Overhead and HA)	Description
Compute Nodes	13 nodes, each with 64 cores and 2 TB (2048 GiB) of memory.
Total Raw Storage	16 nodes (13 compute + 3 control), each with 10 disks of 7.68 TiB each.

Table with example overhead and high availability reserves

Overhead and high availability reserves	
CPU: Overhead	32x4 = 128 (assuming each core provides 4 vCPUs) reserved for management services.
CPU: High Availability (HA) Reserve	20% of the remaining vCPUs.
CPU: Control Plane Requirements	4x4= 16 vCPUs (assuming each core provide 4 vCPUs) reserved for control plane operations.
Memory: Overhead	72 GiB reserved for management services.
Memory: High Availability (HA) Reserve	20% of the remaining memory.
Memory: Control Plane Requirements	24 GiB reserved for control plane operations.
Storage: Total Raw Storage	16x10x7.68 TiB = 1228.8 TiB
Storage: Usable Storage After 3-Way Replication	(1228.8)/3 TiB = 409.6 TiB
Storage: Storage Overhead	Assume 10% overhead for management services and system needs: 40.96 TiB
Storage: Total Available Storage After Overhead	Total Available Storage= (Total Usable Storage) - (Storage Overhead)= 409.6 TiB - 40.96 TiB= 368.64 TiB

Table showing CPU calculation

CPU	Value
Total Physical CPU Cores	Total Physical CPU Cores= 64x13= 832 cores
Total vCPUs	256x13 = 3328 vCPUs (assuming each core provides 4 vCPUs, per node would be 64x4 = 256)
Control Plane Requirements	4x4= 16 vCPUs (assuming each core provide 4 vCPUs) are reserved for control plane operations.
Overhead	32x4 = 128 (assuming each core provides 4 vCPUs) are reserved for management services.
High Availability (HA) Reserve	20% of the remaining vCPUs.
Total Available vCPUs After Control Plane, Overhead, and HA Reserve	Total Available (vCPUs) = (vCPUs_per_node x node_count - control_plane_requirements - overhead) x (1-ha_reserve_percent) x (overcommit_ratio)

CPU	Value
Substituting the values	Total Available vCPUs = $(3328 - 16 - 128) \times 0.8 \times 4 = 10188.8$ vCPUs (Overcommit ratio is assumed to be 4:1) Rounding it down to 10189 vCPUs available for VM deployments.
Comparison with Available CPU	180 vCPUs required < 10189 vCPUs available. Rounding it down to 10189 vCPUs available for VM deployments.

Result: The infrastructure has sufficient CPU resources to support the required VMs even after considering the control plane requirements.

Table showing memory calculation

Memory	Values
Total Physical Memory	Total Physical Memory=2048×13=26624 GiB
Control Plane Requirements	24 GiB reserved for control plane operations.
Overhead	72 GiB reserved for management services.
High Availability (HA) Reserve	20% of the remaining memory.
Total Available Memory After Control Plane, Overhead, and HA Reserve	$Total\ Available\ Memory\ (GiB) = (total_node_memory \times node_count - control_plane_requirements - overhead) \times (1 - ha_reserve_percent)$
Substituting the values	Total Available Memory (GiB)=(2048×13 – 24 – 72) × 0.8= 26528×0.8= 21222.4 GiB Rounding it down to 21222 GiB available for VM deployments.
Comparison with Available Memory	720 GiB required < 21222 GiB available

Result: The infrastructure has sufficient memory resources to support the required virtual machines even after considering the control plane requirements, overhead, and HA.

Table showing storage calculation

Storage	Values
Total Raw Storage	Total Raw Storage=16×10×7.68 TiB= 1228.8 TiB
Total Usable Storage After 3-Way Replication	Total Usable Storage=(1228.8)/3 TiB= 409.6 TiB
Storage Overhead	Storage Overhead= 40.96 TiB
Total Available Storage After Overhead:	Total Available Storage=409.6 TiB – 40.96 TiB= 368.64 TiB
Total Storage required for Type 1 VMs:	Storage for Type 1 VMs= 50×100 GiB= 5000 GiB= 5 TiB
Total Storage required for Type 2 VMs:	Storage for Type 2 VMs= 20×200 GiB= 4000 GiB= 4 TiB
Total Storage required for all VMs:	Total Storage required= 5 TiB+4 TiB= 9 TiB
Comparison with Available Storage:	9 TiB required < 368.64 TiB available

Conclusion

- CPU: 10189 vCPUs available; 180 vCPUs required (Sufficient)
- Memory: 21222 GiB available; 720 GiB required (Sufficient)
- Storage: 368.64 TiB available; 9 TiB required (Sufficient)

The infrastructure can support the deployment of 50 Type 1 VMs and 20 Type 2 VMs, with sufficient CPU, memory, and storage resources. These resources are available after accounting for overhead and high availability reserves.

Setting storage for virtual machines

Virtual machines use block storage and file storage.

Block-mode storage through the `ocs-storagecluster-ceph-rbd-virtualization` storage class is recommended as it provides optimized performance for block IO.

However, for Windows VMs, it is always recommended to use `ocs-storagecluster-ceph-rbd-virtualization` storage class. If you use the `ocs-storagecluster-ceph-rbd` storage class, then Windows VMs may report bad CRC or signature errors due to I/O patterns. The performance of the cluster performance can degrade due to excessive re-transmissions caused by CRC errors that leads to network saturation.

VMs must request RWX storage so that they can be moved between nodes non-disruptively using Live Migration.

- File storage is supported for virtual machines, but it lacks the performance advantage of block storage.
- RWO volumes are supported for virtual machines but are not recommended, as they block Live Migration. VMs using RWO volumes cannot move between nodes without causing disruption.

For more information about live migration, see [Live migration for virtual machines](#).

Fusion Data Foundation can be configured for encryption, with keys managed within the OpenShift® cluster or by an external Key Management Service (KMS). For more information about encryption, see [Preparing to connect to an external KMS server in Fusion Data Foundation](#).

Deploying Red Hat Red Hat OpenShift Virtualization Operator

Procedure to deploy the Red Hat® Red Hat OpenShift Virtualization Operator.

About this task

Red Hat OpenShift Virtualization provides a platform to bring virtual machines (VMs) into containerized workflows by running a virtual machine within a container where you develop, manage, and deploy virtual machines side-by-side with containers in one platform. For more information about how to create and manage VMs, see [Red Hat OpenShift Virtualization](#) and [What you can do with Red Hat OpenShift Virtualization](#).

A list of example VM features that the Red Hat Red Hat OpenShift Virtualization supports:

- Create and manage Linux and Windows virtual machines
- Connect to virtual machines through a variety of consoles and CLI tools
- Import and clone existing virtual machines
- Manage network interface controllers and storage disks attached to virtual machines

Procedure

1. Go to the Red Hat OpenShift® Container Platform Operator Hub.
2. Search for Red Hat OpenShift Virtualization.
3. Install the Red Hat OpenShift Virtualization Operator.
4. Configure the installation parameters to either custom or recommended namespace.
5. Wait for the installation to complete.
6. Go to Red Hat OpenShift Virtualization in Installed Operators page and click Create Hyperconverged to configure the Hyperconverged resource.
Note: When you create the **HyperConverged** CR, ensure you configure the appropriate eviction strategy for your virtual machines in the **HyperConverged** CR. For more information, refer to the [Eviction strategy documentation](#).
7. When the Operator deployment is complete go to Installed Operators and look for Red Hat OpenShift Virtualization within the **openshift-cnv** or your namespace.
8. Check whether the status is successful.
A new Virtualization menu appears. It indicates that your cluster is now ready to deploy virtual machines within a project /or namespace of your choice.

What to do next

- You can create virtual machines with any default size or custom sizes.
For more information about how to deploy and manage virtual machines on Bare Metal clusters, see [Managing virtual machines on Bare Metal Hosted Control Plane cluster](#).
- Use **ocs-storagecluster-ceph-rbd-virtualization** storage class for the OS disk of VMs. For more information about setting storage, see [Setting storage for virtual machines](#).
- Optionally, create a VLAN of type Virtualization VLAN and add the created VLAN to Link. If the primary pod network in OpenShift Virtualization becomes congested, you can improve performance by isolating that traffic onto a dedicated secondary network. For more information about dedicated secondary network, see [Creating dedicated secondary Network in Virtualization](#).
- **Configuring GPU access with NVIDIA vGPU**
NVIDIA vGPU technology enables a single physical GPU to be divided into multiple virtual instances, allowing multiple virtual machines to share GPU resources. This improves GPU utilization, reduces infrastructure costs, and maintains performance isolation for AI, data analytics, and graphics workloads.

Configuring GPU access with NVIDIA vGPU

NVIDIA vGPU technology enables a single physical GPU to be divided into multiple virtual instances, allowing multiple virtual machines to share GPU resources. This improves GPU utilization, reduces infrastructure costs, and maintains performance isolation for AI, data analytics, and graphics workloads.

Important: Ensure that your GPU hardware is supported by NVIDIA vGPU technology. To get the complete list of supported GPU cards, see [NVIDIA documentation](#).

For the procedure to configure NVIDIA vGPU for virtual machines in Red Hat OpenShift Virtualization, see [NVIDIA documentation](#).

Important: While you follow the [NVIDIA documentation](#), take note of the following two steps that must be done differently:

1. To enable sandbox workloads for vGPU, you must configure additional parameters in the **ClusterPolicy** for the GPU operator.

```
sandboxWorkloads.enabled=true
sandboxDevicePlugin.enabled=true
sandboxWorkloads.defaultWorkload=vm-vgpu
vfioManager.enabled=false
```

2. After completing the step creating a **ClusterPolicy** for the GPU operator in the [NVIDIA documentation](#), you must label the GPU node with the specific vGPU device profile.

```
oc label node <gpu-node-name> \
  nvidia.com/vgpu.config=<vgpu-device-name> \
  --overwrite
```

Replace **<gpu-node-name>** with the name of your GPU-enabled node, and **<vgpu-device-name>** with the vGPU profile that you want to enable. For example, on NVIDIA RTX Pro 6000 Blackwell GPUs, a valid vGPU profile is **DC-48Q**. You can find the appropriate **vgpu-device-name** in the **default-vgpu-devices-config ConfigMap**, or in a custom **ConfigMap** if created.

To identify the correct profile, search for the **device_id** that matches your GPU, using the last four characters of the device ID as a reference.

Managing virtual machines on Bare Metal Hosted Control Plane cluster

In a Bare Metal Hosted Control Plane cluster, you create, delete, manage, clone, and monitor virtual machines.

1. Provision a Bare Metal Hosted Control Plane cluster. For the procedure, see [Deploying Bare Metal clusters with Fusion Data Foundation](#).
2. Install Fusion Data Foundation service. See [Installing Fusion Data Foundation on a Hosted Control Plane cluster](#).
3. Install Red Hat OpenShift Virtualization operator.
For the procedure to install Red Hat OpenShift Virtualization operator, see [Deploying Red Hat Red Hat OpenShift Virtualization Operator](#).
4. After the cluster is available, deploy virtual machines on it. You can deploy VMs using default or custom sizes based on resource needs. For more information about the steps to create virtual machines from OpenShift console, see [Red Hat documentation](#).

5. After the VMs are in running state, manage their lifecycle, such as clone, monitor, and decommission tasks.
For more information about these management tasks, see [Creating a virtual machine by using Clone PVC](#) and [Deleting virtual machines Red Hat Documentation](#).

Migrating VMs to Red Hat OpenShift Virtualization

To move from traditional VM-based infrastructure to a Kubernetes-native environment, migrate virtual machines (VMs) to Red Hat OpenShift Virtualization (OSV), which integrates VMs and containers within the same platform.

- [Migrating VMs from VMware vSphere to OpenShift](#)
Red Hat OpenShift Virtualization supports the migration of VMs from VMware vSphere to OpenShift®.

Migrating VMs from VMware vSphere to OpenShift

Red Hat OpenShift Virtualization supports the migration of VMs from VMware vSphere to OpenShift®.

Before you begin

- Ensure that the internal OpenShift registry setup is complete. Use an OpenShift internal registry image from a single namespace to provision workloads across multiple namespaces. After the internal OpenShift registry setup is complete, follow this procedure to use an OpenShift internal registry image that is stored in a single namespace to provision workloads across desired namespaces.
- Deploy the Migration Toolkit for Virtualization (MTV) operator. For more information about deploying MTV operator, see [Installing the Migration Toolkit for Virtualization](#).

About this task

Red Hat OpenShift Virtualization supports the migration of VMs from VMware vSphere to OpenShift. To accelerate this process, it uses Virtual Disk Development Kit (VDDK) images. VDDK enables faster, block-level access to VM disks, reducing transfer times by skipping unused data and improving overall performance. It is useful for large VMs or bulk migrations. For more information about how to build and configure the VDDK image, see [OpenShift](#).

Note: In this procedure, Origin Namespace refers to where the internal image is stored and Destination Namespace refers to where the image are pulled and used by pods.

Procedure

1. Create a Service Account in the destination namespace.
It is the namespace where your pods run and provides access to the image.

```
oc create serviceaccount registry-puller -n <destination-namespace>
```
2. Create an Image Pull Secret in the destination namespace.
Go through the internal OpenShift registry and provide your credentials.

```
oc create secret docker-registry registry-pull-secret \
  --docker-server=<internal-openshift-image-registry> \
  --docker-username=<your_username> \
  --docker-password=<your_password> \
  --docker-email=<your_email> \
  -n <destination-namespace>
```
3. Link the Secret to the Service Account in the destination namespace.

```
oc secrets link registry-puller registry-pull-secret --for-pull -n <destination-namespace>
```
4. Grant Permission to the Service Account to Pull from the origin namespace.
It allows the service account in the destination namespace to pull images from the origin namespace.

```
oc adm policy add-role-to-user system:image-puller \
  system:serviceaccount:<destination-namespace>:registry-puller \
  -n <origin-namespace>
```

High-availability of virtual machines

High availability of virtual machines (VMs) ensure critical applications and services are available even in the event of unplanned scenarios.

IBM Fusion supports the following features for the high availability of VMs.

Live Migration

Use live migration to move VMs from one host to another without downtime. This is useful for load balancing and maintenance. See [Live migration for virtual machines](#).

Failover Clustering

Configure VMs in a failover cluster, which allows VMs to automatically restart on a different host if the original host fails. It is very useful in the event of any unexpected hardware failures or other unplanned incidents. See [Virtual machine failover](#).

Live migration for virtual machines

High availability of virtual machines can be achieved by live migration as the virtual machine continues to be operative and accessible. Live migration is the process of moving a virtual machine that is running from one physical host to another seamlessly without interrupting the workload.

Before you begin

In the `openshift-cnv` namespace, edit the `HyperConverged` CR and add the necessary live migration parameters:

```
oc edit hyperconverged kubevirt-hyperconverged -n openshift-cnv
```

Example:

```
apiVersion: hco.kubevirt.io/v1beta1
kind: HyperConverged
metadata:
  name: kubevirt-hyperconverged
  namespace: openshift-cnv
spec:
  liveMigrationConfig:
    bandwidthPerMigration: 64Mi
    completionTimeoutPerGiB: 800
    parallelMigrationsPerCluster: 5
    parallelOutboundMigrationsPerNode: 2
    progressTimeout: 150
```

About this task

Manually initiate a live migration of a virtual machine instance to another node using either the web console or the CLI. To know more about live migration, see [Red Hat® documentation](#).

If you want to offload live migration traffic from the default pod network to a dedicated secondary network using KubeVirt and Multus, see [Live migration over a dedicated secondary network](#).

Live migration from the user interface

Procedure

1. As an administrator user, log in to the OpenShift® Container Platform console.
2. Go to Virtualization > VirtualMachines.
3. Search for the virtual machine that you want to migrate.
4. Click the ellipses overflow menu of the virtual machine and select Migrate or you can go to the virtual machine Overview screen and select Migrate Virtual Machine from the Actions menu.
The status of the virtual machine changes from Running to Migrating.
5. After the migration completes, in the virtual machine details page, check the hosting node name to confirm the migration.

Live migration from the command line

Procedure

1. Create a migrate.yaml configuration file for the virtual machine instance to migrate.
migrate.yaml:

```
apiVersion: kubevirt.io/v1
kind: VirtualMachineInstanceMigration
metadata:
  name: {{ vm_name }}-migrate
  namespace: {{ namespace }}
spec:
  vmiName: {{ vm_name }}
```

Example:

```
apiVersion: kubevirt.io/v1
kind: VirtualMachineInstanceMigration
metadata:
  name: migration-job
  namespace: openshift-cnv
spec:
  vmiName: icsvm-storage-gui-kocmddajec
```

2. Apply the YAML file to initiate the migration.

```
oc apply migrate.yaml
```

Live migration over a dedicated secondary network

You can offload live migration traffic from the default pod network to a dedicated secondary network using KubeVirt and Multus.

Before you begin

- IBM Fusion with OpenShift® Virtualization installed.
- Multus and Whereabouts (for IPAM) enabled. The default is in OpenShift.
- KubeVirt CLI (**virtctl**) installed.

About this task

By default, all traffic including live migrations flows through the pod network. Though it works well for small workloads, it becomes a problem in production clusters where the migration traffic is memory-intensive or the pod network can become a bottle neck. Hence, as a solution you can route live migration traffic through a Secondary Network using NAD (Network Attached Definition).

Procedure

1. Create a VLAN.
For the procedure to create a VLAN, see [Adding VLANs](#).
2. Define the Migration Network using Network Attachment Definition (NAD).
Create a NetworkAttachmentDefinition (NAD) that represents the dedicated migration network in OpenShift Virtualization. For example, **virtualized-nad**.
 - a. Go to **Networking** in the OpenShift Web Console.
 - b. Click NetworkAttachmentDefinitions (NAD).
Ensure you are in the **openshift-cnv** namespace or the namespace used for KubeVirt components.
 - c. Click Create NAD.
 - d. Go to the YAML tab of your NetworkAttachmentDefinitions (NAD) and replace the **range**, **name**, and **bridge** values as per your environment.
 - e. Click Create to save and apply the NAD.
3. Configure Live Migration to use the secondary network.
After the NetworkAttachmentDefinition (NAD) is created, update the OpenShift Virtualization HyperConverged resource to instruct KubeVirt to use this secondary network for live migrations.
 - a. In the OpenShift web console, go to Operators > Installed Operators.
 - b. Select Red Hat OpenShift Virtualization from the list.
 - c. Click the HyperConverged tab and select the HCI resource. In general, it is **kubevirt-hyperconverged**.
 - d. Click Edit either through YAML or Form edit.
 - e. Locate or add **liveMigrationConfig** section and specify **network** parameter to match the name of your NAD. For example, **virtualized-nad**
4. Attach the Secondary Network (NAD) to your Virtual Machine.
 - a. Go to Virtualization > VirtualMachines.
 - b. Choose the VM (or create a new one) that you want to enable for live migration over the secondary network.
 - c. Click the VM name to open its details page.
 - d. Go to the Network Interfaces tab and click Add Network Interface.
 - e. Enter the following details:
 - Provide a Name. For example, **virtualized-nad**.
 - Enter the Model. The default is **virtio**.
 - In Network, select the previously created NAD in the **openshift-cnv** namespace. In this example, **virtualized-nad**.
 - Select Bridge or masquerade as per your setup. For live migration, it is Bridge.
 - f. Click Save and restart the VM if required.
5. Validate the live Migration over the secondary network.
 - a. Migrate the VM Manually:
 - Go to Virtualization > VirtualMachines.
 - Select the running VM.
 - Click Actions > Migrate to trigger a live migration.
 - b. Monitor the migration status using the UI or CLI and look for **Completed** or **Succeeded** status:

```
oc get vmim -n <namespace>
```
 - c. Monitor the IP Address:
 - i. Check for **TargetNodeAddress**.

```
oc get vmi <vm name> -o jsonpath='{.status.migrationState.targetNodeAddress}' -n <namespace>
```
 - ii. Check Virt-Handler Logs:

```
oc logs -n openshift-cnv <virt-handler-pod-name> -c virt-handler
```

Search for the following log lines:

```
proxy started listening ... outbound: <migNet-socket>
```
 - iii. Validate that the traffic used the secondary interface.
 - d. Verify the Network Interface on VM:

```
ip a
```

Ensure the secondary interface is attached and has an IP from the NAD. For example, **10.200.5.x** if using **whereabouts**.

Virtual machine failover

In IBM Fusion, you can achieve automatic failover during unplanned node failures by using MachineHealthCheck and Self Node Remediation operators. During Stage 2 of the IBM Fusion installation, the **computeInit** Custom Resource (CR) automates the full lifecycle of Workload Failover in OpenShift® environments. From installation to

cleanup, it interprets declarative intent and ensures that all dependent resources are created, updated, and tracked. It eliminates error-prone manual steps. Use this procedure to enable or disable the feature as needed. It is enabled by default during installation.

About this task

A node can be shutdown in a planned graceful way or unexpectedly because of reasons such as power outage or other external factors. A node shutdown could lead to workload failure if the node is not drained before the shutdown. A node shutdown can be either graceful or non-graceful.

Without VM failover automation, a worker node failure leaves the VMs on that node in a state of uncertainty, waiting for recovery. This downtime can cause the application to become unavailable until the node is back online. Using this workload failover feature, the VMs running on the failed node are automatically migrated to another available healthy node. It ensures high availability and minimizes downtime without user intervention. It does not cover live migration for maintenance or manual node migrations. For more information about live migration in IBM Fusion IBM Fusion HCI, see [Live migration for virtual machines](#).

Note: By default, the Workload Failover feature is enabled in the Compute Operator. You can use the following procedure to disable it and re-enable it later if needed.

Procedure

1. Go to the **ComputeInit** custom resource:
2. Open the **ComputeInit** CR.
 - In the OpenShift Console, go to **Administration > CustomResourceDefinitions**.
 - a. In OpenShift console, go to Administration > CustomResourceDefinition.
 - b. Search and open **ComputeInit** CR.
 - c. Select your CR instance and click YAML to edit.
3. Locate the **workloadFailover** section:

Example **workloadFailover** section:

```
workloadFailover:
  disableWorkloadFailover: false
  remediationStrategy: OutOfServiceTaint
  softwareRebootEnabled: false
  unhealthyConditionDuration: "15s"
  maxUnhealthy: "40%"
```

4. To disable, change the **workloadFailover** value of **disableWorkloadFailover** to **true** and save the CR.
If you want to enable the feature, change the value from **true** to **false** in the CR.
5. Re-enable the feature later, if needed:
 - a. Edit the **disableWorkloadFailover** field and set it to **false**:
disableWorkloadFailover: false
 - b. Save the CR.

Backup and restore of virtual machines

IBM Fusion protects virtual machines from data loss and corruption by backing up the virtual machines regularly. The virtual machines can then be restored from a previous backup.

Backup virtual machines

Backup policies define the frequency of backups, their storage locations, and the duration for which they must be retained. A best practice is to store backups in an object storage outside of the OpenShift® cluster, as this allows virtual machines to be recovered even when the original cluster is lost or compromised.

Virtual machine backups are incremental, meaning that only changed data is part of each backup. This approach reduces the amount of network traffic that is needed to transfer backups to object storage, and reduces the object storage requirements.

The IBM Fusion offers the following virtual machine backups through the Backup & Restore service.

In-place backup of virtual machine and Red Hat® OpenShift resources

Virtual machines can be restored in place, or in a different Red Hat OpenShift cluster.

Option to copy backup to object storage

Backups can be stored in object storage that is on a site or in the public cloud.

Integrated backup policy management

Virtual machines are protected by using backup policies, which define the frequency of backups, their storage locations, and the duration for which they must be retained.

Incremental backup of virtual machine

Only changes are included in each backup, reducing the amount of network traffic and object storage utilization.

To protect a group of virtual machines that represents an application, assign a backup policy to the namespace that the virtual machines belong to. It automatically backs up all the virtual machines in the namespace that uses the backup policy.

Note: A Red Hat OpenShift best practice is to create a namespace for a collection of virtual machines that represent an individual application.

To assign backup policies to an application that contains the virtual machines, go to the Applications page in the IBM Fusion user interface. Select the namespace that the virtual machines belong to and then assign a backup policy. Alternatively, you can manage backup policies declaratively by using the Custom Resources. It enables you to manage a large fleet of applications by using a GitOps approach, where a **PolicyAssignment** CR is deployed to the cluster alongside the application.

Restore virtual machines

To recover an application that is made up of virtual machines, select a backup to restore. Use the timestamp of each backup to select the appropriate point in time for restoration. The application can be restored in place, or you can restore the application to a different Red Hat OpenShift cluster.

IBM Fusion provides the following recovery options through its Backup & Restore service:

- You can recover a virtual machine to the same or alternative cluster.
- You can recover all virtual machines in a namespace to an alternative namespace and then delete the virtual machines that are no longer needed.
- You can recover all virtual machines in a namespace to an alternative namespace and then copy files from the target virtual machine by using the command line.
- You can manage the assignment of a backup policy to a high volume of virtual machines by directly working with the Fusion data protection custom resources, specifically the resources that are used to create backup policies and backup policy assignments.
- You can restore subsets of virtual machines that belong to an application by using the following two methods:
 - You can restore the entire application into an alternative namespace and then delete the virtual machines that are no longer needed.
 - You can restore the entire application into a namespace to an alternative namespace and then copy files from the target virtual machine by using the command line.

To validate, restart the virtual machine after recovery.

Achieving data consistency for virtual machine workloads

Achieving data consistency for virtual machines by using file system consistency, crash consistency, or application consistency approaches. For more information, see [Achieving data consistency for virtual machine workloads](#).

Creating a virtual machine by using Clone PVC

A clone is an exact duplicate of an existing storage volume that can be used like any standard volume. You create a clone to capture a point-in-time snapshot of the data.

Procedure

1. Go to Virtualization > Virtual Machines.
2. Click Create virtual machine and select the option from template.
3. Select the virtual machine template used earlier to deploy on primary cluster and click disk source.
If the option does not exist, then click Customise virtual machine.
4. Click Clone PVC and select the PVC project (virtual machine namespace).
5. Select the PVC name.
6. Click Create virtual machine.

Disaster recovery for virtual machines

Disaster Recovery of virtual machines involves creating regular backups, maintaining up-to-date replicas, and implementing robust failover mechanisms. Implementing failover mechanisms ensures high availability and minimizes potential data loss, reducing downtime, and ensuring long-term resilience against disasters.

About this task

The topic provides the procedure on how to enable protection for virtual machines through disaster recovery by using IBM Fusion HCI/IBM Fusion.

Procedure

1. Set up Metro-DR configuration between two clusters.
For the procedure to set up, see [Configuring Metro-DR set up](#).
2. Enable disaster recovery protection for the virtual machine.
For the procedure to enable or enroll virtual machines for disaster protection, see [Enabling and disabling applications for Metro-DR](#). After the application is enrolled for disaster recovery, go the virtual machine Overview tab page and check whether the Metro status is synchronized in the Disaster recovery section. Go to the Replicated applications page to see the virtual machine with details of the primary and partner cluster.
Note: Before enabling disaster recovery protection for a virtual machine, remove any installation ISO volumes. These volumes are typically only required during the initial operating system installation and are not necessary for workload recovery. If an ISO volume must remain attached, reference the ISO persistent volume claim (PVC) directly using `persistentVolumeClaim` instead of creating an upload-based data volume.
3. From the IBM Fusion HCI user interface of the partner cluster, failover virtual machines.
Important: As a prerequisite for virtual machine failover, shut down the virtual machine on the primary cluster.
 - a. In the Red Hat® OpenShift® console of the partner cluster, go to Virtualization > Virtual Machines.
 - b. Search for the virtual machine and from the ellipsis overflow menu, select Stop.Before you delete a virtual machine, make sure to copy the YAML file so you can redeploy the virtual machine using that at a failover site. If you stopped the virtual machine before copying the YAML, restart it after the deployment.
For the procedure to failover, see [Failover applications from site 1 to site 2](#).
4. After the failover is complete, remove the original virtual machine from the primary cluster.
 - a. Go to the Red Hat OpenShift console of the original virtual machine on the primary cluster.
 - b. Go to Virtualization > Virtual Machines.
 - c. Search for the and from the ellipsis overflow menu, select Delete.
 - d. In the Delete VirtualMachine window, click Delete.
 - e. Select the resources of the virtual machine and click Delete.
5. Deploy the virtual machine on the current primary cluster.
 - a. In the virtualMachines page of the Open shift console, click create virtual machine and select the option with YAML.
 - b. Copy paste the YAML file copied from the original cluster.

The status of the newly deployed virtual machine is in Running state.

c. To validate, do the following steps:

- i. Go to Storage PersistentVolumeClaims and check whether the virtual machine is operational. Also, check whether the used capacity of the persistentvolumeclaim is correct.
- ii. Alternatively, check the Used (GiB) capacity column value of the virtual machine in the Applications page of IBM Fusion HCI user interface.

Note: If a virtual machine is created using Red Hat template catalogs, then you can also create Virtual Machine using Clone PVC option. For the procedure to clone, see [Creating a virtual machine by using Clone PVC](#).

6. Initiate the planned failback.

- a. Stop the virtual machine in the current primary cluster.
- b. Go to the the IBM Fusion HCI user interface of the partner cluster and failover the virtual machine.
For the procedure to The primary cluster reverts to the original primary where the virtual machine was set up originally.
- c. Remove the virtual machine from the current primary cluster.

7. Deploy the virtual machine on the partner cluster or the original primary cluster.

- a. In the virtualMachines page of the Open shift console, click create virtual machine and select the option with YAML.
- b. Copy paste the YAML file copied from the original cluster.

The status of the newly deployed virtual machine is in Running state.

c. To validate, do the following steps:

- i. Go to Storage PersistentVolumeClaims and check whether the virtual machine is operational. Also, check whether the used capacity of the persistentvolumeclaim is correct.
- ii. Alternatively, check the Used (GiB) capacity column value of the virtual machine in the Applications page of IBM Fusion HCI user interface.

Note: If a virtual machine is created using Red Hat template catalogs, then you can also create Virtual Machine using Clone PVC option. For the procedure to clone, see [Creating a virtual machine by using Clone PVC](#).

Advanced workloads

IBM Fusion is built to provide enterprise ready deployments for IBM Cloud Paks, IBM watsonx, IBM Maximo®, and Db2 Warehouse.

Every release of IBM Fusion HCI is validated with IBM watsonx to ensure that the infrastructure is compatible.

IBM Cloud Paks support for IBM Fusion

Mapping of IBM Cloud Paks with IBM Fusion.

IBM Cloud Paks	Version	Backup and restore support	Storage support	Hosted Control Plane
IBM Software Hub (formerly Cloud Pak for Data) Important: For virtualization, install the OpenShift® virtualization operator provided by Red Hat®. Do not install the KubeVirt HyperConverged cluster operator from the community operator catalog source. IBM watsonx support in IBM Software Hub: • watsonx Assistant • watsonx.ai • watsonx Code Assistant • watsonx Code Assistant for Red Hat Ansible Lightspeed • watsonx Code Assistant for Z • watsonx Code Assistant for Z Code Explanation • watsonx.data • watsonx.data Premium ◦ DataStax • watsonx.governance • watsonx Orchestrate	5.3.x or later	• Online backup and recovery to the same or alternate cluster using IBM Fusion • Backup and restore to the same cluster using IBM Software Hub native tools	• Global Data Platform • Fusion Data Foundation • IBM Software Hub storage considerations • Red Hat OpenShift Data Foundation	Supported See IBM Software Hub cloud deployment environments

IBM Cloud Paks	Version	Backup and restore support	Storage support	Hosted Control Plane
IBM Cloud Pak for Business Automation	24.0 or later	• Online backup and restore to same or alternate cluster using IBM Fusion • Backup and restore using IBM Cloud Pak for Business Automation native tools	• Global Data Platform • Fusion Data Foundation • IBM Cloud Pak for Business Automation storage considerations • Red Hat OpenShift Data Foundation	Not supported
IBM Cloud Pak for Integration	16.1.0 or later	• Backup and restore using IBM Cloud Pak for Integration native tools	• Global Data Platform • Fusion Data Foundation • IBM Cloud Pak for Integration storage considerations • Red Hat OpenShift Data Foundation	Supported See IBM Cloud Pak for Integration documentation
IBM Cloud Pak for AIOps	4.10.x or later	• Online backup and recovery to the same or alternate cluster using IBM Fusion • Backup and restore using IBM Cloud Pak for AIOps native tools	• Global Data Platform • Fusion Data Foundation • Storage considerations for IBM Cloud Pak for AIOps AI Manager • Red Hat OpenShift Data Foundation	Supported See IBM Cloud Pak for AIOps documentation
IBM Cloud Pak for Security	1.10 or later	Backup and restore using IBM Cloud Pak for Security native tools	• Global Data Platform • Fusion Data Foundation • IBM Cloud Pak for Security storage considerations • Red Hat OpenShift Data Foundation	Not supported
IBM Cloud Pak for Network Automation	2.6.x or later	Backup and restore using IBM Cloud Pak for Network Automation native tools	• Global Data Platform • Fusion Data Foundation • IBM Cloud Pak for Network Automation storage considerations • Red Hat OpenShift Data Foundation	Not supported

For the storage class to use with IBM Cloud Paks, IBM Storage Scale version (All), see [Storage class to use with Cloud Paks](#).

To use IBM Cloud Paks in IBM Fusion, the storage class must include `shared: true`.

- **[Validation tools for IBM Cloud Paks](#)**

Run the storage readiness and performance suites on your IBM Fusion environments. The suites run on OpenShift Container Platform to evaluate the setup and performance of your storage setup.

Validation tools for IBM Cloud Paks

Run the storage readiness and performance suites on your IBM Fusion environments. The suites run on OpenShift® Container Platform to evaluate the setup and performance of your storage setup.

Storage validation tool

Run the IBM Software Hub storage validation tool on your Red Hat® OpenShift cluster to verify your storage setup for use with IBM Software Hub. Set up your environment and before you install your IBM Cloud Paks, run the validation tool. For more information about the tool, see [storage validation tool](#).

Performance validation tool

Run the storage performance tool to ensure that your storage performs properly and you meet the recommended performance guidelines. Collect Storage performance metrics on your Red Hat OpenShift cluster. For more information about the tool, see [k8s-storage-perf GitHub repository](#).

As a prerequisite to run storage performance suite, run the following command to install selinux:

```
pip install selinux
```

The tool validates whether your performance (for example, network, environment) runs at a speed that enables IBM Cloud Paks to run successfully. An example of the output:

Summary	Cluster Name	PVC	Storage Type	Environment	Test Name	Thread Count	write MiB/s	Requirement
	storage-performance-cluster	pvc-sysbench-rwo	Scale	HCI	rndwr_4k_8	8	46.4	Recommended to meet the requirement of 11 MiB/s or higher
	storage-performance-cluster	pvc-sysbench-rwx	Scale	HCI	seqwr_1g_2	2	3766.0	Recommended to meet the requirement of 128 MiB/s or higher
	storage-performance-cluster	pvc-sysbench-rwo	Scale	HCI	seqwr_1g_2	2	3901.2	Recommended to meet the requirement of 128 MiB/s or higher
	storage-performance-cluster	pvc-sysbench-rwx	Scale	HCI	rndwr_4k_8	8	46.1	Recommended to meet the requirement of 11 MiB/s or higher

Here, the PVCs are running against the tests. The thread count specifies the number of simultaneous requests. The write Mb/s indicates the output.

Example of the partial output (from the "all" full metrics run) of a minimum IBM Fusion HCI configuration, that is, for a smallest environment. Depending on your configuration, environment, and network speed, the output would vary.

Summary														
Cluster Name	PVC	Storage Type	Environment	Test Name	Thread Count	write MiB/s	Requirement							
storage-perf	pvc-sysbench	Scale	HCI	rndwr_4k_8	8	46.4	Recommended to meet the requirement of 11 MiB/s or higher							
storage-perf	pvc-sysbench	Scale	HCI	seqwr_1g_2	2	3766	Recommended to meet the requirement of 128 MiB/s or higher							
storage-perf	pvc-sysbench	Scale	HCI	seqwr_1g_2	2	3901.2	Recommended to meet the requirement of 128 MiB/s or higher							
storage-perf	pvc-sysbench	Scale	HCI	rndwr_4k_8	8	46.1	Recommended to meet the requirement of 11 MiB/s or higher							
Detailed Measurements														
Cluster Name	PVC	Storage Type	Environment	Test Name	Thread Count	write MiB/s	Writes/s	read MiB/s	Reads/s	Total Time	Latency Min	Latency Avg	Latency Max	Latency 95th
storage-perf	pvc-sysbench	Scale	HCI	rndwr_4k_8	8	46.4	11893.6	0	0	10	0.3	0.7	95.8	1
storage-perf	pvc-sysbench	Scale	HCI	seqrd_1g_2	2	0	0	7380.8	7.2	10.2	217.2	279.6	583.2	555.4
storage-perf	pvc-sysbench	Scale	HCI	rndrd_4k_8	8	0	0	3142.7	804539.1	10	0	0	2.1	0
storage-perf	pvc-sysbench	Scale	HCI	seqwr_1g_2	2	3766	3.7	0	0	10.3	374.7	540	821.4	670.2
storage-perf	pvc-sysbench	Scale	HCI	seqwr_1g_2	2	3901.2	3.8	0	0	10.4	354.6	521.3	737	695.1
storage-perf	pvc-sysbench	Scale	HCI	rndwr_4k_8	8	46.1	11803.4	0	0	10	0.2	0.7	81.4	1.1
storage-perf	pvc-sysbench	Scale	HCI	seqrd_1g_2	2	0	0	7404.1	7.2	10.2	207.3	280.6	585.3	548.3
storage-perf	pvc-sysbench	Scale	HCI	rndrd_4k_8	8	0	0	3278.2	839227.1	10	0	0	37.7	0

Here, the cluster name is **storage-performance-cluster** of storage type **ocs**. The *Summary* section of the table also includes the requirement recommendations. In this example, for the **rndwr_4k_8** test, the write MiB/s is 46.4 and the recommended is 11 MiB/s or higher. In all the rows, the output is either 2X or more than 2X of the recommendation. It helps you validate whether your environment meets the recommended performance requirements for IBM Cloud Paks.

You can use this feature regardless of IBM Cloud Paks.

IBM Software Hub sizing in the Sales Configurator

The starting point is a minimum IBM Software Hub configuration. If you select services from the list for inclusion, it shows the minimum required configuration. For example, it displays the number of compute nodes, resource pools, and memory to deploy. It also lists the dependencies. For example, if you want to use Watson OpenScale, then you need Watson Machine Learning, Common Core Services, and Analytics Engine Powered by Apache Spark.

Note: Ensure that the IBM Fusion/storage sizing are also considered in your IBM Software Hub sizing.

To view the sales configurator, go to <https://app.ibm.sales.configurator.com/#/zen/configure>.

IBM Maximo® Applications support for IBM Fusion

Mapping of IBM Maximo® Applications with IBM Fusion.

IBM Maximo® Applications	Version	Backup & Restore support	Storage support	Hosted Control Plane
Maximo Core	9.1.x	Online backup and restore for Maximo Core using IBM Fusion	- Global Data Platform - Fusion Data Foundation - Red Hat® OpenShift® Data Foundation	- Supported on Bare Metal Hosted Control Plane - Supported on Virtualized Hosted Control Plane For more information about Hosted Control Plane with IBM Fusion, see IBM Maximo® on Hosted Control Plane.

IBM Maximo® Applications	Version	Backup & Restore support	Storage support	Hosted Control Plane
Maximo Manage	9.1.x	Online backup and restore for Maximo Manage using IBM Fusion	- Global Data Platform - Fusion Data Foundation - Red Hat OpenShift Data Foundation	- Supported on Bare Metal Hosted Control Plane - Supported on Virtualized Hosted Control Plane For more information about Hosted Control Plane with IBM Fusion, see IBM Maximo® on Hosted Control Plane.
Maximo Optimizer	9.1.x	Online backup and restore for Maximo Optimizer using IBM Fusion	- Global Data Platform - Fusion Data Foundation - Red Hat OpenShift Data Foundation	- Supported on Bare Metal Hosted Control Plane - Supported on Virtualized Hosted Control Plane For more information about Hosted Control Plane with IBM Fusion, see IBM Maximo® on Hosted Control Plane.
Maximo Health	Deployed as part of Manage	Online backup and restore for Maximo Health using IBM Fusion	- Global Data Platform - Fusion Data Foundation - Red Hat OpenShift Data Foundation	- Supported on Bare Metal Hosted Control Plane - Supported on Virtualized Hosted Control Plane For more information about Hosted Control Plane with IBM Fusion, see IBM Maximo® on Hosted Control Plane.
Maximo IOT	9.1.x	Online backup and restore for Maximo IOT using IBM Fusion	- Global Data Platform - Fusion Data Foundation - Red Hat OpenShift Data Foundation	- Supported on Bare Metal Hosted Control Plane - Supported on Virtualized Hosted Control Plane For more information about Hosted Control Plane with IBM Fusion, see IBM Maximo® on Hosted Control Plane.
Maximo Monitor	9.1.x	Online backup and restore for Maximo Monitor using IBM Fusion	- Global Data Platform - Fusion Data Foundation - Red Hat OpenShift Data Foundation	- Supported on Bare Metal Hosted Control Plane - Supported on Virtualized Hosted Control Plane For more information about Hosted Control Plane with IBM Fusion, see IBM Maximo® on Hosted Control Plane.
Maximo Predict	9.1.x	Online backup and restore for Maximo Predict using IBM Fusion	- Global Data Platform - Fusion Data Foundation - Red Hat OpenShift Data Foundation	- Supported on Bare Metal Hosted Control Plane - Supported on Virtualized Hosted Control Plane For more information about Hosted Control Plane with IBM Fusion, see IBM Maximo® on Hosted Control Plane.
Maximo Collaborate (formerly Assist)	9.1.x	Online backup and restore for Maximo Collaborate (formerly Assist) using IBM Fusion	- Global Data Platform - Fusion Data Foundation - Red Hat OpenShift Data Foundation	- Supported on Bare Metal Hosted Control Plane - Supported on Virtualized Hosted Control Plane For more information about Hosted Control Plane with IBM Fusion, see IBM Maximo® on Hosted Control Plane.
Maximo Visual Inspection Note: To check supported GPU models, see Maximo Visual Inspection documentation .	9.1.x	Online backup and restore for Visual Inspection using IBM Fusion	- Global Data Platform - Fusion Data Foundation - Red Hat OpenShift Data Foundation	- Supported on Bare Metal Hosted Control Plane - Supported on Virtualized Hosted Control Plane For more information about Hosted Control Plane with IBM Fusion, see IBM Maximo® on Hosted Control Plane.

For the general Maximo BR procedure, see <https://github.com/IBM/storage-fusion/tree/master/backup-restore/recipes/Maximo/2.9.x>.

- **IBM Maximo® Application Suite**
IBM Maximo® Application Suite is a collection of AI-driven asset management applications that gains enhanced backup, restore, and storage capabilities when deployed with IBM Fusion.
- **IBM Maximo® on Hosted Control Plane**
Use the IBM Maximo® IBM Operator catalog and monthly updates for the latest information about the Fusion operator.

IBM Maximo® Application Suite

IBM Maximo® Application Suite is a collection of AI-driven asset management applications that gains enhanced backup, restore, and storage capabilities when deployed with IBM Fusion.

IBM Maximo® Application Suite provides powerful AI-driven asset and analytics solutions for your enterprise needs.

IBM Maximo® Application Suite is a powerful collection of applications, industry solutions, add-ons, and tools.

When you deploy it from IBM Fusion, it enhances backup, restore, and storage capabilities across IBM Maximo® Application Suite.

Install

The IBM Maximo® CLI is the preferred way to install IBM Maximo® as it provides an automated deployment for this type of workload. For more information, see [IBM Maximo® KC](#) and [IBM Maximo® Application Suite CLI](#).

Tip: To customize IBM Maximo® Application Suite instances with extra features that might be unavailable in IBM Maximo® Application Suite CLI, you can use ansible-devops for advanced configuration. For more information, see [MAS Devops Ansible Collection](#).

For installation sizing calculator guidance, see [Sizing guidance](#).

Hosted Control Plane support

To install IBM Maximo® Application Suite on a Hosted Control Plane, see [IBM Maximo® on Hosted Control Plane](#).

Limitations

If you plan to use any IBM Maximo® application dependent on Kafka such as IOT and Monitor, do not use the Strimzi open source operator in conjunction with IBM Fusion Backup & Restore. Instead, use the Streams for Apache Kafka by Red Hat® (formerly AMQ-Streams). Ensure that you match the version available in the IBM Fusion Backup & Restore namespace with the Streams operator that you are planning to use for IBM Maximo® Application Suite. For more information about the limitations, see [IBM Maximo® limitations](#).

Backup & Restore is not supported for IBM Maximo® IoT, IBM Maximo® Monitor, and IBM Maximo® Predict, but they can be installed on any cluster that has Red Hat OpenShift Virtualization installed.

IBM Maximo® on Hosted Control Plane

Use the IBM Maximo® IBM Operator catalog and monthly updates for the latest information about the Fusion operator.

For the list of IBM Maximo® deployments, see [IBM Maximo® Applications support for IBM Fusion](#).

If you plan to use IBM Maximo® in Hosted Control Plane with IBM Fusion you must deploy Fusion operator and Fusion Services by logging into the Hosted Control Plane cluster and use the following procedure:

- Install IBM Fusion on Hosted Control Plane cluster. See [Installing IBM Fusion on On-premises Bare Metal](#).
- Install Fusion Data Foundation. See [Installing Fusion Data Foundation on the hosted cluster](#).
- Install Backup & Restore Spoke. See [Backup & Restore](#).

Install

The CLI is the preferred way to install as it provides an automated deployment for this type of workload. For more information, see [Maximo KC](#) and [MAS CLI](#).

Tip: To customize IBM Maximo® Application Suite instances with extra features that might be unavailable in IBM Maximo® Application Suite CLI, you can use ansible-devops for advanced configuration. For more information, see [Maximo Application Suite Devops Ansible Collection](#).

For installation sizing calculator guidance, see [Sizing guidance](#).

IBM watsonx

IBM Fusion HCI enables optimized Data and AI solutions. It is built to provide enterprise-ready deployments of IBM watsonx.

Up and running quickly with IBM Fusion HCI

IBM Fusion HCI provides a Bare Metal appliance to get up and running quickly with IBM watsonx. The hyper-converged solution provides Bare Metal compute nodes, GPU nodes, high-speed switches, and everything that you need to host your Data and AI platform. The automated installer deploys Red Hat® OpenShift®. High-performance container native storage is preconfigured to run IBM Software Hub that further simplifies the deployment.

Enterprise-grade resiliency for watsonx

IBM Fusion HCI is built with resiliency in mind. The appliance features a fully redundant networking, and its container native storage protects against node or drive failures by using erasure coding. The IBM watsonx configuration is protected and it uses built in backup and recovery capabilities to recover your IBM watsonx deployment to another cluster in an event of a disaster.

Accelerating watsonx.data queries with IBM Fusion HCI

IBM Fusion HCI accelerates watsonx.data queries by providing a high speed-distributed cache based on IBM technology that is used for High-Performance Computing. When you run queries, intelligent caching serves metadata and data, cutting down on the queries that go to the object storage.

- [Deploying watsonx.data capabilities](#)
The deployment of watsonx.data On-premises is supported by IBM Fusion HCI and IBM Storage Ceph, which provide all of the infrastructure that you need for your stand-alone data lakehouse.
- [Deploying watsonx.ai capabilities](#)
You can access watsonx.ai services on the IBM Fusion HCI.
- [Deploying IBM® watsonx.governance capabilities](#)
The deployment of IBM® watsonx.governance On-premises is supported by IBM Fusion HCI.

Deploying watsonx.data capabilities

The deployment of watsonx.data On-premises is supported by IBM Fusion HCI and IBM Storage Ceph, which provide all of the infrastructure that you need for your stand-alone data lakehouse.

Important: Do not install KubeVirt HyperConverged Cluster Operator. It can cause problems when you install IBM Software Hub software. IBM Fusion HCI is a hosting platform for IBM watsonx.data and it provides the following capabilities:

- Data sharing and self-service access
- Data caching to accelerate watsonx.data performance.
- Local S3 object store.
- IBM Storage Ceph provides an external S3 object store for watsonx.data. This S3 object store can be the main S3 object store for watsonx.data, or alongside S3 object store with other on-premise or public cloud object stores. The IBM Storage Ceph object storage interface (Ceph Object Gateway) is compatible with a large subset of the Amazon S3 RESTful API. For more information about IBM Storage Ceph, see <https://www.ibm.com/docs/en/storage-ceph/6>.
- Ability to include GPU servers in the IBM Watsonx solution

These high-level instructions show how to prepare IBM Fusion HCI so that you can install watsonx.data and make use of buckets with storage acceleration.

There are three main steps in this process:

For detailed information about planning, implementation, monitoring, and backup and restore, see [Accelerating IBM watsonx.data with IBM Fusion HCI Redpaper](#).

1. Upgrade OpenShift® Container Platform 4.14 or higher.
2. Configure the Multicloud Object Gateway that provides access to accelerated buckets.
The Multicloud Object Gateway (MCG) provides an object endpoint that watsonx.data and other workloads can connect to access multiple buckets, including storage acceleration buckets. The Multicloud Object Gateway is provided by the Red Hat® OpenShift Data Foundation operator.

Install the Red Hat OpenShift Data Foundation operator into Red Hat OpenShift Data Foundation.

- a. Search for Red Hat OpenShift Data Foundation in OperatorHub.
 - b. Install the Red Hat OpenShift Data Foundation operator.
 - c. Follow the instructions to [Deploy standalone Multicloud Object Gateway](#). When you are prompted for a StorageClass in *step 3 of section 3.3*, use the `ibm-storage-fusion-cp-sc` StorageClass that is configured by default in IBM Fusion HCI.
3. Configure Advanced File Management (AFM nodes) in the HCI appliance to enable storage acceleration.
IBM Fusion HCI uses special Advanced File Management (AFM) nodes to connect to external object storage and provide data caching that is used for storage acceleration. Install these AFM nodes in the IBM Fusion HCI. You must have already installed them as a part of setting up the physical appliance.

To use, add the AFM nodes to the OpenShift cluster. Follow the [Upsizing nodes](#) instructions to add the AFM nodes to the OpenShift cluster and configure them for storage.

Attach a storage accelerated bucket to a watsonx.data catalog:

- a. Create an AFM fileset and attach it to a bucket.
- b. Expose the accelerated bucket through the Multicloud Gateway.
- c. Connect the accelerated bucket to a catalog.
 - i. Log in to watsonx.data console.
 - ii. From the navigation menu, select Infrastructure Manager.
 - iii. To define and connect a bucket, click Add component and select Add bucket.
 - iv. In the **Add bucket** window, provide the details to connect to existing externally managed object storage.

Deploying watsonx.ai capabilities

You can access watsonx.ai services on the IBM Fusion HCI.

To use watsonx.ai on premises, purchase IBM Fusion HCI and install watsonx.ai application as part of IBM Software Hub. You can also install watsonx.ai on IBM Fusion HCI by using the IBM container registry through an operator.

For more information about watsonx.ai, see <https://www.ibm.com/products/watsonx-ai>.

The watsonx.ai is supported on a single IBM Fusion HCI with up to four G03 GPU nodes: Each node can have up to 8x H100 NVL 94GB GPU PCIe cards or 8x Nvidia L40S 48GB GPU cards (32 total GPU cards per rack).

Optionally, you can add tolerances for watsonx.ai workloads to run on the GPU nodes.

Important: Install KubeVirt HyperConverged Cluster Operator only from the Red Hat® Operators catalog. The version provided by the Community Operators catalog cause problems when you install the IBM Software Hub software.

IBM Fusion HCI is a hosting platform for watsonx.ai and it provides the following capabilities:

- Use the watsonx.ai user interface and REST API interfaces.
- Schedule regular online backups of a watsonx.ai instance to recover to an earlier point in time in the event of data loss or corruption.
- Monitor the model serving and tuning pipeline KPIs by using built in OpenShift® monitoring capabilities.

- Use the watsonx.ai health and performance monitoring through the IBM Software Hub common services.
- Extend the Backup & Restore service recipes of IBM Fusion HCI for the watsonx.ai component as well.

Note: In this release, watsonx.ai support is not available for high-availability IBM Fusion HCI.

Deploying IBM® watsonx.governance capabilities

The deployment of IBM® watsonx.governance On-premises is supported by IBM Fusion HCI.

The IBM® watsonx.governance includes tools for governing models and the usage resources for evaluating and explaining models. When you run model evaluations and explanations with IBM® watsonx.governance, you consume resources. Based on your requirements, set the amount of usage resources to consume.

An IBM Cloud Object Storage service instance gets automatically provisioned to provide storage for the assets you create or add to workspaces. Information in IBM Cloud Object Storage is encrypted and resilient. Each workspace has its dedicated bucket.

You can use IBM® watsonx.governance tools to govern models in the following ways:

- **Monitor and evaluate models:** You can monitor model output and explain model predictions. Your IBM® watsonx.governance model monitoring and evaluation tools are in projects and deployment spaces.
- **Track and document AI use cases:** You can view model lifecycle status, general model and deployment details, training information and metrics, and deployment metrics. Your IBM® watsonx.governance model tracking tools in AI use cases.

Important: Do not install KubeVirt HyperConverged Cluster Operator. It can cause problems when you install IBM Software Hub software.

For more information about planning, prerequisites, implementation, and usage, see [IBM Software Hub documentation](#).

AI workloads on IBM Fusion

IBM Fusion HCI is built to handle complex container AI and VM workloads by using its advanced GPU nodes. IBM Fusion HCI combined with IBM watsonx offers a consistent high performance across a wide range of container AI and VM workloads. Every release of IBM Fusion HCI is validated with IBM watsonx to ensure that the infrastructure is compatible.

You can select the most suitable GPU node based on your specific AI workload requirements. For details on supported GPU types and their hardware configurations, see [GPU nodes](#).

Node labeling and GPU virtualization techniques can effectively enhance performance and ensure efficient resource management for both complex AI container workloads and virtual machine (VM) workloads.

Node labeling for GPU reservation

IBM Fusion HCI uses labels to reserve GPU nodes for AI workloads.

For example, the IBM Fusion Backup & Restore uses the `gpu.isf.ibm.com` label to control the placement of its pods. To prevent Backup & Restore workloads on GPU nodes, run the following command from the OpenShift® cluster to label the GPU nodes.

```
oc label node/<node name> gpu.isf.ibm.com=""
```

The IBM Fusion service pods avoid nodes with such a label. You can use this approach for other workloads.

For example, the IBM Fusion Backup & Restore uses the `gpu.isf.ibm.com` label to manage the placement of its pods effectively. To restrict IBM Fusion Backup & Restore workloads from running on GPU nodes, run the following command to apply this label to these nodes in the OpenShift cluster. After the nodes are labeled, the Backup & Restore pods automatically avoid GPU nodes with this label. This approach can also be adapted for other workloads to ensure resource optimization and placement control.

GPU virtualization options

IBM Fusion provides the following GPU virtualization options:

- PCI Passthrough for VMs to access GPU
- vGPU for VMs

The Peripheral Component Interconnect (PCI) passthrough feature enables virtual machines to directly interact and manage hardware devices. When you configure this feature, it allows these devices to function as if they are physically connected to the guest operating system, thereby ensuring smooth and uninterrupted operation. This setup is particularly useful for applications requiring direct hardware access, such as graphics-intensive tasks or specialized hardware control. For more information about this feature, see [Red Hat® documentation](#).

In case of vGPU for VMs, some graphics processing unit (GPU) cards support the creation of virtual GPUs (vGPUs). OpenShift Virtualization can automatically create vGPUs and other devices whenever an administrator provides configuration details in the **HyperConverged** custom resource (CR). This automation is especially useful for large clusters. For more information about this feature, see [Red Hat documentation](#) and [NVIDIA documentation](#).

Administering

You can manage and administer hardware, monitor and collect logs, understand events, raise call tickets, work with APIs, manage users, and understand the UI.

- [Managing the infrastructure and storage of IBM Fusion HCI](#)

You can manage your appliance infrastructure by up sizing compute nodes and storage disks. In addition, you can administer and configure aspects of storage

integration with the IBM Fusion HCI offering.

- [User management](#)
Use the role-based user restrictions and user management capabilities to administer IBM Fusion HCI.
- [Knowing your IBM Fusion user interface](#)
Learn the various key elements of the IBM Fusion user interface for ease of use and navigation.
- [Upgrading IBM Fusion](#)
Upgrade to the latest version so you can have access to the new functionalities and improvements that enhance your overall experience with IBM Fusion HCI.

Managing the infrastructure and storage of IBM Fusion HCI

You can manage your appliance infrastructure by up sizing compute nodes and storage disks. In addition, you can administer and configure aspects of storage integration with the IBM Fusion HCI offering.

- [Administering nodes and racks](#)
Administering nodes and service node in the system includes day-to-day operations such as power-on, power-off, placing node in maintenance, upscale, and up-size storage disks. You can add new racks to your cluster or edit its details.
- [Shutting down and restarting IBM Fusion HCI rack](#)
Procedures to gracefully shut down and restart IBM Fusion HCI. The process vary depending on whether the storage is Fusion Data Foundation or Global Data Platform.
- [Rack reset](#)
Rack reset automates the process of resetting a rack to a clean, factory-ready state. Use this feature when you need to reinstall the rack or recover from configuration issues.
- [Networking](#)
Configure and administer network settings for IBM Fusion.
- [Customer Replacement Units \(CRU\)](#)
List of Customer Replacement units for your reference.
- [Observability](#)
Observability in IBM Fusion enables centralized, multi-cluster monitoring that uses open source technologies like Prometheus, Thanos, and Grafana. This solution collects metrics from managed clusters, provides global querying and long-term storage, and delivers unified dashboards for visualization and alerting.
- [Administering and configuring storage in IBM Fusion HCI](#)
Administer and configure IBM Storage Scale storage integration for the IBM Fusion HCI appliance.

Administering nodes and racks

Administering nodes and service node in the system includes day-to-day operations such as power-on, power-off, placing node in maintenance, upscale, and up-size storage disks. You can add new racks to your cluster or edit its details.

For any user interface related issues, see [IBM Fusion HCI user interface issues](#).

After installing IBM Fusion HCI and adding an AMD GPU node to the OpenShift® cluster, IBM Fusion HCI automatically installs the AMD GPU Operator. In an online cluster, IBM Fusion HCI automatically configures the AMD GPU driver. For an offline or disconnected cluster, you must manually configure the AMD GPU driver. For more information, see [Configuring the AMD GPU driver in an offline or disconnected cluster](#).

- [Administering the service node](#)
Administering the service node in the system includes day-to-day operations such as monitoring the health, performing power operations, collecting logs, and doing firmware updates whenever it is available.
- [Adding a Day 2 service node](#)
This section provides the steps for adding a Day 2 service node to an existing IBM Fusion HCI rack.
- [Administering the node](#)
Administering the nodes in the system includes day-to-day operations such as monitoring the health, putting a node into maintenance mode, and performing power operations whenever it is available.
- [Restarting Baseboard Management Controller \(BMC\)](#)
The Baseboard Management Controller (BMC) restart is a process used to perform a restart of BMC. This restart is typically performed when the BMC is not functioning correctly or when there are any active node health events. The BMC restart might remove any false health events raised.
- [Scaling the cluster](#)
As workloads in the cluster increase, you must add more CPU, memory, GPU, or storage to accommodate them. CPU and memory can be increased by adding additional compute nodes to the cluster. For workloads that require GPUs, you can add specialized GPU nodes to the cluster. Storage can be scaled by adding additional disks to existing storage nodes, or adding additional storage nodes to the cluster. If you want to scale your cluster beyond a single rack, then you can add up to two expansion racks, enabling your cluster to host more compute, storage, and GPU nodes.
- [Node firmware](#)
IBM Fusion HCI continuously monitors the firmware installed on each node. If a node is found to be running a firmware version lower than the Fusion-certified level, the system automatically initiates a firmware upgrade. If the upgraded firmware requires a reboot to take effect, the node is marked as Upgrade available.
- [Upgrading the NVIDIA GPU driver with the NVIDIA GPU operator](#)
After installing IBM Fusion HCI and adding a GPU node to the OpenShift cluster, the Node Feature Discovery (NFD) component and the NVIDIA GPU operator are automatically installed. The NFD component labels the hardware capabilities of the GPU node, and the NVIDIA GPU operator automates the deployment and management of NVIDIA drivers and related components required for GPU accelerated workloads.
- [Configuring the AMD GPU driver in an offline or disconnected cluster](#)
After the AMD GPU Operator is running, manually create a `DeviceConfig` custom resource to deploy and configure the AMD GPU driver on your nodes.
- [Customizing Node Feature Discovery \(NFD\) CR](#)
Use the instructions to customize the Node Feature Discovery (NFD) configuration to meet your specific requirements.
- [Converting compute node to AFM node](#)
Convert a Lenovo compute node to a AFM node through backend CR.

The following section provides the prerequisite to remove worker node from the IBM Fusion HCI cluster.

- [Configuring GPU upsize on Dell systems](#)

Configure GPU upsize for Dell systems in IBM Fusion HCI.

- [Node issues](#)

This topic provides a comprehensive list of common troubleshooting steps and known issues that may arise while working with compute nodes.

Administering the service node

Administering the service node in the system includes day-to-day operations such as monitoring the health, performing power operations, collecting logs, and doing firmware updates whenever it is available.

View service node details

1. From the IBM Fusion HCI user interface, click Infrastructure > Overview page.
2. Click the service node that is placed at RU23, close to the optional KVM service console.
It opens a Service node slide out pane.
3. Click view full details to see Service node page that includes the front, rear, and internal graphical views, recent events, and other details of the service node and its internal components.

Download service node logs

1. In the service node details page, click Actions > Download logs to download the logs of the service node.
2. In the confirmation window, click Collect.

Power operations on the service node

Power operations on a node server, such as powering on, powering off, or restarting, are crucial for maintenance, troubleshooting, system recovery.

Power on and power off operations on a service node:

1. In the service node details page, click Actions > Power off or Power on to power off or power on the service node respectively.
2. In the confirmation window, select Power off node to shut down and Power on node to start up.

Restart operations on a service node

1. From the Actions drop-down menu, click Restart to restart the service node.
2. In the confirmation window, click Restart node.

Adding a Day 2 service node

This section provides the steps for adding a Day 2 service node to an existing IBM Fusion HCI rack.

Before you begin

Ensure that you meet these prerequisites before adding a Day 2 service node:

1. Create DNS entry:
 - a. Create a DNS record for the service node by using the format `servicenode-1.<domain.com>`.
 - b. Ensure that both forward (A/AAAA) and reverse (PTR) lookups are properly configured.
2. DHCP configuration (if applicable):
If the existing cluster uses DHCP-based IP assignment, create a DHCP reservation for the service node by using its MAC address. For more information about DHCP setup, see [Setting up DHCP](#).
3. Cluster information:
Keep the following cluster details readily available:
 - OpenShift® Bare metal VLAN ID
 - Rack generation type (Gen1 or Gen2)
4. Switch IP addresses:
Retrieve the IP addresses of the following switches:
 - High-Speed Switch 1 (RU20)
 - High-Speed Switch 2 (RU21)
 - Management Switch 1 (RU18)
 - Management Switch 2 (RU19)
 To obtain the IP addresses, follow these steps:
 - a. Log in to the OpenShift console user interface and go to Workloads > ConfigMaps.
 - b. Select the project `ibm-spectrum-fusion-ns`.
 - c. Search for `kickstart` and open the `kickstart-<serial>` ConfigMap.
 - d. Scroll down to locate the IPv4 addresses of the switches. If IPv4 is not available, retrieve the IPv6 addresses.
5. Switch credentials (ISFUSER):
Obtain the password for user `ISFUSER` on all switches (RU18, RU19, RU20, RU21).

To retrieve the passwords:
 - a. Log in to the OpenShift console user interface and go to Workloads > Secrets.

- b. Select the project **ibm-spectrum-fusion-ns**.
- c. Search by using:
 - **hspeed1** (High-Speed Switch 1), **hspeed2** (High-Speed Switch 2)
 - **mgmt1** (Management Switch 1)
 - **mgmt2** (Management Switch 2)
- d. Open the secret named in the format **<switch-name>-<serial>-<secret>**.
6. Static IP configuration (if applicable):

If the cluster uses static IP addressing, keep the following details available for the service node:

 - Bare metal network IP (for example: **10.1.1.100/24**)
 - Gateway IP
 - DNS server IP
 - NTP server IP
7. Upsize the service node only when the cluster, switches and nodes are healthy and no maintenance activities are in progress.

Procedure

To add a Day 2 service node to an existing IBM Fusion HCI rack, follow these steps:

1. Install the service node in the existing IBM Fusion HCI rack.
2. Place the service node at **RU33** for a Gen1 rack, or place it at **RU23**.

Tip: A rack is considered as a Gen1 rack if its control nodes are models 9155-C01 or 9155-C05.
3. Cable the service node at your site.

Note: The connection and wiring remain the same for Gen1, Gen2, and later versions of existing racks.

 - a. Connect the high-speed network interfaces:
 - i. Connect Service Node 25GbE Port 1 to High-Speed Switch 1 (RU20), Port 1 using a QSFP-to-SFP adapter, and a 25GbE cable.
 - ii. Connect Service Node 25GbE Port 2 to High-Speed Switch 2 (RU21), Port 1 using a QSFP-to-SFP adapter, and a 25GbE cable.
 - b. Connect the service node to the management switches:
 - i. Connect the Service Node IMM/BMC port to Management Switch 1 (RU18), Port 33.
 - ii. Connect Service Node 4-port 1GbE NIC – Port 1 to Management Switch 2 (RU19), Port 33.
 - iii. Connect Service Node 4-port 1GbE NIC – Port 2 to Management Switch 1 (RU18), Port 35.
 - iv. Connect Service Node 4-port 1GbE NIC – Port 3 to Management Switch 2 (RU19), Port 35.
 - c. Connect the out-of-band interface of the service node:
 - i. Connect Service Node 4-port 1GbE NIC - Port 4 to the customer data center network to carry out-of-band traffic.
4. Power on the service node and connect with KVM. Then log in to the RHEL OS using default user **kni** and password **passw0rd**.
5. Change to the following directory:

```
cd /home/kni/isfconfig
```

6. Run the following command to change the permission for the script:

```
chmod +x servicenode_script_1.sh
```

7. Locate the script **servicenode_script_1.sh** in the current directory and run the script 1:

```
./servicenode_script_1.sh
```

After script 1 completes successfully, IBM Fusion HCI automatically discovers the node, performs the required scale-up operation, and displays the node in the IBM Fusion HCI user interface.

To set up vault secrets and certification, execute the **servicenode_script_2_install.sh** script as mentioned in the following steps.

Important: If the IBM Fusion HCI rack is using an IPv6 stack on the provisioning network, run the **./servicenode_script_2_install.sh** script. After running the script, the service node appears in the IBM Fusion HCI user interface.

8. Log in to the service node using the hostname displayed in IBM Fusion HCI UI. Go to Infrastructure > Overview > Service Node > Details Hostname with user as **kni** and password as **passw0rd**.

Set the IBM Fusion HCI namespace environment variable to **ibm-spectrum-fusion-ns**.

For example:

```
export FUSION_NAMESPACE="ibm-spectrum-fusion-ns"
```

9. Ensure that the following files are present in the **/home/kni/isfconfig** directory:

- **kickstart.json**
- **appliance-info.json**

10. Run the following **oc login** command to log in to the OpenShift Container Platform cluster:

```
KUBECONFIG=/tmp/remote-ocp-config oc login --token=sha256~TOKEN --server=https://api.rackName.fusion.tadn.ibm.com:6443 --insecure-skip-tls-verify=true
```

11. Run the following command to verify whether you are logged in to the cluster or not.

```
KUBECONFIG=/tmp/remote-ocp-config oc get secret -n ${FUSION_NAMESPACE}
```

If you are unable to see the secret list in **ibm-spectrum-fusion** namespace, then check the **oc login** command again and make sure that you get the correct remote access to the cluster.

12. Run the following command to change the permission for the script:

```
chmod +x servicenode_script_2_install.sh
```

13. Run the following command to keep a backup of the vault files:

```
sudo cp -r /var/vault /var/vault_backup/
```

14. Check if the service node entry is present in the **KickStart** configmap by running the following command:

```
export KUBECONFIG=/tmp/remote-ocp-config && \
KICKSTART_CM=$(kubectl get configmap appliance-info -n ibm-spectrum-fusion-ns -o json | jq -r '.data | to_entries[0].value
```

```
| fromjson | .kickstartCM') && \
kubectl get configmap "$KICKSTART_CM" -n ibm-spectrum-fusion-ns -o json | jq -r '.data."kickstart.json"' | jq -r
'.computeNodeIntegratedManagementModules[] | select(.type=="servicenode")'
```

If the command returns a result for **"servicenode-*"**, proceed to the next step. Otherwise, wait until the entry is added to the **KickStart** configmap.
If the service node entry is not added to the **KickStart** configmap after 10 minutes, contact [IBM Support](#).

- Important: To run the **servicenode_script_2_install.sh** script, remote login to the OpenShift Container Platform cluster is required. Ensure that you have the correct access credentials before executing the script. If login issues occur, resolve them before proceeding with script execution.
Run the **servicenode_script_2_install.sh** script that is located in the **/home/kni/isfconfig/** directory by using the following command:

```
KUBECONFIG=/tmp/remote-ocp-config /home/kni/isfconfig/servicenode_script_2_install.sh
```

Ensure that the script execution is successful.

- After the script completes successfully, the IBM Fusion dashboard displays a notification. Use the notification to download the **vault-secret**, **vault-login-secret**, and **servicenode-snuser-credentials** secrets. Store all three secrets securely and keep them accessible for future use.
Remember: The **servicenode-snuser-credentials** secret in the **ibm-spectrum-fusion-ns** namespace contains the credentials for the **snuser** account that you can use to connect to the service node.
- After completing the previous steps, run the following command to delete the temporary configuration file.

```
rm /tmp/remote-ocp-config ; rm /tmp/extracted_*
```

- If you backed up the vault secret and vault login secret, then you can delete the **/var/vault_backup** directory from the newly added service node.

```
rm -rf /var/vault_backup/
```

- To enable automated credential rotation, manually update the base rack **PlatformConfig** file after successfully adding the service node. For more information, see [Enabling password rotation for IBM Fusion HCI system](#).

If the service node does not appear in the IBM Fusion HCI user interface, contact [IBM Support](#).

Administering the node

Administering the nodes in the system includes day-to-day operations such as monitoring the health, putting a node into maintenance mode, and performing power operations whenever it is available.

For any node drain issues during maintenance, see [Issues related to IBM Fusion HCI node drains](#).

Node inventory tabs: Configured, Discovered and Hosted inventory

From the IBM Fusion HCI menu, click **Infrastructure > Nodes**. The Node page includes Configured nodes and Discovered nodes tabs. By default, the Node page opens the Configured nodes tab.

Go to Discovered nodes tab to add discovered nodes in a rack that were not added to the OpenShift® cluster earlier.

Node details

The following table provides the node details in the nodes list:

	Description
Name	The name of the node. Naming convention of nodes added by installation or upsize: compute-<i><rackid></i>-<i><rack unit number></i>.<i><domainname></i> For a single rack, rackid is always 1.
Hardware status	The node Status column also displays the health of the node.  indicates that the status is healthy  indicates warning status  indicates critical status The node Status column that is shown on the node inventory page is the node hardware monitoring state on the IBM Fusion user interface. A node is monitored by connecting to its remote management module. Hence, the node state is a reflection of its connectivity to the monitoring module and its ability to fetch the monitoring data. Important: - This state does not reflect node operating system state and their readiness state in the OpenShift cluster. As a result, the node status between IBM Fusion and OpenShift user interface might not be the same. : - When the IBM Fusion user interface shows Running and the OpenShift user interface shows Not Ready, then follow the steps that are mentioned in the Compute node issues to resolve the OpenShift node status issue. To see the OpenShift state, go to Dashboard > OpenShift section.
Type	The options are Compute only, Compute storage, AFM, or GPU.

	Description
Firmware	The firmware status of the node.
S/N	The hardware serial number.
Rack	The name of the rack.
Rack unit	The rack unit position of the node in the rack.
CPU cores	The amount of CPU in cores.
Memory (GB)	The amount of memory in GB.

Use the settings icon to customize the columns. You can customize the number of rows that must be displayed in a page, jump to a specific page, or go to the previous or next page.

Use the Search text box to filter and find a specific node.

Node power operations

Node actions from the ellipsis overflow menu of a node record:

- Enable maintenance or Disable maintenance When the node is moved to maintenance successfully, the ellipsis overflow menu option shows Disable maintenance option and the Enable maintenance option is available when the node is not already in maintenance.
- **Power operations:**

Power on and power off operations on a node:

Note: Do all power operations only from the IBM Fusion HCI user interface.

1. Move the node to maintenance.
2. In the ellipsis menu of the node, click Power off node to power off the node.
3. In the confirmation window, click Power off.
4. In the ellipsis menu of the node, click Power on node to power on the node.
5. In the confirmation window, click Power on.
6. After you complete the maintenance operations, from the ellipsis overflow menu of the node, click Power on node to power on the node.

Restart and shutdown operations on a node

1. Move the node to maintenance.
2. In the ellipsis menu of the node, click Restart node or Shutdown node. Alternatively, you can click the Manage resources in the node details > Inventory tab page and then do power operations.
3. In the confirmation window for restart or shutdown actions, click Restart node or Shutdown node accordingly.
Note: If you shutdown a node, then the node goes offline. While offline, all data collection for this node stops and no changes or upgrades can be made.

If you want to understand Scale behavior during node reboots, see [Scale behavior during node restarts](#).

Enable and disable node maintenance

When you put a node into maintenance mode, it marks the node to Scheduling disabled and also drains workload from it. You can place a node to maintenance from the user interface or through any operation that needs a server reboot.

To run power operations, place a node in a maintenance mode.

The following procedure guides you with the steps to enable or disable maintenance mode on a node from the user interface.

Procedure

1. In the Nodes page, click the ellipsis menu of the node you want to move to maintenance and click Enable maintenance mode.
2. In the Enable maintenance mode confirmation window, click Enable.
3. Wait for node to go to maintenance mode.
4. After all the required maintenance operations are completed, move the node out of maintenance. From the ellipsis overflow menu of a node that is in maintenance, select Disable maintenance mode option.

Maintenance node operation timeout is configurable now. The default value is 15 minutes and configurable time can go up to 40 minutes. Edit the **MaintenanceWarningTimeout** value to configure the maintenance operation.

Important:

- You cannot move more than one node to maintenance at a time. Also, if the GPFS cluster health is degraded, node maintenance will not succeed. If you ignore, then the IBM Fusion HCI user interface shows a failed message:

"Detected problem in previous maintenance operation"

Fix the root cause of the issue in events or CR status:

```
oc describe cmt <instance node name> -n <fusion namespace>
```

- If you face an issue retrieving the compute nodes and network components after maintenance mode operation, log out and log in from the user interface.
- The maintenance mode on a node can take four minutes to 30 minutes to succeed, depending on the workload on the node and the Scale PodDisruptionBudget. If it takes more than 30 minutes, then the operation gets timed out eventually. For more information about this issue, see [Issues related to IBM Fusion HCI node drains](#).
- When you put a node into maintenance mode from IBM Fusion HCI user interface, it marks a node to Scheduling disabled and also drains workload from it.

Restarting Baseboard Management Controller (BMC)

The Baseboard Management Controller (BMC) restart is a process used to perform a restart of BMC. This restart is typically performed when the BMC is not functioning correctly or when there are any active node health events. The BMC restart might remove any false health events raised.

Before you begin

The BMC restart causes the BMC to restart, which temporarily disrupts system management functions. Therefore, critical functions like monitoring and firmware upgrade for a node are paused until the BMC is back online.

About this task

Use the following instruction to restart the BMC.

Procedure

1. Log in to the IBM Fusion HCI user interface.
2. Go to Infrastructure > Nodes.
3. In the Nodes page, click the ellipsis menu of the node you want to reset and click Restart BMC.
4. In the Restart Baseboard Management Controller (BMC) confirmation window, click Restart.
5. Alternatively, you can perform the BMC restart from the node page as follows:
 - a. In the Nodes page, click the node that you want to restart.
 - b. From the Actions drop-down menu, click Restart BMC to restart the node.

Note: After resolving a monitoring degraded error, it may take few minutes for the node status to update to **Normal** in the user interface.

Scaling the cluster

As workloads in the cluster increase, you must add more CPU, memory, GPU, or storage to accommodate them. CPU and memory can be increased by adding additional compute nodes to the cluster. For workloads that require GPUs, you can add specialized GPU nodes to the cluster. Storage can be scaled by adding additional disks to existing storage nodes, or adding additional storage nodes to the cluster. If you want to scale your cluster beyond a single rack, then you can add up to two expansion racks, enabling your cluster to host more compute, storage, and GPU nodes.

- [Adding nodes to the cluster](#)
After installing new node hardware in an existing rack, or adding an additional rack of hardware, you complete a procedure to configure the nodes so that they are monitored and added to the OpenShift® cluster.
- [Adding storage](#)
You can add additional storage nodes or add disks to existing nodes.

Adding nodes to the cluster

After installing new node hardware in an existing rack, or adding an additional rack of hardware, you complete a procedure to configure the nodes so that they are monitored and added to the OpenShift® cluster.

- [Configuring nodes for management](#)
How to configure the newly installed nodes so that they are monitored and added to the OpenShift cluster. For nodes that contribute to storage, add them to the storage cluster.
- [Adding expansion racks](#)
You can expand your IBM Fusion HCI with an additional rack. You only need as few as one node, along with the necessary switches, to add the rack successfully.

Configuring nodes for management

How to configure the newly installed nodes so that they are monitored and added to the OpenShift® cluster. For nodes that contribute to storage, add them to the storage cluster.

Before you begin

Meet the following prerequisites for all node types in the specified sequence:

1. Ensure switches are in healthy state and connections between node and switches are correct.
2. The purchased quantity of nodes are delivered to your location with the following information:
 - For Compute-storage nodes, the received new node must have a specific number of NVMe drives. That is, the new node must have the same number of disks as the ones that are already there.
 - All new nodes must have a MAC address from IBM.

Note: Update your Dynamic Host Configuration Protocol (DHCP) and Domain Name System (DNS) Configuration to include reservations for all nodes in the IBM Fusion HCI. For more information about the prerequisite, see [Setting up DHCP for IBM Fusion HCI](#) and [Setting up DNS](#). In case of Static IP, you must update the DNS for the new nodes. For more information about the prerequisites, see [Setting up Static IP](#) and [Setting up DNS](#). These configurations are based on the MAC addresses shared with you by IBM.
3. Ensure that the IBM Support Representative inserted the nodes in the appropriate rack slots and connected the network and power cables as per the wiring prescription of IBM Fusion HCI rack.
4. The IBM Fusion appliance is up and running.
5. Ensure that all the prechecks are successful and node is in Ready to add state in the Provision Status column.
6. Red Hat® OpenShift is up and running and the existing nodes are healthy.
7. When you add a node to Red Hat OpenShift, the operation might get stuck for a long time in the node network configuration policy creation stage. To avoid this issue, do the steps that are mentioned in the troubleshooting section before you add the node. For the workaround steps, see [Node issues](#).

8. Naming convention of nodes that are added: **compute-*<rackid>-<rack unit number>.<domainname>***

For a single rack, the rackid is always 1. For multi-rack, rackid is the rack number where the node is added. For an example guidance for the base system, see [host name conventions](#).

Upsizing when backup or restore is in progress

When a backup or restore job is in progress, you must not upsize the nodes. For scale-out or scale-up operation, turn off the IBM Fusion backup or restore jobs, if any. Do not back up or restore when an upsize action is in progress.

Upsize nodes to brand-new racks

1. Upsize node must be powered on only on a running IBM Fusion HCI (stage 2 complete). Otherwise, keep the upsized node powered off (remove the power cables from the node).
2. Complete the installation.
3. Plug-in the power and switch on the node.

About this task

- The following node types are supported in this release:
 - Compute-only and compute-storage server models: 9155-C10 (32 core node), 9155-C14 (64 core node), 9155-D10 (32 core node), 9155-D14 (64 core node)
 - GPU node models: 9155-G01, 9155-G03, 9155-G04, and 9155-DG1, DG2, DG3, and DG4
 - Active File Management (AFM) server model 9155-F01
 - Service node model: 9155-B01

For hardware configuration of compute-storage or compute-only nodes, see [Hardware overview](#).

- In IBM Fusion HCI rack, when nodes are added they must be added into the lowest available rack position to maintain mechanical stability.

- Allowed node configuration combinations for high-availability multi-rack:

- Select same number of nodes from all three racks. A minimum of three nodes are required for the configuration.
- For scale out, add an equal number of storage nodes from each rack.
- For scale up, add same number of disks across each rack.

Note: Do not deviate from these specification as it can result in an imbalanced configuration of a Data Foundation cluster.

- For the two-availability-zone and arbiter node (2AZ and arbiter node) configuration, during capacity scaling, add disks in multiples of four and distribute them evenly across both zone.

Important: Upgrading Gen2 storage to Gen1 racks is supported for Red Hat OpenShift Data Foundation configurations, but not supported for Global Data Platform configurations.

Procedure

1. After a node is physically added to a rack, networking is done, and powered on, log in to IBM Fusion HCI user interface.
2. Go to Infrastructure > Nodes.
3. Verify that the BMC of the new node has a reachable IPv4 address.
 - a. Locate the network access label on the pull-out information tab at the front of the node. The label displays the Link Local Address (LLA) MAC address.
 - b. On the service node, run the following command to resolve the MAC address to an IPv4 address:

```
/home/kni/isfconfig/mac-to-ipv4.sh lla-mac-address
```

For example:

```
[kni@localhost ~]$ /home/kni/isfconfig/mac-to-ipv4.sh e8:80:88:07:39:9b
MAC: e8:80:88:07:39:9b → IP: 169.253.19.183
```

- c. Verify SSH connectivity to the IP address from the service node by using the default credentials:
 - Dell nodes: **root / calvin**
 - Lenovo nodes: **USERID / PASSWORD**

```
ssh user@ipv4-address
```

Note: If the IP address is not reachable, assign an IPv4 address to the iDRAC (Dell) or IMM (Lenovo) of the node before you continue.

4. Check whether the node you added to the physical hardware is available in the Discovered nodes tab.

If there are any errors in the configuration, then **Error connecting to node** message gets displayed in the State column. All of the error conditions have built-in retries. Whenever the event persists for a longer duration, support tickets get raised to check the appliance. If the condition is transient, it recovers automatically. Otherwise, IBM Support checks the appliance.

Check whether the node is in Ready to add state in the Provision Status column. If the node is in Not ready to add state, then prechecks are not successful. Select the node that is in error state and click View details. It opens a Pre-check list side pane where you can see failure prechecks details.
5. To add a node to the OpenShift cluster, select the nodes and click Add to cluster.

The user interface displays the progress of the node addition. To view the nodes progress for addition, select that specific node.
6. In the Add node window, click Add to confirm.
7. Go to the Configured nodes tab to see whether the newly added node is in the list with the State as Adding to OpenShift.

Note: If the node is compute-only and the storage is Global Data Platform, proceed with adding it to the storage cluster. If the storage is Fusion Data Foundation, add the node to the OpenShift Container Platform cluster, then skip all subsequent steps in this procedure.
8. When all the nodes are ready for storage configuration, add them to the storage cluster: This final step allows workloads on the nodes to access storage, so complete this step before stateful workloads are scheduled on the nodes.

Option	Description
--------	-------------

Option	Description
Global Data Platform	To configure node for Global Data Platform, do the following steps: - Go to the Global Data Platform page. The following notification is displayed: <code>Nodes are ready for storage</code> - The Storage status of the nodes in the Nodes list is Ready for storage and the Type is Storage. - Click Configure nodes link in the notification. - In the Configure <node type> nodes window, click Install. The Storage status of the nodes in the Nodes list changes to Installing Storage software. After the configuration is complete, a success notification is displayed and the Storage status of the node changes to Ready. - Repeat steps for the remaining available node types one by one.
Fusion Data Foundation	- Go to Local storage page. - Click Add nodes. If nodes are available for addition, it is enabled. - In the Add storage nodes page, go through the details and Add. After the selected nodes are added successfully, the status of the node changes to Ready.

- To verify storage nodes, do the following steps:
 - Go to the node details page.
 - In the Inventory tab, go to Disks tab.
 - Check the new size. Also, check whether the disk information reflects the newly added drive.
 - Check the total disk count and Raw capacity after you add the disk.
 - Go to Infrastructure > Dashboard.
 - In the Disks tile, check total disk count and Raw capacity.

Adding expansion racks

You can expand your IBM Fusion HCI with an additional rack. You only need as few as one node, along with the necessary switches, to add the rack successfully.

Before you begin

The IBM Service Support Representative must have completed the setup stage installation for the expansion rack.
Important: To add a new rack and expand your current IBM Fusion HCI infrastructure, contact [IBM support](#).

Procedure

- From the IBM Fusion HCI menu, click Infrastructure > Overview.
- Click Add rack.
The Add rack wizard page is displayed.
- In the Getting started wizard page, go through the details and click Next to initiate the discovery process.
- In the Discovery wizard page, wait for the rack discovery to complete.
In this page, IBM Fusion HCI enables expansion of rack, connects to the provisioned node, and discovers rack data.
Errors might occur during the discovery step because of the following reasons:
 - Unable to establish connection to the provisioned node on the new rack. To resolve this issue, revisit your DNS configuration and retry.
There are Retry and Cancel options on this page. If the discovery fails, it can be retried by clicking retry and if you wish to cancel, click Cancel.
- Choose a zone from the Availability zone drop-down list.
- Click Next.
- In the Validation wizard page, check whether all the nodes are validated properly.
The IBM Fusion HCI validates the configuration of each node as a preparatory step so as to join the cluster. You need as few as one node, along with the necessary switches to add the rack successfully.
This page continuously shows the number of nodes that are successfully validated. If the validation does not complete within the stipulated time, the validation operation fails and message corresponding to that gets displayed.

If issues exist, then check your connections or fix problematic nodes and retry. You cannot proceed with errors, so click Save & Quit. Click Collect logs to download and view logs.
In this page, if rack addition fails with the following error message, then contact IBM Support:

`Rack import timeout`

The Retry on this page refreshes the node validation status.
- If the session is lost during the add rack operation, do the following steps:
 - Log in to IBM Fusion HCI user interface.
 - Go to Infrastructure > Nodes.
A `Scale out operation not completed` notification is displayed on the page.
 - Click Resume process link in the `Scale out operation not completed` notification.
Use Resume process to continue the add rack operation from where you left off.

For any errors in rack addition due to `timeout` issues, go to the Infrastructure > Nodes > Discovered nodes tab page to know more details.
- Click Next.
The optional Node selection wizard page is displayed.
- Optionally, in the Node selection wizard page, you can open the Edit node selection and edit node assignments.

By default, IBM Fusion HCI automatically configures all nodes in the rack. The Edit node selection shows a table where you can deselect nodes. If you do not deselect, then the nodes get added automatically to the OpenShift® cluster. Your deselection depends on the amount of nodes required for your storage building block. For example, you have twenty nodes and six nodes are required for storage building block. The table displays only the remaining fourteen nodes. Also, a summary section is displayed with the following details:

- Nodes
- CPUs
- Memory (GB)
- Usable capacity (TiB)

The values of the summary section changes dynamically based on your selection and deselection.

11. Click Next.

The Finish wizard page is displayed.

12. In Finish wizard page, click Finish to close the Add rack wizard.

The IBM Fusion HCI adds these nodes to the OpenShift cluster. After the add rack operation is complete, the user interface shows auxiliary rack related nodes in the Discovered node tab. To add more racks, click Actions > Add rack again and follow the steps mentioned in this procedure.

13. Select nodes and click Add to cluster.

The IBM Fusion HCI starts to add nodes to the OpenShift cluster.

- [Viewing rack details](#)

You can view the details of all the racks in your high availability cluster.

Viewing rack details

You can view the details of all the racks in your high availability cluster.

Procedure

1. From the IBM Fusion HCI menu, click Infrastructure > Nodes.

2. In the Configured nodes tab, go to Actions and click Rack details.

The Rack details window is displayed with the following information:

- Link name
- Baremetal VLAN ID
- Baremetal VLAN
- Storage VLAN ID
- Port type
- Native VLAN ID
- Transceiver

3. Expand the individual racks to view network details added during the setup installation stage.

Adding storage

You can add additional storage nodes or add disks to existing nodes.

- [Adding additional storage nodes](#)

As the disk slots fill up on existing storage nodes in the cluster, you can add additional storage nodes to increase the amount of available storage. All storage nodes must have an equal number of disks, so new storage nodes must match the disk configuration of the storage nodes that are already in the rack.

- [Adding new disks to existing Global Data Platform nodes](#)

If storage gets added at the hardware level, then the new storage information is available on the IBM Fusion HCI user interface. You can add storage to the cluster by adding additional disks to the storage nodes in the cluster. Each storage node must have the same number of disks, so make sure to add an equal number of disks to each node in the cluster.

- [Adding new disks to existing Fusion Data Foundation nodes](#)

After you add additional disks to Fusion Data Foundation storage nodes, it auto detects the new disks and auto expands the capacity to Fusion Data Foundation storage cluster. Each storage node must have the same number of disks, so make sure to add an equal number of disks to each node in the cluster.

Adding additional storage nodes

As the disk slots fill up on existing storage nodes in the cluster, you can add additional storage nodes to increase the amount of available storage. All storage nodes must have an equal number of disks, so new storage nodes must match the disk configuration of the storage nodes that are already in the rack.

About this task

After the storage node hardware is added to the rack, configure them for management. For the actual procedure, see [Configuring nodes for management](#).

Adding new disks to existing Global Data Platform nodes

If storage gets added at the hardware level, then the new storage information is available on the IBM Fusion HCI user interface. You can add storage to the cluster by adding additional disks to the storage nodes in the cluster. Each storage node must have the same number of disks, so make sure to add an equal number of disks to each node in the cluster.

Before you begin

Ensure that the following conditions are met:

- No node is in maintenance mode.
- Ensure that operations leading to node reboot are not performed.
- Do not initiate an upgrade of OpenShift®, IBM Fusion HCI, or node firmware until the new storage addition is complete.
- Number of disks is the same for all servers in the storage cluster.
If you want disk upsize, then add same number of disks to all storage nodes available in the cluster. For example, a cluster has a base minimum of six storage nodes, then at least $6 \times 2 = 12$ disks with two disks each must be added. For nodes, if the cluster has six storage nodes with two disks each, you can add one more node with two disks. Now, your storage cluster has seven storage nodes with two disks each.
- Storage nodes must have an even number of disks.
- During installation or upgrade, the pod may get stuck in `container creating` state and the crash loop might fail with attach volume. For such error scenarios, do the following workaround steps:
 1. Unschedule the node from which you were trying to attach volume.
 2. Delete the pod that got stuck in `container creating` state.
 3. Run upsize again.
- For hardware configuration of compute-storage or compute-only nodes, see [Hardware overview](#).

About this task

Note: If you are on a Metro-DR setup, then ensure that both sites have the same storage capacity. If you upsize storage disks on one site, ensure that you upsize the storage capacity on the second site at the earliest. If you do operations on the local and remote cluster during this mismatch, IBM is not responsible for any data loss or inconsistencies. If you face any disk failures, ensure that you rectify them and bring both site 1 and site 2 at the same level at the earliest. If you face any issues during disk upsize, see [Global Data Platform service issues](#).

Procedure

1. In the IBM Fusion menu, go to Global Data Platform depending on your storage type.
2. Click Actions > Add disk.
A window opens with details of the newly added storage at the hardware level.
If you are not able to see additional disks even after 1 hour, contact IBM Support.
3. Go through the storage details and click Add.
Note: It is a best practice to add a bunch of storage nodes at a time and not one-by-one.
The following message is displayed:

```
Request accepted successfully
```

All new disks on all nodes get added automatically and disk selection is not required.
4. To verify, go to the node details page and check the Disks tab. For more information about the procedure, see [Node or service node details](#).

Adding new disks to existing Fusion Data Foundation nodes

After you add additional disks to Fusion Data Foundation storage nodes, it auto detects the new disks and auto expands the capacity to Fusion Data Foundation storage cluster. Each storage node must have the same number of disks, so make sure to add an equal number of disks to each node in the cluster.

Before you begin

Ensure that the following conditions are met:

- No node is in maintenance mode.
- Ensure that operations leading to node reboot are not performed.
- Do not initiate an upgrade of OpenShift®, IBM Fusion HCI, or node firmware until the new storage addition is complete.
- The number of disks must be the same on all nodes in the storage cluster.
If you want disk upsize, then add the same number of disks to all storage nodes in the cluster. For example, if a cluster has a base minimum of six storage nodes, then at least $6 \times 2 = 12$ disks with two disks each must be added. For nodes, if the cluster has six storage nodes with two disks each, you can add one more node with two disks. The storage cluster now has seven storage nodes with two disks each.
- Each storage node supports 2–10 disks, including an odd number of disks.
- During installation or upgrade, the pod may get stuck in `container creating` state and the crash loop might fail with attach volume. For such error scenarios, do the following workaround steps:
 1. Unschedule the node from which you were trying to attach volume.
 2. Delete the pod that got stuck in `container creating` state.
 3. Run upsize again.
- For hardware configuration of compute-storage or compute-only nodes, see [Hardware overview](#).

About this task

If you face any issues during disk upsize, see [Troubleshooting Fusion Data Foundation service issues](#).

Procedure

1. In the IBM Fusion menu, go to Data Foundation.
Wait for the new capacity to be shown in the Data Foundation page.
2. To verify, go to the node details page and check the Disks tab. For more information about the procedure, see [Node or service node details](#).

Node firmware

IBM Fusion HCI continuously monitors the firmware installed on each node. If a node is found to be running a firmware version lower than the Fusion-certified level, the system automatically initiates a firmware upgrade. If the upgraded firmware requires a reboot to take effect, the node is marked as Upgrade available.

Before you begin

Ensure that you mirror Red Hat® operator images (**node-maintenance-operator** and **self-node-remediation**) to your enterprise registry when working in an air-gapped environment. For more information, see [Mirroring Red Hat operator images to enterprise registry](#).

About this task

Note:

This automated firmware management applies to the following node types:

- Nodes in the base OpenShift® Container Platform cluster
- Nodes in Hosted Control Plane clusters
- Service nodes
- Nodes not part of any cluster

For service nodes and unclustered nodes, IBM Fusion HCI automatically handles the reboot process.

You can verify the status of the firmware in the Infrastructure > Nodes page. In the Firmware level column, you can find the firmware status that is associated with the release. In the following table, you can see some of the possible firmware statuses:

Status	Description
Up to date	It indicates that the node firmware matches the Fusion-certified level.
Upgrade available	A new firmware update is available for the node, user needs to trigger upgrade from the Upgrades page on the IBM Fusion HCI user interface.
Upgrade pending	The node is scheduled for reboot.
Upgrade failed	Firmware upgrade failed; contact IBM support for assistance. For cause, resolution, and troubleshooting for Update failed, see Troubleshooting update failures section.
Upgrade stalled	Firmware upgrade failed during the maintenance mode or reboot stage. For cause, resolution, and troubleshooting for Update stalled, see Remediating a maintenance drain failure .

Do not start a Hosted Control Plane node firmware upgrade in the following conditions:

- If a node is in maintenance mode.
- If a node is pending in maintenance mode operation.
- If a node health is critical.

Procedure

1. Go to Infrastructure > Nodes in the IBM Fusion HCI user interface.
2. Identify nodes marked as Upgrade available.
3. Do the following steps to reboot the nodes:
 - a. Go to Settings > Upgrades in the IBM Fusion HCI user interface.
 - b. Click the Node firmware under the Rolling upgrades section.
A side panel opens with the nodes details.
 - c. Select the cluster that you want to reboot and click Upgrade.
The upgrade progress in detail can be monitored from the side panel.

IBM Fusion HCI automatically checks the environment before node reboot. If it is safe to proceed, the selected nodes get restarted in a rolling fashion to minimize impact to the OpenShift cluster.

Note:

- Do not trigger the Add Node to Cluster action for nodes that are listed under the Discovered tab if their firmware upgrade is still in progress.
- IBM Fusion HCI performs pre-reboot checks to ensure it is safe to proceed. If conditions are met, nodes are rebooted in a rolling fashion to minimize impact on cluster operations.
- If a node is in an upgrade-failed state, first resolve the underlying issues. Then, delete the **cfw** Custom Resource (CR) to restart the upgrade process. After you delete the CR, the system automatically retries the operation.
- During the node firmware upgrade, the node health status can change from Normal to Monitoring Degraded or Critical because system components are involved. This status usually resolves automatically after the upgrade completes. If the status remains Monitoring Degraded or Critical after the upgrade, contact IBM Support.

Troubleshooting update failures:

Firmware Update failed status can occur because of the following reasons:

Silent firmware flashing failed OR new firmware not reflected after reboot

This may be due to hardware errors. As a resolution, follow the steps to resolve the issue:

- a. If Call Home is configured, a support case event **BMYC00009** is automatically opened; no further action is required.
- b. If Call Home is not configured, then contact [IBM support](#) for assistance.

Node failed to move to maintenance mode

When a user triggers a node or cluster reboot, the upgrade may fail if the node cannot drain pods before reboot. As a resolution, drain the pods manually and then resume the upgrade. For more information about draining the pods, see [Remediating a maintenance drain failure](#).

Upgrade gets stalled due to node being stuck in **NotReady** state

This may be due to multiple errors such as issues in node restart, certificate errors, and OpenShift Container Platform node status shows **NotReady**. As a resolution, follow the steps to resolve the issue:

- For node restart issues, see [Issues in node restart](#).
- For certificate errors, see [Node in NotReady state due to certificate errors in OpenShift pods](#).
- For node status shows **NotReady** in the OpenShift Container Platform, see [OpenShift Container Platform node status shows NotReady but IBM Fusion HCI user interface node status shows as Running](#).

Upgrading the NVIDIA GPU driver with the NVIDIA GPU operator

After installing IBM Fusion HCI and adding a GPU node to the OpenShift® cluster, the Node Feature Discovery (NFD) component and the NVIDIA GPU operator are automatically installed. The NFD component labels the hardware capabilities of the GPU node, and the NVIDIA GPU operator automates the deployment and management of NVIDIA drivers and related components required for GPU accelerated workloads.

During Stage 2 deployment, if the system detects an NVIDIA GPU node, the Fusion operator automatically sets the **manageNvidiaGPUOperator** field to **true** in the **ComputeInit** custom resource and installs the latest supported version of the NVIDIA GPU operator.

The **manageNvidiaGPUOperator** setting controls the automatic installation and upgrade of the NVIDIA GPU Operator.

Value	Description
True (default)	Automatically installs and upgrades the NVIDIA GPU operator when GPU nodes are detected
False	NVIDIA GPU operator installation and upgrades are managed manually.

Manual NVIDIA GPU operator management

To manually manage the NVIDIA GPU operator lifecycle, update the **manageNvidiaGPUOperator** field in the **ComputeInit** custom resource before you perform NVIDIA GPU node upsize operations or use a NVIDIA GPU operator version other than the latest supported stable version that is installed by IBM Fusion HCI.

1. Run the following command to update the **manageNvidiaGPUOperator** field to false:

```
oc patch computeinit computeinit \
-n ibm-spectrum-fusion-ns \
--type=merge \
-p '{"spec":{"manageNvidiaGPUOperator":false}}'
```

2. Run the following command to verify that the update is applied successfully:

```
oc get computeinit computeinit \
-n ibm-spectrum-fusion-ns \
-o jsonpath='{.spec.manageNvidiaGPUOperator}'
```

When the **manageNvidiaGPUOperator** attribute is set to **false**, IBM Fusion HCI does not automatically install, upgrade, or reinstall the NVIDIA GPU operator. You must manually manage the NVIDIA GPU operator lifecycle, including maintaining a version other than the latest supported stable version that is installed by IBM Fusion HCI.

To restore automatic NVIDIA GPU operator lifecycle management, update the field to true.

Upgrading the NVIDIA GPU operator

In IBM Fusion HCI 2.13 and later releases, the NVIDIA GPU operator is automatically upgraded to the latest supported stable version.

Automatic upgrade behavior

- The latest supported NVIDIA GPU operator version is installed by default.
- Upgrading to IBM Fusion HCI 2.13 or later automatically upgrades the NVIDIA GPU operator.

Manual upgrade procedure

Manual upgrade procedures are required only when the **manageGPUOperator** parameter is set to **false**.

NVIDIA DCGM exporter dashboard

The NVIDIA DCGM exporter dashboard displays GPU related metrics and monitoring graphs. The configuration of the NVIDIA DCGM exporter dashboard is automated.

Viewing GPU metrics

To monitor GPU performance, you can access GPU metrics through the OpenShift Container Platform web console. Ensure that you must have the OpenShift Container Platform web console access and NVIDIA DCGM exporter dashboard available in the console.

Administrator perspective:

In the OpenShift Container Platform web console from the side menu, switch to the Administrator perspective, then navigate to **Observe > Dashboards** and select **NVIDIA DCGM Exporter Dashboard** from the Dashboard list.

Developer perspective:

If the dashboard is added to the developer perspective, in the OpenShift Container Platform web console from the side menu, switch to the Developer perspective, navigate to **Observe > Dashboards** and select **NVIDIA DCGM Exporter Dashboard** from the Dashboard list.

For more information, see [NVIDIA documentation](#).

Configuring the AMD GPU driver in an offline or disconnected cluster

After the AMD GPU Operator is running, manually create a **DeviceConfig** custom resource to deploy and configure the AMD GPU driver on your nodes.

Before you begin

Complete all AMD GPU Operator image mirroring steps before proceeding. See [Mirroring AMD GPU Operator images \(offline install\)](#).

Procedure

1. Add a Docker registry secret to the **builder** ServiceAccount in the **openshift-amd-gpu** namespace.
The AMD GPU driver build uses the **builder** ServiceAccount to authenticate and push the compiled driver image to the private registry specified in the **DeviceConfig**.

```
oc create secret docker-registry amdgpu-registry \
--docker-server=<PRIVATE-REGISTRY> \
--docker-username=<USERNAME> \
--docker-password=<PASSWORD> \
-n openshift-amd-gpu

oc secrets link builder amdgpu-registry --for=pull,mount -n openshift-amd-gpu
```

2. Create the **DeviceConfig** custom resource in the **openshift-amd-gpu** namespace.
Replace the three registry fields in the following CR with the correct paths for your enterprise registry.

Field reference

Field	Description	Example
<code>spec.driver.image</code>	Repository where the compiled AMD GPU kernel module image is built and pushed by the operator at runtime.	<code>myregistry.example.com:5000/amd-gpu_kmod</code>
<code>spec.driver.imageBuild.baseImageRegistry</code>	Registry path where all images have been mirrored. This is your TARGET_PATH from the mirroring step. The operator pulls base images (UBI, driver toolkit) from here.	<code>myregistry.example.com:5000/amd-mirror</code>
<code>spec.driver.imageBuild.sourceImageRepo</code>	Full path to the mirrored AMD GPU driver source image. This must be <TARGET_PATH>/rocm/amdgpu-driver , the exact path where the driver image was mirrored.	<code>myregistry.example.com:5000/fusion-mirror/rocm/amdgpu-driver</code>

```
cat > deviceconfig-driver-cr.yaml <<EOF
apiVersion: amd.com/v1alpha1
kind: DeviceConfig
metadata:
  name: driver-cr
  namespace: openshift-amd-gpu
spec:
  selector:
    feature.node.kubernetes.io/amd-gpu: 'true'
  driver:
    enable: true
    driverType: container
    useSourceImage: true
    version: '31.40'
    image: ${TARGET_PATH}/amdgpu_kmod
    imageBuild:
      baseImageRegistry: ${TARGET_PATH}
      sourceImageRepo: ${TARGET_PATH}/rocm/amdgpu-driver
  devicePlugin:
    enableDevicePlugin: true
    enableNodeLabeller: true
    kubeletSocketPath: /var/lib/kubelet/device-plugins
  metricsExporter:
    enable: true
    serviceType: ClusterIP
    port: 5000
    podResourceAPISocketPath: /var/lib/kubelet/pod-resources
  resource:
    requests:
      cpu: 500m
      memory: 512M
    limits:
      cpu: '2'
      memory: 4G
  prometheus:
    serviceMonitor:
      enable: true
      interval: 60s
      honorLabels: true
      attachMetadata:
        node: true
EOF

oc apply -f deviceconfig-driver-cr.yaml
```

Note: The operator builds the kernel module image from the mirrored **amdgpu-driver** source image and pushes the result to **spec.driver.image**. The build might take several minutes per node.

3. Verify the AMD GPU driver deployment.
 - a. Check that all pods are running in the **openshift-amd-gpu** namespace:

```
oc get pods -n openshift-amd-gpu
```

Wait until all pods are in **Running** or **Completed** state. You can expect pods for the operator manager, the device plugin, the metrics exporter, and the KMM build pods (which transition to **Completed** after the driver image is built).

- b. Verify the **DeviceConfig** CR is in Ready state:

```
oc get deviceconfig driver-cr -n openshift-amd-gpu -o yaml
```

In the **status** section, confirm the following conditions:

- The **Ready** condition has **status: "True"** and **reason: OperatorReady**.
- The **driver**, **devicePlugin**, and **metricsExporter** sections each show **availableNumber** equal to **desiredNumber**.

Expected output excerpt:

```
status:
  conditions:
    - reason: OperatorReady
      status: "True"
      type: Ready
  driver:
    availableNumber: 1
    desiredNumber: 1
  devicePlugin:
    availableNumber: 1
    desiredNumber: 1
  metricsExporter:
    availableNumber: 1
    desiredNumber: 1
```

Quick status check:

```
oc get deviceconfig -n openshift-amd-gpu
```

c. Verify AMD GPU labels on the nodes:

```
oc get nodes -l feature.node.kubernetes.io/amd-gpu=true
```

Inspect the full set of AMD GPU labels on a specific node:

```
oc get node <node-name> -o json \
  | jq '.metadata.labels | with_entries(select(.key | startswith("amd.com") or startswith("feature.node.kubernetes.io/amd")))'
```

Expected output:

```
{
  "amd.com/gpu": "1",
  "feature.node.kubernetes.io/amd-gpu": "true"
}
```

• [Disabling automatic installation and upgrade of the AMD GPU Operator](#)

After installing IBM Fusion HCI and adding an AMD GPU node to the OpenShift® cluster, the Node Feature Discovery (NFD) component and the AMD GPU Operator are automatically installed. The NFD component labels the hardware capabilities of the GPU node, and the AMD GPU Operator automates the deployment and management of AMD drivers and related components required for GPU-accelerated workloads.

Disabling automatic installation and upgrade of the AMD GPU Operator

After installing IBM Fusion HCI and adding an AMD GPU node to the OpenShift® cluster, the Node Feature Discovery (NFD) component and the AMD GPU Operator are automatically installed. The NFD component labels the hardware capabilities of the GPU node, and the AMD GPU Operator automates the deployment and management of AMD drivers and related components required for GPU-accelerated workloads.

During Stage 2 deployment, if the system detects an AMD GPU node, IBM Fusion HCI automatically sets the **manageAMDGPUOperator** field to **true** in the **ComputeInit** custom resource and installs the latest supported version of the AMD GPU Operator on the OpenShift cluster.

The **manageAMDGPUOperator** setting controls the automatic installation and upgrade of the AMD GPU Operator.

Value	Description
True (default)	Automatically installs and upgrades the AMD GPU Operator when GPU nodes are detected.
False	You manage AMD GPU Operator installation and upgrades manually.

Manual AMD GPU Operator management

To manually manage the AMD GPU Operator lifecycle, update the **manageAMDGPUOperator** field in the **ComputeInit** custom resource before you perform AMD GPU node upsize operations or use an AMD GPU Operator version other than the latest supported stable version that is installed by IBM Fusion HCI.

1. Run the following command to set the **manageAMDGPUOperator** field to **false**:

```
oc patch computeinit computeinit \
  -n ibm-spectrum-fusion-ns \
  --type=merge \
  -p '{"spec":{"manageAMDGPUOperator":false}}'
```

2. Run the following command to verify that the update is applied successfully:

```
oc get computeinit computeinit \
  -n ibm-spectrum-fusion-ns \
  -o jsonpath='{.spec.manageAMDGPUOperator}'
```

When the **manageAMDGPUOperator** attribute is set to **false**, IBM Fusion HCI does not automatically install, upgrade, or reinstall the AMD GPU Operator. You must manually manage the AMD GPU Operator lifecycle, including maintaining a version other than the latest supported stable version that is installed by IBM Fusion HCI.

To restore automatic AMD GPU Operator lifecycle management, update the field to **true**.

Customizing Node Feature Discovery (NFD) CR

Use the instructions to customize the Node Feature Discovery (NFD) configuration to meet your specific requirements.

The NFD operator and node feature discovery CR are automatically created by IBM Fusion if one or more GPU nodes exist in the cluster. The NFD CR provides a way to configure the NFD daemon set to orchestrate all resources needed to run the NFD daemon set.

The NFD CR configuration is defined in a YAML file that specifies the parameters for the NFD daemon set. The configuration includes settings for the operand, topology updater, and worker configuration.

```
apiVersion: nfd.openshift.io/v1
kind: NodeFeatureDiscovery
metadata:
  name: nfd-instance
  namespace: openshift-nfd
spec:
  instance: ''
  operand:
    imagePullPolicy: Always
    image: 'registry.redhat.io/openshift4/ose-node-feature-discovery-rhel9:v4.18'
    topologyUpdater: false
    workerConfig:
      configData: |
        core:
          # labelWhiteList:
          # noPublish: false
          sleepInterval: 60s
          # sources: [all]
          # klog:
          #   addDirHeader: false
          #   alsoLogToStderr: false
          #   logBacktraceAt:
          #   logToStderr: true
          #   skipHeaders: false
          #   stderrThreshold: 2
          #   v: 0
          vmModule:
          ## NOTE: the following options are not dynamically run-time
          ##       configurable and require a nfd-worker restart to take effect
          ##       after being changed
          #   logDir:
          #   logFile:
          #   logFileMaxSize: 1800
          #   skipLogHeaders: false
        sources:
          # cpu:
          #   cpuid:
          ## NOTE: whitelist has priority over blacklist
          #   attributeBlacklist:
          #     - "BMI1"
          #     - "BMI2"
          #     - "CLMUL"
          #     - "CMOV"
          #     - "CX16"
          #     - "ERMS"
          #     - "F16C"
          #     - "HTT"
          #     - "LZCNT"
          #     - "MMX"
          #     - "MMXEXT"
          #     - "NX"
          #     - "POPCNT"

If you want to customize the existing NFD CR based on your requirements, see [Configuring the Node Feature Discovery Operator](#) in *Red Hat OpenShift Container Platform* documentation.

Converting compute node to AFM node

Convert a Lenovo compute node to a AFM node through backend CR.

Before you begin

- Compute only node must be a part of the storage cluster. To upsize the node to the storage cluster, see [Configuring nodes for management](#).
- The Global Data Platform service must be healthy before you begin the node conversion process.

Procedure

1. Run the following command to provide a name of the node in the `spec` section > `nodeToBeDesignatedAsAfm` field of the `storagemanager` custom resource.

```
oc patch Scale storagemanager -n ibm-spectrum-fusion-ns --type='json' -p='[{"op": "add", "path":
"/spec/nodeToBeDesignatedAsAfm", "value": "<compute-only_node_name>"}]'
```

2. Run the following command to verify whether the `storagemanager` custom resource field is updated with the provided node name:

```
oc get Scale storagemanager -n ibm-spectrum-fusion-ns -oyaml | grep nodeToBeDesignatedAsAfm
```

The progress can be tracked through the status field `userDesignatedAfmNodeStatus` on the `storagemanager` custom resource.

```
oc get Scale storagemanager -n ibm-spectrum-fusion-ns -oyaml | grep userDesignatedAfmNodeStatus
```

Example output:

```
userDesignatedAfmNodeStatus: IN-PROGRESS
```

After you successfully convert the node from Compute to AFM, the status of the `userDesignatedAfmNodeStatus` in the `storagemanager` custom resource displays as `COMPLETED`.

```
oc get Scale storagemanager -n ibm-spectrum-fusion-ns -oyaml | grep userDesignatedAfmNodeStatus
```

Example output:

```
userDesignatedAfmNodeStatus: COMPLETED
```

After you complete the node conversion process, the node name gets added to the `designatedAfmNodes` field in the status section.

3. Run the following command to obtain a list of all the converted nodes:

```
oc get Scale storagemanager -n ibm-spectrum-fusion-ns -o=jsonpath='{.status.designatedAfmNodes[*]}'
```

4. Run the following command to verify the role of the node:

```
oc get node <node_name> -oyaml | grep 'scale.spectrum.ibm.com/role'
```

Example command:

```
oc get node compute-1-ru10.rackae1.mydomain.com -oyaml | grep 'scale.spectrum.ibm.com/role'
```

Example output:

```
scale.spectrum.ibm.com/role: afm
```

5. Run the following command to verify whether the required taints are applied on the node.

```
oc get node <node_name> -o=jsonpath='{.spec.taints}'
```

Example:

```
oc get node compute-1-ru10.rackae1.mydomain.com -o=jsonpath='{.spec.taints}'
```

6. Go to the Global Data Platform page on the IBM Fusion HCI user interface and ensure that the node type displays AFM correctly.

Prerequisite for removing worker node from the IBM Fusion HCI cluster

The following section provides the prerequisite to remove worker node from the IBM Fusion HCI cluster.

Procedure

1. Start a debug session on the node by running the following command:

```
oc debug node/<NODE_NAME>
```

2. When the debug pod starts, switch to the host environment:

```
chroot /host
```

3. Set the fallback option:

```
mokutil --set-fallback-noreboot true
```

Example

```
> oc debug node/compute-1-ru5.isf-rackae4.mydomain.ibm.com
Starting pod/compute-1-ru5isf-rackae4mydomainibmcom-debug-c4jxg ...
To use host binaries, run `chroot /host`
Pod IP: 172.25.100.28
If you don't see a command prompt, try pressing enter.

sh-5.1# chroot /host

sh-5.1# mokutil --set-fallback-noreboot true
```

Configuring GPU upsize on Dell systems

Configure GPU upsize for Dell systems in IBM Fusion HCI.

Before you begin

Note: If a Dell GPU upsize operation is in progress, do not start an upsize operation on any other node. IBM Fusion HCI supports only one Dell GPU node upsize operation at a time, and parallel upsize operations are not supported.

Contact [IBM Support](#) to determine the following information:

- The switches that are connected to the GPU.
- The ports that are assigned for GPU connectivity.

Procedure

1. Identify the available ports on the switch.

- In the OpenShift® console, go to Administration > CustomResourceDefinition > Switch.
- Select the high-speed switch for the corresponding rack.
- Verify port configuration.

For example:

```
swp1 - configured: yes
swp2 - configured: yes
swp3 - configured: yes
swp4 - configured: yes
swp5 - configured: yes
swp6 - configured: no
```

d. Identify the last configured port and the next two consecutive available ports.

For example:

- Last configured port: **swp5**

- Next two consecutive available ports: **swp6** and **swp7**
- Update the Link CR with the available ports.
 - In the OpenShift console, go to Administration > CustomResourceDefinition > Links.
 - Select the Link instance for the rack.
 - Update **portList** by adding the available ports in the **spec** section:

```
spec:
  availableLinkTypes:
    - availableTransceivers:
        - Single QSFP
        - 2x Splitter QSFP
        - 4x Splitter QSFP
      linkType: customer_links
  switches:
    - portList:
        - '32'
        - '31'
        - '6'
        - '7'
      switchList:
        - hspeed1-f791047
        - hspeed2-f791047
```

- If ports are already allocated, run the following command to allow deletion of existing **bond0_links**:

```
oc patch link <link_instance_name> \
  -n ibm-spectrum-fusion-ns \
  --type=merge \
  --subresource=status \
  -p '{"status":{"allowBond0LinkDeletion":true}}'
```

Tip: Ports 6 and 7 might already be associated with **bond0_links**. This step enables their removal.

- Remove the existing bond links from the Link CR **spec**.

Important: Copy configuration details from **b_6** before removing it, as this information is required in the next step.

- In the Link CR **spec**, remove the following entries:

- **b_6**
- **b_7**

- Wait a few minutes and verify that the entries are removed from both **spec** and **status**.

Note: If you encounter the following webhook error, complete the steps to resolve it before you continue:

```
admission webhook "vlinkuser.network.isf.ibm.com" denied the request:
Another operation is in progress on Link resource.
```

- Go to Workloads > ConfigMaps > isf-network-coordination.
- Check the YAML **data** section:

```
data:
  entryTypes: 'bond0_links'
  operationInProgress: 'True'
  operationType: 'add'
  resource: 'link'
```

- Update **operationInProgress** to **'False'**.

- Add a new GPU link in the Link CR **spec** with the following parameters:

- **name**: **gpu_bond<starting_port>**
- **ports**: Two consecutive ports (for example, 6,7)
- **uuid**: Same as the name
- **vlanNames / vlanIds**: Copy from removed **b_6**
- **linkType**: **gpu_dell_2x2_links**

Example configuration:

```
spec:
  aggregation: true
  switches:
    - hspeed2-f791047
    - hspeed1-f791047
  transceiver: 2x Splitter QSFP
  vlanNames: 'vlan1512,Default Native,testvlan2004'
  name: gpu_bond6
  ports: '6,7'
  linkType: gpu_dell_2x2_links
  vlanIds: '1512,1,2004'
  nativeVlan: Default Native
  uuid: gpu_bond6
  vlanType: trunk
```

After a few minutes, the status updates. Expected status example:

```
status:
  gpu_bond6:
    aggregation: true
    switches:
      - hspeed2-f791047
      - hspeed1-f791047
    transceiver: 2x Splitter QSFP
    vlanNames: 'vlan1512,Default Native,testvlan2004'
    name: gpu_bond6
    linkCreated: true
    ports: '6,7'
    linkType: gpu_dell_2x2_links
    vlanIds: '1512,1,2004'
    linkState: true
```

```
nativeVlan: Default Native
uuid: gpu_bond6
vlanType: trunk
```

Ensure that `linkCreated: true` and `linkState: true` are present.

6. Remove ports 6 and 7 from the switch `portList` in the Link CR:

```
switches:
- portList:
- '32'
- '31'
```

Wait until the ports are unconfigured on the switch. Verify that `uplinkPortConfigStatus` shows the following state:

```
uplinkPortConfigStatus:
'31': ready
'32': ready
```

7. Update the compute network handshake.
 - a. In the OpenShift console, go to Workloads > ConfigMaps > `computenetworkhandshake`.
 - b. Select the instance for the node. For example: `computenetworkhandshake-1-ru6`.
 - c. Run the following command to patch the instance:

```
oc patch computenetworkhandshake computenetworkhandshake-1-ru6 \
-n ibm-spectrum-fusion-ns \
--subresource=status \
--type=merge \
-p '{"status":{"message":"SwitchConfigurationSucceeded","switchConfigured":true}}'
```

8. Run the following command to set `allowBond0LinkDeletion` back to `false`:

```
oc patch link <link_instance_name> \
-n ibm-spectrum-fusion-ns \
--type=merge \
--subresource=status \
-p '{"status":{"allowBond0LinkDeletion":false}}'
```

Node issues

This topic provides a comprehensive list of common troubleshooting steps and known issues that may arise while working with compute nodes.

Node halts at UEFI blue screen during deployment or expansion

Problem statement

During Stage 2 cluster deployment or node addition to the OpenShift® Container Platform cluster, a Lenovo compute or control node might halt at a UEFI blue screen. The node waits indefinitely for user input in the pre-OS stage, which prevents Red Hat Enterprise Linux CoreOS (RHCOS) from booting and joining the cluster. This issue is specific to Lenovo ThinkSystem nodes during bare-metal deployment and expansion.

Confirm that the node is stuck at the UEFI blue screen prompt by checking the following symptoms:

- **Stage 2 deployment:** The installation fails at the **OpenShift Installation** stage.
- **Node addition:** The operation fails at the **Configuring node** stage with the error: `Unable to add a new node. OpenShift node not found after Bare metal host provisioning. Please Contact IBM Support.`

Run the following command and confirm that the **STATE** for the target node is **provisioned**:

```
oc get bmh -n openshift-machine-api
```

Run the following command. If the BareMetalHost (BMH) shows **provisioned** but the node does not appear in the output after 15–20 minutes, the node has likely halted at the UEFI prompt:

```
oc get nodes
```

Resolution

Before you begin, retrieve the following information:

- **BMC IP address:** Replace `<rackname>` with the rack name. During Stage 2 deployment, open `~/isfconfig/kickstart-<rackname>.json` on the provisioner node and locate the `ipv4` address under the BMC configuration. During node addition or expansion, retrieve the BMC IP of the node from the `ipv4` field in the kickstart ConfigMap:

```
oc get configmap kickstart-<rackname> -n ibm-spectrum-fusion-ns -o yaml
```

- **BMC credentials:** Run the following commands to extract the decoded username and password:

```
export BMC_SECRET="<node-name>-bmc-secret"
export NAMESPACE="openshift-machine-api"
```

```
# Extract BMC Username
echo "BMC Username: $(oc get secret ${BMC_SECRET} -n ${NAMESPACE} -o jsonpath='{.data.username}' | base64 -d)"
```

```
# Extract BMC Password
echo "BMC Password: $(oc get secret ${BMC_SECRET} -n ${NAMESPACE} -o jsonpath='{.data.password}' | base64 -d)"
```

Use one of the following options to clear the UEFI blue screen prompt:

Option A: BMC web console (recommended)

1. Establish SSH local port forwarding to forward both the Lenovo XClarity Controller (XCC) web dashboard port and the remote console viewer port:

```
sudo ssh -L 443:<BMC-IP>:443 -L 3900:<BMC-IP>:3900 kni@<provisioner-ip>
```

Enter your local machine password for `sudo`, followed by the provisioner credentials.

2. Open a browser and go to `https://localhost`.
3. Log in using the BMC credentials that you retrieved.
4. In the navigation menu, go to Remote Console.
5. In the Remote Console Preview section, click the pop-out launch icon.
6. In the remote viewer window, locate the blue UEFI dialog that displays **Boot Option Restored** or **Reset System**.
Note: If the prompt displays "Press any key to stop system reset", press any key or use the virtual keyboard immediately.
7. Use the arrow keys to select **Always continue boot** and press Enter. The server resumes booting into RHCOS.

Note: Exit the SSH port forwarding session after the node is added to the cluster.

Option B: Redfish API (no console access)

If you cannot reach the graphical remote console, clear the persistent boot override programmatically.

1. From a host with network access to the Baseboard Management Controller (BMC) (for example, the provisioner node), run the following command and confirm that the output returns **"Continuous"**:

```
curl -k -u <BMC_USER>:<BMC_PASSWORD> \
  https://<BMC_IP>/redfish/v1/Systems/1 | jq '.Boot.BootSourceOverrideEnabled'
```

2. Reset the boot source override to allow normal local disk boot:

```
curl -k -X PATCH \
  -u <BMC_USER>:<BMC_PASSWORD> \
  -H "Content-Type: application/json" \
  -d '{"Boot": {"BootSourceOverrideEnabled": "Disabled", "BootSourceOverrideTarget": "None"}}' \
  https://<BMC_IP>/redfish/v1/Systems/1
```

Wait 10 minutes after the server resumes booting. If the node is not added to the cluster, approve any pending certificate signing requests (CSRs):

```
oc get csr -o name | xargs -r oc adm certificate approve
```

Result

Verify that the node joins the cluster within 5–10 minutes:

```
oc get nodes -w
```

If the node does not join the OpenShift Container Platform cluster after completing all the steps, contact [IBM Support](#).

Unable to add node to OpenShift Container Platform

Problem statement

The node cannot be added to the OpenShift Container Platform cluster.

Cause

The issue might be caused by a hung power operation (powerop) for the node. This can be identified by checking the logs on the system.

Symptoms

- The power operation is not progressing.
- The live powerop CR logs for the node are blank or do not show any activity.
- The powerop CR is not getting updated.

Resolution

To resolve this issue, follow these steps:

1. Check the live logs on the system for the powerop operation.
2. If the logs are blank or not updating, delete the powerop CR by running the following commands in the `ibm-spectrum-fusion-ns` namespace:

```
oc get cpr
```

```
oc delete cpr <node-powerop-cr-name>
```

Important: Wait for the command to delete the powerop CR. Avoid forceful deletion as it may cause further issues.

3. After deleting the powerop CR, verify if the node can be added to the OpenShift Container Platform cluster.
4. If the issue persists, contact [IBM support](#).

mmaddnode command fails during node upsize on storage cluster

Resolution

After the initial failure of the `mmaddnode` command during node addition, run the following command to remove the files that do not get cleaned up properly:

```
oc exec -it compute-1-ru13 -c config -- /bin/sh
sh-5.1# rm /var/mmfs/gen/mmsdrfs
```

NVMe drives missing on XCC but seen on CoreOS

Resolution

1. Run `resetsp` to restart the BMC.
2. If the step 1 does not resolve the issue, run `OS reboot` command to reboot the node.
3. If both step 1 and step 2 do not resolve the issue, then contact [IBM support](#) to replace the faulty drive or faulty NVMe backplane.

Issues in node restart

Problem statement

Sometimes, after you restart a node, it may not change its state to ready and the `ovs-configuration.service` may fail.

Resolution

As a resolution, restart the node. For more information about Scale behavior during node restarts, see [Scale behavior during node restarts](#).

GPU operator error

Certain Linux kernels that have KASLR enabled might experience a known issue with **High**

Memory Mode initialization. This issue can cause CUDA initialization to fail. As a workaround, disable the **High Memory Mode**. For more information, see [Disable High Memory Mode](#).

Management switch high availability is lost

When the management switch high availability is lost due to the management switch at RU18 being down, the cluster continues to function, but autodiscovery of nodes is not supported.

Incorrect port speed display for up Ports on configured and discovered nodes

Sometimes, the port speed for all up ports on configured and discovered nodes may be displayed as 0 Gbps instead of the actual speed.

Upgrade progress display error

After initiating an upgrade, the IBM Fusion HCI user interface upgrade page may briefly display Upgrade available instead of showing the upgrade in progress. This is a display issue only and the upgrade is running in the background. Wait for a while for the upgrade progress status to be reported.

GPU node capacity value shows 0

Problem statement

It is observed that sometimes users might see GPU node capacity as 0 and also that the NFD discovery instance has the **nfd-worker-xxx** in a constant crashloopback.

Resolution

This issue was observed in OpenShift Container Platform release 4.10.21. Upgrade the OpenShift Container Platform to 4.10.61, reinstall the NFD operator with the NFD Discovery CR, and install the NVIDIA operator and create the cluster policy that detects the GPUs.

Compute nodes in a hung state

Resolution

Steps to restart when the compute nodes get into a hung state:

As a prerequisite, you must have administrator access to Red Hat® OpenShift and OC (Red Hat OpenShift CLI) command access to the cluster.

1. Log in to OpenShift UI.
2. Go to Compute > Bare Metal Hosts.
3. Ensure to select **openshift-machine-api** project on the Bare Metal Hosts page.
4. From the ellipsis menu, click Power Off for the node.
5. Power it on again and check whether the issue is resolved.

Pod migration gets stuck in the Terminating or ContainerCreating state

Problem statement

A controller node goes down and the migration of the pod gets stuck in Terminating or ContainerCreating state.

Resolution

As a workaround, delete the container creating pod so that it can get scheduled in another available controller node.

Compute node can abruptly become unreachable

Problem statement

A compute node can abruptly become unreachable either due to a power outage or network disruption.

Cause

The pods that run on that specific compute node might have not got evacuated cleanly and they remain stuck in **Terminating** or **Unknown** state.

Resolution

To ensure a complete evacuation and migration of the pod that is stuck on the failed node, force delete the pod manually by using the following command:

```
oc delete pod <pod name> --grace-period=0 --force --namespace <namespace>
```

Add rack workflow from base rack fails in node validation

Problem statement

Add rack workflow from base rack fails in node validation for the nodes of auxiliary rack in case of high availability cluster.

Cause

The issue might occur because monitoring failed for the nodes of the auxiliary rack.

Resolution

1. Before performing the add rack operation, ensure that all the nodes on the auxiliary rack are healthy and that there are no warnings, critical events or any component failures on any of the nodes.
2. Restart the BMC on the failing nodes to clear the events on the compute node.

OpenShift Container Platform node status shows NotReady but IBM Fusion HCI user interface node status shows as Running

Problem statement

The Running state of the node on the IBM Fusion HCI user interface indicates that the Baremetal node is healthy and running. Whenever you see IBM Fusion HCI node status is Running and OpenShift Container Platform node status is Not ready, then follow the steps in the resolution.

Resolution

1. Log in to OpenShift user interface.
2. Go to Compute > Bare Metal.
3. From the ellipsis menu, click Power Off for the node.
4. Power it on again and check if the issue is resolved.

Node goes missing from the IBM Fusion HCI rack graphical view

Problem statement

OpenShift Container Platform node status shows **Ready** even though the IBM Fusion HCI user interface node status shows the node state as **Error connecting to node**

For more information about node status, see [Monitoring hardware from IBM Fusion HCI user interface](#).

This issue might occur due to the power or network issues.

Resolution

The node can be viewed graphically in the user interface of the IBM Fusion HCI rack after it gets into a healthy state. For more information, see [Monitoring hardware from IBM Fusion HCI user interface](#).

1. Get the name of the compute-operator pod name:

```
oc get po -n ibm-spectrum-fusion-ns | grep isf-compute-operator
```

2. Copy the OneCli folder from the operator pod:

```
oc rsync -c manager isf-compute-operator-controller-manager-<pod name>:/fw/onecli
```

Note: For the subsequent commands, create a separate session.

3. Start a debug pod on the target node (BMC has error connecting to the node) that is in Ready state.

```
oc debug node/<nodename>
```

4. Get the debug pod name:

```
oc get po -A -o wide | grep <nodename> | grep debug
```

5. Copy the local copy of the OneCli folder to debug pod.

```
oc rsync onecli pod/<debug pod>:/tmp
```

6. From the other session, run the following command to restart the node:

```
cd /tmp/onecli
./onecli misc rebootbmc
```

7. Go to the Infrastructure > Nodes and wait for the following error message to go away:

```
Error connecting to node
```

It takes around three minutes for the error to disappear from the page.

Node in NotReady state due to certificate errors in OpenShift pods

Problem statement

Issues can occur when a node is in the **NotReady** state. One common reason is that the OpenShift network related pods go into a **crashloopbackoff** state due to an expired certificate file.

Diagnose

Follow the steps to diagnose the issue:

1. Check the output using the following command.

```
oc get co
```

2. If you see any error message related to network, then check if any of the pods in namespace **openshift-ovn-kubernetes** are in crashing state.
3. If a pod is crashing state, then check the logs for it using following command.

```
oc logs <pod-name> -c ovnkube-controller -n openshift-ovn-kubernetes
```

Check for error related to wrong certificate.

```
I1210 14:50:40.305586 78501 certificate_store.go:130] Loading cert/key pair from "/etc/ovn/ovnkube-node-certs/ovnkube-c
I1210 14:50:40.305640 78501 certificate_store.go:130] Loading cert/key pair from "/etc/ovn/ovnkube-node-certs/ovnkube-c
F1210 14:50:40.305690 78501 ovnkube.go:136] failed to start the node certificate manager: failed to initialize the cert
```

4. In a similar way, check if any pod contains issue in namespace **openshift-multus**.

Resolution

Follow the steps to resolve the issue:

1. Use the following steps to resolve the crashing pod issue in **openshift-ovn-kubernetes** namespace:
 - a. Run the following command to change the project.

```
oc project openshift-ovn-kubernetes
```

- b. Run the following command to log in to the failing pod.

```
oc rsh <pod-name>
```

- c. Run **rm -rf /etc/ovn/ovnkube-node-certs/ovnkube-client-current.pem**

- d. Run the following command to restart the crashing pod.

```
oc delete <pod-name>
```

2. Use the following steps to resolve the crashing pod issue in **openshift-multus** namespace:
 - a. Run the following command to check the node of the failing pod.

```
oc get pods -n openshift-multus -owide
```

- b. Run the following command to log in to the respective node .

```
oc debug node/<node-name>
```

- c. Run the following command to delete the **symlink**.

```
rm -rf etc/cni/multus/certs/multus-client-current.pem
```

After fixing the pods in both the namespaces, check if the error message is gone in the output of `oc get co`. The node should come into **Ready** state in sometime.

Use these common troubleshooting tips and tricks when you work with IBM Fusion HCI.

Add node failure

Node addition failures and their resolutions.

Add node failure due to inspection error

Cause

This issue occurred because of ipmitool version in the rack. Run the following command to know the version number of the IPMI:

```
portcontrol -ipmi on
```

Example response:

```
The current security settings require incoming IPMI over LAN to use cipher suite ID 17.  
If you are using the IPMITool utility (prior to version 1.8.19), you must specify the option <-C 17>.  
To effectively enable this service, you must ensure that 'ipmi' is selected in the '-ai' option of the 'users' command.  
ok
```

```
ipmitool -V
```

Example response:

```
ipmitool version 1.8.18
```

Diagnosis

1. Log in to the compute operator pod by using the manager container.

```
oc rsh -c manager <pod_name>
```

2. Go to fw/onecli directory.
3. Run the following command to create a output directory:

```
./OneCli config set IMM.Security_Mode Compatibility --bmc  
USERID:'Wo6k5tSKT0'@[fd8c:215d:178e:c0de:ea80:88ff:fe07:b66b] --never-check-trust
```

Example output:

```
Create output directory at /fw/onecli/logs/OneCli-20241007-062329-988988/ failed with error is 13  
  
[WARNING]: No permission to create output directory at /fw/onecli/logs/OneCli-20241007-062329-988988/  
All output file will not be saved. You can specify another directory by "--output" parameter or with higher permission.  
  
Start to connect BMC at fd8c:215d:178e:c0de:ea80:88ff:fe07:b66b to apply config set  
Connected to BMC at IP address by REDFISH  
Invoking SET command ...  
IMM.Security_Mode=Compatibility  
/fw/onecli/logs/OneCli-988988-20241007-062329/common_result.xml: cannot open file  
  
No permission to create output directory at /fw/onecli/logs/OneCli-20241007-062329-988988/  
All output file will not be saved.  
Succeed.
```

Resolution

To resolve the issue, see [IPMI check Error](#).

Add node failure to OpenShift Container Platform cluster

Node addition to the Red Hat® OpenShift® Container Platform cluster fails.

Severity

Warning or Error

Explanation

Node addition to the Red Hat OpenShift Container Platform cluster reports a failure. As a part of the node addition process, IBM Fusion HCI validates and runs a few steps. If any of these validations or steps fail, a node addition failure gets reported.

Some of the reported failures can auto resolve after a few minutes because the IBM Fusion HCI retries the same validation and steps in every reconciliation cycle. You can view the actual failure reason in the status of the `computeprovisionworker` CR.

In the following example, the `message` field indicates a node DNS validation failure. Determine the failure message from the `computeprovisionworker` CR status, and follow the steps in the *Recommended actions* section.

```
oc -n ibm-spectrum-fusion-ns get cpw provisionworker-compute-1-ru5 -o yaml  
apiVersion: install.isf.ibm.com/v1  
kind: ComputeProvisionWorker  
metadata:
```

```

creationTimestamp: "2024-05-01T21:39:53Z"
generation: 1
name: provisionworker-compute-1-ru5
namespace: ibm-spectrum-fusion-ns
resourceVersion: "8733225"
uid: 3aa59cb6-c032-4b31-98ec-26284ed4588a
spec:
  location: RU5
  rackSerial: 8Y2DXXX
status:
  hostname: compute-1-ru5.mycluster.mydomain.com
  installStatus: Installing
  ipAddress: XX.YY.ZZ.15
  location: RU5
  macAddress: 08:xx:eb:ff:yy:zz
  machineSetScaled: true
  message: DNS validation for node failed.
  messageCode: IOCPW0011
  name: provisionworker-compute-1-ru5
  nodeType: storage
  ocpRole: compute-1-ru5
  oneTimeNetworkBoot: Completed
  rackName: mycluster
  startTimestamp: "2024-05-01T21:39:54Z"

```

Recommended actions

DNS validation for node failed

The error indicates a node DNS validation failure, which can be intermittent because of an unsuccessful DNS call. It eventually succeeds in the next cycle. However, if the issue persists for more than 10 minutes, check the DHCP and DNS configurations to confirm that the correct FQDN to IP exists for the DNS lookup and reverse lookup. After you fix the issue, the node addition in IBM Fusion HCI proceeds automatically to the next step.

Unable to add a node and failed to set boot order

Usually, this failure gets resolved in the subsequent reconcile cycles. If it persists more than 10 minutes, then a Baseboard Management Controller (BMC) restart can resolve the issue. Sometimes, the IMM does not respond to **ipmi** or **redfish** commands. Contact IBM support to restart the BMC. After your restart the BMC, the error gets resolved in the subsequent reconciliation cycles.

Failed to read userconfig secret object

The error indicates that an intermittent API error exists in reading the OpenShift Container Platform secret. It can occur due to a delay in the API response or some other network interruption. This error self-resolves automatically in the successive reconciliation cycles.

Failed to read kickstart configmap data

The error indicates that an intermittent API error exists in reading the OpenShift Container Platform configmap. It can occur due to a delay in the API response or some other network interruption. It self-resolves automatically in the successive reconciliation cycles.

Unable to add a node and the Red Hat OpenShift node did not transition to Ready state

The CSRs pending for approval is the most common reason for this error. The IBM Fusion HCI operator approves these CSRs as a part of the node addition process. If it does not occur as a rare case scenario, manually approve them to resolve the issue. Run the following commands to check and approve the pending CSRs:

1. Run the following command to look for pending CSRs:

```
oc get csr | grep -i pending
```

2. Run the following command to approve pending CSRs:

```
oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs
oc adm certificate approve
```

Failed to scale machineset during new node addition

As a part of the Red Hat OpenShift cluster expansion process, a Bare Metal host object gets created for every node that is added to the cluster. This Bare Metal host object go through the following states: **registering** > **inspecting** > **available** > **provisioning** > **provisioned**. After the Bare Metal host becomes **available**, the replica of the Bare Metal machineset CR in the OpenShift Container Platform cluster increases by one to start the machine creation process of that host. If that step fails, then you can see a reported error in the **compute provisionworker** status. The Fusion operator tries to increase it in the next reconcile cycle again and that eventually succeeds. If it does not succeed in a rare case scenario, do the following steps to manually increase the replica count of the machineset CR.

1. Run the following command to get the machineset name:

```
oc get machinesets -n openshift-machine-api | tail -1 | awk '{print $1}'
```

2. Run the following command to get the machineset current replica count:

```
oc get machinesets -n openshift-machine-api | grep worker | awk '{print $2}'
```

3. Run the following command to increase the replica by one:

```
oc scale --replicas=<old replica count from step2> + 1 machineset <machineset name from step 1> -n openshift-machine-api
```

In the subsequent reconciliation cycles, the node addition process moves to the next steps and gets reflected in the IBM Fusion HCI user interface.

Node might contain an invalid hostname (localhost)

The error indicates that the added host did not get the expected fully qualified hostname assigned from DHCP. A common reason for this error is that the DHCP server does not get configured correctly. Check the following content in the DHCP server:

1. Hostname option is set for this host entry
2. No mistakes exist in the mac address that is used for this host entry
3. DHCP service is running and it is reachable from the host

After you fix the issue on the DHCP side, restart the node by using the Bare Metal host object from the Red Hat OpenShift console. To restart the node, do the following steps from the OpenShift Container Platform web console:

1. Go to Home > Search.
2. Search for CRs with **ComputePowerOp**. It lists CRs and nodes in the cluster.
3. Go to the CR of the node to restart and then go to the YAML tab.
4. Add the following line to **Spec** to power off the node.

```
powerOP: GracefulShutdown
```

if you want to power on the node, change the line to the following line:

```
powerOP: On
```

Unable to add one or more nodes as they contain an invalid hostname (localhost)

This error indicates that the host you want to add did not get the expected valid fully qualified hostname assigned from DHCP. A common reason for this error is that the DHCP server is not configured correctly. In a DHCP server, check whether the following conditions exist:

- Hostname option is set for this host entry
- No mistake in the mac address used for this host entry
- DHCP service is running and DHCP is reachable from the host

After you fix the DHCP issues, restart the node to proceed with the node addition. To restart node, do the following steps from the Red Hat OpenShift Container Platform web console:

1. Go to Home > Search.
2. Search for CRs with **ComputePowerOp**.
3. Go to the CR of the node to restart and then go to the YAML tab.
4. Add the following line to **Spec** to power off the node.

```
powerOP: GracefulShutdown
```

if you want to power on the node, change the line to the following line:

```
powerOP: On
```

Node hardware failure

This error indicates that add node fails due to any problem with node hardware.

Check compute monitoring CR of the node and take an appropriate action to resolve the issue.

For example:

```
NodeType: storage
nodeMonStatus:
  eventCode: BMYC00003
  message: One or more component on the node 169.253.1.6 is in critical state.
  messageArg:
    - 169.253.1.6
  messageCode: BMYM01004E
  state: Critical
  activeEvents:
    - Power Supply 2 has Failed.
    - Sensor PSU 2 Failure has transitioned to critical from a less severe state.
    - 'Non-redundant:Sufficient Resources from Redundancy Degraded or Fully Redundant for Power Resource has asserted.'
```

Issues related to IBM Fusion HCI node drains

Use these common troubleshooting tips and tricks when you work with IBM Fusion HCI.

Issues related to draining IBM Fusion HCI node

Pod Distribution Budget (PDB) limits the number of Pods of a replicated application that are down simultaneously from voluntary disruptions. Scale uses PDB to ensure that storage does not get corrupted and minimum number nodes are available. You may experience delays or failure in node drain or node restart during any of the following operations:

Note: You must never reboot a node before it is drained successfully. Always perform node power operations from the IBM Fusion HCI user interface as it ensures successful node drain.

- Configuration updates
 - Red Hat® OpenShift® Machine Config Operator (MCO)
 - IBM Fusion component specification changes
- Upgrade
 - OpenShift Container Platform upgrades
 - IBM Fusion software upgrades
 - Firmware upgrades
- User Initiated
 - Maintenance operation
 - kdump enabling/disabling
 - Operations that result in node restart
 - Node drain

Cause

The PDB configuration is set by Scale to control the node drain so that the Scale cluster remains healthy always, and you can drain only an allowed quantity of nodes at any time. For more details, see [Scale behavior during node restarts](#).

Resolution

When node drain hangs due to any of the suggested operations, then do the following steps:

1. Run the following command to identify the pod that causes the issue.

```
oc describe cmt <target node name> -n ibm-spectrum-fusion-ns
```

The command lists pods pending for eviction.

2. Go through events of the node having the issue:

Scenario where drains are prevented by an application

If drains are prevented by an application, consult the owner of the application to proceed with the drain, and manually drain the node. For more information about the issue and to troubleshoot, see [Identifying applications preventing cluster maintenance](#) in *IBM Storage Scale Container Native* documentation.

Scenario where drains are prevented by VM

Check [Identifying applications preventing cluster maintenance](#) in *IBM Storage Scale Container Native* documentation to determine the node that is waiting for reboot and check whether live migration is set up properly to allow VM to migrate to a different node. For more information about setting up live migration, see [Virtual machine live migration](#) in *Red Hat OpenShift Container Platform* documentation.

Scenarios where issue is due to node maintenance

- The maintenance mode on a node can take from four minutes to thirty minutes to succeed. If the maintenance mode operation is taking more than 30 minutes, then Fusion continues to retry draining the pods with a warning event BMYCO0012, and gets timed out eventually. If you want to stop the retries, then delete the **Computemaintenance** CR instance. Run the following command to delete **Computemaintenance** CR instance.

```
oc delete cmt <instance-nodename> -n ibm-spectrum-fusion-ns
```

- If it takes a long time and you want to continue the operation, check the pod that is pending by using the **oc get pods** command. If the pod name belongs to IBM Storage Scale, see [Identifying applications preventing cluster maintenance](#) in *IBM Storage Scale Container Native* documentation. If issue persists, collect Scale system health and Scale logs, and contact IBM support.

If you want to understand Scale behavior during node reboots, see [Scale behavior during node restarts](#) section.

Scale behavior during node restarts

Restart of a node can happen due to various reasons such as an MCO roll out, user initiated, or as part of firmware or software upgrades. Scale has a maximum tolerance on the number of nodes that are in unavailable or in not ready state. It is based on the erasure code that is configured for the storage cluster. To stay within this tolerance, Scale uses the POD Disruption Budget (PDB) feature of OpenShift.

Scale CNSA implements PDB with a "maxUnavailable=0", which means that it does not allow a Scale pod to go down without its knowledge. Even with a "maxUnavailable=0" PDB, the design does allow for cluster updates. In this configuration, MCO is prevented from taking down the node and draining the CNSA core pod. The Scale CNSA pod detects the operation, drains the applications, and then exits itself, thus freeing the node up for the operation to continue.

If any application refuses to unmount, or if the scale core pod itself determines the cluster, then it goes into a bad or hung state. If it goes down, then things pause until the condition gets resolved.

For more information about identifying applications that prevent cluster maintenance, see [Identifying applications preventing cluster maintenance](#) in *IBM Storage Scale Container Native* documentation.

Remediating a maintenance drain failure

To remediate a maintenance drain failure, follow these steps:

1. In the OpenShift web console, check the status of the stalled upgrade by using one of the following methods:
 - On the individual node's page, click View Pods.
 - Go to Settings > Upgrades, locate the Node firmware card under Rolling Upgrades, select the node with the status Upgrade Stalled, and click View Pods. Note: The View Pods option in the OpenShift console applies to OpenShift Container Platform nodes for IBM Fusion HCI version 2.12.0. For Hosted Control Plane nodes, eviction must be performed manually.
2. After accessing the View Pods page, you can see a list of all pods, including their current state and namespace.
3. Check the pods listed under pendingPods of the **Compute Maintenance** custom resource (CR) that are scheduled for eviction as part of this CR. To access the **Compute Maintenance** CR, follow these steps:
 - Command line:

```
oc get cmt -n ibm-spectrum-fusion-ns // to fetch the instances
oc get cmt <cmt-name> -oyaml -n ibm-spectrum-fusion-ns
```
 - OpenShift console:
 - Go to Administration > CustomResourceDefinitions, and search for ComputeMaintenance.
 - Click ComputeMaintenance.
 - Select Instances to view the CR.
4. Troubleshoot stalled pods:
 - a. Copy the name of the stalled pod.
 - b. Search for the pod on the View Pods page.
 - c. Check the pod state and investigate why it is not draining. For detailed troubleshooting steps, see [Issues related to draining IBM Fusion HCI node](#).
5. If the issue persists, contact IBM Support.

Dell node issues

This topic provides a comprehensive list of common troubleshooting steps and known issues that may arise while working with the Dell nodes.

Known issues

The following known issues exist while you work with the compute nodes. The workarounds are included wherever possible. If you come across an issue that cannot be solved by using these instructions, contact [IBM Support](#).

Upgrade progress display error:

After initiating an upgrade, the IBM Fusion HCI user interface upgrade page may briefly display Upgrade available instead of showing the upgrade in progress. This is a display issue only and the upgrade is running in the background. Wait for a while for the upgrade progress status to be reported.

Troubleshooting issues

The following troubleshooting issues exist while you work with the compute nodes with workarounds included wherever possible. If you come across an issue that cannot be solved by using these instructions, contact [IBM support](#).

Unable to add node to OpenShift Container Platform

Problem statement

The node cannot be added to the OpenShift® Container Platform cluster.

Cause

The issue might be caused by a hung power operation (powerop) for the node. This can be identified by checking the logs on the system.

Symptoms

- The power operation is not progressing.
- The live powerop CR logs for the node are blank or do not show any activity.
- The powerop CR is not getting updated.

Resolution

To resolve this issue, follow these steps:

1. Check the live logs on the system for the powerop operation.
2. If the logs are blank or not updating, delete the powerop CR by running the following commands in the **ibm-spectrum-fusion-ns** namespace:

```
oc get cpr
oc delete cpr <node-powerop-cr-name>
```

Important: Wait for the command to delete the powerop CR. Avoid forceful deletion as it may cause further issues.

3. After deleting the powerop CR, verify if the node can be added to the OpenShift Container Platform cluster.
4. If the issue persists, contact [IBM support](#).

Unable to add GPU node to compute cluster

Problem statement

Unable to add a GPU node to the compute cluster due to a failure in importing the system configuration.

Symptoms

When attempting to add a Dell GPU DG4 node to the compute cluster, the following issues occur:

- Dell iDRAC issue (LC068) causes the GPU node configuration to fail in IBM Fusion compute configuration CR.
- Failure to set the network boot order while adding the node to the OpenShift Container Platform due to a Redfish call error. The error message indicates: **errorCode: SYS011, message: Pending configuration values are already committed**, unable to perform another set operation.

Cause

The cause of the issue is attributed to a Dell iDRAC issue (LC068) and a Redfish call failure to set PXE settings.

Resolution

To resolve this issue, contact [IBM support](#).

Dell nodes job queue creation fails

Problem statement

Dell nodes job queue creation fails due to internal memory overload.

Cause

Due to a bug in the **LCLogAggregation** function in current versions of **iDRAC**, an issue has arisen with the management of event logs within the internal **Lifecycle Controller (LCC)** partition. This malfunction causes iDRAC to encounter an internal error, which prevents the creation of configuration jobs. As a result, node configuration changes cannot be applied because the internal memory lacks sufficient space to accommodate new tasks. An following is an example error that is seen from the terminal when you try to create the job:

```
racadm>>jobqueue create BIOS.Setup.1-1 -s TIME_NOW -r pwr cycle
ERROR: JCP012: The operation failed due to an internal iDRAC error.
Retry the operation. If the issue persists, reset iDRAC and retry the operation.
racadm>>
```

Resolution

1. Get the **ini** file to send to Dell support team:

```
racadm -r <iDRAC ip> -u <iDRAC user> -p <iDRAC password> debug unblock rootshellash <date(yyyy-mm-dd)> <date next month(yyyy-mm-dd)> -f <service tag>.ini
```

For example:

```
racadm -r 169.253.1.3 -u root -p calvin debug unblock rootshellash 2025-08-20 2025-09-20 -f JW47NW3.ini
```

2. With the new `ini` file from Dell support team enable "debug grant":

```
racadm -r <iDRAC IP> -u <iDRAC user> -p <iDRAC password> debug grant -f <service tag>.ini
```

For example:

```
racadm -r <iDRAC IP> -u root -p calvin debug grant -f Case_#214177489_-_4X47NW3.ini
```

3. Ssh to iDRAC:

```
ssh <iDRAC IP>
```

4. Open debug mode:

```
debug invoke rootshellash
```

5. Change to root:

```
/tmp $ su -
```

6. Extract the event.log:

```
/home/root# scp /flash/data1/LCL/event.log root@1<iDRAC IP>:/tmp
```

7. Remove event-log:

```
/home/root# rm /flash/data1/LCL/event.log
```

8. Disable LCLogAggregation:

```
set iDRAC.Logging.LCLogAggregation 0
```

9. Reset iDRAC:

```
racreset
```

10. Wait for two to five minutes and check if the `jobqueue` command is working.

XLR660 iDRAC dedicated network port failover limitation

Problem statement

The XLR660 includes a dedicated iDRAC (Integrated Dell Remote Access Controller) network port to provide out-of-band management capabilities and this dedicated iDRAC port does not support network failover. If the iDRAC port loses connectivity, the system does not automatically reroute management traffic through other available network interfaces.

Service impact

In such failover scenarios, the IBM Fusion user interface may display a **Error Connecting to Node** message on the nodes page. It impacts the hardware monitoring and firmware monitoring capabilities, which retrieve the system information, adapter information, storage information, firmware status and power operation of IBM Fusion get fail.

Resolution

If you see this issue, contact [IBM support](#).

Service node issues

Common troubleshooting steps and known issues that might arise while working with the service node.

Known issues

The following known issues exist while you work with the service node. The workarounds are included wherever possible. If you come across an issue that cannot be solved by using these instructions, contact [IBM Support](#).

Service Node Power Operations Failure

Service node power operations initiated from the IBM Fusion HCI user interface may consistently fail due to interference from the GNOME Display Manager (GDM) service on the service node OS. To resolve this issue, verify that the GDM service is not blocking the instructions sent by the Dell iDRAC as follows:

- Run the following command to check GDM service:

```
systemctl status gdm
```

- If the GDM service is running, then run the following command to stop it:

```
systemctl stop gdm
```

Trigger the service node power operation again. The operation should now succeed.

Troubleshooting issues

The following troubleshooting issues exist while you work with the service node with workarounds included wherever possible. If you come across an issue that cannot be solved by using these instructions, contact [IBM support](#).

Regenerate a certificate and exchange it with the OpenShift cluster

Problem statement

The TLS certificate on the service node no longer matches the certificate that is stored in the OpenShift® Container Platform secret. As a result, the controller cannot establish a secure connection to the service node APIs.

Resolution

1. SSH into the service node and run the following command to get the fully qualified hostname:

```
hostname -f
```

2. Ensure that the certificate script has the correct permissions to execute:

```
sudo chown kni:kni /home/kni/isf-ui/conf/cert.sh
sudo chmod 500 /home/kni/isf-ui/conf/cert.sh
```

3. Run the certificate generation script and specify the hostname as an argument. The command uses `sudo env PATH=...` to ensure that `kubectl` is located correctly in `/usr/local/bin`, because `sudo` resets the `PATH` environment variable and excludes `/usr/local/bin` by default:

```
sudo env PATH=$PATH:/usr/local/bin timeout 300 bash /home/kni/isf-ui/conf/cert.sh <hostname>
```

The script generates the following files:

- Certificate: `/etc/pki/tls/certs/server.crt`
- Private key: `/etc/pki/tls/private/server.key`

These paths are defined in the service node app configuration at `/home/kni/isf-ui/conf/app.conf`:

```
HTTPSCertFile = /etc/pki/tls/certs/server.crt
HTTPSKeyFile  = /etc/pki/tls/private/server.key
```

4. From the service node terminal, display the contents of both files:

```
# Display the certificate
sudo cat /etc/pki/tls/certs/server.crt

# Display the private key
sudo cat /etc/pki/tls/private/server.key
```

5. Update the secret `install-ui-api-certificate` in the `ibm-spectrum-fusion-ns` namespace. Set the `server.crt` field with the full contents of `/etc/pki/tls/certs/server.crt` and the `server.key` field with the full contents of `/etc/pki/tls/private/server.key`. The secret structure looks similar to:

```
kind: Secret
apiVersion: v1
metadata:
  name: install-ui-api-certificate
  namespace: ibm-spectrum-fusion-ns
data:
  server.crt: <base64-encoded certificate>
  server.key: <base64-encoded private key>
type: Opaque
```

6. To update the secret by using CLI, Base64-encode both files and patch the secret:

```
CRT=$(sudo cat /etc/pki/tls/certs/server.crt | base64 -w 0)
KEY=$(sudo cat /etc/pki/tls/private/server.key | base64 -w 0)

oc patch secret install-ui-api-certificate -n ibm-spectrum-fusion-ns \
  --type='json' \
  -p="[{\"op\":\"replace\",\"path\":\"/data/server.crt\",\"value\":\"${CRT}\"},
  {\"op\":\"replace\",\"path\":\"/data/server.key\",\"value\":\"${KEY}\"}]"
```

Cleaning up localhost node from the IBM Fusion HCI cluster

Follow the instructions to clean up the localhost node from the IBM Fusion HCI cluster.

About this task

The localhost node must not be added to the OpenShift® cluster, as it creates an issue at a later stage. A couple of OpenShift objects are created when the localhost node is added to the IBM Fusion HCI cluster.

Important: The example commands and outputs in this topic are for guidance only. Do not copy and run the example commands and YAMLS as they are presented. Instead, ensure you replace the placeholders with your relevant values.

Procedure

Follow the steps to clean up the localhost node so that the node addition can retry after you resolve the DHCP or DNS misconfiguration issues.

- a. Run the following command to edit the `ComputeProvisionWorker CR` of the compute node that indicated an error message `This node might contain an invalid hostname (localhost)`.
For example:

```
oc edit cpw provisionworker-compute-1-ru5
```

Edit the respective CR to update the location information to an empty string to ensure that the `ComputeProvisionWorker` controller is not involved when you clean different objects of the compute node.

For example:

```
oc edit cpw provisionworker-compute-1-ru5
```

```
...
spec:
  location: ""
```

- b. Delete the respective machine object of the compute node.

You need to identify the machine object first and then mark it with an annotation. Then, scale down the machineset object to delete the machine object.

- i. Run the following command to get the machine object name from the BMH object.

```
oc -n openshift-machine-api get bmh, machine
```

Example output:

NAME	STATE	CONSUMER	ONLINE	ERROR	AGE
baremetalhost.metal3.io/compute-1-ru5	provisioned	isf-rackae6-42ps4-worker-0-r6fmw	true		22h
baremetalhost.metal3.io/compute-1-ru6	provisioned	isf-rackae6-42ps4-worker-0-t922n	true		22h
baremetalhost.metal3.io/compute-1-ru7	provisioned	isf-rackae6-42ps4-worker-0-g842m	true		22h
baremetalhost.metal3.io/control-1-ru2	externally provisioned	isf-rackae6-42ps4-master-0	true		44h
baremetalhost.metal3.io/control-1-ru3	externally provisioned	isf-rackae6-42ps4-master-1	true		44h
baremetalhost.metal3.io/control-1-ru4	externally provisioned	isf-rackae6-42ps4-master-2	true		44h

NAME	PHASE	TYPE	REGION	ZONE	AGE
machine.machine.openshift.io/isf-rackae6-42ps4-master-0	Running				44h
machine.machine.openshift.io/isf-rackae6-42ps4-master-1	Running				44h
machine.machine.openshift.io/isf-rackae6-42ps4-master-2	Running				44h
machine.machine.openshift.io/isf-rackae6-42ps4-worker-0-g842m	Running				22h
machine.machine.openshift.io/isf-rackae6-42ps4-worker-0-r6fmw	Running				22h
machine.machine.openshift.io/isf-rackae6-42ps4-worker-0-t922n	Running				22h

In this example, the BMH object of **compute-1-ru5** maps to the **isf-rackae6-42ps4-worker-0-r6fmw** of the machine object.

- ii. Mark the machine object to delete by a special annotation **machine.openshift.io/cluster-api-delete-machine: delete-me**. The special marking helps to override the machine deletion policy rule.

For example:

```
oc -n openshift-machine-api edit machine isf-rackae6-42ps4-worker-0-r6fmw

apiVersion: machine.openshift.io/v1beta1
kind: Machine
metadata:
  annotations:
    machine.openshift.io/cluster-api-delete-machine: delete-me
...
```

- iii. Now you need to scale down the machineset object so that the deletion of the machine object gets initiated.

Note: After the machineset scale down is performed, the machine objects corresponding to **compute-1-ru5** are cleaned up, and the status of the BMH object corresponding to **compute-1-ru5** changes to deprovisioning.

```
oc -n openshift-machine-api get machineset
```

Example output:

NAME	DESIRED	CURRENT	READY	AVAILABLE	AGE
isf-rackae6-cltp4-worker-0	3	3	3	3	8h

```
oc -n openshift-machine-api get machineset -oyaml | grep replicas
```

Example output:

```
replicas: 3
```

Example command:

```
oc -n openshift-machine-api scale --replicas=<old replica value - 1> machineset <machine set name>

machineset.machine.openshift.io/isf-rackae6-42ps4-worker-0 scaled
```

- iv. After the machineset scale down is performed successfully, the status of the BMH object corresponding to **compute-1-ru5** changes to ready.

Important: This activity might take few minutes, and wait for it to be reflected against the BMH object before proceed with the further steps.

- c. Delete the compute nodes in the node object from the OpenShift Container Platform cluster if anything present.

```
oc get nodes
```

Example output:

NAME	STATUS	ROLES	AGE	VERSION
compute-1-ru6.yourdomain.com	Ready	worker	21h	v1.23.17+16bcd69
compute-1-ru7.yourdomain.com	Ready	worker	21h	v1.23.17+16bcd69
control-1-ru2.yourdomain.ibm.com	Ready	master,worker	43h	v1.23.17+16bcd69
control-1-ru3.yourdomain.com	Ready	master,worker	43h	v1.23.17+16bcd69
control-1-ru4.yourdomain.com	Ready	master,worker	43h	v1.23.17+16bcd69
localhost	Ready	worker	20h	v1.23.17+16bcd69

```
oc delete node localhost
```

- d. Delete the BMH object of the compute node.

```
# oc -n openshift-machine-api get bmh
```

Example output:

NAME	STATE	CONSUMER	ONLINE	ERROR	AGE
compute-1-ru5	available		false		24h
compute-1-ru6	provisioned	isf-rackae6-42ps4-worker-0-t922n	true		24h

compute-1-ru7	provisioned	isf-rackae6-42ps4-worker-0-g842m	true	24h
control-1-ru2	externally provisioned	isf-rackae6-42ps4-master-0	true	46h
control-1-ru3	externally provisioned	isf-rackae6-42ps4-master-1	true	46h
control-1-ru4	externally provisioned	isf-rackae6-42ps4-master-2	true	46h

Example command

```
oc -n openshift-machine-api delete bmh compute-1-ru5
baremetalhost.metal3.io "compute-1-ru5" deleted
```

e. Delete all pending `CertificateSigningRequests` corresponding to the localhost node.

```
for i in `oc get csr --no-headers | grep -i system:node:localhost | grep -i pending | awk '{ print $1 }'`;do oc delete csr $i; done
```

f. Fix the DNS or DHCP issue to get the correct hostname for the corresponding compute node instead of the local host.

g. Delete the `ComputeProvisionWorker` object of the compute node.

```
oc -n ibm-spectrum-fusion-ns get cpw
```

Example output:

NAME	AGE
provisionworker-compute-1-ru5	24h
provisionworker-compute-1-ru6	24h
provisionworker-compute-1-ru7	24h

Example command:

```
oc -n ibm-spectrum-fusion-ns delete cpw provisionworker-compute-1-ru5
compute.provisionworker.install.isf.ibm.com "provisionworker-compute-1-ru5" deleted
```

h. If the issue occurs during installation at the time of OpenShift configuration, the node conversion resumes automatically. If the issue occurs during the node upsize, then retry the node addition.

Shutting down and restarting IBM Fusion HCI rack

Procedures to gracefully shut down and restart IBM Fusion HCI. The process vary depending on whether the storage is Fusion Data Foundation or Global Data Platform.

- [Shutting down and restarting IBM Fusion HCI rack with Data Foundation storage](#)
Perform a complete, planned shutdown and restart of an IBM Fusion HCI rack that uses Fusion Data Foundation storage. Follow each step in sequence and do not proceed to the next step until each validation check passes.
- [Shutting down and restarting IBM Fusion HCI rack with Global Data Platform](#)
Procedure to gracefully restart the IBM Fusion rack with Global Data Platform storage.

Shutting down and restarting IBM Fusion HCI rack with Data Foundation storage

Perform a complete, planned shutdown and restart of an IBM Fusion HCI rack that uses Fusion Data Foundation storage. Follow each step in sequence and do not proceed to the next step until each validation check passes.

Before you begin

This procedure covers a complete, planned shutdown and restart of an IBM Fusion HCI rack that uses Fusion Data Foundation storage. For racks that use Global Data Platform storage, see [Shutting down and restarting IBM Fusion HCI rack with Global Data Platform](#).

The procedure has three major phases:

1. **Pre-shutdown validation (Steps 1–2)** — Confirm the cluster and storage are healthy before you begin.
2. **Graceful shutdown (Steps 3–6)** — Stop workloads, back up cluster state, drain and shut down nodes in the correct order, then completely power off the hardware.
3. **Restart and recovery (Step 7)** — Restore power, bring up nodes in the correct order, validate the cluster and storage at each stage, and scale applications back up.

Important: The shutdown and restart sequence is order-sensitive. Skipping or reversing the node power-on order in Step 7 can leave storage unavailable for worker nodes and cause application pod failures. Follow each step in sequence and do not proceed to the next step until each validation check passes.

Node roles in this procedure

Table 1. Node role definitions

Term	Description
Control nodes	OpenShift® Container Platform control plane nodes. These run the Kubernetes API server, etcd, and the IBM Fusion HCI operator pods. A typical IBM Fusion HCI rack has three control nodes.
Storage nodes	Nodes that run Fusion Data Foundation storage services, including the Ceph OSD, monitor, MDS, and manager pods (<code>rook-ceph-*</code>).
Compute nodes	All remaining worker nodes, including compute-only nodes and GPU nodes. These run application workloads but do not host storage services.

The service node is a separate management node that runs outside the OpenShift Container Platform cluster. It remains available throughout the shutdown procedure and can be used to monitor node state and run `oc` commands after the cluster is shut down.

Install the OpenShift CLI (`oc`) on the service node or on your workstation before you start. For installation steps, see [Downloading command line tools](#). Verify your installation by running `oc version`.

You must have `cluster-admin` privileges for the OpenShift Container Platform cluster.

Procedure

1. Verify cluster health before shutdown.

Confirm that no disruptive operation is in progress and that all nodes are in the **Ready** state.

Check that all cluster operators are available and that no machine config update is in progress:

```
oc get co
oc get mcp
```

All cluster operators must show **AVAILABLE=True**, **PROGRESSING=False**, and **DEGRADED=False**. All machine config pools must show **UPDATED=True** and **DEGRADED=False**.

Note: If any operator or pool is progressing or degraded, wait for it to settle before continuing. Do not begin the shutdown while an update is in progress.

Confirm all nodes are in the **Ready** state:

```
oc get nodes
```

All nodes must appear as **Ready**. If any node is **NotReady**, investigate and resolve the issue before continuing. Proceeding with a degraded node can prevent safe shutdown of the cluster.

2. Verify Fusion Data Foundation storage health.

Before stopping applications, confirm that the Fusion Data Foundation storage cluster is in a healthy state.

- a. In the OpenShift Container Platform web console, click **Storage > Data Foundation**.
- b. In the Status card of the Overview tab, click **Storage system**.
- c. In the notification window, click the **Storage system** link.
- d. In the Status card of the Block and File tab, verify that the storage system shows **Healthy** with a green indicator.

Warning: If the storage system shows a Warning or Error state, contact IBM Support before proceeding. Shutting down storage that is already degraded can result in data loss.

3. Check whether there are any active Backup & Restore jobs.

If a Backup & Restore job or application synchronisation is in progress, wait for it to complete before continuing. Ensure that no data operation is in progress for any job or application before you proceed with the shutdown.

4. Stop applications that consume storage from Fusion Data Foundation.

Applications that write to Fusion Data Foundation persistent volumes must be stopped before the storage layer is shut down. Stopping application I/O before shutdown prevents write errors and potential data corruption.

- a. Identify deployments that mount Fusion Data Foundation persistent volume claims (PVCs).

Run the following command to list all PVCs that are bound to Fusion Data Foundation storage classes:

```
oc get pvc -A -o wide | grep -E "(ocs-storagecluster|rook-ceph)"
```

Note the namespace and deployment name for each PVC in use.

- b. Scale down each identified deployment to zero replicas.

For each deployment that mounts a Fusion Data Foundation PVC, run:

```
oc scale deployment/<deployment-name> --replicas=0 -n <namespace>
```

Repeat for every deployment identified in the previous substep.

- c. Verify that all application I/O has stopped.

Confirm that no pods are still running that mount Fusion Data Foundation storage:

```
oc get pods -A | grep -v Completed | grep -v Running
```

All application pods that were using Fusion Data Foundation PVCs must be in the **Terminating** or **Completed** state, or must no longer appear. Do not proceed until application I/O has stopped.

5. If you have enabled IBM Data Cataloging, place the service in an idle state on the OpenShift Container Platform environment before continuing.

For the shutdown procedure for IBM Data Cataloging, see [Graceful shutdown](#).

6. Shut down the OpenShift Container Platform cluster.

- a. If the cluster-wide proxy is enabled, export the **NO_PROXY**, **HTTP_PROXY**, and **HTTPS_PROXY** environment variables on the node from which you run **oc** commands.

To check whether the proxy is enabled, run:

```
oc get proxy cluster -o yaml
```

- b. Take an etcd backup on one of the control nodes.

Open a debug shell on a control node:

```
oc debug node/<control-node-name>
```

Change the root to the host filesystem. This step is required before the backup script can access the necessary host paths:

```
chroot /host
```

Run the cluster backup script:

```
/usr/local/bin/cluster-backup.sh /home/core/assets/backup
```

When the backup completes successfully, two files are produced in the backup directory:

```
/home/core/assets/backup/
├── snapshot_<timestamp>.db
└── static_kuberesources_<timestamp>.tar.gz
```

Verify that both files are present before continuing. The `snapshot_*.db` file contains the etcd snapshot; the `static_kubernetes_*.tar.gz` file contains static pod manifests and certificates.

Important: If either file is missing, the backup did not complete successfully. Do not proceed with the shutdown until a successful backup exists. Exit the debug session:

```
exit
exit
```

- c. Copy the etcd backup files to the service node or an external system.

```
rsync -avz core@<control-node-name>:/home/core/assets/backup/ /path/to/backup/destination/
```

Confirm that both files (`snapshot_*.db` and `static_kubernetes_*.tar.gz`) are present in the destination before continuing.

- d. Drain workloads from each node before shutdown.

Draining each node gracefully evicts running pods and prevents abrupt termination. Drain compute nodes first, then storage nodes, then control nodes — one node at a time.

```
oc adm drain <node-name> --ignore-daemonsets --delete-emptydir-data --force
```

After draining each node, verify that only DaemonSet pods remain:

```
oc get pods -A -o wide | grep <node-name>
```

- e. Shut down compute nodes.

```
for i in $(oc get nodes | grep compute | awk '{print $1}'); do
  oc debug nodes/$i -- chroot /host shutdown -h 1
done
```

- f. Shut down storage nodes.

```
for i in $(oc get nodes | grep storage | awk '{print $1}'); do
  oc debug nodes/$i -- chroot /host shutdown -h 1
done
```

Note: Adapt the `grep` pattern to match the node role labels in your cluster. Run `oc get nodes --show-labels` to confirm the label values before running the loop.

- g. Shut down control nodes.

```
for i in $(oc get nodes | grep -v compute | grep -v storage | grep -v NAME | awk '{print $1}'); do
  oc debug nodes/$i -- chroot /host shutdown -h 1
done
```

Note: IBM Fusion HCI operator pods have affinity to control nodes in general and are not pinned to a single control node. All control nodes can be shut down in this loop with no special last-node sequencing required.

7. Power off the rack nodes completely.

Understand the power states before you proceed:

Table 2. Node power states

Method	What it does
IBM Fusion HCI UI shutdown	Shuts down the CoreOS operating system on the node. The underlying hardware and the Baseboard Management Controller (BMC) remain powered on.
Physical power button	Pressing the physical power button also shuts down CoreOS only. It does not power off the underlying hardware or the BMC.
Complete hardware power-off	The only way to completely power off a node, including the BMC, is to unplug the Power Distribution Unit (PDU) connection between the rack and the customer data centre.

If your maintenance procedure requires only an OS-level shutdown — for example, for an OpenShift Container Platform-level maintenance task — Step 6 already performed that shutdown. No further action is required in this step.

If your maintenance procedure requires complete hardware power-off — for example, for physical rack maintenance, component replacement, or a facility power event — unplug the PDU connections between the rack and the customer data centre for each node, and confirm with the facility team that power has been removed.

Note: After unplugging the PDU, the BMC is no longer powered and cannot be used to remotely manage the nodes until PDU power is restored. The switches shut down automatically when the rack is unplugged and come back up automatically when power is restored.

8. Power on the rack and restore the cluster.

Power on nodes in the following order: **(1) control nodes → (2) storage nodes → (3) compute nodes**. Validate readiness at each stage before proceeding to the next.

Important: Do not power on compute nodes until all required `rook-ceph-*` pods are in the **Running** state. Powering on compute nodes before Fusion Data Foundation storage is healthy causes application pods to fail with **FailedMount** errors.

- a. Restore power to the rack.

If you unplugged the PDU connections in Step 7, reconnect them and confirm with the facility team that power has been restored. Wait approximately 2–3 minutes for the hardware to initialise before continuing.

- b. Press the power button on the service node (Rack Unit 23).

- c. Press the power button on each control node (Rack Units 2, 3, and 4).

- d. Wait 20 minutes for the service node and control plane to initialise.

Note: The OpenShift Container Platform and IBM Fusion HCI user interfaces are not available until the control nodes have fully started. Do not attempt to access them before the wait period has elapsed.

- e. Verify that the service node is reachable.

Confirm that you can connect to the service node over SSH or through its management interface.

- f. Verify that the OpenShift Container Platform and IBM Fusion HCI user interfaces are reachable.

Open the OpenShift Container Platform web console and the IBM Fusion HCI UI in a browser and confirm that both load successfully before continuing.

- g. Power on all storage nodes, then power on all compute nodes.
Press the power button on each storage node, then press the power button on each compute node (compute-only and GPU nodes).

Important: Do not power on compute nodes until the Fusion Data Foundation storage pods are healthy. In the OpenShift Container Platform web console, go to **Storage > Data Foundation > Overview** and confirm the storage system status shows **Healthy** before you power on compute nodes. Powering on compute nodes before storage is healthy causes application pods to fail with **FailedMount** errors.

- h. Scale up the Fusion Data Foundation application deployments.
For each deployment that was scaled to zero in Step 4, scale it back up to its original replica count:

```
oc scale deployment/<deployment-name> --replicas=<original-count> -n <namespace>
```

After scaling up all deployments, verify that the application pods are running:

```
oc get pods -n <namespace>
```

Verify that application I/O to Fusion Data Foundation storage is restored by checking **Storage > Data Foundation > Overview** and confirming the storage system status returns to **Healthy**.

- i. If you placed IBM Data Cataloging in an idle state in Step 5, bring it back to a running state.
For the procedure, see [Returning IBM Data Cataloging to a running state](#).

Shutting down and restarting IBM Fusion HCI rack with Global Data Platform

Procedure to gracefully restart the IBM Fusion rack with Global Data Platform storage.

Before you begin

Install OpenShift® Command Line Interface (CLI):

1. Log in to OpenShift Container Platform web console.
2. Click ? in the title bar, and click **Command Line Tools**.
The **Command Line Tools** page is displayed.
3. In the **Command Line Tools**, click **Download oc** for <your platform>.
4. Save the file.
5. Unpack the downloaded archive file.
6. Move the **oc** binary to a directory on your path.
7. Run the file to install the OpenShift CLI.

Procedure

1. Capture health check report before bringing down the rack. It helps to check for any preexisting issues post power-on.
Note: The health report must be saved to a different system.

Global Data Platform

For Global Data Platform storage, run the following OC commands to get the system health status before shutdown:

- a. Run the following commands to list the pods, cluster operators, and nodes.

```
oc get po -A | grep -v Running | grep -v Completed
oc get co
oc get nodes
```

- b. Change to **ibm-spectrum-scale** namespace:

```
oc project ibm-spectrum-scale
```

- c. Log in to a running pod. For example, **compute-1-ru5** pod:

```
oc rsh compute-1-ru5
```

- d. Run the following command to get the state of the GPFS daemon on one or more nodes.

```
mmgetstate -a
```

- e. Run the following command to display the current configuration information for a GPFS cluster.

```
mmfscluster
```

2. Check whether there exists any active Backup & Restore jobs. If Backup & Restore or application synch is in progress, then wait for them to complete. Wait for in progress workload operations to complete. Before you proceed with the shutdown of the storage cluster, ensure that no data is in progress for any job or application.
3. Run the following steps based on whether your rack is a stand alone or is in a disaster recovery setup (Metro-DR):

Stand-alone

- a. Run the following command to shut down:

```
mmshutdown -a
```

- b. Run the following command to verify whether all nodes are down:

```
mmgetstate -a
```

- c. Exit from the pod

```
exit
```

Metro-DR

If you plan to shut down a site, ensure that you failover your applications to the other site.

- a. Shutdown scale pods on affected site by using the **mmshutdown** directly in the pod Terminal.
- b. Run **exit** to exit from the pod

4. Run the following storage commands to shut down the storage cluster.

Global Data Platform cluster

- a. Switch the project to **ibm-spectrum-scale-operator**.

```
oc project ibm-spectrum-scale-operator
```

- b. Set the replicas in the deployment configuration:

```
oc scale --replicas=0 deployment ibm-spectrum-scale-controller-manager
```

- c. Switch the project to **ibm-spectrum-scale**.

```
oc project ibm-spectrum-scale
```

- d. Log in to compute-1-ru<x>:

```
oc rsh compute-1-ru<x>
```

5. Place the IBM Data Cataloging service in an idle state on the Red Hat® OpenShift environment. For more information about the procedure, see [Graceful shutdown](#).
6. Shut down the Red Hat OpenShift Container Platform cluster.

- a. If the cluster-wide proxy is enabled, be sure to export the NO_PROXY, HTTP_PROXY, and HTTPS_PROXY environment variables. To check if the proxy is enabled, run **oc get proxy cluster -o yaml**.
- b. Take etcd backup.

```
oc debug node/<node_name> (any one control node)
```

```
sh-4.15# /usr/local/bin/cluster-backup.sh /home/core/assets/backup
```

- c. Copy the etcd backup to external system.

```
snapshot_.db and static_kubereresources_.tar.gz
```

You can use the **oc rsync** command to copy the files to an external system. You need two terminals for this operation.

- i. Open terminal one.
- ii. Run the following commands for etcd backup:

```
oc debug node/<node_name>
```

```
sh-4.15# /usr/local/bin/cluster-backup.sh /home/core/assets/backup
```

In **oc debug**

node/<node_name> command, use any one control node.

- iii. Run the following command and record the new pod name:
It is the source pod, and the backup files reside inside the pod.

```
oc debug
```

Do not close the terminal 1.

- iv. Open terminal two and run the following command to copy the file to the local folder:

```
oc -n <namespace_of_debug_pod> rsync <source_podname_in_above_step>:/home/core/assets/backup/snapshot_.db  
<local_folder_path>
```

If required, add the namespace of the debug node pod location.

- v. Repeat the step ii to copy another backup file to the external system.
- vi. Close the terminal windows after all the files are copied.

For more information about the procedure, see [Copy local files to or from a remote directory](#) in *Red Hat OpenShift Container Platform* documentation.

- d. Ensure that you take off the workloads before you shut down the nodes.
- e. Run the following commands to shut down the nodes:
Ensure that the control node hosting the IBM Fusion operators is powered off last. Shutting down this node prematurely results in loss of access to both the IBM Fusion and OpenShift Container Platform user interfaces.
Finally, shutdown the OpenShift control plane nodes.

```
for node in $(oc get nodes -o jsonpath='{.items[*].metadata.name}');  
do oc debug node/${node} -- chroot /host shutdown -h 1;  
done
```

After 3 to 5 minutes, the Red Hat OpenShift Container Platform becomes inaccessible.
This step brings down all the software on the rack. The rack is ready to be powered off.

7. Physically press the power off button of the nodes and the rack.

Note:

- This physical power off indicates to the Baseboard Management Controller (BMC) that you intend to keep the node powered down and prevents automatic restart.
- The switches do not have the option to shutdown, and they can only be rebooted. When you power off the entire rack (unplugged), the switches shut down automatically. Similarly, when the power is restored to the rack, the switches comes up automatically.

8. Power on the rack.
 - a. Power on the rack.
 - b. Go to the physical node and click the power button to power on all the nodes.
Power on all control nodes. After all control nodes are up, power on compute nodes.
 - c. After all the nodes are up and cluster operators are up (except image registry), run the following commands to ensure that the OpenShift cluster is up along with the IBM Fusion operators.

```
oc get po -A | grep -v Running | grep -v Completed
oc get co
oc get nodes
```

- d. For Global Data Platform, bring back the Scale.

```
oc project ibm-spectrum-scale-operator
oc scale --replicas=1 deployment ibm-spectrum-scale-controller-manager
```

Give it a few minutes and check the cluster or storage dashboard.

- e. Run the following commands to ensure that the storage pods are up:

Global Data Platform

- i. Switch namespace to **ibm-spectrum-scale**:

```
oc project ibm-spectrum-scale
```

- ii. Verify whether all pods are in running state in the **ibm-spectrum-scale** project:

```
oc get pods
```

- iii. To run commands on a node, run the following **rsh** command:

```
oc rsh compute-t-ru<x>
```

- iv. Run the following command to get the state of the GPFS daemon on one or more nodes.

```
mmgetstate -a
```

- v. Switch project to **ibm-spectrum-scale-csi**:

```
oc project ibm-spectrum-scale-csi
```

- vi. Verify whether all pods are in running state in the **ibm-spectrum-scale-csi** project. This may take sometime.

```
oc get pods
```

9. Bring back IBM Data Cataloging to a running state.
For the procedure, see [Returning IBM Data Cataloging to a running state](#).

Rack reset

Rack reset automates the process of resetting a rack to a clean, factory-ready state. Use this feature when you need to reinstall the rack or recover from configuration issues.

Overview

Rack reset prepares your IBM Fusion HCI rack for a fresh installation by:

- Discovering all hardware devices (compute nodes, switches, BMCs)
- Resetting devices to factory defaults (credentials, configurations)
- Applying baseline switch configurations
- Generating stage 1 installation files (kickstart.json, rackInfo.json)

After rack reset completes successfully, the rack is ready for stage 1 and stage 2 OpenShift® installation.

Key benefits

- Automated workflow: Eliminates manual configuration steps
- Consistent results: Resets all hardware to a known baseline state
- Efficient: Completes rack preparation in approximately 60-90 minutes
- Recovery capability: Automatically resumes from failure points without restarting

Use cases

Use rack reset in the following scenarios:

Table 1. Primary use cases

Scenario	Description	When to use
Fresh reinstallation	Complete reinstallation of IBM Fusion HCI.	When you need to start from a clean state.
Configuration recovery	Fix misconfigured hardware.	When hardware settings are corrupted.
Hardware replacement	Reset after replacing failed components.	After hardware maintenance.
Upgrade preparation	Clean state before major upgrades.	When recommended by IBM Support.

Warning: Rack reset is a destructive operation. All existing configurations are removed. All data on compute nodes is erased, and the OpenShift cluster is deleted. This operation cannot be undone. Always backup critical data before proceeding.

Prerequisites

Before performing rack reset, ensure that the following prerequisites are met.

Service node requirements

- The service node is installed and operational in the rack.
- It is typically located at RU23 (Rack Unit 23) for Day 0 service node topology and RU33 for Day 2 service node topology.
- It is connected to all rack components.
- Rack setup is completed up to Stage 2.
- The Vault must be active and unsealed. If the Vault is sealed, follow the instructions in [Troubleshooting Vault](#) to unseal it.
- If secret rotation is enabled on the cluster, ensure that it is completed successfully.
- Ensure that the internal Vault on the service node is synchronized with the master OpenShift Container Platform secret. To verify synchronization, in the IBM Fusion HCI console, check for the event: [BMVIN4033](#). If this event is present, the internal Vault contains the same data as the master OpenShift secret and synchronization is complete. If [BMVIN4034](#) event is present, then fix the issue that is related to the Vault. For Vault-specific issues related to secret update, see [Common issues and resolution](#).
- Out of band IP is configured for the service node.

Network requirements

- All devices are connected to a management network.
- Forward and reverse DNS entries are configured for all devices.
- DHCP reservations are configured (if using DHCP).
- The `httpd` service must be running. If the service is stopped, restart by using the following commands:

```
systemctl start httpd
systemctl enable httpd
```

- Required firewall ports are open on the service node:
 - Port 22 (SSH)
 - Port 443 (HTTPS)
 - Port 3000 (Stage 2 UI)
 - Port 3900 (IMM console access)

Hardware requirements

- All compute nodes and switches are powered on.
- The cabling is complete and correct.
- All node Baseboard Management Controllers (BMCs) are reachable.
- Switch management interfaces are accessible.

Access and credentials

- Valid service node UI credentials are available.
- Re-enter your password to authorize the rack reset.
- Rack reset specific Vault credential secrets including `CNIMMSecret`, `SwitchSecret`, `KickStartSecret`, and `awxadmin` must be present in the HashiCorp Vault (managed automatically).
- Before starting a rack reset, review the contents of the `kickstart` ConfigMap in the `ibm-spectrum-fusion-ns` namespace:

```
oc project ibm-spectrum-fusion-ns
oc get cm
oc get cm | grep kickstart
```

If the `ipv6ULA` or `ipv6LLA` fields are empty for any node, contact [IBM Support](#) before initiating rack reset.

Time requirements

- Allocate 60-90 minutes for complete rack reset.
- Schedule an appropriate maintenance window for downtime.
- Ensure stable power and network connectivity during the operation.

Before you begin

- Backup all critical data. Contact [IBM Support](#) for backup procedures.
 - Verify that all prerequisites are met.
- Use the following checklist to verify all prerequisites:
- The service node is powered on and accessible through OOB network IP
 - All BMCs are reachable
 - All switches are powered on
 - Network connectivity is verified
 - DNS/DHCP is configured correctly
 - You have service node UI credentials
 - Maintenance window is scheduled
 - Critical data backed up
 - Stakeholders are notified
- For Day 2 service node topology and service node upgrade scenarios, back up the `vault-secret` and `vault-login-secret` from OpenShift Container Platform.

Prepare an upgraded service node (versions prior to 2.14) for rack reset

1. Copy privateRepoImages.json from Entitled System Support (ESS) to path: /home/kni/isf-ui/conf/privateRepoImages/privateRepoImages.json
2. Restart the UI service:

```
sudo systemctl restart isf-ui.service
```

Perform rack reset

Use IBM Fusion HCI installer UI running on the service node to access the rack reset feature.

To perform rack reset, follow these steps:

1. Open a web browser (Google Chrome, Firefox, or Microsoft Edge recommended).
2. Go to the service node UI by using the out of band IP:

https://<service-node-ip>:3000/dashboard

3. Accept the security certificate warning (self-signed certificate):
 - Click Advanced or Show Details.
 - Click Proceed to site or Accept Risk and Continue.
4. Log in to the service node UI:
 - Username: Your service node username
 - Password: Your service node password
5. Click Factory Reset.
6. In the Factory reset dialog, re-enter your password to confirm the operation.
Note: This step is a security measure for destructive operations. Use the same password that you used to log in.
7. Click Reset.

The rack reset workflow launches. An AWX workflow job is created on the service node, and the Progress monitoring page appears.

Rack reset workflow phases

The rack reset workflow executes the following phases automatically:

Phase 1: Device inventory creation (5-10 minutes)
Discovers all hardware devices in the rack.

Phase 2: Server configuration (50 minutes)

- Factory reset of BMCs
- Configuration of BMCs
- RAID configuration
- System product identifier configuration
- RHEL installation
- Configuration of boot order of CoreOS
- Cleanup of NVMe disks
- BMC and OS time synchronization with NTP server

Phase 3: Switch configuration (15-20 minutes)

- Restore switches to IBM Fusion defaults

Phase 4: Generation of Stage 1 deliverables (5-10 minutes)

- Generate kickstart.json
- Generate rhel.json
- Generate <rack serial>_adaperMacAddress.json
- Generate rackInfo.json

Total estimated time: 60-90 minutes

Recovery procedures

Rack reset includes recovery mechanisms to handle failures and resume operations.

Automatic recovery (checkpoint-based)

Rack reset includes automatic checkpoint-based recovery. If a workflow fails, you can re-launch it.

1. Review error logs to understand what failed.
 2. Fix the underlying issue (for example, power on a device or fix network).
 3. Re-launch rack reset from the UI.
- The workflow automatically resumes from the last successful checkpoint.

Example:

```
Previous Run:
✓ Discovery complete
✓ Normalization complete
✓ Switch firmware complete
✗ Node firmware failed (node03 unreachable)
```

```
After fixing node03 and re-launching:
Discovery skipped (already complete)
Normalization skipped (already complete)
Switch firmware skipped (already complete)
▶ Node firmware resumed (retry node03)
```

Manual recovery

If automatic recovery does not work, you can perform manual recovery.

Forced complete restart

To start the Rack reset workflow from the beginning, follow these steps:

1. Log in to the service node by using SSH:

```
ssh kni@<service-node-ip>
```

2. Remove the rack reset checkpoint file:

```
sudo rm /var/lib/awx/checkpoints/rack_reset/{rack_id}.json
```

3. Re-launch the Rack reset workflow from the service node UI.

- [Monitoring rack reset](#)

The service node UI provides real-time monitoring of the rack reset workflow, enabling you to track progress and respond to any issues that occur during the reset process.

- [Post-rack reset](#)

After rack reset completes successfully, you must proceed with stage 1 and stage 2 installations to deploy OpenShift.

- [Troubleshooting and known limitations for rack reset](#)

Troubleshooting steps and known issues for rack reset.

Monitoring rack reset

The service node UI provides real-time monitoring of the rack reset workflow, enabling you to track progress and respond to any issues that occur during the reset process.

Real-time progress monitoring

The service node UI provides real-time monitoring of the rack reset workflow through a dedicated progress dashboard:

Status indicators

The workflow uses visual indicators to communicate the current state of the rack reset process:

Table 1. Status indicators

Icon	Status	Description
▶	In Progress	Workflow currently executing
✓	Completed	Workflow finished successfully
✗	Failed	Workflow encountered an error

Handling workflow failures

If the workflow fails during execution, complete the following steps:

1. Review error messages in the logs.
2. Fix the underlying issue based on the error message guidance.
3. Re-launch rack reset from the service node UI.
4. The workflow automatically resumes from the last successful checkpoint.

Tip: The rack reset workflow includes automatic checkpoint recovery. When you re-launch after a failure, the workflow skips completed phases and resumes from where it stopped, saving time and avoiding redundant operations.

Post-rack reset

After rack reset completes successfully, you must proceed with stage 1 and stage 2 installations to deploy OpenShift®.

Stage 1 installation

Stage 1 installation prepares the infrastructure for OpenShift deployment.

Prerequisites

- Rack reset must be completed successfully.
- The service node is accessible.

Proceed with the stage 1 installation. For more information, contact [IBM Support](#).

Preparing for stage 2 installation

Before starting stage 2 installation, complete the following preparation steps.

1. Generate an SSH key pair by running the following command:

```
ssh-keygen -t rsa -b 4096 -f /home/kni/.ssh/id_rsa -N ""
cat > /home/kni/.ssh/config << 'EOF'
Host *
  StrictHostKeyChecking no
  UserKnownHostsFile=/dev/null
  IdentityFile /home/kni/.ssh/id_rsa
EOF
```

2. Configure Vault based on your service node topology:

- For Day 0 service node topology: Retrieve the Vault keys from the earlier downloaded keysAndPassword.zip file after successful stage 2 completion.

- For Day 2 service node topology and service node upgrade scenario: Retrieve the Vault keys from the backup of **vault-secret** and **vault-login-secret** taken before executing rack reset.
 - Note: The vault.config file must contain encoded content for the Vault root token and unseal keys.
3. Create the following files in the /var/vault directory path by using the vault.config file and **vaultLogin** content:
- vault.config
 - unsealKey1
 - unsealKey2
 - unsealKey3
 - unsealKey4
 - unsealKey5
 - rootToken
 - vaultLogin

Important: The content of all these files must be Base64-encoded.

Example of vault.config file:

```
Unseal Key 1: 20vcme9qFfZoJJ2D1401TkHMudcZ9yoSPG405rrPkpsa
Unseal Key 2: Kvsahf3pocBmM/F8CEd+E9WknXn18cp+Emdhjo7noV2L
Unseal Key 3: /B5aCjleJwIKM1oB7vF5f8kr7n3FiRgGvRlJMAAt+kr04
Unseal Key 4: zbgQhs8v1PnHrXeAR24z7ELFdjnlgpvqfME0mfWQbGCs
Unseal Key 5: 3KFyWLCGnRy0ry/Q279HB4aRR8H5aXWfQ8TkrSulaPoj

Initial Root Token: hvs.etJ4YvVk5O26fqXS91jP0XFR

Vault initialized with 5 key shares and a key threshold of 3. Please securely
distribute the key shares printed above. When the Vault is re-sealed,
restarted, or stopped, you must supply at least 3 of these keys to unseal it
before it can start servicing requests.

Vault does not store the generated root key. Without at least 3 keys to
reconstruct the root key, Vault will remain permanently sealed!

It is possible to generate new unseal keys, provided you have a quorum of
existing unseal keys shares.
```

Stage 2 installation (OpenShift installation and IBM Fusion HCI setup)

Stage 2 installation deploys OpenShift and configures IBM Fusion HCI.

Prerequisites

- The stage 1 installation is completed successfully.
- The service node UI is accessible.

Proceed with the stage 2 installation. For more information, see [Installing IBM Fusion HCI](#).

Troubleshooting and known limitations for rack reset

Troubleshooting steps and known issues for rack reset.

Cannot access service node UI

Symptoms

- The browser cannot connect to **https://<service-node-ip>:3000**.
- The connection is timed out or refused.

Possible causes

- The service node powered off.
- Network connectivity issue.
- Firewall is blocking port 3000.
- The service node is not running.

Resolution

1. Verify that the service node is powered on:

```
ping <service-node-ip>
```

2. Check that the firewall allows port 3000:

```
# Run the following command on the service node
sudo firewall-cmd --list-ports
```

```
# It must show: 3000/tcp
```

3. Verify that the service is running:

```
# SSH to service node
ssh kni@<service-node-ip>
```

```
# Check service status
sudo systemctl status isf-ui
```

- Restart the service if needed:

```
sudo systemctl restart isf-ui
```

Failed to retrieve AWX credentials

Symptom

When you click Factory reset, the Rack reset UI throws an error.

Possible causes

- The Vault is not in an active state.
- The Vault service is not running.
- The Vault is sealed.
- The **awxadmin** secret is not present in the Vault.

Resolution

- Verify that the vault service is running:

```
sudo systemctl status vault
```

- Start the vault service, if not running:

```
sudo systemctl start vault
```

- Unseal the Vault, if Vault is sealed:

```
sudo vault operator unseal <Vault unseal keys obtained from Openshift cluster or downloaded zip>
```

- Check for **awxadmin** secret:

```
sudo vault kv list secret/node
```

- Create **awxadmin** secret if it does not exist in Vault:

```
export KUBECONFIG=/etc/rancher/k3s/k3s.yaml
kubectl get secret awx-admin-password -n awx -o jsonpath='{.data.password}' | base64 -d
sudo vault kv put secret/node/awxadmin username=admin password=<password obtained from previous step>
```

Failed to initialize AWX client

Symptom

When you click Factory reset, the Rack reset UI throws an error.

Possible causes

- The AWX service is not running.
- AWX pods are not in a running state.
- Firewall issues

Resolution

- Verify AWX service:

```
curl -k "https://localhost"
```

- Verify whether the AWX pods are running:

```
kubectl get pods -n awx
```

- Retrieve AWX logs and contact [IBM Support](#):

```
kubectl logs -n awx deployment/awx-operator-controller-manager
kubectl logs -n awx <pod> --previous
```

Configure Boot Order workflow fails

Symptom

The Configure Boot Order workflow fails for a few baseboard management controllers (BMCs).

Possible causes

- The BMC is not reachable.
- The BMC is in an inconsistent state.

Resolution

- Check BMC reachability from the service node:

```
ping <BMC ipv6>
```

- If BMC is reachable, run **resetip**:

- Retrieve failed BMC credentials from **KickStartSecret** in Vault by using the following command:

```
sudo vault kv get secret/KickStartSecret
```

- Log in to BMC by using the obtained IP and credentials.

- c. Run the `resetap` command.
- d. Retry the Factory Reset workflow.

Known limitations

- For IBM Fusion HCI systems running a fresh installation of version 2.14 or upgraded to 2.14, performing a rack reset followed by a reinstallation does not enable FIPS mode.

Networking

Configure and administer network settings for IBM Fusion.

Configuring network settings

Configure your network settings so that you can connect to the system, modify the existing network configurations.

- [Configuring network connections](#)
To configure and manage network connections of your IBM Fusion appliance, add VLANs and then link to the system.
- [Upgrading switch firmware](#)
Upgrade switch firmware.
- [Creating dedicated secondary Network in Virtualization](#)
If the primary pod network in OpenShift® Virtualization becomes congested, you can improve performance by isolating that traffic onto a dedicated secondary network.
- [Provisioning additional networking](#)
Provision additional networking for direct network access to a container or to a virtual machine.
- [Networking issues](#)
A list of all troubleshooting and known issues that exist in the networking of IBM Fusion HCI.

Configuring network connections

To configure and manage network connections of your IBM Fusion appliance, add VLANs and then link to the system.

About this task

- [VLANs](#)
A virtual local area network (VLAN) is a network concept and is central in directing traffic to your resources. It is an isolated broadcast domain that is created within a switch and is used to isolate broadcast traffic on the public and private networks.
- [Links](#)
In the Links section, you add links and configure their settings based on the VLANs that are defined in the VLANs section.

VLANs

A virtual local area network (VLAN) is a network concept and is central in directing traffic to your resources. It is an isolated broadcast domain that is created within a switch and is used to isolate broadcast traffic on the public and private networks.

Overview

VLANs are managed automatically with no need to interact directly with them, and they are assigned or removed according to the requirements. Each VLAN created within a switch is isolated from other VLANs. The network traffic can pass from one VLAN to another by adding a routing device. The routing functions must be provided at the data center core network. VLANs provide one method of packet identification, and they allow multiple workloads to coexist on the same system.

Work with your VLANs to add connections to the system as part of your network configuration.

Important: Perform VLAN operations, including create, modify, and delete actions, only when all high-speed switches are online. Offline switches may cause these operations to fail and result in errors.

- [Adding VLANs](#)
As part of your network configuration, you can add one or more VLANs.
- [Deleting VLANs](#)
As part of your network configuration, you can delete a VLAN.

Adding VLANs

As part of your network configuration, you can add one or more VLANs.

Before you begin

Note:

- You can create VLAN only of type **Custom VLAN**, **Native VLAN**, and **Virtualization VLAN**.
- **Virtualization VLAN** addition is supported on all new IBM Fusion HCI installations with version 2.10 or later.
- If you need to create a **Virtualization VLAN** on a IBM Fusion HCI cluster that is already upgraded to version 2.10, then you must first run a migration script. To run the migration script, reach out to [IBM support](#).
- In a multi-rack setup, connect the Internal Management VLAN only to the default link (port 31). Connecting it to a non-default link (example, port 32) may cause the VLAN ID to not display in the link CR, although the VLAN name is still visible. If this occurs, resolve the issue by removing the Internal Management VLAN from the non-default link and reconnecting it to the default link (port 31).

Procedure

1. Click Infrastructure > Network.
The Network page gets displayed.
2. Click VLANs tab.
The VLANs tab page gets displayed. It lists all VLANs in a table format with Name, Type, VLAN ID, Allow multiple VLAN link, and VLAN status columns. Use the settings icon to customize the column headers.
3. Click Create VLAN.
The Add VLAN slide out pane gets displayed.
4. Provide the VLAN details.

- **Name**
Enter a name of the VLAN.
- **VLAN ID**
Enter VLAN ID to uniquely identify it.
- **Type**
Select a type of VLAN from the drop-down list. For example, **Native VLAN**.
- **Allow multiple link**
Select or clear the Allow multiple link check-box. If you select Allow multiple link, the VLAN can be used for more than one link.

Note: To add a VLAN to the uplinks of all racks in a multitrack cluster, ensure that Allow multiple link is always selected.

5. Click Add to apply your changes.
You can see the new record in the VLANs table of the Network page. For more information, see [Switch details](#).
Note: In case of failures, check whether any high-speed switches are down.

What to do next

To modify a VLAN name on IBM Fusion HCI, you must first delete the existing VLAN and then create a new one with the correct name. For more information about deleting VLAN, see [Deleting VLANs](#).

Deleting VLANs

As part of your network configuration, you can delete a VLAN.

Procedure

1. From the menu, go to the Infrastructure > Network page.
The Network page gets displayed.
2. Click VLANs tab to open the VLANs tab page.
3. Select a VLAN record that you want to delete.
To search for a specific record, see [Switch details](#).
4. Click the ellipsis icon and select Delete.
A confirmation message gets displayed. Any changes to network configuration may result in connectivity issues.
5. Click Delete to proceed with the delete operation.

Links

In the Links section, you add links and configure their settings based on the VLANs that are defined in the VLANs section.

Work with the links to add network connections to your IBM Fusion appliance as part of your network configuration.

Note: If you are using a multi-rack setup, you must manage your Alternative network configuration and the links.

Important: Perform link operations, including create, modify, and delete actions, only when all High-speed switches are online. Offline switches may cause these operations to fail and result in errors.

- [Adding links](#)
As part of your network configuration, you can add links based on the VLANs that you defined in the VLANs section.
- [Editing links](#)
As part of your network configuration, you can configure the link settings based on the VLANs that you defined in the VLANs section.
- [Deleting Links](#)
As part of your network configuration, you can delete links.

- [Adding additional ports for uplink](#)

You can enable additional switch ports for network uplinks by configuring the ports for connectivity.

Adding links

As part of your network configuration, you can add links based on the VLANs that you defined in the VLANs section.

About this task

If you are using a multi-rack setup, you must manage your Alternative network configuration and the links. The Add link page is not available for you.

Important: Ensure that you add links in a sequential order, and do not add multiple links at a time.

Procedure

1. Click **Infrastructure > Network**.
The Network page is displayed.
2. Click **Links** tab to open it.
3. Click **Create link**.
The Add link slide out pane gets displayed.
4. Provide the link details.
 - **Link name**
Specify a name in Link name to uniquely identify a link.
 - **Port**
Select one of the available options from the Port list. The port selection is made on both switches. You can select more than one port.
 - **Port type**
Select **Access** or **Trunk** from the Port Type list. The **Access** port provides access to a single VLAN only.
Important: Always choose **Trunk** as port type. Select **Access** only when the uplink switch is not VLAN aware.
 - **Transceiver**
Select one of the available options from the Transceiver list. The transceiver defines the speed and wire type to be used for the link.
 - **Aggregation**
Select one of the available options from the Aggregation list.
 - **VLANs**
Select one or more VLANs from the VLANs list. You can assign multiple VLANs from this multi-select label list. The Default Native list is populated with the selected VLANs. The Internal Storage VLAN option is available to externalize local storage.
 - **Native VLAN**
Select native VLAN whenever the port type is **Trunk**.
5. Click **Save** to apply your changes and to add the link.
You can see the new record in the Links table of the Network page. For more information, see [Switch details](#).

Editing links

As part of your network configuration, you can configure the link settings based on the VLANs that you defined in the VLANs section.

Procedure

1. Click **Infrastructure > Network**.
The Network page is displayed.
2. Click **Links** tab to display the Links section.
3. Select a link record that you want to edit.
4. At the end of the record, click the ellipsis menu to view more actions and then click **Edit**.
The Edit links pane is displayed.
5. Edit the link details.
You can edit all the values of a link.
6. Click **Save** to apply your changes and to add the link.
You can see the edited record in the Links table of the Network page. For more information, see [Switch details](#).

Deleting Links

As part of your network configuration, you can delete links.

Procedure

1. From the menu, go to the **Infrastructure > Network** page.

- The Network page gets displayed.
2. Click Links tab to open the Links tab page.
3. Select a link record that you want to delete.
4. Click the ellipsis icon and select Delete.
A confirmation message gets displayed. Any changes to network configuration may result in connectivity issues.
5. Click Delete to proceed with the delete operation.

Adding additional ports for uplink

You can enable additional switch ports for network uplinks by configuring the ports for connectivity.

Before you begin

Ensure that the following conditions are met before you begin:

- No existing connections are present on the ports.
- The ports are not configured as split ports.
- The ports do not appear in any port group or list other than `customerPorts`.

About this task

By default, you can connect your network to a rack by using only two fixed switch ports, 31 and 32. These ports are statically reserved for customer-facing connectivity, which limits the number of physical uplinks available for customers to connect to their network infrastructure.

This fixed port assignment restricts scalability and flexibility in rack networking. The two-port model restricts the customers who require additional uplinks for redundancy, higher bandwidth, or custom network topologies. To address this limitation, dynamic customer port support allows additional switch ports to be configured for customer network connectivity.

With dynamic port support, you can:

- Use any available customer uplink ports.
- Improve redundancy and fault tolerance.
- Distribute traffic more efficiently across multiple uplinks.
- Support complex or custom network topologies.
- Continue using existing configurations on ports 31 and 32 without modification.

Procedure

1. Verify switch port availability:
 - a. In the IBM Fusion HCI user interface, go to Administration > CustomResourceDefinition > Switch.
 - b. Select the high-speed switch for the corresponding rack.
 - c. Verify that ports do not appear in any list other than `customerPorts` and are not part of any other port group or list in the `spec` section.

Example switch names:

- `hspeed1-f42051`
- `hspeed2-f42051`

2. Add ports to the `Available` section:
 - a. Go to Administration > CustomResourceDefinition > Links.
 - b. Select the Link instance for the corresponding rack.
 - c. Add ports to the `portList`.

Example:

```
availableLinkTypes:
- availableTransceivers:
  - Single QSFP
  - 2x Splitter QSFP
  - 4x Splitter QSFP
  linkType: customer_links
  switches:
  - portList:
    - '32' # Cumulus: use 31, 32
    - '31'
    switchList:
    - hspeed1-f421051
    - hspeed2-f421051
```

- d. Save the changes.
3. Create a link from the new ports:
 - a. Wait a few minutes for the added ports to appear in the IBM Fusion HCI UI.
 - b. Go to Infrastructure > Network > Links.
 - c. Click Create link.
The Add link slide out pane opens.
 - d. Enter the required information:
 - Link Name
 - Rack
 - Port
 - Port type
 - Transceiver

- Aggregation
- VLANs
- Native VLAN
- e. Click Add.
- 4. Verify that the controller configures the ports:
 - a. Wait while the controller applies the configuration to the switches.
 - b. Confirm that the **Link** CR status changes to **Configured**.
 - c. If configuration fails, review the error details.

Results

- The selected ports are available as customer uplinks.
- You can configure up to four uplink ports per rack, and the controller automatically configures the switch ports.

Upgrading switch firmware

Upgrade switch firmware.

Before you begin

- Upgrade the IBM Fusion HCI management software.
- Post the upgrade of IBM Fusion HCI management software, check whether the firmware upgrade exists by using any of the following methods:
 - Open the Red Hat® OpenShift® Container Platform web console. In the Overview page, go to Activity, Recent events section and check whether you see the following message:

```
IBM Fusion firmware upgrade available for switches.
```

- Open the user interface. It displays notifications in the following locations:
 - In the bell icon, you can see the following messages for the switch :

```
Switch firmware upgrades are available
```

- In the Infrastructure > Network, you can see the following message:

```
Firmware upgrade to version <version_number> is available
```

About this task

- The following are the tasks that the administrator must be aware of during the firmware upgrade.
 - The administrator can upgrade the high-speed switches and spine switches with the model SN3700C or SN3700V, and management switches with models SN2201 and AS4610.
 - The firmware upgrade triggers on high-speed switches, followed by management and spine switches.
 - The firmware upgrade happens on the primary and secondary switches.
 - The secondary switches are upgraded first, followed by the primary switches during the upgrade process.
 - If the secondary switch firmware upgrade fails, then the related primary switch is not marked for the upgrade.
 - If a firmware update fails, a warning is raised for that switch. That warning can be seen in the Recent Events or Events sections.

Note:

- Do the switch firmware upgrade in the specified sequence.
- Upcoming software upgrades are scheduled for the following network switches:
 - The high speed switches with model SN3700C or SN3700V should be upgraded to 5.16.1.
 - The management switches with model SN2201 should be upgraded to 5.16.1.
 - The management switches with model AS4610 should be upgraded to 4.3.4.

Procedure

1. Go to Infrastructure > Network.
The Network page gets displayed. The Switches tab is open by default.
2. Click Upgrade all.
The Upgrade firmware window gets displayed. It shows how many switches to upgrade along with the estimated time.
Note: After the switch firmware upgrade is triggered, do not click anything in this page until the upgrade process is complete.
The Upgrade firmware window gets displayed. The IBM Fusion HCI runs prechecks on registry access, Fusion operator status, and DNS resolution.
3. If there are blocker issues, contact IBM Support.
 - a. To know more the fixes for blockers or warnings, contact IBM Support.
The IBM Fusion HCI user interface takes you to the Network page wherein a Upgrade pre-check report window displays all the Blocking issues and Issues (optional). If the upgrade fails, check the `updateStatus` in the `switchupgrade` CR.
 - b. Contact IBM to know more about how to fix an issue.
 - c. Fix all the blocking issues.
4. After the pre-checks complete without any blocker issues, click Upgrade now.
The following message appears to confirm the initiation of upgrade:

```
Switch Firmware upgrade in-progress
```

For example:

```
Switch Firmware upgrade in-progress
1 out of 2 switches upgraded
```

To know more details about the upgrade that is in progress, click View details in the notification tab of the Network page. A slide out pane displays more information about the upgrade that is in progress, including errors and warnings. Guidance links are available against the corresponding warnings and errors.

Creating dedicated secondary Network in Virtualization

If the primary pod network in OpenShift® Virtualization becomes congested, you can improve performance by isolating that traffic onto a dedicated secondary network.

Procedure

1. Open IBM Fusion user interface.
2. Create VLAN and wait until the VLAN status is Normal.
For more information about how to add VLANs, see [Adding VLANs](#).
3. Go to Links page and edit an existing link that supports the VLAN that you just created.
In the Edit link pane, select `Virtualization` option from the VLANs drop-down list.
4. Create Network Attached Definition (NAD).
 - a. In the OpenShift console, go to Networking, > NetworkAttachmentDefinition.
 - b. In the Create NetworkAttachmentDefinition, select `Linux Bridge` in the Network Type.
 - c. Update Bridge name.
It is part of Config Map in `isf-spectrum-fusion-ns` namespace under `isf-virtualization-bridge`.
Example ConfigMap with bridgename:

```
kind: ConfigMap
apiVersion: v1
metadata:
  name: isf-virtualization-bridge
  namespace: ibm-spectrum-fusion-ns
  uid: a107f372-aaaa-445c-bd19-0aab9a97aaa4
  resourceVersion: '11882214'
  creationTimestamp: '2025-04-02T07:29:58Z'
data:
  '805': br805
```

5. Create Virtual Machine and bridge bind it with the NAD you created in the previous step.
 - a. In the OpenShift console, go to Virtualization, > VirtualMachines.
 - b. In create virtual machines, select the Red Hat Enterprise Linux 9 VM template.
 - c. In the Customize and create VirtualMachine, click Add network interface.
 - d. In the Add network interface window, select the VLAN you created for the Network and click Save.
6. Open the newly created virtual machine and go to the Console tab.
7. Log in with your credentials.
8. Run the following commands to list the IP addresses:

```
ip addr
```

Get the interface name from the virtual machine console.

9. Create the file and update it with details:

```
cat <<EOF >/etc/sysconfig/network-scripts/ifcfg-<Interface-name>
BOOTPROTO=static
DEVICE=<Interface-name>
# HWADDR=$HW_ADDR
ONBOOT=yes
TYPE=Ethernet
USERCTL=no
IPADDR=<IP_ADDR>
GATEWAY=<GATEWAY>
NETMASK=<NETMASK>
DNS1=<DNS_IP>
EOF
```

You can get the values of Gateway, Netmask, DNS, VLAN from your network team. Validate the file:

```
cat /etc/sysconfig/network-scripts/ifcfg-eth1
```

10. Run the following commands to assign the IP and make secondary as primary:

```
sudo ip link set <interface-name> down
sudo ip link set <interface-name> up
sudo systemctl restart NetworkManager
```

Wait for the IP to get assigned.

If the multiple network interfaces exist, then disable the other one so that the secondary network interfaces are enabled and ping [google.com](#) to verify.

11. Validate the Network Manager status:

- a. List all connections:

```
nmcli connection show
```

- b. Disable eth0 (primary connection) and enable eth1 (secondary connection):

```
nmcli connection down <UUID>
```

- c. Show network status:

```
nmcli general status
```

- d. Show active connections:

```
nmcli connection show --active
```

The secondary network is now enabled and primary default eth0 is disabled.
e. Ping google.com to check traffic on the secondary network.

Provisioning additional networking

Provision additional networking for direct network access to a container or to a virtual machine.

Before you begin

As a prerequisite, deploy the Red Hat® Red Hat OpenShift Virtualization Operator within IBM Fusion HCI. For the procedure to deploy, see [Deploying Red Hat Red Hat OpenShift Virtualization Operator](#).

Procedure

1. Define the network range and the VLAN for which the external network traffic will traverse.
 - a. Log in to IBM Fusion HCI user interface.
 - b. Go to Networking page and go to VLAN tab.
 - c. Click Add VLAN to define a new VLAN.
 - d. Select the VLAN Type as `Virtualization VLAN`.
 - e. Add the newly Defined VLAN to the Uplink ports on the high speed switches.
In the Edit LINK slide out panel, select value for VLANs and Save.
2. Log in to OpenShift® Container Platform web console.
3. Go to Administration > CustomResourceDefinitions.
4. Search for `nodeNetworkConfigurationPolicies.nmstate.io` and click to open it.
5. In the Instances tab, view the NNCP policy created with the previously created VLAN ID. For example, if the created VLAN ID is "2222", the NNCP policy name is "br2222-bond0-policy".
6. Copy the bridge name. In this example, it is "br2222".
7. Select your project or namespace and go to Networking > NetworkAttachmentDefinitions.
8. In the NetworkAttachmentDefinitions, click Create Network Attachment Definition to create a new Network Attachment Definition specific to the desired namespace.
You can reuse the same network attachment definitions across multiple namespaces.
9. Select Linux bridge from the Network Type drop-down list.
Note: When creating the NAD, include only the bridge details. Do not add VLAN information, as this disrupts VM communication.
10. Add `br2222` in the Bridge name and click Create.
11. Check whether the Bridge Name is same as the one created by the node network policy. In this example, it is "br2222".
12. You can now attach a second network adapter to your virtual machine at the time of network configuration, and assign it to the defined network attachment definition. It allows access to the external network.

What to do next

Ensure you delete the secondary VLAN. For steps, see [Secondary VLAN detaching](#).

- [Secondary VLAN detaching](#)
Use these instructions to detach the secondary VLAN.

Secondary VLAN detaching

Use these instructions to detach the secondary VLAN.

If there are any NADs created for the secondary VLAN and are used as additional NIC for VMs, then the additional interface must be detached.

1. Log in to the OpenShift® Container Platform web console.
2. Go to Network > NetworkAttachmentDefinition.
3. Select the NAD and go to the YAML tab, and change the namespace to the appropriate namespace.
4. Click the ellipsis icon and select Delete NetworkAttachmentDefinition.
5. From the IBM Fusion HCI user interface, go to Infrastructure > Network.
6. Click Links tab.
The default Link detail appears .
7. Edit the default link and remove the secondary VLAN. For steps, see [Editing links](#).
8. Go to the VLANs tab and delete the VLAN that needs to be deleted. For steps, see [Deleting VLANs](#).

Networking issues

A list of all troubleshooting and known issues that exist in the networking of IBM Fusion HCI.

Configuring the F5 load balancer

Problem statement

You can use an external load balancer in place of the default load balancer to access the Red Hat® OpenShift® cluster after the installation of IBM Fusion HCI.

Resolution

You can use node placement and toleration to place `router-default` pods to the infrastructure nodes on your environment, then you can configure external load balancer to route traffic to the infrastructure nodes.

1. Run the following command to label worker nodes as infrastructure nodes. Use the correct compute nodes for your environment.

```
oc label nodes compute-1-ru5.rackd.mydomain.com node-role.kubernetes.io/infra=''  
oc label nodes compute-1-ru6.rackd.mydomain.com node-role.kubernetes.io/infra=''
```

2. Create a `default.yaml` file to place `router-default` pods to the infrastructure nodes.

```
apiVersion: operator.openshift.io/v1  
kind: IngressController  
metadata:  
  name: default  
  namespace: openshift-ingress-operator  
spec:  
  nodePlacement:  
    nodeSelector:  
      matchLabels:  
        node-role.kubernetes.io/infra: ""  
    tolerations:  
      - effect: NoSchedule  
        operator: Exists  
  replicas: 2  
status: {}
```

3. Run the following command to apply the change.

```
oc apply -f default.yaml
```

4. Run the following command to verify that the `router-default` pods are running on the infrastructure nodes.

```
oc -n openshift-ingress get pod -o wide
```

Example output:

NAME	READY	STATUS	RESTARTS	AGE	IP	NODE	NOM
router-default-6c8f978c-9bd9j	1/1	Running	0	23m	172.20.240.29	compute-1-ru6.rackd.mydomain.com	<no
router-default-6c8f978c-zglxz	1/1	Running	0	23m	172.20.240.28	compute-1-ru5.rackd.mydomain.com	<no

5. Configure your external load balancer. For more information, see [Configuring an external load balancer](#).

Missing network events that are raised during port down or up on a management switch

Problem statement

If a `cumulusLinkDown` event is observed on the IBM Fusion HCI user interface for any high-speed or management switches, then follow the steps that are mentioned in the following resolution section.

Resolution

Do the following workaround steps:

1. Go to Infrastructure > Network > Switches .
2. In the ellipsis menu of the switch, click Run Command.
3. Select net show interface all from the list and click Run.
4. Check whether the state of the port is **UP**, **DN**, or **ADMDN**.
 - a. If the state of the port is **UP**, then the port is recovered and is up and running. In this scenario, the event is not a new entry and can be ignored.
 - b. If the state of the port is **DN** or **ADMDN**, then contact [IBM support](#) to check the switch.

Management switch unavailability

Problem statement

A management switch is not available.

Resolution

Do the following steps to log in to the management switch and resolve the issue.

1. Run the following `oc` command to get the corresponding switch IPv6 or IPv4 address.

```
oc get switches <switchName> -o yaml | grep switchIpAddress
```

For example:

If the switch name is `mgmt1-rackc`, then run the following command:

```
oc get switches mgmt1-rackc -o yaml | grep switchIpAddress
```

2. Run the following `oc` command to get the switch login credentials from the switch secret.

```
oc get secrets <switchName>-secret -oyaml | grep defaultUserName  
oc get secrets <switchName>-secret -oyaml | grep defaultUserPasswr
```

For example:

```
oc get secrets mgmt1-rackc-secret -oyaml | grep defaultUserName  
oc get secrets mgmt1-rackc-secret -oyaml | grep defaultUserPasswr
```

3. Run the following command to decode both the username and password, obtained from the previous step.

```
echo <username/password> | base64 -d
```

4. Use the username and password that is decoded from the previous step to login to the switch from one of the compute nodes. From the Red Hat OpenShift user interface, go to one of the compute node terminals.

```
ssh ~<username>@<switchIpAddress>~
```

5. SSH to log in to the switch and go to the root user.

```
sudo su
```

6. Check the values of `ClientAliveInterval` and `ClientAliveCountMax` in `sshd_config`.

```
root@mgmt1-rackc:mgmt:~$ cat /etc/ssh/sshd_config | egrep "ClientAliveInterval|ClientAliveCountMax"
#ClientAliveInterval 0
#ClientAliveCountMax 3
```

7. Update `/etc/ssh/sshd_config` file with `ClientAliveInterval` as 600 and `ClientAliveCountMax` as 0, and save the file.

```
vi /etc/ssh/sshd_config
"Remove "#" on both lines and change the values as given below and Save the file(Press Esc to enter Command
mode, and then type :wq to write and quit the file)"
ClientAliveInterval 600
ClientAliveCountMax 0
```

8. Check that the values of `ClientAliveInterval` and `ClientAliveCountMax` are correctly set.

```
root@mgmt1-rackc:mgmt:~$ cat /etc/ssh/sshd_config | egrep "ClientAliveInterval|ClientAliveCountMax"
ClientAliveInterval 600
ClientAliveCountMax 0
root@mgmt1-rackc:mgmt:~$
```

9. Restart the `sshd` service.

```
root@mgmt1-rackc:mgmt:~$ sudo systemctl restart sshd
```

10. Run the following command to clear the SSH sessions that belong to `ISFUSER` (most of the SSH session belongs to `ISFUSER`).

```
for i in `ps -aef | grep ssh | grep ISFUSER | awk {'print $2'}`; do echo $i; kill -9 $i; done
```

Switches moved to critical state after you power off TOR

Problem statement

Switches are in critical state because the high availability cluster connectivity breaks between the racks.

Cause

The switches from one rack do not share loopback Anycast IP to the spine and other switches.

Resolution

Important: This issue and its workaround steps are applicable only to a high availability cluster.

1. Log in to all high-speed switches
2. Run the following `oc` command to get the corresponding switch IPv6 or IPv4 address.

```
oc get switches <switchName> -o yaml | grep switchIpAddress
```

For example, if the switch name is `hspeed1-rackc`, then run the following command:

```
oc get switches hspeed1-rackc -o yaml | grep switchIpAddress
```

3. Run the following `oc` command to get the switch login credentials from the switch secret.

```
oc get secrets <switchName>-secret -oyaml | grep defaultUserName
oc get secrets <switchName>-secret -oyaml | grep defaultUserPasswrd
```

For example, if the switch name is `hspeed1-rackc`, then run the following command:

```
oc get secrets hspeed1-rackc-secret -oyaml | grep defaultUserName
oc get secrets hspeed1-rackc-secret -oyaml | grep defaultUserPasswrd
```

4. Run the following command to decode both the username and password, obtained from the previous step.

```
echo <username/password> | base64 -d
```

5. Use the decoded username and password from the previous step to login to the switch from one of the compute nodes. From the Red Hat OpenShift user interface, go to one of the compute node terminals.

```
ssh ~<username>@<switchIpAddress>~
```

6. Run the following command to restart `frr` service on the switch.

```
sudo systemctl restart frr
```

Adding a VLAN fails on a expansion rack setup

Problem statement

Adding a VLAN fails on a expansion rack setup with the combination of gen1 and gen2 racks.

Resolution

If you face any issues during adding a VLAN on an expansion rack setup, then contact [IBM support](#).

Network adapters validation fails

Problem statement

The network adapter validation fails during replacing a network adapter.

Resolution

As a resolution, ensure you update the kickstart file whenever you replaces a network adapter. Also, update the kickstart with the MAC address of the replaced network adapter.

Admin network in a critical state

Problem statement

The admin network is in a critical state, showing an error on the IBM Fusion HCI user interface because pods are unable to communicate between sites.

Cause

The submariner gateway pods are unable to establish a connection after Site1 is recovered, preventing the submariner from connecting successfully.

Diagnosis

Follow the steps to diagnose through user interface:

1. Log in to the site2 OpenShift Container Platform user interface.
2. Go to Administration > CustomResourceDefinitions.
3. Search for MetroDR and select MetroDR from the list.
4. Go to Instances tab and select metrodrsite.
5. Go to YAML tab and check `submarinerMonitoringCommandOutput` under `metroDRSiteStatus`.
6. Check whether you see the following error for the node.

```
control-1-ru4.rackae1.mydomain active 0 connections out of 1 are established
```

7. Note down the node name.

Follow the steps to diagnose through CLI:

1. Log in to the site2 OpenShift Container Platform user interface.
2. Run the following command.

```
oc get mdr -o yaml
```

3. Check `submarinerMonitoringCommandOutput` under `metroDRSiteStatus` in the output.
4. Check whether you see the following error for the node.

```
control-1-ru4.rackae1.mydomain active 0 connections out of 1 are established
```

5. Note down the node name.

Resolution

Follow the steps to resolve the issue through user interface:

1. Log in to the OpenShift Container Platform user interface of the site2.
2. Go to Workloads > Pods
3. Select submariner-operator from the Project drop-down.
4. Click Manage columns icon which is present beside the search bar.
5. Select Node under the Additional columns.
The pods details appears.
6. Restart or delete the submariner-gateway pod which is on the node name that you have noted from the diagnose steps.
7. The error resolves automatically after you applying the resolution steps. If the issue persists, contact IBM support.

Follow the steps to resolve the issue through CLI:

1. Log in to the OpenShift Container Platform user interface of the site 2.
2. Run the following command to get the list of submariner gateway pods.

```
oc get pods -o wide -n submariner-operator | grep submariner-gateway
```

Example output:

submariner-gateway-jc6pt	1/1	Running	1	16h	172.20.102.26	control-1-ru3.racka
submariner-gateway-kpqpq	1/1	Running	1	16h	172.20.102.25	control-1-ru2.racka
submariner-gateway-mp7jt	1/1	Running	2 (16h ago)	16h	172.20.102.27	control-1-ru4.racka

3. Run the following command to delete the gateway pod which is on the node name that you noted from the diagnose steps.

```
oc delete pod <podname> -n submariner-operator
```

Example output:

```
oc delete pod submariner-gateway-mp7jt -n submariner-operator
pod "submariner-gateway-mp7jt" deleted
```

4. The error resolves automatically after you applying the resolution steps. If the issue persists, contact IBM support.

- [Removing and replacing Customer Replacement Units \(CRU\)](#)

Removing and replacing CRU includes the guidelines and instructions that need to take care when you remove the CRU.

Removing and replacing Customer Replacement Units (CRU)

Removing and replacing CRU includes the guidelines and instructions that need to take care when you remove the CRU.

- [Removing and replacing the power supply unit](#)
Remove the existing power supply unit of the server and replace it with a new one.
- [Replacing an NVMe disk](#)
Follow the instructions to replace an NVMe disk.
- [Disconnecting and connecting power cords](#)
Steps to disconnect and connect existing power cords to the server.

Removing and replacing the power supply unit

Remove the existing power supply unit of the server and replace it with a new one.

Before you begin

Prerequisites for removing the power supply unit

- The server is shipped with two power supply by default. In this case, the power supply is hot pluggable and redundant.
- Ensure that you power off the server and disconnect all the power cords and network cables before you remove the power supply unit.
- Ensure that you put the node into maintenance mode. For more about node maintenance, see [Administering the node](#).
- Ensure that you install an additional hot-swap power supply to support redundancy.

- Ensure that you wear an ESD wrist strap when you remove the power supply unit.
- Ensure that you handle the component carefully and include more than one qualified person to perform the task if the component weight is more than 18 kg (40 lb).

Prerequisites for replacing the power supply unit

- The server is shipped with only one power supply by default. In this case, the power supply is non-hot swap.
- Ensure that you power off the server and disconnect all the power cords and network cables before you replace the power supply unit.
- Ensure that you put the node into maintenance mode. For more about node maintenance, see [Administering the node](#).
- Ensure that you install an additional hot-swap power supply to support redundancy.

- Ensure that you wear an ESD wrist strap when you replace the power supply unit.
- Ensure that you handle the component carefully and include more than one qualified person to perform the task if the component weight is more than 18 kg (40 lb).

About this task

Remove and replace the power supply unit in the specified order. For more information about the part numbers, see

Procedure

1. Remove the power supply unit as follows:
 - a. Disconnect the power cord from the hot-swap power supply and the electrical outlet.
 - b. Slide the release tab toward the handle and carefully pull the handle backwards at the same time to remove the hot-swap power supply out of the chassis.
2. Replace the power supply unit as follows:
 - a. Take the new part out of the package and place it on a static-protective surface.
 - b. Remove the power supply filler if it is installed.
 - c. Place the new hot-swap power supply into the bay and push until it gets into position.
 - d. Connect the power supply unit to a properly grounded electrical outlet.

What to do next

1. Install a power supply filler or a new power supply to cover the slot.
2. If you are instructed to return an old hot-swap power supply, follow all packaging instructions and use any packaging materials provided.
3. If the server is turned off, turn on the server. Ensure that both the power input LED and the power output LED on the power supply are lit, indicating that the power supply is operating properly.

Replacing an NVMe disk

Follow the instructions to replace an NVMe disk.

About this task

The procedure steps are applicable only for the Global Data Platform storage. For Data Foundation storage, see [Disk replacement and OpenShift dedicated OSD failure recovery](#).

Procedure

1. Open the IBM Fusion HCI user interface.
2. Click the App Switcher icon in title bar and click Storage outbound arrow from the list.
As soon as you click the Storage outbound arrow, the IBM Storage Scale user interface is displayed.
3. Click Sign In to login to the IBM Storage Scale user interface.
4. Click the Events icon and check whether there is any error event showing the bad disk.
5. Click Run Fix Procedure and follow the instructions to replace the bad disk.
As soon as you click the Run Fix Procedure, the Fix Procedure: Replace Disks page is displayed.
6. Click Next.
7. Replace the disk physically and select the The disk has been replaced check box.
8. Click Finish.

The message is displayed in the Fix Procedure: Replace Disks page:

```
Successfully replaced the disks
```

9. Click Close.

What to do next

1. Ensure that the error event of a bad disk disappears from the Events page.
2. Ensure that the new disk shows up with the different serial number in the Physical Disks page.
3. Check the file system mount and physical disks in a core scale pod.
 - Run the OC command to check Scale core pod.

```
oc get pod
```

```
NAME READY STATUS RESTARTS AGE
```

```
compute-0 2/2 Running 0 17d
```

```
compute-1 2/2 Running 0 17d
```

```

```
control-1 2/2 Running 0 17d
```

```
control-2 2/2 Running 0 17d
```

- Run the OC command to see all the containers in this pod.

```
oc describe pod/compute-2 -n ibm-spectrum-scale
```

- Run the following command to check the file system mount.

```
mmismount all
```

- Run the following commands to check the current physical disks health.

```
mmvdisk pdisk list --rg all --not-ok
```

```
mmvdisk: All pdisks are ok.
```

```

```

Disconnecting and connecting power cords

Steps to disconnect and connect existing power cords to the server.

Before you begin

Prerequisites for removing the power supply unit

- The server is shipped with two power supply by default. In this case, the power supply is hot pluggable and redundant.
- Ensure that you power off the server and disconnect all the power cords and network cables before you remove the power supply unit.
- Ensure that you put the node into maintenance mode. For more about node maintenance, see [Administering the node](#).
- Ensure that you install an additional hot-swap power supply to support redundancy.

- Ensure that you wear an ESD wrist strap when you remove the power supply unit.
- Ensure that you handle the component carefully and include more than one qualified person to perform the task if the component weight is more than 18 kg (40 lb).

Prerequisites for replacing the power supply unit

- The server is shipped with only one power supply by default. In this case, the power supply is non-hot swap.
- Ensure that you power off the server and disconnect all the power cords and network cables before you replace the power supply unit.
- Ensure that you put the node into maintenance mode. For more about node maintenance, see [Administering the node](#).
- Ensure that you install an additional hot-swap power supply to support redundancy.

- Ensure that you wear an ESD wrist strap when you replace the power supply unit.
- Ensure that you handle the component carefully and include more than one qualified person to perform the task if the component weight is more than 18 kg (40 lb).

Procedure

1. Important:

- Ensure that all power cables are properly connected when connecting power to the product. Connect all power cords to a properly wired and grounded electrical outlet for the racks with AC power. Ensure that the outlet supplies proper voltage and phase rotation according to the PDU or system rating plate.
- If IBM supplied the power cords, then connect power to this unit only with the IBM provided power cord.
- The product might be equipped with multiple power cords.

Disconnect and connect the power cords in the specified order.

- a. Ensure that the mating connector of the power supply is free of any dirt or obstacles.
- b. For AC power, remove the power cords from the outlets.
- c. Unplug the power cord from the power supply.

2. Connect the power cord as follows:

- a. Connect the power cord to the power supply.
- b. For AC power, attach the power cords to the outlets.

Observability

Observability in IBM Fusion enables centralized, multi-cluster monitoring that uses open source technologies like Prometheus, Thanos, and Grafana. This solution collects metrics from managed clusters, provides global querying and long-term storage, and delivers unified dashboards for visualization and alerting.

- [AI-enabled observability with Red Hat OpenShift Lightspeed](#)

Simplify observability across clusters through smart agents.

- [Monitoring IBM Fusion HCI](#)

IBM Fusion HCI provides multiple ways to monitor the health of the hardware and software.

- [IBM Fusion metrics](#)

This section describes the metrics that are used in IBM Fusion.

- [Enabling observability for IBM Fusion clusters](#)

Use these instructions to enable multi-cluster observability for IBM Fusion clusters.

- [IBM Fusion Call Home Telemetry](#)

IBM Fusion Call Home Telemetry enhances supportability by providing IBM with valuable insights into system configuration and performance. Telemetry data is

collected from various components and securely transmitted to IBM, helping support teams proactively identify issues and optimize system behavior based on real-world usage.

AI-enabled observability with Red Hat OpenShift Lightspeed

Simplify observability across clusters through smart agents.

Red Hat® OpenShift® Lightspeed provides an AI-based chat window that understands OpenShift and the current cluster state. When integrated through the Model Context Protocol (MCP), the chat window retrieves live data from the cluster when configured. As a result, responses reflect the current state rather than static documentation. You interact exclusively through the chat window: you submit a query, Lightspeed uses MCP to retrieve the required data, and then explains and summarizes the results. This approach provides a single location for monitoring health, troubleshooting issues, and reviewing summarized information without switching between the OpenShift console and other tools.

One place to ask questions

Use the Lightspeed chat window, either in the OpenShift console or from an IDE through MCP, to ask about cluster health, workloads, and issues. The chat window uses MCP to access live cluster state and, when available, metrics and alerts, providing a consolidated conversational view.

On-demand debugging and analysis

Ask questions such as *What's wrong with the cluster?*, *Why is this failing?*, or *Show me what's running in this namespace*. The LLM retrieves current data through MCP and combines it with the knowledge of OpenShift to provide focused, context-aware responses without running anything in the background.

Summarized insights

Request high-level overviews in plain language, such as *Summarize what's unhealthy* or *What's going on in this project?* The chat window used MCP to retrieve the relevant resources and return concise summaries, enabling quick triage and deeper investigation only when required.

Integration with existing tools

MCP complements existing monitoring tools rather than replacing them by adding a chat window on top. Continue to use Grafana for dashboards and Prometheus for metrics, while using Lightspeed for quick queries, summaries, and guided troubleshooting based on the same data.

Monitoring IBM Fusion HCI

IBM Fusion HCI provides multiple ways to monitor the health of the hardware and software.

- [Monitoring hardware from IBM Fusion HCI user interface](#)

The IBM Fusion HCI user interface provides an enhanced hardware monitoring experience. With hardware monitoring, you can quickly determine a hardware component in the IBM Fusion HCI that needs your attention.

- [Monitoring and logging by using any monitoring tool](#)

IBM Fusion provides multiple ways to monitor the health of the hardware and software.

Monitoring hardware from IBM Fusion HCI user interface

The IBM Fusion HCI user interface provides an enhanced hardware monitoring experience. With hardware monitoring, you can quickly determine a hardware component in the IBM Fusion HCI that needs your attention.

Hardware monitoring provides overall and individual health and inventory information of servers and switches, and their components such as CPUs, DIMMs, Storage Drives, Adapters, Fans, PSUs.

Go to [Infrastructure > Overview](#) in the IBM Fusion HCI user interface to view the graphical view of the hardware appliance. Under the Resource summary section, you can find the total number of nodes, switches, and service node along with their health statuses. Hover over a graphical view of the hardware appliance to identify units in the rack. Also, you can zoom in and out to focus on specific sections of the rack for detailed inspection and use [Add rack](#) to add extra racks and useful when there are more than three racks to look at.

- For node, it shows the name of the hardware, the health status, the type of node, inventory, and the rack unit.
- For switch, it shows the name of hardware, the health status, the type of switch, inventory, and the rack unit.
- For service node, it shows the name hardware, the health status, the type of node, inventory, and the rack unit.

In a graphical view of the IBM Fusion HCI rack, the color of the hardware component represents the health status. Additionally, you can view the different colors and their prominence under the graphical view of the hardware appliance. The nodes and switches are shown as per their appropriate locations in the actual physical rack. For more information on rack unit numbers and location, see [Hardware overview](#).

The following picture shows a sample Overview dashboard page with a single rack. In this example, the rack shows degraded state for management switch in Rack Unit 18 and critical state for a storage node at Rack Unit 8 and high speed switch at Rack Unit 20.

Figure 1. Overview page showing a rack and its components

The following figure shows a base and expansion rack setup. In this example, the power supply is lost for management switch in base rack at Rack Unit 18 and storage node in expansion rack at Rack Unit 2:

Figure 2. Base and expansion rack with critical errors

You can identify the node that has a hardware issue based on the legend displayed in the IBM Fusion HCI user interface:

- The color green indicates that the status of the hardware is in normal and healthy state.
- The color red indicates critical errors in the hardware and needs attention.
- The color gray indicates that the hardware is in inactive and power off state.
- The color blue with diagonal stripes indicates that an action is in progress on the hardware, such as power up, power down, or a firmware upgrade.
- The color yellow denotes warning.

For more information about node and switch monitoring, see [Node monitoring](#) and [Switch monitoring](#).

- **Node monitoring**

Node monitoring provides continuous tracking details of the health, performance, and availability of nodes within a hardware appliance.

- **Switch monitoring**

Switch monitoring provides continuous tracking details of the health, performance, and availability of switches within a hardware appliance. With switch monitoring, you can track switch status and quickly determine used and unused ports, fans, loosen or unseated connection details of the switch in the IBM Fusion HCI. This topic provides you instructions and guidelines to monitor switches from the Overview dashboard page.

Node monitoring

Node monitoring provides continuous tracking details of the health, performance, and availability of nodes within a hardware appliance.

It helps administrators quickly identify the following issues:

- Active and inactive drives
- Invalid configurations
- Loose or unseated hardware connections

It provides real-time insights into node status, allowing for proactive maintenance and efficient troubleshooting.

Use these instructions and guidelines to monitor nodes from the Overview dashboard page.

1. Go to Infrastructure > Overview in the IBM Fusion HCI user interface to view the graphical view of the hardware appliance.

Under the Resource summary section, you can find the following details:

- The total number of nodes
- The current health status of each node
- A graphical representation of the hardware appliance

Figure 1. Example Overview page showing error for a node

In the graphical view of the hardware appliance, the color indicates the health status of a node.

2. Hover over a graphical view of the hardware to identify node details.

For node or service node, it shows the name of the hardware, the health status, the type of node, and the rack unit.

3. Go through the color indicators and decode their statuses.
4. Fix errors, failures, and warnings based on the guidance.
5. After all the errors and failures are fixed, go to the Overview dashboard page and check the health status of problematic nodes. For more information about nodes, see [Node or service node details](#).

Understanding color indicators and decoding status

Node or service node in Green color

It indicates that the node or service node is in a healthy or normal state, and no action is required.

Node or service node in Red or Yellow color

It indicates that the node is failed or in a degraded state. Do the following steps to resolve the issue:

- Click the component that is in red or yellow color.
A slide out window is displayed with the Hardware status, type, firmware, S/N, rack, and rack unit details. For more information about nodes, see [Node or service node details](#).
- Go through the details in the slide out window. If you want more information about the node, click View full details.
It opens Nodes page that includes the front, rear, and inside view of the node, recent events, and additional details of the node and its internal components.
- Select Front in the Components section to see front view of the node and hover over a graphical view to check internal components such as used and unused drive slots along with their connection status.
To debug further, click the internal component that is in red color. It opens a new slide out pane for drives with more details such as name, slot, type, status, total capacity (GB), and serial number.
- Select Back in the Components section to see back view of the node and hover over a graphical view to check internal components such as used and unused adapter slots along with their invalid configuration and loosen or unseated connection details.
To debug further, click the internal component that is in red or yellow color. It opens a new slide out pane for adapters with more details such as slot, port, type, speed, status, network address, adapter, bond, and connected to.
- Select Internal in the Components section to see internal view of the node and hover over a graphical view to check internal components such as used and unused DIMM slots, CPUs, and fans status.
To debug further, click the internal component that is in red or yellow color. It opens a new slide out pane with more details. For example, for a DIMM, you can see details such as slot, state, capacity, memory type, and serial number.
- Click View table to check all internal components and their status in the table format.
It opens Components table page that includes Storage Drives, OS Drives, Ports, CPUs, DIMMs, Fans, and PSUs in seven tab pages. For more information about node details, see [Node or service node details](#).
- Go through the Recent events section to understand the error.
Note: The recent events pane includes details of the last five events that occurred for the node.
- Click View all to go to the events page and view all recent events on the hardware component.
The BMYxxx code and the error message inform you about the error and possible corrective actions.
- Go through the Details section to get more details of the node such as type, model, S/N, IP address, rack, rack unit, firmware, architecture, CPU cores, frequency, memory, energy consumption, and temperature.
Important: Click Details under Firmware in the Details section to get more details about the firmware versions.
- Click Actions drop down to download the logs of the node and to do power operations, restarting the node, and node maintenance activities. For more information, see [Administering nodes and racks](#).
- To diagnose and take corrective action, try the following options:
 - Check whether the hardware is in the correct position. To view the rack positions of the nodes, see [Hardware overview](#).
 - Check the BMYxxx errors. For more information about individual BMYxxx codes and their corrective action, see [Compute events and error codes](#).
If you are not able to fix the issue, contact [IBM support](#).

Node or service node in Gray color

It indicates that the node is in a disabled or powered off state.

To power on or power off the hardware, see *Node power operations* section in [Administering nodes and racks](#).

Node or service node in color blue with diagonal stripes

It indicates that an action is in progress on the hardware, such as power on and power down.

To know more about the actions on a node hardware, see the following links:

- Power operations. See [Administering nodes and racks](#).
- Configuration expansion. See [Scaling the cluster](#). Here, you can see the procedure to add nodes to the cluster or add storage to a node. To add a rack, see [Adding expansion racks](#).
- [Node or service node details](#)
The Nodes page in the IBM Fusion HCI user interface provides information about nodes and their health status.

Node or service node details

The Nodes page in the IBM Fusion HCI user interface provides information about nodes and their health status.

From the IBM Fusion HCI menu, click Infrastructure > Nodes. The Nodes page provides the details of the nodes in a table format. The column headers that are displayed by default in the table are Name, Hardware status, Type, Firmware level, Serial number, Rack name, Rack Unit number, CPU cores, and Memory (GB) details. Use the Search field to filter and find records. The settings icon helps you to customize the column headings of these tables. Decide the number of records per page by using the Items per page drop-down list of the table. You can traverse to the previous or next page views. Select a number from the drop-down list of the page numbers to jump to a specific page view.

Click the node name link that you want to manage. It opens Nodes page that includes the front, rear, and inside graphical view, recent events, and other details of the node and its internal components. Select Front, Back, and Internal in the Components section to see front, back, and inside views of the node and hover over a graphical view to check internal components and their status. To debug further, click the internal component that is in red color. It opens a new slide out pane and provides more details about the drives and adapters.

The following picture shows an example of a front and rear views of the Lenovo compute storage node.

Figure 1. Compute storage node

Click View table to check all internal components and its status in the table format. It opens Components table page that includes Storage Drives, OS Drives, Ports, CPUs, DIMMs, Fans, and PSUs in seven tabs.

Component	Details
Storage drives	It displays a list of storage drives. The column headers that are displayed by default in the table are Name, Slot, Status, Type, and Total Capacity (GB).
OS drives	It displays a list of OS drives. The column headers that are displayed by default in the table are Name, Slot, Status, Type, and Total Capacity (GB).
Ports	It displays a list of ports. The column headers that are displayed by default in the table are Slot, Status, Speed (Gbps), Network address, Adapter, Bond, and Connected to details.
CPUs	It displays a list of CPUs. The column headers that are displayed by default in the table are Name, Health, State, Cores, Threads, and Clock speed (MHz).
DIMMs	It displays a list of DIMMs. The column headers that are displayed by default in the table are Slot, Status, Serial number, Type, and Capacity.
Fans	It displays a list of Fans. The column headers that are displayed by default in the table are Name, Health, and Speed (RPM).
PSUs	It displays a list of PSUs. The column headers that are displayed by default in the table are Name, Status, Capacity (watts), Manufacturer, Model, Part number, and Firmware.

Click Actions drop down to download the logs of the node and to do power operations, restarting the node, and node maintenance activities. For more information, see [Administering nodes and racks](#).

Click View all in the Recent events panel to go to the events page and view all recent events on the hardware component.

Note: The recent events pane includes details of the last five events that occurred for the node.
If you want more information about the node, go through Details section to get more details of the node as follows:

Node details	Description
Type	The type of the node (the options are Compute only, Compute storage, AFM, or GPU).
Model	The model number of the node.
S/N	The hardware serial number.
IP address	This is IP address of the BMC of the node and not the Host/OS/payload.
Rack	The name of the rack.
Rack unit	The rack position of the node in the rack.
Host name	The host name of the rack.
Firmware	The firmware version of the node. Click View all to find the detailed firmware versions of the hardware components.
Architecture	The architecture details of the node.
CPU cores	The number of CPU in cores.
Frequency	Each CPU frequency of the node.
Memory	The amount of memory in GB.
Energy consumption	The energy that is used by the CPU and Server in watts.
Temperatures	Ambient CPU 1, CPU 2, and Exhaust temperature in Centigrade.

Switch monitoring

Switch monitoring provides continuous tracking details of the health, performance, and availability of switches within a hardware appliance. With switch monitoring, you can track switch status and quickly determine used and unused ports, fans, loosen or unseated connection details of the switch in the IBM Fusion HCI. This topic provides you instructions and guidelines to monitor switches from the Overview dashboard page.

1. Go to Infrastructure > Overview in the IBM Fusion HCI user interface to view the graphical view of the hardware appliance.
Under the Resource summary section, you can find the total number of switches along with their health statuses.

Figure 1. Example Overview page showing error for a switch

- In the graphical view of the hardware appliance, the color indicates the health status of a node.
2. Hover over a graphical view of the hardware to identify switch details.
For switch, it shows the name of the hardware, the health status, the type of switch, and the rack unit.
3. Go through the color indicators and decode their statuses.
4. Fix errors, failures, and warnings based on the guidance.

5. After all the errors and failures are fixed, go to the Overview dashboard page and check the health status of problematic nodes. For more information about nodes, see [Switch details](#).

Understanding color indicators and decoding status

Important: The color gray does not exist for the switches as failed, degraded, or normal are the available states.

Switch in Green color

It indicates that the switch is in a healthy or normal state, and no action is required.

Switch in Red or Yellow color

It indicates that the switch is failed or in a degraded state. Do the following steps to resolve the issue:

- Click the component that is in red or yellow color.
The slide out pane is displayed with the Hardware status, type, firmware, s/n, rack, and rack unit.
- Go through the details in the slide out pane. If you want more information about the switch, click View full details. Alternatively, go to the Network page > Switches tab and click the switch name link.
It opens Network page that includes the graphical view, recent events, and other details of the switch and its internal components.
- Select Front in the Components section to see front view of the switch and hover over a graphical view to check internal components status such as used and unused port slots along with their working status.
- Select Back in the Components section to see back view of the switch and hover over a graphical view to check internal components used and unused fan slots along with their working status.
To debug further, click the internal components such as fans and PSUs that are in red or yellow color. It opens a new slide out pane for fans and PSUs with more details such as slot, speed, and state.
- Click View table to check all internal components and its status in the table format.
It opens Components table page that includes Ports, Fans, and Power supply in three tab pages. For network details, see [Switch details](#).
- Go through the Recent events section to understand the error.
- Click View all to go to the events page and view all recent events on the hardware component.
The BMYxxx code and the error message informs you about the error.
- Go through the Details section to get more details of the switch such as type, model, IBM S/N, manufacture S/N, rack unit, rack, and firmware.
- To diagnose and take corrective action, try the following options:
 - Check whether the hardware is in the correct position. To view the rack positions of the switch, see [Hardware overview](#).
 - Check the BMYxxx errors. For more information about individual BMYxxx network codes and their corrective action, see [Network events error codes](#).
If you are not able to fix the issue, contact [IBM support](#).

Switch in color blue with diagonal stripes

It indicates that a firmware upgrade is in progress. See [Upgrading switch firmware](#).

- [Switch details](#)

The Network page in the IBM Fusion user interface provides information about switches, VLANs, and links in the system.

Switch details

The Network page in the IBM Fusion user interface provides information about switches, VLANs, and links in the system.

From the IBM Fusion HCI menu, click Infrastructure > Network. The Network page displays Switches, Links, and VLAN in three tab pages. Click each tab to view the respective details in a table format. Use the Search field to filter and find records. The settings icon helps you to customize the column headings of these tables. Decide the number of records per page by using the Items per page drop-down list of the table. You can traverse to the previous or next page views. Select a number from the drop-down list of the page numbers to jump to a specific page view.

Switches tab page

The Switches is the default tab page that gets displayed when you click Infrastructure > Network. It displays a list of high speed, internal management, and spine switches (for high-availability cluster and expansion cluster) in a table format. The column headers that are displayed by default in the table are Name, Hardware

status, Type, Model, Firmware, IBM S/N, Rack, and Rack unit. Click

(Run command icon) to run a command to work with the switch. For more information about run command, see [Running commands for switches](#). You cannot delete a switch from this tab page.

Switch details

Click the switch name link that you want to manage. It opens the Network page that includes the graphical view (front and back), recent events, and other details of the switch and its internal components and statuses. Hover over a graphical view of the switch to check internal components and status. To debug further, click the internal component that is in a critical or degraded state. It opens a new slide out pane for ports with more details such as port, speed, and status.

The following images shows examples of management and high-speed switches of the Lenovo hardware.

Figure 1. Management switch

Figure 2. High-speed switch

Click the View table to check all internal components and its status in the table format. It opens Components table page that includes Ports, Fans, and Power supply in three tabs.

Component	Details
Ports	It displays a list of ports. The column headers that are displayed by default in the table are Port, Status, and Speed (Gbps).
Fans	It displays the status of the fans of the switch.
Power supply	It displays the status of the power supply of the switch.

Click View all in the Recent events panel to go to the events page and view all recent events on the hardware component.

Note: The recent events pane includes details of the last five events that occurred for the switch.

If you want more information about the switch, go through Details section to get more details of the switch.

	Description
Type	The type of the switch (the options are Spine, Management, and High-speed).
Model	The model number of the switch.
IBM S/N	The hardware serial number.
Manufacture S/N	The IPv6 address of the switch.
Rack unit	The rack unit position of the switch in the rack.
Rack	The name of the rack.
Firmware	The firmware version of the switch.

Click Run command to run a command to work with the switch. For more information about run command, see [Running commands for switches](#).

Links tab page

Click Links tab to view a list of all available links in a table format. The column headers that are displayed by default are Name, Type, Port number, Transceiver, Aggregation, VLANs, and Native VLAN. To add a new link, click Create link. For more information about adding new link, see [Adding links](#). Click edit icon to edit the link or delete icon to delete it.

VLANs tab page

Click VLAN tab to view a list of all available VLANs in a table format. The column headers that are displayed by default in the table are Name, Type, Status, ID, and Multiple links. To add a new VLAN, click Create VLAN. For more information about creating VLAN, see [Adding VLANs](#). Click edit icon to edit the VLAN or delete icon to delete it. If a VLAN is associated to a link, then you cannot delete it.

- [Running commands for switches](#)

As part of your network configuration, you can run a command to work with the switches. The Network page in the IBM Fusion user interface provides information about switches in the system.

Running commands for switches

As part of your network configuration, you can run a command to work with the switches. The Network page in the IBM Fusion user interface provides information about switches in the system.

Procedure

1. Click Infrastructure > Network.
The Network page is displayed.
2. Click Switches to display the Switches section.
3. Determine the switch record that you want to work with.
4. Click Run command.
The Run command pane is displayed.
5. Click Command drop-down list to view the available command options.
6. Select a command option from the list.
7. Click Run to apply the command to the switch.
A window with the command information is displayed. If the command information is extensive, click Show more or Show less to expand or collapse the selected option to view more information about the command. You can also use the Copy to clipboard option to copy the command information for reference.
8. Click Done to complete the changes.
You can see the updated record in the Switches section of the Network page. For more information, see [Switch details](#).
9. Optional: Click Reset if you want to undo the current changes.

Monitoring and logging by using any monitoring tool

IBM Fusion provides multiple ways to monitor the health of the hardware and software.

- Events are fed into the Red Hat® OpenShift® event manager
The following example IBM Fusion events for your reference:
 - Hardware events for IBM Fusion HCI, including switches and nodes
 - Events that are related to the data services of IBM Fusion, such as backup and restore

As IBM Fusion feeds events into Red Hat OpenShift event manager, they show up in the integration that you use to monitor OpenShift events.

- Metrics are fed into Prometheus
IBM Fusion feeds metrics into a Red Hat OpenShift Prometheus instance.

The advantage is that they are available in any monitoring tool you are using with Prometheus, such as Grafana. IBM Fusion provides a set of default Grafana dashboards and an access link to the interface.

- IBM Fusion provides logs for its services
- IBM Fusion provides a user interface that shows the status of the system
- IBM Fusion provides CRs that reflect the status of the system

Events and metrics provide observability that can be fed into other monitoring systems, such as Grafana and ELK.

Important:

- IBM Fusion does not install Grafana and ELK as part of its installation.
- If you already have monitoring tools that you use in your environment, then you can feed IBM Fusion observability into these existing tools. For example, if you use Grafana to monitor your OpenShift environment, then you can import metrics and dashboards of IBM Fusion into its instance.

Monitoring

The metrics are collected from network and compute components and sent to Prometheus, which is then propagated to Grafana for visualization.

Follow the steps to access IBM Fusion information in Grafana. After Grafana is installed and Prometheus data source is configured, you can import dashboards of IBM Fusion with the following steps:

Important:

- You must have a working Grafana instance.
- The OpenShift Container Platform version must be at 4.14 or later.
- The following steps 1 - 5 explain how to configure Prometheus data sources. If it is already configured, then you can directly go to step 6.

Important: Ensure that you change the namespace or project before following the steps. Run the following command to change the namespace.

oc project <your-grafana-namespace>

1. Create a ServiceAccount associated with your Grafana, and replace the namespace.

```
oc create serviceaccount grafana -n <your-grafana-namespace>
```

2. Create a Role Binding to a ServiceAccount that is associated with your data source in Grafana, and replace the namespace. So, that can use the Prometheus cluster.

```
oc create clusterrolebinding grafana-cluster-monitoring-view \
--clusterrole=cluster-monitoring-view \
--serviceaccount=<your-grafana-namespace>:grafana
```

3. Create a secret of type **service-account-token** by using the following sample YAML.

```
apiVersion: v1
kind: Secret
type: kubernetes.io/service-account-token
metadata:
  name: grafana-secret
  annotations:
    kubernetes.io/service-account.name: grafana
```

4. Run the following command to get a token.

```
oc get secret grafana-secret -ojsonpath='{.data.token}' | base64 -d
```

5. Configure Grafana with a Prometheus data source and authentication.

- a. Log in to Grafana user interface.
- b. From the menu, go to Configurations and select Data Sources.
- c. Click Add data sources and select Prometheus.
- d. Update the following values:

URL

Run the following command to get the address of the Cluster Prometheus Route.

```
oc get route prometheus-k8s -n openshift-monitoring
```

Enable Skip TLS Verify parameter under Auth section.

Custom HTTP Headers

```
HTTP Method: GET
Header: Authorization
Value: bearer <token-from-step-4>
```

6. Download the **JSON** file for each of the dashboard:

- For network and compute **JSON** files, see <https://www.ibm.com/support/pages/node/7027780>.

7. Import the files in the Grafana dashboard. For the procedure to import files in Grafana dashboard, see [Importing files](#).

Note: Select Upload JSON file option and upload **JSON** downloaded in step 6.

8. Verify whether that Grafana dashboard is imported correctly.
9. Click Dashboards menu and choose the newly imported dashboard.

Viewing dashboard

In Grafana, you can view different dashboards for network and compute wherein the following metrics are captured for each component and represented graphically:

The following metrics are captured for each of the components:

- **Network**
 - High-speed switches
 - Management switches
 - Spine switches
- **Compute**
 - Energy status
 - Thermal status

An example Grafana screen that shows the networking dashboard of IBM Fusion for a high-speed switch.

An example Grafana screen that shows the compute dashboard of IBM Fusion:

Note: For Dell hardware, the **Energy Stats** panels do not display any data.

For more information about Grafana, see <https://grafana.com/docs/>. For more information about Prometheus, see <https://prometheus.io/docs/introduction/overview/>.

- **[Paid account access to Docker Hub for Grafana installation and deployment](#)**

The default installation configuration for Grafana uses the free account quota to pull images from Docker Hub. If you see that the Grafana POD is in an error state due to **image pull** error, then it means that you must use a paid account to pull Grafana images from Docker Hub to complete the deployment. Redeploy Grafana by using an API key provided by Docker Hub. If redeployment is not done, then you must wait for few hours till the free quota is reset by Docker Hub and then images can be pulled again.

- [Creating an audit index pattern and visualize audit data in Kibana](#)
From the Kibana console, create a basic index pattern.

Paid account access to Docker Hub for Grafana installation and deployment

The default installation configuration for Grafana uses the free account quota to pull images from Docker Hub. If you see that the Grafana POD is in an error state due to **image pull** error, then it means that you must use a paid account to pull Grafana images from Docker Hub to complete the deployment. Redeploy Grafana by using an API key provided by Docker Hub. If redeployment is not done, then you must wait for few hours till the free quota is reset by Docker Hub and then images can be pulled again.

Complete these steps to for Grafana installation and redeployment.

1. Log in to Docker. For more information, see [Log in to Docker](#).
2. Create a Pull Secret. For more information, see [Create a Secret based on existing Docker credentials](#).
3. Update the pull secret in **ServiceAccounts**. Do these steps:
 - a. Log in to the OpenShift® Container Platform web management console.
 - b. Click User Management > ServiceAccounts. The ServiceAccounts page is displayed.
 - c. Search for grafana-serviceaccount by Name. Click to open it in the ServiceAccount details page, then click the YAML tab.
 - d. Update the secret name under imagePullSecrets. For example, specify the pull secret name as follows.

```
name: ibm-spectrum-fusion-registrykey
```

4. Go to Workloads > Pods.
5. Select ibm-spectrum-fusion-ns namespace from the Project list.
6. Restart the Grafana deployment Pod. You can see that Pods are up and running. The status indicates as **Running** against each Pod.

Creating an audit index pattern and visualize audit data in Kibana

From the Kibana console, create a basic index pattern.

By using the Kibana console, you can create a basic index pattern. Do these steps.

1. From the IBM Fusion user interface, click the App launcher (the icon with nine dots).
2. Click the outbound arrow to open the Kibana console in another window.
3. Log in to the Kibana console with the user credentials.
Note: The Kibana console shares a single sign-on authentication with the IBM Fusion user interface.
4. Click Management > Index Patterns. The Create index pattern page is displayed if you are adding the first index pattern. For more information, see [Red Hat® OpenShift® Container Platform](#) documentation.
5. In Step 1 of 2: Define index pattern, enter the Index pattern. You must create index patterns when logged into Kibana the first time for the **app**, **infra**, and **audit** indices. You can enter wildcard characters (*). For example, enter **audi***.
6. Click Next step.
7. In the Step 2 of 2: Configure settings, use the **@timestamp** time field to view their container logs.
8. Click Create index pattern to add the index pattern.

For example, if you entered **audi*** in the index pattern. The Fields tab page lists every field in the **audi*** index and the field's associated core type as recorded by Elasticsearch.

9. Click Discover menu to visualize the audit data.

IBM Fusion metrics

This section describes the metrics that are used in IBM Fusion.

Platform

Metric	Description
isf_cluster_details	It displays the details about the cluster (version, platform, and environment).
isf_service	It displays the health status of the installed services ('1' for healthy, '0' for unhealthy).
isf_environment_risk	It displays the count of active environment risks on the cluster.
isf_service_upgrade_risk_count	It displays the count of active upgrade pre-check risks per service on the cluster.

Hardware

Metric	Description
isf_switches_info	It displays the switch details (Model, Type, Vendor, IBM MTM).
isf_switches_port	It displays the overall health of the port group ('1' for healthy, '0' for unhealthy).
isf_nodes_info	It displays the nodes hardware details (Node Type, IBM-MTM, Vendor).
isf_node_upgrade_risk_count	It displays the count of active upgrade pre-check risks per node on the cluster.
isf_switch_upgrade_risk_count	It displays the count of active upgrade pre-check risks per switch on the cluster.

Fusion events

Metric	Description
fusion_events_total	It displays the count of total unique fusion events created.
fusion_duplicate_events_total	It displays the count of total fusion events that are identified as duplicate.
fusion_hardware_events_total	It displays the count of total fusion events that are associated with a hardware asset.

Storage

Metric	Description
isf_local_storage_total_gib	It displays the local storage type and its usable capacity metric in GiB.
isf_local_storage_used_percentage	It displays the percentage of local storage used.

Switches

CPU metrics

Metric	Description
ssCpuUser	It displays the percentage of CPU time that is spent for running user-level processes.
ssCpuSystem	It displays the percentage of CPU time that is spent for running system or kernel-level processes.
ssCpuIdle	It displays the percentage of time when the CPU is idle.

Memory metrics

Metric	Description
memTotalReal	It displays the total physical memory that is installed on the switch.
memAvailReal	It displays the amount of physical memory currently free or available.

Interface traffic metrics

Metric	Description
ifInOctets	It displays the total bytes received on an interface.
ifOutOctets	It displays the total bytes transmitted out of an interface.

Sensor and temperature metrics

Metric	Description
psu1TempOrAmbientTemp	It displays the PSU1 temperature or ambient temperature based on switch model.
psu2Temp	It displays the temperature of the PSU2.
cpuPackageSensor	It displays the temperature of the CPU package.
cpuCoreSensor0	It displays the temperature of CPU core 0.
cpuCoreSensor1	It displays the temperature of CPU core 1.
portAmbientSensor	It displays the ambient temperature near front-panel ports.
mainBoardAmbientSensor	It displays the ambient temperature on the main system board.
asicTempSensor	It displays the temperature of the switch's main forwarding Application-Specific Integrated Circuit (ASIC).

Interface status metrics

Metric	Description
ifOperStatus	It displays the operational state of the interface (1 = up, 0 = down).
ifAdminStatus	It displays the admin-configured state of the interface (0 = up, 1 = down).

Password rotation

Global password rotation status

Metric	Description
password_rotation_current_status	It indicates the overall password rotation status for an asset and component. The value is 0 for success and 1 for failure. The metric is labeled by asset_name and component_name , allowing status tracking per asset and per system component.

Serviceability-related password rotation metrics

Metric	Description
fusion_serviceability_pwd_rotation_total	It displays the total number of password rotation attempts for serviceability credentials. The result label indicates whether the rotation attempt is successful or failed.
fusion_serviceability_pwd_rotation_current_error_code	It displays the current password rotation error state for a serviceability asset (0 for pass, 1 for fail).
fusion_serviceability_pwd_rotation_last_success_timestamp_seconds	It displays the Unix timestamp of the last successful password rotation for a serviceability asset.
fusion_serviceability_pwd_rotation_period_seconds	It displays the configured password rotation period in seconds for a serviceability credential type.

Compute-related password rotation metrics

Metric	Description
compute_pwd_rotation_total	It displays the total number of password rotation attempts for compute assets. The result label indicates whether the rotation attempt was a success or failure .
compute_pwd_rotation_current_error_code	It displays the current error state for compute password rotation. The value indicates status (0 = healthy or no failure, 1 = password reset failed, 2 = Kubernetes secret update failed).
compute_pwd_rotation_last_success_timestamp_seconds	It displays the Unix timestamp of the last successful password rotation for a compute asset.

Installation-related password rotation metrics

Metric	Description
fusion_install_pwd_rotation_total	It displays the total number of password rotation attempts for installation assets. The result label indicates whether the rotation attempt was a success or failure .
fusion_install_pwd_rotation_current_error_code	It displays the current error state for installation password rotation (0 for pass, 1 for fail).
fusion_install_pwd_rotation_last_success_timestamp_seconds	It displays the Unix timestamp of the last successful password rotation for an installation asset.

Service node upgrade

Trigger metrics

Metric	Description
fusion_update_servicenode_upgrade_triggered_total	It displays the total number of service node upgrade trigger attempts, labeled by result (success or failure). The metric pre-initializes both label values to 0 at startup.

Terminal state metrics

Metric	Description
fusion_update_servicenode_upgrade_completed_total	It displays the total number of service node upgrades that reached the COMPLETED terminal state successfully.
fusion_update_servicenode_upgrade_failed_total	It displays the total number of service node upgrades that reached the FAILED terminal state, including upgrades that exhaust the maximum failure count.

Timestamp metrics

Metric	Description
fusion_update_servicenode_upgrade_last_start_timestamp_seconds	It displays the Unix timestamp in seconds of the most recent successful upgrade trigger. The value is 0 until the first trigger occurs.
fusion_update_servicenode_upgrade_last_completion_timestamp_seconds	It displays the Unix timestamp in seconds of the most recent successful upgrade completion. The value is 0 until the first completion occurs.

Recording rules

The following recording rules belong to the **fusion_update_servicenode_recording_rules** group and are evaluated every 30 seconds:

Metric	Description
fusion_update_servicenode_upgrade_error_rate	It displays the proportion of terminal upgrades that failed. The value is always bounded between 0 and 1. The metric uses fusion_update_servicenode_upgrade_triggered_total as the denominator because internal MaxFailCount retries do not call TriggerUpgrade() again.
fusion_update_servicenode_upgrade_success_rate	It displays the proportion of terminal upgrades that are completed successfully. The value is always bounded between 0 and 1.
fusion_update_servicenode_upgrade_duration_seconds	It displays the elapsed seconds since the last upgrade was triggered. The value is non-zero only while an upgrade is in flight. The metric is suppressed once the completion timestamp is greater than or equal to the start timestamp, and suppressed on startup when the start timestamp is 0.

Log collector

Job metrics

Metric	Description
logcollector_jobs_total	It displays the total number of log collection jobs by status. The status label indicates the job state: created , completed , or failed .
logcollector_job_duration_seconds	It displays the duration of a complete log collection job in seconds, from start to finish, tracked by job name. The name label identifies the job and the status label indicates completed or failed .

Metric	Description
logcollector_job_package_size_bytes	It displays the size of the final compressed log package in bytes, tracked by job name. The name label identifies the job and the status label indicates completed or failed .
logcollector_active_jobs	It displays the number of currently active log collection jobs.

Log type metrics

Metric	Description
logcollector_log_type_duration_seconds	It displays the duration of individual log type collections. The log_type label identifies the type of log being collected and the status label indicates success , error , or skipped .

Device collection metrics

Metric	Description
logcollector_device_collection_duration_seconds	It displays the duration of device log collections for BMC and switches. The device_type label identifies the device: bmc (Baseboard Management Controller) or switch (network switch). The status label indicates success , error , or skipped .

Storage metrics

Note: Storage metrics are enabled only when using PVC (Persistent Volume Claim) storage. Set the environment variable **STORAGE_TYPE=pvc** to enable these metrics.

Metric	Description
logcollector_storage_free_bytes	It displays the free storage space in bytes. The metric updates every 30 seconds.
logcollector_storage_utilization_percent	It displays the storage utilization as a percentage between 0 and 100. The metric updates every 30 seconds.

Must-gather cleanup metrics

Metric	Description
logcollector_must_gather_cleanup_duration_seconds	It displays the duration of must-gather cleanup operations with bucketed input size and file count. The input_size_bucket label identifies the size bucket of the input data, the file_count_bucket label identifies the file count bucket, and the status label indicates success , error , or skipped .

Backup and Restore

Job processing times

Metric	Description
idp_job_duration_ms	Time a backup or restore job took to complete.
idp_inventory_time_ms	Time it took for the inventory portion of a job.
idp_resource_group_time_ms	Time it took for the resource group portion of a job.
idp_volume_group_time_ms	Time it took for the volume group portion of a job.
idp_create_snapshot_time_ms	Time it took to take a snapshot of the PVCs.
idp_data_transfer_time_ms	Time it took for the data transfer portion of the job.
idp_hook_execution_time_ms	Time it took to run Recipe hooks.

In-progress jobs

Metric	Description
idp_active_jobs	Total number of active jobs.
idp_total_time_active_ms	Total time jobs were active.
idp_total_time_queued_ms	Time jobs were queued waiting to be processed.
idp_backups_inprogress	Number of in-progress backup jobs.
idp_restores_inprogress	Number of in-progress restore jobs.
idp_backup_deletes_inprogress	Number of in-progress delete jobs.
idp_backups_queued	Number of backup jobs queued.
idp_restores_queued	Number of restore jobs queued.
idp_backup_deletes_queued	Number of delete jobs queued.

Policies

Metric	Description
idp_policies_assigned_to_bsl_count	Number of policies assigned to a BSL.
idp_backup_policy_window_duration_minutes	Policy's configured time window duration.
idp_backup_policy_apps_assigned_count	Number of applications assigned to a policy.
idp_backup_policy_apps_assigned_per_cluster_count	Number of applications assigned to a policy per cluster.

Backup storage locations

Metric	Description
idp_bsl_connection_status	Connection status of BSLs.
idp_backup_location_bucket_capacity_bytes	BSL bucket capacity.
idp_used_capacity_bytes	Gauge for used BSL capacity in bytes.

Completed job status

Metric	Description
idp_backup_service_total_backups	Total number of backup jobs.
idp_backup_service_active_backups_count	Number of active backup jobs.
idp_backup_service_completed_backups	Number of completed backup jobs.
idp_backup_service_failed_backups	Number of failed backup jobs.

Metric	Description
idp_backup_service_cancelled_backups	Number of cancelled backup jobs.
idp_backup_service_total_restores	Total number of restore jobs.
idp_backup_service_completed_restores	Number of completed restore jobs.
idp_backup_service_failed_restores	Number of failed restore jobs.
idp_backup_service_cancelled_restores	Number of cancelled restore jobs.
idp_backup_service_total_deletebackups	Total number of delete jobs.
idp_backup_service_completed_deletebackups	Number of completed delete jobs.
idp_backup_service_failed_deletebackups	Number of failed delete jobs.

Enabling observability for IBM Fusion clusters

Use these instructions to enable multi-cluster observability for IBM Fusion clusters.

Before you begin

Ensure that you met the following prerequisites:

- Network connectivity between clusters and the hub or query endpoint.
- S3-compatible object storage for long-term metrics retention.

About this task

Achieve a comprehensive multi-cluster observability solution for IBM Fusion by using Red Hat® Advanced Cluster Management or an existing Thanos and Grafana infrastructure. Multi-cluster observability uses open source technologies to create a centralized monitoring solution:

- **Thanos** - Provides global querying across multiple Prometheus instances and long-term metrics storage in S3-compatible object stores.
- **Grafana** - Delivers visualization dashboards for metrics analysis and alerting.
- **Prometheus** - Collects metrics from each managed cluster and sends data to the hub cluster.

It delivers **centralized fleet-wide monitoring** through unified dashboards, enabling proactive issue identification and management across the following IBM Fusion components:

- Fleet overview
- Unhealthy data services
- Active environmental risks
- Unhealthy statuses of nodes and switches
- Event metrics
- Upgrade risks for IBM Fusion services, nodes, and switches
- Storage cluster health
- Switch monitoring:
 - Resource utilization (CPU and memory)
 - Network interface health
 - Thermal monitoring (PSU, CPU core, port, board, ASIC)

Procedure

Resources for custom IBM Fusion observability dashboards or configuration YAMLS are available through the [GitHub](#) repository.

What to do next

The centralized dashboard represents a fundamental shift from reactive to proactive infrastructure management, ensuring your IBM Fusion fleet maintains optimal performance while minimizing the risk of undetected issues escalating into service outages.

IBM Fusion Call Home Telemetry

IBM Fusion Call Home Telemetry enhances supportability by providing IBM with valuable insights into system configuration and performance. Telemetry data is collected from various components and securely transmitted to IBM, helping support teams proactively identify issues and optimize system behavior based on real-world usage.

Telemetry automatically collects and transmits the data from IBM Fusion components, such as software applications or hardware devices. Also, it is used to gather information about system configuration, usage patterns, and performance metrics. For steps to enable call home telemetry, see [Enabling Call Home for IBM Fusion HCI](#). Note: The system uploads Call Home telemetry data every 24 to 26 hours.

The following details are collected and uploaded as part of call home telemetry support:

IBM Fusion cluster details

Collects statistical insights into IBM Fusion resources, such as the number of pods, deployments, and other key components, along with version and health status details for both OpenShift® and IBM Fusion. Also, it collects node storage consumption details for OpenShift.

IBM Fusion license data

Collects IBM Fusion licensing data. For more information on licensing metrics, see [Understanding the IBM Fusion license report](#).

IBM Fusion events data

Collects the summary of IBM Fusion events by severity and event ID.

IBM Fusion Services

Collects the details such as name, version, health, and upgrade details of different fusion services installed in the cluster. If Backup & Restore service is installed, then it shows the success % of backups and restores.

Hosted clusters

Collects basic count and health status of hosted clusters that are deployed.

Virtual machines

Collects basic count and health status of virtual machines that are created on cluster.

Basic rack details

Collects configuration details including serial number, model, storage type, multi-rack setup, proxy enablement, Disaster Recovery (DR) enablement, IBM serial number, and other IBM Fusion HCI rack-specific parameters.

Node and switch health monitoring

Collects hardware and health details for nodes and switches, including name, vendor, model, firmware, and type. Also, it captures component-level stats such as memory, processors, fans, GPU nodes, cards, power supplies (for nodes), and relevant metrics for switches.

Administering and configuring storage in IBM Fusion HCI

Administer and configure IBM Storage Scale storage integration for the IBM Fusion HCI appliance.

About storage administration and configuration

The IBM Fusion appliance supports customer workloads on OpenShift® Container Platform.

IBM Fusion supports only file-based storage classes that are based on IBM Storage Scale CSI driver.

The IBM Spectrum® Storage Scale Erasure Code Edition (ECE) layer does the hardware storage aggregation of the NVMe disks that are attached to the individual compute nodes of the appliance. The CSI layer provides virtualized storage over the physical storage aggregated by the ECE for consumption by the workloads that run on OpenShift Container Platform.

Note: IBM Fusion HCI brings out of the box IBM Storage Scale Erasure Code Edition (ECE) as the cloud native storage option.

- [Monitoring storage options from IBM Storage Scale Erasure Code Edition \(ECE\) console](#)

From the IBM Storage Scale Erasure Code Edition (ECE) console, you can manage file systems, node addition, disk replacement, AFM management. In addition, you can monitor the health check, and serviceability. From the IBM Fusion user interface, you can manage storage node addition.

Monitoring storage options from IBM Storage Scale Erasure Code Edition (ECE) console

From the IBM Spectrum® Storage Scale Erasure Code Edition (ECE) console, you can manage file systems, node addition, disk replacement, AFM management. In addition, you can monitor the health check, and serviceability. From the IBM Fusion user interface, you can manage storage node addition.

IBM Fusion includes a storage platform layer based on IBM Storage Scale. IBM Fusion brings together the unstructured data management capabilities of IBM Storage Scale. IBM Fusion combines IBM Storage Scale functions with backup and restore software. Operations can protect data directly to cloud or to a remote IBM Storage Scale system and then even archive to tape.

Access the IBM Storage Scale Erasure Code Edition (ECE) console from the IBM Fusion user interface to work with the storage options.

1. From the Dashboard menu in the IBM Fusion user interface, click Storage Software to open the IBM Storage Scale Erasure Code Edition (ECE) console.
2. Log in to the IBM Storage Scale Erasure Code Edition (ECE) console for storage management and to use the features for advanced configurations.

Note: The IBM Storage Scale Erasure Code Edition (ECE) console shares a single sign-on authentication with the IBM Fusion user interface.

See the following menu options on the IBM Storage Scale Erasure Code Edition (ECE) console that you can use to work with the storage options of IBM Fusion.

Home

It provides an overall summary of the IBM Storage Scale system configuration, status of its components, and services that are hosted on it.

Monitoring

It provides a dashboard to display the predefined performance charts and the customized chart. You can use more of the monitoring options that are available in this menu for working with the storage options.

Nodes

It monitors the performance and health status of the nodes that are configured in the cluster. You can also create and manage user-defined node classes from the Nodes page. As part of the IBM Fusion tasks, click Files, File Systems to manage nodes or disks for storage.

- **Add nodes or disks:** To add nodes or disks from the IBM Fusion user interface, see [Configuring nodes for management](#) and [Adding additional storage nodes](#). Separate procedures are involved for adding AFM, GPU, and storage nodes.
- **Disk replacement:** Replace the disks from the IBM Storage Scale Erasure Code Edition (ECE) console. For more information, see [Disk Replacement](#) and [Replacing disks in a GPFS file system](#).

Cluster

It monitors the network and network adapter performance and health statuses.

Storage

It helps to monitor the performance, health status, and configuration aspects of all available pools in the IBM Storage Scale cluster.

Services

It monitors and manages various services that are hosted on the IBM Fusion system.

Support

You can download diagnostic data to troubleshoot the reported IBM Fusion issues. You can also configure the call home feature that automatically notifies the IBM® Support for the reported issues.

For more information, see the [IBM Storage Scale](#) documentation.

User management

Use the role-based user restrictions and user management capabilities to administer IBM Fusion HCI.

IBM Fusion user interface is configured with OpenShift® Container Platform to have a single sign-on. For the first time login to IBM Fusion user interface and OpenShift Container Platform web management console, use the **kubeadmin**, which is the default user for both. To authenticate the default user login, use the password that got generated during the installation of IBM Fusion.

Note: For security reasons, create a user with **cluster-admin** role and delete the default **kubeadmin** user.

For more information about roles, see [Default cluster roles](#) in *Red Hat OpenShift Container Platform* documentation.

User roles

Role-based access control (RBAC) objects determine whether a user is allowed to do an action within a project. By using role-based access control, you can set the resources and permissions available to a user. Role can be assigned to a user or group with role bindings. Role binding has the mapping of a role to a user or user group. You can bind your users to the following two default OpenShift cluster level roles:

Role	Permissions
cluster-admin	A super-user that can do any action in any project. When bound to a user with a local binding, they have full control over quota and every action on every resource in the project.
view	A user who cannot do any modifications, but can see most of the objects in a project. They cannot view or modify roles or bindings.

You can create more users and user groups. You can also update or delete existing users by using the **cluster-admin** user roles.

Add user to a role

Step 1: Get user and their role details:

To get all users and their cluster wide roles, run the following command:

```
oc get clusterrolebindings -o json | jq -r '.items[] | {role: .roleRef.name, users: .subjects[]?.name} | select(.users != null)'
```

Alternatively, you can run the following commands:

- Find all Users with a specific role:

```
oc get clusterrolebindings -o json | jq -r '.items[] | select(.roleRef.name == "<role>") | {role: .roleRef.name, users: .subjects[]?.name}'
```

For example, you want the list of all users in cluster-admin role:

```
oc get clusterrolebindings -o json | jq -r '.items[] | select(.roleRef.name == "cluster-admin") | {role: .roleRef.name, users: .subjects[]?.name}'
```

Example output:

```
{
  "role": "cluster-admin",
  "user": "ft-admin"
}
{
  "role": "cluster-admin",
  "user": "openshift-apiserver-operator"
}
{
  "role": "cluster-admin",
  "user": "openshift-config-operator"
}
{
  "role": "cluster-admin",
  "user": "service-ca-operator"
}
```

- Find a specific user role in a cluster:

```
oc get clusterrolebindings -o json | jq -r '.items[] | select(.subjects[]?.name == "<username>") | {role: .roleRef.name, user: "<username>}"'
```

For example, you want to find the role of ft-admin in a cluster:

```
oc get clusterrolebindings -o json | jq -r '.items[] | select(.subjects[]?.name == "ft-admin") | {role: .roleRef.name, user: "ft-admin}"'
```

Example response:

```
{
  "role": "cluster-admin",
  "user": "ft-admin"
}
```

Step 2: Add user to a role:

Add user to cluster-admin role:

```
oc adm policy add-cluster-role-to-user cluster-admin <username>
```

For example, add sf-admin user to cluster-admin role:

```
oc adm policy add-cluster-role-to-user cluster-admin sf-admin
```

Add user to view role:

```
oc adm policy add-cluster-role-to-user view <username>
```

For example, add sf-usr user to view role:

```
oc adm policy add-cluster-role-to-user view sf-usr
```

To know more about OpenShift Container Platform RBAC, see [Using RBAC to define and apply permissions](#) in *Red Hat OpenShift Container Platform* documentation.

For more information about authentication and authorization, see [Understanding authentication](#) in *Red Hat OpenShift Container Platform* documentation.

RBAC permissions for IBM Fusion HCI user interface

The following table displays the RBAC permissions for IBM Fusion HCI user interface.

Table 1. RBAC for IBM Fusion HCI users

User interface page or menu option	Cluster-admin	View user
Events	You can mark events as fixed	You cannot mark events as fixed
Applications	- You can assign policies to applications - You can restore application backup - You can enable or disable applications for disaster recovery	- You cannot assign policies to applications - You cannot restore application backup - You cannot enable applications for disaster recovery
Backup policies	- You can add, edit, or delete policies - You can add, edit, or delete backup locations	- You cannot add, edit, or delete policies - You cannot add, edit or delete backup locations For the procedure to manage the backup and restore of your application namespace as a view user through CRs, see Self-service Backup & Restore
Backup policies		
Infrastructure > Compute page	- Can upsize nodes or add storage disks. - Can manage node resources like moving a node to maintenance, power on a node, and so on.	- Cannot upsize nodes or add storage disks. - Cannot manage node resources.
Infrastructure > Network page	- Can run commands on switches - Can add VLANs and Links.	- Cannot run commands on switches. - Cannot add VLANs and Links.
Settings > Call Home page.	Can enable IBM Call Home or edit Call Home details.	Cannot enable Call Home or edit Call Home details.
Settings > Encryption page.	- Can edit encryption settings. - Can delete encryption settings.	- Cannot edit encryption settings. - Cannot delete encryption settings.
From the title bar, click the help icon and select Collect support logs.	- Can generate logs and log sets. - Can enable Call Home.	- Cannot generate logs or log sets. - Can download generated logs.
App Switcher icon in title bar > Storage outbound arrow	- Can replace disk (pdisk replacement). - Can download snap. - Can manage events (mark as resolved, fix, hide tip, notification, and others).	Cannot configure, modify, or manage the system or its resources.
Disaster recovery	- Can set up site 1, site 2, and tiebreaker in Metro Sync DR. - Can upgrade local, remote and tiebreaker clusters - Can failover applications from one site to another	- Cannot set up site 1, site 2, and tiebreaker in Metro Sync DR. - Cannot upgrade local, remote and tiebreaker clusters - Cannot failover applications from one site to another
Services	- Can enable and disable IBM Fusion services - Can upgrade IBM Fusion services	- Cannot enable and disable IBM Fusion services - Cannot upgrade IBM Fusion services
Applications icon in title bar > OpenShift outbound arrow	For more information about the permissions of the role, see Using RBAC to define and apply permissions in <i>Red Hat OpenShift Container Platform</i> documentation. Note: Menu option is available to navigate to OpenShift console with same login credentials.	

Configure identity providers

Step 1: Configure identify providers

- LDAP

Configure your organizations LDAP with OpenShift to access IBM Fusion user interface. For the more information and procedure, see [Configuring an LDAP identity provider](#) in *Red Hat OpenShift Container Platform* documentation.

- **htpasswd**

Configure htpasswd identity provider to create users that can access OpenShift and IBM Fusion user interface. To configure the user with htpasswd identity provider, see [Configuring an htpasswd identity provider](#) in *Red Hat OpenShift Container Platform* documentation.

Step 2: Bind your user to a role or to a group.

The user or group can have `cluster-admin` or `view` roles.

Step 3: Log in to IBM Fusion user interface

Log in to IBM Fusion user interface by using the newly created or added user.

Knowing your IBM Fusion user interface

Learn the various key elements of the IBM Fusion user interface for ease of use and navigation.

To open the user interface from any of the supported browsers:

1. Log in to OpenShift® Container Platform using kubeadmin.
2. Click the Applications icon in the title bar and click IBM Fusion.
3. In the IBM Fusion user interface, click Let's get started in the Welcome to IBM Fusion page.

The Quick start page is the landing page of IBM Fusion user interface.

From this Quick start page, you can provide storage for container workloads, backup and restore the applications and control plane data, manage IBM Fusion HCI hardware, upgrade components, investigate events and open support tickets.

The following options are available in the landing page of IBM Fusion user interface:

- You can do the following tasks from the navigation menu:
 - Click Events to view IBM Fusion events. They are Kubernetes native events that include filter-specific labels. For more information about the events page, see [Analyzing events in IBM Fusion HCI](#).
 - Click Applications to backup and restore application and its resources. For more information about how to backup and restore applications, see [Backup & Restore of your applications and virtual machines](#).
 - Click Backup policies to define parameters that are applied to backup jobs. For steps to create new policies or work with existing policies, see [Backup policies](#).
 - Click Infrastructure to manage the compute and network for the IBM Fusion HCI appliance. For more information about compute and network, see [Administering the node](#) and [Review IBM Fusion HCI network architecture](#).
 - Click Settings to do the following:
 - IBM Fusion
You can set up encrypted data at rest by connecting to a Security Key Lifecycle Manager. For more information about how to set up encryption, see [Configuring encryption for Global Data Platform storage](#).
 - IBM Fusion HCI
Enable Call Home and upgrade IBM Fusion HCI components. For more information about Call Home and upgrade, see [Enabling Call Home for IBM Fusion HCI](#) and [Implementing a comprehensive upgrade procedure](#) respectively.
- From the applications icon in the title bar, you can quickly navigate to the following consoles by using their corresponding outbound arrows:
 - Click OpenShift console to go to the OpenShift web management console. From the title bar of OpenShift console, click Red Hat applications, IBM Fusion to navigate to IBM Fusion.
 - IBM Fusion HCI specific outbound links
Apart from OpenShift console link, IBM Fusion HCI has the following additional outbound links:
 - Click Prometheus to go to Prometheus console. It is a monitoring solution for storing metrics. You must enable Grafana to use this option. For procedure to enable, see [Monitoring and logging by using any monitoring tool](#).
 - Click Storage to go to the IBM Storage Scale ECE user interface.
 - Click IBM Cloud to go to IBM Cloud.
- The following details and options are available in the title bar:
 - Displays the cluster ID of IBM Fusion.
 - Click the help icon on the title bar of the page to do the following tasks:
 - Click Open support case to create a support ticket with IBM.
 - Click Collect support logs to download support logs.
 - Click IBM Documentation to view IBM Documentation for IBM Fusion.
 - Click About to know the version of IBM Fusion.
 - The bell icon is visible on the IBM Fusion user interface only when any event or alert occurs and is available for the user. You can also click View all events to go the Events page.
 - Click the user icon to do the following tasks:
 - View the currently logged in user. Click user to view and manage the profile details of the logged in user.
 - Click Logout to log out of the IBM Fusion.

Note: To close all open sessions in IBM Fusion, log out of both IBM Fusion UI console and OpenShift Container Platform UI console.
- **[Working with the dashboard](#)**
Dashboard provides an overview of the infrastructure, managed clusters, hardware status, services health, storage, backup jobs, and environmental risks of the IBM Fusion HCI.
- **[Browser requirements](#)**

- **[Icons used in the user interface](#)**
A reference to the icons used in the user interface and their naming convention.

- [IBM Fusion HCI user interface issues](#)

A list of all known issues in the IBM Fusion user interface.

Working with the dashboard

Dashboard provides an overview of the infrastructure, managed clusters, hardware status, services health, storage, backup jobs, and environmental risks of the IBM Fusion HCI.

Account

The Account menu includes the following information:

- IBM Fusion license and audit metrics report. Go to Account > License usage and click the download icon to get the detailed license and audit metrics report. To understand the metrics, see [Understanding the IBM Fusion license report](#).

Details

The Details section includes the following hardware information:

- Cluster ID details.
- Infrastructure details.
- OpenShift® version details. Click Upgrade pre-check next to OpenShift version to open a slide out pane Upgrade pre-check to find the details of issues during the OpenShift upgrade. To debug further, click the outbound arrows to find exact problem details and possible prevention steps. Important: The upgrade pre-check identifies issues to be resolved before an upgrade is attempted, not the results of an upgrade operation.
- Total number of nodes added to the cluster.

Services

The Services section includes the following information:

- It provides a detailed list of services that are installed on the IBM Fusion HCI and their health status.
- Click View services to go to Services page to view the list of available and installed services on the IBM Fusion HCI along with their health status.

Hardware status

The Hardware status section includes the following information:

- It provides the number of hardware components in the IBM Fusion HCI that needs your attention.
- Click View hardware to go to Overview page to view the graphical view of the hardware appliance where you can find the total number of nodes, switches, and service node along with their health statuses.

Environmental risks

The Environmental risks section includes the following information:

- It provides the number of environmental risks present in the IBM Fusion HCI that needs your attention.
- Click View risks to open a slide out pane Environmental risks to check a detailed list of risks that might impact your workloads and upgrades. To debug further, click the outbound arrows to find exact problem details and possible prevention steps.

Managed clusters

The Managed clusters section provides the number of hosted cluster created. Click Learn how to create a hosted cluster to view the steps to create a hosted cluster. Important:

- Ensure that a local storage service (either Data Foundation or Global Data Platform) is installed.
- The local storage must be configured.

Backup jobs over time

The Backup jobs over time section includes the total number of backups available.

Important:

- Ensure that the Backup & Restore service is installed to view backup jobs details. To get steps to install Backup & Restore service, click View Backup & Restore.
- Ensure that a local storage service (either Data Foundation or Global Data Platform) is installed.
- The local storage must be configured.

Local storage

The Local storage section provides a circular pie chart that is used versus the available capacity of the storage. The storage capacity is represented in GiB and the Used capacity is represented graphically and in percentage. Click View storage to go to Local storage page to view the usable capacity, services health, and storage nodes details.

Important:

- Ensure that a local storage service (either Data Foundation or Global Data Platform) is installed.
- The local storage must be configured.

Replication

The Replication section includes the following information.

- Status of the both site 1 and site 2, such as connected or not.
- Type of the disaster recovery.
- Total numbers of applications added to the backup information. Click View topology to find the tiebreaker details whether the tiebreaker is connected between the site 1 and site 2.

Important:

- A replication card is displayed unless the Data Foundation local storage service is installed (replication is only supported for Global Data Platform storage).
- Also the content of the card available only after Global Data Platform local storage is configured.

- [Understanding the IBM Fusion license report](#)

Use these instructions to get a detailed explanation of each metric and how to interpret them to ensure compliance with IBM Fusion licensing terms.

Understanding the IBM Fusion license report

Use these instructions to get a detailed explanation of each metric and how to interpret them to ensure compliance with IBM Fusion licensing terms.

IBM Fusion licenses require entitlements for the following key components:

- [Cores managed](#)
- [Threads per core \(SMT\)](#)
- [Backup subscribed storage](#)
- [Services deployed](#)
- [Storage capacity provisioned or accessed](#)

Cores managed

- Cores on all applicable nodes in the cluster must be entitled by using IBM Fusion licenses with a VPC metric or a managed server metric. For IBM Fusion HCI, for calculating the metric, the **PROCESSOR_CORE** metric considers all nodes by default, whereas in IBM Fusion, only worker nodes are considered.
- The reported value of **PROCESSOR_CORE** is obtained from a native OpenShift® API for each node and aggregated by the IBM Fusion license service.
- The quantity of cores that are included in IBM Fusion licenses with a compute metric must meet or exceed the **PROCESSOR_CORE** reported value.

IBM clients who purchase certain IBM Software products, such as IBM Cloud Pak, Watson, or Maximo Application Suite, may be entitled to use IBM Fusion as a supporting program within their license agreement.

Key entitlement details:

- Restrictions may apply to services and storage capacity, but not to the number of cores, unless otherwise stated.
- Clients using IBM Fusion as a supporting program must replace their entitlement with paid licenses to remove the restrictions.

Deployment requirements:

- IBM Fusion licenses with a managed server metric can only be deployed on x86 bare metal nodes.
- IBM Fusion licenses with a VPC metric can be deployed on any node type, including physical, virtual, on-premises, or public cloud.

Threads per core (SMT)

The value reflects the maximum value of threads per core among all the nodes in the environment. The metric is reported in the licensing report and named as **NODE_SMT_MAX**.

Backup subscribed storage

This value helps understand the total storage capacity, which is covered with backup and assigned a backup policy. The metric is reported in the licensing report and named as **BACKUP_STORAGE_GB**, and the value is reported in GiB.

Note: If two clusters are connected and configured as a hub and spoke, for spoke applications that are backed up on the hub, the metric value does not reflect the total storage capacity.

Services deployed

- Clients can install services from IBM Fusion using operators that are included in the product.
- Each service flag should be validated against the Fusion licenses purchased or applied to the observed cluster to ensure compliance.
- Restrictions of use in other products, such as IBM Cloud Paks, are applicable if IBM Fusion is deployed using terms from those products.

When a client installs services from IBM Fusion, they must ensure that the services are licensed for use. Each installed service has a flag with a value of 1. To validate, check the flag against the purchased or applied IBM Fusion licenses for the cluster.

Key considerations:

- Validate each service flag against the applicable license terms.
- If using IBM Cloud Paks, follow the restrictions of use for those products.
- Non-compliance may occur if services are used without proper licensing.

For example, if the **BACKUP_RESTORE_SERVICE** metric is 1 and IBM Cloud Pak license terms are used, the deployment may not be compliant.

Storage capacity provisioned or accessed

- IBM Fusion licenses usually include an allowance for provisioning or accessing storage in the cluster such as Fusion Data Foundation, IBM Storage Scale, IBM Storage Ceph Pro. Other types of storage can be accessed using Fusion services such as object storage, or a third-party storage array with Fusion Access.
- Each type of permitted provisioning or access method is reported in a metric with the prefix **STORAGE_**. For example, **STORAGE_FDF** can be provisioned within the cluster (locally) or provisioned outside the cluster (externally).
- Clients should validate that the storage capacities and types that are deployed are covered by IBM Fusion licenses and any product-specific licenses. For example, client may already own IBM Storage Scale and then add to it using their Fusion entitlements when setting up their Fusion cluster. Combining licenses for the same type of IBM storage from different sources is usually permitted.
- If the cluster is configured with the GDP remote mount metric, the **STORAGE_GDP_REMOTE_MOUNT** metric reports the total usable capacity in GiB.

Some Fusion licenses include an entitlement for primary storage and allow core deployment. If this entitlement is not enough, you can buy additional primary storage expansion parts to increase the capacity.

Primary storage:

Primary storage refers to the usable capacity available to a cluster.

IBM Software Entitlements:

If you are using IBM Software entitlements with limited storage capacity, you can increase your storage entitlements by replacing the included licenses with paid Fusion licenses.

- Replace the licenses with paid Fusion licenses that meet the processor core requirements.
- Buy additional capacity entitlements to cover any remaining storage needs.

Browser requirements

List of supported web browsers for IBM Fusion HCI user interface.

In general, IBM Fusion HCI user interface works with most of the modern web browsers. The following table lists the browsers that are tested against IBM Fusion HCI user interface. Keep your browser version up to date with at least the last two versions so that the user interface works without issues.

Browsers	Supported
Mozilla Firefox	Supported
Google Chrome	Supported
Safari	Supported
Microsoft® Edge	Supported

Icons used in the user interface

A reference to the icons used in the user interface and their naming convention.

Table 1. Symbol references

Icon	Naming convention used
	Green tick mark to indicate healthy, completed,
	Warning
	Critical, Not connected, Failed transferring data
	Canceled
	Search filter
	Information
	Launch YAML
	Restore
	Ellipsis overflow menu
	Settings
	External link
	Outbound arrow
	Run command for switch

IBM Fusion HCI user interface issues

A list of all known issues in the IBM Fusion user interface.

Known issues in the node management pages

- If you use the IBM Fusion user interface to move a node to maintenance mode, then the user interface might show the status of the node as Ready.
- Only one node can go down at a time for maintenance and power down operation. If you place a second node in maintenance, then the user interface does not show any error message instead shows the node with status as Ready (maintenance mode in progress).
- During backend upgrades, the BMC reboots automatically for changes to take effect. As a result, monitoring may temporarily fail to connect. The health status incorrectly shows an error during this reboot period. The update status incorrectly defaults to Up-to-date when the upgrade is still in progress. However, the status recovers to Updating after the BMC connection is successful.

General issues

- To close or terminate all open sessions in IBM Fusion, log out of both IBM Fusion UI console and OpenShift® Container Platform UI console.
- Sometimes during upgrades and the nodes are down, a red toast notification appear on the user interface when you configure the remote filesystem even though file system is recovered and shows connected. In such case, you need to be explicitly close the notification.

API reference

List of all REST API references for IBM Fusion HCI.

For authentication of IBM Fusion REST APIs, ensure you have a valid Red Hat® OpenShift® Container Platform bearer token in Authorization header:

For example,

```
Authorization : Bearer sha256~4rpK-5GEwvgGKnXbBtMJ9dcaRDhIqOxt5BihZ1NVt20
```

IBM Fusion console route is the host for all these APIs. To access the console route, do the following steps:

1. Log in to Red Hat OpenShift Container Platform.
2. Go to Network > Routes page.
3. In the Routes page, search for Console. Ensure that you are in `ibm-spectrum-fusion-ns` project.
Note: All the APIs mentioned in swagger are not applicable to IBM Fusion HCI.

If you want to use the API, then use the following command to get the route:

```
oc get route console -n <namespace where fusion is installed>
```

Example:

```
oc get route console -n ibm-spectrum-fusion-ns
```

Example result:

NAME	HOST/PORT		PATH	SERVICES	PORT	TERMINATION	W.
console	console-ibm-spectrum-fusion-ns.apps.domain.com	isf-svc	<all>	reencrypt		None	

The list of APIs to understand the endpoints, methods (GET, POST, PUT, DELETE), parameters, and authentication requirements:

- [IBM Fusion appliance management API](#)
- [Active file management \(AFM\) APIs](#)
- [Serviceability APIs](#)
- Services APIs
For Backup & Restore service APIs, see [Backup and restore as code](#).

For IBM Data Cataloging service APIs, see [IBM Data Cataloging REST APIs](#).

IBM Fusion appliance management API

The IBM Fusion HCI API references.

- [Compute APIs](#)
- [Networking APIs](#)
- [Upgrade APIs](#)
- [Active File Management APIs](#)

Compute APIs

List of compute monitoring CRs

```
GET /api/v1/compute-monitorings
```

Get a specific `ComputeMonitoring` CR

```
GET /api/v1/compute-monitorings/<node-name>
```

List of `ComputeConfiguration` CRs

```
GET /api/v1/compute-configurations
```

Enable maintenance mode for compute node

```
POST /api/v1/compute/update/maintenancemode/<node-name>
```

Payload:

```
{"maintenanceMode": "true"}
```

Power operation for compute node

```
POST /api/v1/compute/update/poweroperation/<node-name>
```

Payload:

```
{"maintenanceMode": "true"}
```

Note: The node must be in maintenance mode before calling this API. To enable the maintenance mode, call the *Enable maintenance mode for compute node* API.

Add new compute node

```
POST /api/v1/computeconfig
```

Payload:

```
[{"linkLocal": "<linklocaladdress>", "ru": "<RUnumber>", "ibmSerialNumber": "<ibmserialnumber>", "rackSerialNumber": "<rackname>"}]
```

To check the added node, check the `successNodes` field in the response. An empty list means that the compute node failed to add to the cluster.

Add node to storage cluster (scale out)

```
PUT /api/v1/compute/scaleout
```

Payload:

```
{"scaleOutNodes": "compute-0,compute-2,compute-3"}
```

To confirm success of scale out, call the `GET compute node` API.

Check compute node storage

```
GET /api/v1/addstorage/info
```

Add storage disks (scale up)

```
PUT /api/v1/compute/scaleup
```

This API is applicable only if additional storage disks are available.

```
GET /api/v1/addstorage/info before this.
```

For successful scale, check storage information. To check the information, call the *Check compute node storage* API before and after this PUT API call.

Networking APIs

Note: If you using Alternative network configuration, then the links related APIs are not applicable.

List all network switches

```
GET /api/v1/network/switches
```

List all network VLANs

```
GET /api/v1/network/vlans
```

List all network links

```
GET /api/v1/network/links
```

List all network switch commands

```
GET /api/v1/network/listcommands
```

Run network switch command

```
GET /api/v1/networkcommands/<switch-name>/<command>
```

Create new VLAN

```
POST /api/v1/network/vlans/rack-vlans/add/
```

Payload:

```
{"vlanId":<vlan-id>,"vlanName":<vlan-name>,"vlanType":<vlan-type>,"multipleLinks": <yes/no>}
```

Update VLAN

```
POST /api/v1/network/vlans/rack-vlans/update/<vlan-id>
```

Payload:

```
{"vlanId":<vlan-id>,"vlanName":<vlan-name>,"vlanType":<vlan-type>,"multipleLinks": <yes/no>}
```

Create new link

```
POST /api/v1/network/links/rack-links/add/
```

Payload:

```
{"name":<link-name>,"ports":<port>,"vlanType": <type>,"transceiver":<transceiver-value>,"aggregation":true,"nativeVlan":<native-vlan-name>,"vlanNames":<vlan-names> }
```

Edit the link

```
POST /api/v1/network/links/rack-links/update/<uuid>
```

Payload:

```
{ "name": <link-name> , "ports": <port> , "vlanType": <type> , "transceiver": <transceiver-value> , "aggregation": true , "nativeVlan": <native-vlan-name> , "vlanNames": <vlan-names> }
```

Upgrade

IBM Fusion upgrade status

```
GET /api/v1/upgrade
```

Serviceability APIs

The serviceability API references for Call Home, Events, Logs, and Remote support.

- [Call Home APIs](#)
- [Event APIs](#)
- [Log APIs](#)
- [Remote support APIs](#)

IBM Call Home APIs

Get IBM Call Home data

```
GET /api/v1/callhome
```

GET response:

```
{
  "context": "",
  "clusterName": "isf-rackb",
  "domainName": "<domainname>",
  "organization": "ABS_Corp_Dummy",
  "customerid": "2434-4343",
  "email": "test_user@in.ibm.com",
  "customername": "Test User",
  "servicetype": "fullService",
  "agreesprivacy": true,
  "customeraddress": "",
  "contact": "(000)-123456-78",
  "machineaddress": "13th Street. 47 W 13th St, New York, NY 10011, USA.",
  "machinezip": "123456",
  "machinecity": "Newyork",
  "machinestate": "Newyork",
  "machinecountry": "US",
  "skipCallHome": false,
  "isBYOS": false
}
```

Update IBM Call Home data

```
PUT /api/v1/callhome/update
```

The payload is the same as the response to GET Call Home Data. All the fields are mandatory, even when we plan to update a few of them. Sending an incomplete payload may result in an error.

If Call Home is not configured, then the GET does not return data.

```
{
  "agreesPrivacy": true,
  "servicetype": "fullService",
  "organization": "ABS_Corp_Dummy",
  "customerid": "2434-4343",
  "customername": "Test User",
  "contact": "(000)-123456-78",
  "email": "test_user@in.ibm.com",
  "machineaddress": "13th Street. 47 W 13th St, New York, NY 10011, USA. 20 Cooper Square",
  "machinecountry": "US",
  "machinecity": "Newyork",
  "machinestate": "Newyork",
  "machinezip": "123456"
}
```

Turn off Call Home

```
PUT /api/v1/callhome/turnoff
```

Payload:

```
data: {
  "removeconfig": "true"
}
```

Upload Call Home Telemetry

Post API to upload telemetry data to IBM Call Home.

```
POST /api/v1/callhomeclient/telemetryupload
```

Event APIs

Get Events

```
GET /api/v1/eventmanager/events?${queryString}
```

Get event categories

```
GET /api/v1/eventmanager/eventcats
```

Get event stats

```
GET /api/v1/eventmanager/eventstats?${query}
```

For example, query 'Fixed=false' gets unfixed events.

Mark an event as fixed

```
PUT /api/v1/eventmanager/events/${eventId}
```

Payload:

```
{ annotations: { isf_fixed: 'true' } }
```

Note: This API is applicable only for unfixed and open Call Home tickets.

Log APIs

Get all log collector sets

```
GET /api/v1/logcollector
```

Create log collector set

```
POST /api/v1/logcollector
```

Payload:

```
{ "requests": { "storage": { "type": "list-entry", "source-list": "isf-collection-sets", "list-entry": "storage-sds" } } }
```

Payload for Fusion core:

```
{
  "requests": {
    "fusion-core": {
      "type": "list-entry",
      "source-list": "isf-collection-sets",
      "list-entry": "fusion-core"
    }
  }
}
```

Payload for service node:

```
{
  "requests": {
    "servicenode": {
      "type": "service-node-logs"
    }
  }
}
```

Payload for node logs:

```
{
  "requests": {
    "node-logs": {
      "type": "imm-logs",
      "name": "node-name1,node-name2,node-name3"
    }
  }
}
```

Payload for switch logs:

```
{
  "requests": {
    "network-switches": {
      "type": "switch-logs",
      "name": "switch-name1,switch-name2,switch-name3"
    }
  }
}
```

Payload for Backup & Restore:

```
{
  "requests": {
    "backup-and-restore": {
      "type": "list-entry",
      "source-list": "isf-collection-sets",
      "list-entry": "service-backup-and-restore"
    }
  }
}
```

Payload for Backup & Restore agents:

```
{
  "requests": {
    "backup-and-restore-agent": {
      "type": "list-entry",
      "source-list": "isf-collection-sets",
      "list-entry": "service-backup-and-restore-agent"
    }
  }
}
```

Payload for IBM Data Cataloging service:

```
{
  "requests": {
    "data-cataloging": {
      "type": "list-entry",
      "source-list": "isf-collection-sets",
      "list-entry": "service-data-cataloging"
    }
  }
}
```

Payload for Red Hat® OpenShift® Data Foundation:

```
{
  "requests": {
    "data-foundation": {
      "type": "list-entry",
      "source-list": "isf-collection-sets",
      "list-entry": "service-data-foundation"
    }
  }
}
```

Payload for Red Hat OpenShift Data Foundation Multicloud Object Gateway (MCG) only:

```
{
  "requests": {
    "data-foundation": {
      "type": "list-entry",
      "source-list": "isf-collection-sets",
      "list-entry": "service-data-foundation-MCG-only"
    }
  }
}
```

Payload for Global Data Platform:

```
{
  "requests": {
    "global-data-platform": {
      "type": "list-entry",
      "source-list": "isf-collection-sets",
      "list-entry": "service-global-data-platform"
    }
  }
}
```

Payload for Global Data Platform remote mount:

```
{
  "requests": {
    "global-data-platform": {
      "type": "list-entry",
      "source-list": "isf-collection-sets",
      "list-entry": "service-global-data-platform-remote-mount"
    }
  }
}
```

Payload for Content-Aware Storage (CAS):

```
{
  "requests": {
    "content-aware-storage": {
      "type": "list-entry",
      "source-list": "isf-collection-sets",
      "list-entry": "service-content-aware-storage"
    }
  }
}
```

Payload for Red Hat OpenShift Virtualization:

```
{
  "requests": {
    "virtualization": {
      "type": "collection-set",
      "collections": {
        "cnv-logs": {
          "type": "virtualization"
        }
      }
    }
  }
}
```

```
}
```

Example response for Red Hat OpenShift Data Foundation:

```
{"jobid": "odf-20221103062933"}
```

The `jobid` returned by POST call is used for getting the status.

For example:

```
GET /api/v1/logcollector/odf-20221103062933
```

Log set download

```
GET /api/v1/logcollector/<job-id>/results
```

This GET command downloads log sets.

Delete log set

```
Delete /api/v1/logcollector/${jobid}
```

Remote support APIs

You can call these API's from the cluster Fusion ui route.

Get remote support status

```
GET /api/v1/service-node/remote-support
```

Sample request:

```
curl --request GET --url https://<fusion-url>/api/v1/service-node/remote-support
```

Sample GET response:

```
{
  "status": "running",
  "startTime": "2024-06-10T11:31:30Z",
  "stopTime": "2024-06-10T11:33:30Z",
  "isConfigured": true,
  "isProxy": false
}
```

Start remote support connection

```
POST /api/v1/service-node/remote-support/start
```

Sample request:

Note: Ensure you update the fields with the actual values.

```
curl --request POST --url https://servicenode-host:3000/api/v1/service-node/remote-support/start --header 'X-Username: sn_username' --header 'X-Password: sn_password' --cacert /etc/pki/tls/certs/server.crt --data '{
  "activeHours": 24
}'
```

Sample POST response:

```
{
  "status": "success",
  "message": "",
  "messageCode": "",
  "messageArgs": null,
  "errorMessage": ""
}
```

Stop remote support connection

```
POST /api/v1/service-node/remote-support/stop
```

Sample request:

```
curl --request POST --url https://<fusion-url>/api/v1/service-node/remote-support/stop
```

Sample POST response:

```
{
  "status": "success",
  "message": "",
  "messageCode": "",
  "messageArgs": null,
  "errorMessage": ""
}
```

Test remote support connection

```
GET /api/v1/service-node/remote-support/connection-status
```

Sample request:

```
curl --request GET --url https://<fusion-url>/api/v1/service-node/remote-support/connection-status
```

Sample GET response:

```
{
  "status": "success"
}
```

Configure remote support connection

```
POST /api/v1/service-node/remote-support/configuration
```

Sample request:

Note: Ensure you update the fields with the actual values.

```
curl --request POST --url https://servicenode-host:3000/api/v1/service-node/remote-support/configuration --header 'X-Username: sn_username' --header 'X-Password: sn_password' --cacert /etc/pki/tls/certs/server.crt --data '{
  "customerNumber": "customerName",
  "company": "company"
}'
```

Sample POST response:

```
{
  "status": "success",
  "message": "",
  "messageCode": "",
  "messageArgs": null,
  "errorMessage": ""
}
```

Disable remote support connection

```
Delete /api/v1/service-node/remote-support/configuration
```

Sample request:

```
curl --request DELETE --url https://<fusion-url>/api/v1/service-node/remote-support/configuration
```

Sample response:

```
{
  "status": "success"
}
```

Get proxy details

GET API to get proxy details for remote support.

Sample request:

```
curl --request GET --url 'https://<fusion-url>/api/v1/service-node/proxy?proxyType=remoteSupport'
```

Sample response:

```
{
  "host": "samplehost",
  "port": "8080",
  "username": "proxy_username",
  "password": ""
}
```

Set up proxy for remote support

POST API to set up proxy for remote support.

```
curl --request POST --url https://<fusion-url>/api/v1/service-node/proxy --data '{ "proxyType": "remoteSupport", "host": "samplehost", "port": "8080", "username": "proxy_username", "password": "proxy_password" }
```

```
{
  "status": "success"
}
```

Delete proxy

Delete API to clean up proxy for remote support.

Sample request:

```
curl --request DELETE --url https://localhost:3001/api/v1/service-node/proxy --data '{ "proxyType": "remoteSupport" }'
```

```
{
  "status": "success"
}
```

Note: Sometimes, though the APIs return 200, the operation for PUT and POST may be unsuccessful. In such cases, use other corresponding GET APIs to confirm the operation.

The Active file management (AFM) API references.

Retrieve the authorization token

For the CURL command, see [Active file management \(AFM\) fileset creation](#)

Retrieve the filesystem name (*filesystem_name*) that is mounted on the OpenShift® Container Platform cluster:

```
curl -k -H "Authorization:Token <token retrieved from the previous command>" -X GET --header 'content-type:application/json' https://<spectrum_scale_gui_route>/scalemgmt/v2/filesystems
{
  "filesystems" : [ {
    "name" : "ibmspectrum-fs"
  } ],
  "status" : {
    "code" : 200,
    "message" : "The request finished successfully."
  }
}
```

Example:

```
curl -k -H "Authorization:Token 07b0a89c-5a62-4b8d-b709-b5b51b2a394c" -X GET --header 'content-type:application/json' https://ibm-spectrum-scale-gui-ibm-spectrum-scale.apps.isf.ibm.com/scalemgmt/v2/filesystems
{
  "filesystems" : [ {
    "name" : "ibmspectrum-fs"
  } ],
  "status" : {
    "code" : 200,
    "message" : "The request finished successfully."
  }
}
```

Create AFM fileset

```
curl -k -H "Authorization:Token <"Token Value"> -X POST --header 'content-type:application/json' --header 'accept:application/json' -d '{
  "filesetName": "<"Name of fileset">",
  "path": "<"filesystem mount point">/<"fileset name">",
  "afmTarget": "<"NFS export path">",
  "afmMode": "independent-writer"
}' <"Scale route URL">/scalemgmt/v2/filesystems//filesets
{
  "jobs" : [ {
    "jobId" : 2000000011591,
    "status" : "RUNNING",
    "submitted" : "2023-01-12 12:33:46,219",
    "completed" : "N/A",
    "runtime" : 3,
    "request" : {
      "data" : {
        "afmMode" : "independent-writer",
        "afmTarget" : "<"NFS export path">",
        "filesetName" : "<"fileset Name">",
        "path" : "<"filesystem mount point">/<"fileset name">"
      },
      "type" : "POST",
      "url" : "/scalemgmt/v2/filesystems//filesets"
    },
    "result" : { },
    "pids" : [ ]
  } ],
  "status" : {
    "code" : 202,
    "message" : "The request was accepted for processing."
  }
}
```

Example:

```
curl -k -H "Authorization:Token 07b0a89c-5a62-4b8d-b709-b5b51b2a394c" -X POST --header 'content-type:application/json' --header 'accept:application/json' -d '{
  "filesetName": "afmScale",
  "path": "/mnt/ibmspectrum-fs/afmScale",
  "afmTarget": "nfs://9.30.44.36/mnt/fs1/fset1",
  "afmMode": "independent-writer"
}' https://scalemgmt/v2/filesystems/ibmspectrum-fs/filesets
{
  "jobs" : [ {
    "jobId" : 2000000011591,
    "status" : "RUNNING",

        "afmTarget" : "nfs://9.30.44.36/mnt/fs1/fset1",
        "filesetName" : "afmScale",
        "path" : "/mnt/ibmspectrum-fs/afmScale"
      },
      "type" : "POST",
      "url" : "/scalemgmt/v2/filesystems/ibmspectrum-fs/filesets"
    },
    "result" : { },
    "pids" : [ ]
  } ],
  "status" : {
    "code" : 202,
    "message" : "The request was accepted for processing."
  }
}
```

```

    },
    "result" : { },
    "pids" : [ ]
  },
  "status" : {
    "code" : 202,
    "message" : "The request was accepted for processing."
  }
}

```

Get cache status

```
curl -k -H "Authorization:Token "<"Token value">" -X GET --header 'content-type:application/json' <"Scale Route URL">/scalemgmt/v2/filesystems/<"filesystem Name">/afm/state
```

For eg:

Example:

```
curl -k -H "Authorization:Token 07b0a89c-5a62-4b8d-b709-b5b51b2a394c" -X GET --header 'content-type:application/json' https://ibm-spectrum-scale-gui-ibm-spectrum-scale.apps.<domainname>/scalemgmt/v2/filesystems/ibmspectrum-fs/afm/state
{
  "filessetAfmStateList" : [ {
    "cacheState" : "Active",
    "filessetName" : "afmfsetnfs",
    "filesystemName" : "ibmspectrum-fs"
  }, {
    "cacheState" : "Active",
    "filessetName" : "afmpallavi",
    "filesystemName" : "ibmspectrum-fs"
  }, {
    "cacheState" : "Active",
    "filessetName" : "afms",
    "filesystemName" : "ibmspectrum-fs"
  }, {
    "cacheState" : "Active",
    "filessetName" : "cosfset1",
    "filesystemName" : "ibmspectrum-fs"
  }, {
    "cacheState" : "Active",
    "filessetName" : "afmScale",
    "filesystemName" : "ibmspectrum-fs"
  }, {
    "cacheState" : "Active",
    "filessetName" : "afmScalePal",
    "filesystemName" : "ibmspectrum-fs"
  }, {
    "cacheState" : "Active",
    "filessetName" : "afmScaleS",
    "filesystemName" : "ibmspectrum-fs"
  } ],
  "status" : {
    "code" : 200,
    "message" : "The request finished successfully."
  }
}

```

Get job status

```
curl -k -H "Authorization:Token "<"Token Value">" -X GET --header 'content-type:application/json' <"Scale Route URL">/scalemgmt/v2/jobs/
```

Example:

```
curl -k -H "Authorization:Token 07b0a89c-5a62-4b8d-b709-b5b51b2a394c" -X GET --header 'content-type:application/json' https://ibm-spectrum-scale-gui-ibm-spectrum-scale.apps.<domainname>/scalemgmt/v2/jobs/2000000011591
{
  "jobs" : [ {
    "jobId" : 2000000011591,
    "status" : "COMPLETED",
    "submitted" : "2023-01-12 12:33:46,219",
    "completed" : "2023-01-12 12:33:55,845",
    "runtime" : 9626,
    "request" : {
      "data" : {
        "afmMode" : "independent-writer",
        "afmTarget" : "nfs://9.30.44.36/mnt/fs1/fset1",
        "filessetName" : "afmScale",
        "path" : "/mnt/ibmspectrum-fs/afmScale"
      },
      "type" : "POST",
      "url" : "/scalemgmt/v2/filesystems/ibmspectrum-fs/filessets"
    },
    "result" : {
      "progress" : [ ],
      "commands" : [ "mmcrfileset 'ibmspectrum-fs' 'afmScale' --inode-space new --inode-limit '1M:50K' --allow-permission-change 'chmodAndSetAcl' -p 'afmTarget=nfs://9.30.44.36/mnt/fs1/fset1' -p 'afmMode=independent-writer' ", "mmlinkfileset 'ibmspectrum-fs' 'afmScale' -J '/mnt/ibmspectrum-fs/afmScale' " ],
      "stdout" : [ "EFSSG0070I File set afmScaleS created successfully.", "EFSSG0078I File set afmScale successfully linked.\n" ],
      "stderr" : [ ],
      "exitCode" : 0
    }
  } ],
}
```

```
"pids" : [ ]
} ],
"status" : {
"code" : 200,
"message" : "The request finished successfully."
}
```

Upgrading IBM Fusion

Upgrade to the latest version so you can have access to the new functionalities and improvements that enhance your overall experience with IBM Fusion HCI.

To achieve the upgrade, you must follow these steps in sequence:

1. Upgrade IBM Fusion HCI software to the most recent version.
2. Upgrade all services in the specified sequence. For more information about the service upgrades, see [Upgrading IBM Fusion HCI services](#).
3. Upgrade Red Hat® OpenShift® Container Platform.

Each step builds on the previous one, so ensure they are performed in the correct order for a successful upgrade. Before you begin each of the upgrades, thoroughly review the prerequisites, support matrix, limitations, and known issues.

The IBM Fusion software is upgraded from the OpenShift console.

You can upgrade the services from the Services page or the Settings > Upgrades page of the IBM Fusion user interface.

When you upgrade from the Services page, you can initiate upgrade of individual services based on the availability of a new version. In the Upgrade page, you can initiate multiple non-disruptive and rolling upgrades of service in parallel. For both non disruptive and rolling upgrades, you can view the status of the prechecks and monitor the progress of the upgrade. In the Services page, click View upgrade details of a ongoing service upgrade and in the Upgrade page, you can click the service tile of an ongoing upgrade to monitor the pre-check results and the progress of the upgrade in a slide out pane.

In addition, in the Upgrade page, you can do rolling disruptive upgrade where the upgrade mandates a node restart. To minimize the impact on the workloads, these restarts happen one at a time.

- [Implementing a comprehensive upgrade procedure](#)
As an administrator user, upgrade components of IBM Fusion HCI from 2.12.x or 2.13.x to 2.14.0. The IBM Fusion HCI upgrade involves both software and firmware as applicable.

Upgrading Red Hat OpenShift Virtualization on IBM Fusion HCI is done based on Red Hat guidelines.
- [Upgrading the service node](#)
Upgrade the service node to the latest version from the IBM Fusion UI.
- [Troubleshooting upgrade issues](#)
Known upgrade issues for IBM Fusion HCI 2.14, categorized by symptom and component, with resolution steps.

Implementing a comprehensive upgrade procedure

As an administrator user, upgrade components of IBM Fusion HCI from 2.12.x or 2.13.x to 2.14.0. The IBM Fusion HCI upgrade involves both software and firmware as applicable.

Before you begin

- Go through the prerequisites before you upgrade. For more information about the prerequisites, see [Prerequisites](#).
- Go through the following considerations that impact the IBM Fusion HCI upgrade procedure:
 - Follow the sequence mentioned in the procedure of this topic. Wait for each step to complete before you begin the next step in sequence.
 - Service upgrades are mandatory after the IBM Fusion HCI software upgrades.
- Go through the issues related to upgrade. For more information about troubleshooting issues, see [Troubleshooting upgrade issues](#).

About this task

The procedure ensures that IBM Fusion software, data services, and OpenShift® Container Platform are brought up to their most recent version.

Note: Follow the sequence mentioned in this procedure.

Procedure

1. Upgrade IBM Fusion HCI management software.
See [Upgrading IBM Fusion HCI management software](#). For procedure to upgrade IBM Fusion HCI with disaster recovery setup, see [Upgrading a disaster recovery setup](#).
2. Upgrade the storage service. For more information about upgrade, see [Upgrading IBM Fusion HCI services](#).
3. Upgrade the Backup & Restore service. For more information about the steps to upgrade, see [Upgrading IBM Fusion HCI services](#).
4. Upgrade the IBM Data Cataloging service. For more information about the steps to upgrade, see [Upgrading IBM Fusion HCI services](#).
5. Optionally, if you want to upgrade OpenShift Container Platform, see [Upgrading OpenShift Container Platform](#). For more information about Red Hat OpenShift Container Platform, see [Red Hat OpenShift Container Platform](#) documentation.
For the supported version of Red Hat OpenShift Container Platform, see [Support matrix for IBM Fusion HCI versions](#).

What to do next

- Before you proceed to work with IBM Fusion HCI, go through the known issues and troubleshooting mentioned in [Troubleshooting upgrade issues](#).

Before you upgrade IBM Fusion HCI

Prerequisites for IBM Fusion HCI upgrade procedure. Review this topic before you begin an upgrade.

General

- If you previously ran the authority-reduction script (`updateFusionAuthority.sh reduce-authority`) to remove cluster-admin-level permissions from IBM Fusion operators, you must restore authority before you upgrade. Failure to restore authority will cause the upgrade to fail. Run the following command before proceeding:

```
./updateFusionAuthority.sh restore-authority
```

For full instructions, see [Reduce and restore operator cluster-admin privileges](#).
- You must be on IBM Fusion HCI version 2.13.x to move to 2.14.0.
- For supported OpenShift® Container Platform versions, see [Support matrix](#).
Note: For the procedure to upgrade OpenShift Container Platform, see [OpenShift Container Platform upgrade](#). For storage support related information, see [Support matrix](#).
- If you installed IBM Fusion HCI in the previous version by using offline or online installation mode, then do not change the mode during the upgrade to the new version. To change the installation mode, reinstall IBM Fusion HCI.
- Logs that you collected by using the IBM Fusion Collect logs user interface page gets deleted after the upgrade process completes. Download the needed logs before you begin the upgrade. In addition, check system health from the log collections.
- The IBM Fusion HCI operator upgrade can get stuck during upgrade due to a known Red Hat OLM issue. The issue is specific to Red Hat OpenShift Container Platform versions 4.14, 4.15, 4.16, 4.17, and 4.18. Resolve the problem before you proceed with the upgrade. For the resolution steps, see [Hot fix page](#).
- For upgrading Hosted Control Plane (HCP) clusters in offline environment, IBM Fusion catalog source must be created in IBM Fusion HCI. For more information, see [End-to-end mirroring of IBM Fusion HCI and its services images to the enterprise registry](#).

Setup enterprise registry

If you installed the earlier version of IBM Fusion HCI by using your enterprise registry, then follow the steps to mirror images in your enterprise registry.

- Mirror IBM Fusion HCI images, IBM Storage Scale images, Fusion Data Foundation, Backup & Restore, and IBM Data Cataloging images. For steps to mirror, see [End-to-end mirroring of IBM Fusion HCI and its services images to the enterprise registry](#).
- Update the global pull secret with the mirror registry credentials to which the current version images are mirrored. If you are mirroring to the same enterprise registry that you used for the previous version, skip this step.
- Modify the image content source policy `isf-operator-index` to add the new mirror that points to the new registry for each source defined in the image content source policy. If you are mirroring to the same enterprise registry that you used for the previous version, skip this step.

See the sample for image content source policy:

Note: After the IBM Fusion HCI is upgraded, you can see all the new IBM Fusion services that are introduced in 2.14.0. If you want to install the new services, add image content source policy and the related image. For more information, see [End-to-end mirroring of IBM Fusion HCI and its services images to the enterprise registry](#).

```
apiVersion: operator.openshift.io/v1alpha1
kind: ImageContentSourcePolicy
metadata:
  name: isf-operator-index
spec:
  repositoryDigestMirrors:
    # for scale
    - mirrors:
      - "<Old ISF enterprise registry>/<Old ISF target-path>"
      - "<Old ISF enterprise registry>/<New ISF target-path>"
      source: cp.icr.io/cp/spectrum/scale
    - mirrors:
      - "<Old ISF enterprise registry>/<Old ISF target-path>"
      - "<Old ISF enterprise registry>/<New ISF target-path>"
      source: icr.io/cpopen
    #for IBM Fusion operator
    - mirrors:
```

```

- "<old ISF enterprise registry>/<Old ISF target-path>"
- "<Old ISF enterprise registry>/<New ISF target-path>"
source: cp.icr.io/cp/isf

# for ose-kube-rbac-proxy
- mirrors:
- "<New ISF enterprise registry>/<New ISF target-path>/openshift4/ose-kube-rbac-proxy"
source: registry.redhat.io/openshift4/ose-kube-rbac-proxy

```

- For offline, check whether the `ibm-opencloud` and `ibm-operator-catalog` catalog source are in an error state. If they are in an error state and not in use, then delete them.

- To validate if `catalogsource` are in use or not, run the following command to list all the subscriptions in IBM Fusion HCI cluster.

```
oc get sub -A
```

If the catalog source name under source fields does not show `ibm-opencloud` and `ibm-operator-catalog` in the output, then it is not in use.

- Run `oc get catsrc -A` command to ensure that the following catalog sources are present and in ready state:

- `isf-catalog` or `fusion-catalog`
- `redhat-operators`

- Run the following command to check whether `olm pod catalog-operator` is running in `openshift-operator-lifecycle-management` project:

```
oc -n openshift-operator-lifecycle-manager get po
```

Metro-DR

- CSI configmap**

Run the following command to tune CSI configmap:

```
oc -n ibm-spectrum-scale-csi create configmap ibm-spectrum-scale-csi-config --from-literal=VAR_DRIVER_DISCOVER_CG_FILESET=DISABLED
```

Network

- If you are using the proxy in an online or offline environment, then make sure to add all the `ipv6LLA` of the rack nodes to the OpenShift Proxy. You can find the `ipv6LLA` values in the kickstart-config map in the IBM Fusion namespace. The `ipv6LLA` values are added in the `noProxy` key inside the `spec` section.

```
oc edit proxy cluster
```

Example:

```

apiVersion: [config.openshift.io/v1] (http://config.openshift.io/v1)
kind: Proxy
metadata:
  name: cluster
spec:
  httpProxy: http://<IP>:<PORT>/
  httpsProxy: http://<IP>:<PORT>/
  noProxy: . [base.test.net] (http://base.test.net/), 9999,metal3-state.openshift-machine-
api,5050,6385,8089,6180,80,8084,fe80::72e2:84ff:fe23:78df,fd8c:215d:178e:c0de:72e2:84ff:fe23:78df,fe80::72e2:84ff:fe23:77f
3,fd8c:215d:178e:c0de:72e2:84ff:fe23:77f3,fe80::72e2:84ff:fe23:78c3,fd8c:215d:178e:c0de:72e2:84ff:fe23:78c3

```

Node

- Do not start node upsize or scale disk scale out until upgrade is complete.
- Ensure that no operation is done on OpenShift Container Platform cluster that causes machine configuration rollout, for example:
 - Node maintenance
 - Node reboot
 - Old firmware upgrade
 - Image content source policy update
 - Pull secret updates

Upgrading a disaster recovery setup

Use this procedure to upgrade IBM Fusion HCI with Metro-DR setup.

About this task

In Metro-DR upgrade, you must follow the upgrade of sites in the specified order.

In IBM Fusion HCI release, multi rack is only supported with Data Foundation storage and not with Global Data Platform.

Important: Contact [IBM support](#) before you begin the upgrade of Metro-DR deployment.

Procedure

- Upgrade site 1.
For the procedure to upgrade, see the single rack upgrade procedure in [Upgrading IBM Fusion](#).
- Upgrade site 2.
For the procedure to upgrade, see the single rack upgrade procedure in [Upgrading IBM Fusion](#).

3. For Metro-DR, upgrade Tiebreaker. For the tiebreaker upgrade procedure, see [Upgrading the tiebreaker from IBM Storage Scale 5.2.3.x to 5.2.3.9](#).

Upgrading the tiebreaker from IBM Storage Scale 5.2.3.x to 5.2.3.9

Upgrade the tiebreaker node from IBM Storage Scale 5.2.3.x to 5.2.3.9 as part of upgrading a Metro-DR deployment to IBM Fusion HCI 2.14.0.

Before you begin

- You must have the entitlement access to download the scale code package.
- You must have a minimum of 2 GB available to download the package.

Procedure

1. SSH into the tiebreaker virtual machine.
2. Download the IBM Storage Scale Data Management 5.2.3.9 from IBM Entitled System Support.
 - a. Log in to IBM Entitled System Support - <https://www.ibm.com/servers/eserver/ess/landing/index.html>.
 - b. Go to My entitled software > Software Downloads.
 - c. In the Product, search for 5771-PP7 (IBM Fusion HCI) and click Add Product.
The Storage_Scale_Data_Management-5.2.3.9-x86_64-Linux.tar.gz is available for IBM Storage Scale Data Management.
 - d. Select the Storage_Scale_Data_Management-5.2.3.9-x86_64-Linux.tar.gz file to download.
3. Run the following command to extract the IBM Storage Scale package:

```
chmod +x Storage_Scale_Data_Management-5.2.3.9-x86_64-Linux.tar.gz
./Storage_Scale_Data_Management-5.2.3.9-x86_64-Linux.tar.gz
```

4. Go to directory /usr/lpp/mmfs/5.2.3.9/ansible-toolkit.
5. Run setup command to install ansible.

```
./spectrumscale setup -s <Tiebreaker IP>
```

6. Run the following command to add the tiebreaker node:

```
./spectrumscale node add <Tiebreaker IP> -a
```

7. Run the following command for upgrade precheck:

```
./spectrumscale upgrade precheck --skip ssh
```

8. Run the following command to upgrade tiebreaker:

```
./spectrumscale upgrade run --skip ssh
```

9. Reboot the tiebreaker.

Upgrading IBM Fusion HCI management software

This topic outlines the steps to upgrade IBM Fusion HCI management software from 2.13.x release to 2.14.0.

Before you begin

- Go through the prerequisites before you upgrade. For more information about the prerequisites, see [Prerequisites](#).
- If you upgrade IBM Fusion HCI that is part of a Metro-DR configuration, then see [Upgrading a disaster recovery setup](#).
- If you are using a private image registry, mirror the IBM Fusion HCI images to the registry before you upgrade. For the procedure and images to download, see [Mirroring IBM Fusion HCI images](#).
- If you are using a private image registry, mirror the Red Hat® images to the registry before you upgrade. For the procedure and images to download, see [Mirroring Red Hat operator images to enterprise registry](#).
- Before you upgrade Fusion operator, you must perform preventive steps so that the operator upgrade does not get stuck. For more information about the steps, see [Operator upgrade can get stuck for IBM Fusion HCI](#).
- Check the compatibility of your underlying storage before you proceed with the upgrade. For more information about the version support, see [Support matrix](#), [Global Data Platform storage support for multi rack](#), and [Fusion Data Foundation storage compatibility across rack configurations](#).

About this task

- The IBM Fusion HCI does automatic prechecks during upgrade to help you detect and fix errors.
Important: You can also directly upgrade from version 2.12.x to 2.14.0. For more information, see [Enhanced upgrade experience](#).

Procedure

1. Log in to the OpenShift® Container Platform management console as a cluster administrator.
2. From the navigation menu, click Operators, Installed Operators and ensure that you select **ibm-spectrum-fusion-ns** project.
3. From the Installed Operators list, select IBM Fusion that is on your existing version. The Details tab opens by default.
4. Go to Subscription tab and check whether the Update approval is Manual or Automatic. If it is Automatic, change the Update approval to Manual.
5. Find CatalogSource section in the same tab, then click the fusion-catalog link.
6. In the YAML tab, update the value of the **image** under the **spec** section to reference the target image.

- a. For online upgrade:

```
spec:
  displayName: IBM Fusion Catalog
  image: 'icr.io/cpopen/isf-operator-catalog:2.14.0-linux.amd64'
  publisher: IBM
  sourceType: grpc
```

- b. Apply the catalog source from the mirrored location. See [Mirroring IBM Fusion HCI images](#).

Apply the catalog source from the mirrored location

- In the OpenShift Container Platform management console, change the namespace to **ibm-spectrum-fusion-ns** and click the installed IBM Fusion HCI operator.
- Go to the Subscription tab and click Edit subscription.
- Update the source to the newly generated IBM Fusion catalog name.

```
spec:
  channel: v2.0
  installPlanApproval: Manual
  name: isf-operator
  source: ibm-spectrum-fusion-catalog
  sourceNamespace: openshift-marketplace
  status:
```

- Save the YAML.
- In the OpenShift Container Platform management console, change the namespace to the **ibm-spectrum-fusion-ns** and then click the installed IBM Fusion HCI operator.
- Approve the install plan manually:
 - Go to the Subscription tab.
 - Click Upgrade available in the Upgrade status section. Alternatively, go to Operators > Installed Operators and click Upgrade available in the Status of the IBM Fusion record.
 - In the InstallPlan details, click Preview InstallPlan. It lists all the install components before approving.
 - Click Approve to begin upgrade.
- Wait for the upgrade to complete.
- Verify whether the IBM Fusion HCI management software is in succeeded state and the version is displayed correctly. Also, in the Subscription tab, ensure that the upgrade status displays Up to date.

What to do next

Important: After you upgrade IBM Fusion HCI, the Backup & Restore service goes to a Unknown state. Upgrade Backup & Restore service for the state to change to Healthy.

- [Enhanced upgrade experience](#)
This topic describes the process for upgrading IBM Fusion HCI from version 2.12.x directly to 2.14.0, bypassing the intermediate 2.13.x releases, on supported configurations.

Enhanced upgrade experience

This topic describes the process for upgrading IBM Fusion HCI from version 2.12.x directly to 2.14.0, bypassing the intermediate 2.13.x releases, on supported configurations.

To upgrade IBM Fusion HCI from 2.12.x to 2.14.0 directly, ensure the following prerequisites are met:

- IBM Fusion HCI version must be on 2.12.x.
 - The OpenShift® version is either 4.18.x or 4.19.x (for Multi-Rack 2AZ topologies only).
 - Ensure that the firmware for both the switch and node is updated to IBM Fusion HCI version 2.12.0.
 - Ensure that the Fusion Data Foundation service is installed and configured.
- Important: Global Data Platform topologies are not supported for direct upgrade from 2.12.x to 2.14.0
- If using Content-Aware Storage 1.0.x, upgrade to at least Content-Aware Storage 1.0.7 before initiating the IBM Fusion HCI upgrade.

Table 1. Supported Enhanced Upgrade Topologies

Support matrix for enhanced upgrade experience from 2.12.x to 2.14.0					
Topology	Fusion Data Foundation	Global Data Platform	Backup & Restore	IBM Data Cataloging	Content-Aware Storage
Single rack and expansion rack	Supported	Not supported	Supported	Supported	Supported
Multi-Rack 2AZ (OpenShift Container Platform)	Supported	Not supported	Supported	Supported	Supported

Important: Any topology not listed here must first be upgraded to IBM Fusion HCI 2.13.x to upgrade to version 2.14.0.

Upgrading IBM Fusion HCI services

You can choose to upgrade the installed services from the IBM Fusion HCI user interface.

Before you begin

If you choose to upgrade IBM Fusion HCI services using the Enterprise Registry, ensure that you mirror the images to your Enterprise Registry before you begin the upgrade. For more information, see [End-to-end mirroring of IBM Fusion HCI and its services images to the enterprise registry](#).

About this task

Remember: For N-1 upgrade scenarios (for example, 2.13 with a service node to 2.14), the IBM Fusion dashboard displays a notification after the IBM Fusion upgrade completes. Use the notification to download the `vault-secret`, `vault-login-secret`, and `servicenode-snuser-credentials` secrets. Store all three secrets securely and keep them accessible for future use.

Important:

- For an offline installation, ensure that you have completed mirroring and updated `ImageContentSourcePolicy/ImageDigestMirrorSet` for deployed services. Otherwise, you see catalog source pods failing with an `imagepullbackoffs` error and no upgrade button shows for services.
- Before upgrading OADP or AMQ version for an offline install, ensure that the catalogsource pods are in running state.

You can view the availability of an upgrade in the following user interface pages:

- In the IBM Fusion user interface:
 - Click the bell icon and view notifications in System notifications.
 - Notification banner on the Services page.
 - Settings > Upgrade page.
- [Migrating Global Data Platform remote mount](#)
Migrate the Global Data Platform remote mount service when installing or upgrading Fusion Data Foundation 4.21 or later.
- [Upgrading Fusion Data Foundation](#)
Steps to upgrade the Fusion Data Foundation service.
- [Upgrading Global Data Platform](#)

- [Upgrading Software Hub service](#)
Steps to upgrade the Software Hub service.

Migrating Global Data Platform remote mount

Migrate the Global Data Platform remote mount service when installing or upgrading Fusion Data Foundation 4.21 or later.

Before you begin

Ensure that the following conditions are met before starting the migration:

- No backup or restore jobs are running.
- The IBM Storage Scale cluster is healthy:
 - Run the `mmhealth` command.
 - Verify that all components report a healthy status.
- No MachineConfigPool (MCP) rollout is in progress.
- Global Data Platform version is 6.0.0.3. If the current version is 6.0.0.2, upgrade it to 6.0.0.3 before proceeding. For instructions, see [Upgrading Global Data Platform](#).

About this task

This procedure does not apply when IBM Spectrum® Storage Scale Erasure Code Edition (ECE) is used as local storage. It applies only when Fusion Data Foundation is used as local storage.

Starting with Red Hat® OpenShift® Container Platform 4.21 and Fusion Data Foundation 4.21, the Global Data Platform remote mount service is integrated into Fusion Data Foundation as external Scale.

In earlier releases, Global Data Platform was bundled separately with IBM Fusion. From Fusion Data Foundation 4.21 onward:

- No separate upgrade option is available for version 6.0.1.0 and later. Global Data Platform remote mount upgrades and the migration of IBM Storage Scale remote mount (CNSA) from version 6.0.0.3 to 6.0.1.0 or later are performed automatically in the background during Fusion Data Foundation installation or upgrade.

Important: Upgrading the Global Data Platform remote mount service triggers a MCP rollout. During the upgrade, the tile might briefly display Degraded. After the MCP rollout completes, the status returns to Running.

- Each Fusion Data Foundation release includes an updated IBM Storage Scale build, which is applied automatically.
- Future updates to IBM Storage Scale are delivered through Fusion Data Foundation upgrades.

The migration workflow depends on your deployment scenario.

Procedure

Scenario 1: Only Global Data Platform remote mount is installed

If Global Data Platform remote mount 6.0.0.3 is installed and Fusion Data Foundation is not installed:

- Install Fusion Data Foundation 4.21 or later. For instructions, see [Installing Fusion Data Foundation](#).

During installation:

- The system automatically triggers the Global Data Platform remote mount migration.
- Global Data Platform remote mount is upgraded to version 6.0.1.0 or later as part of the process.

Scenario 2: Both Fusion Data Foundation and Global Data Platform remote mount are installed

If Fusion Data Foundation 4.20 or earlier and Global Data Platform 6.0.0.3 are already installed:

1. Disable the Fusion Data Foundation automatic upgrade to prevent unintended upgrade behavior.
2. Manually trigger the Fusion Data Foundation upgrade from version 4.20 to 4.21 or later. For instructions, see [Upgrading Fusion Data Foundation](#).

During the upgrade:

- Global Data Platform remote mount migration runs and completes automatically.
- No separate action is required for migration.

Results

After the Fusion Data Foundation installation or upgrade and the Global Data Platform migration are complete:

- The Global Data Platform remote mount service is upgraded to 6.0.1.0 or later.
- The Global Data Platform remote mount service is in healthy state.
- All IBM Storage Scale pods run in a single namespace, `ibm-spectrum-scale`.

Upgrading Fusion Data Foundation

Steps to upgrade the Fusion Data Foundation service.

Before you begin

- Important: If you upgrade from Fusion Data Foundation 4.21.z to 4.22, you must upgrade to Fusion Data Foundation 4.22.2 or later. Upgrades to Fusion Data Foundation 4.22.0 or 4.22.1 are not supported and fail.
- Important: If you upgrade to Fusion Data Foundation 4.21 or later and the Global Data Platform remote mount service installed and configured, the service is automatically migrated to version 6.0.1.0. If automatic updates are enabled, disable automatic upgrades before proceeding. Review the supported [migration](#) scenarios before you proceed with the upgrade.
- Optional: To reduce the upgrade time for large clusters, increase the `maxUnavailable` value for the `nodePlugin` update strategy on the Container Storage Interface (CSI) drivers. Run the following commands:

```
VAL=$(oc get nodes -o name | awk 'END {printf "%.0f\n", NR * 0.2}') && oc patch driver openshift-storage.rbd.csi.ceph.com -n openshift-storage --type='merge' -p "{\"spec\":{\"nodePlugin\":{\"updateStrategy\":{\"rollingUpdate\":{\"maxUnavailable\":\"$VAL\"}}}}}" && oc patch driver openshift-storage.cephfs.csi.ceph.com -n openshift-storage --type='merge' -p "{\"spec\":{\"nodePlugin\":{\"updateStrategy\":{\"rollingUpdate\":{\"maxUnavailable\":\"$VAL\"}}}}}"
```

This affects CephFS and CephRBD daemonsets and allows the pods to restart simultaneously or be unavailable, which reduces the upgrade time. For an optimal value, you can set the parameter values to 20%. However, if the value is too high, disruption for new volumes might be observed during the upgrade.

The version of Data Foundation service is dependent on the version of OpenShift® Container Platform.

About this task

For more information about the storage version support, see [IBM Fusion support matrix](#).

When you order and upsize Logical Volume Manager (LVM) drives in the upgraded IBM Fusion HCI 2.13 version, IBM Fusion HCI automatically detects the presence of control plane drives and configures them for LVM. However, if LVM is already enabled in your existing installation of IBM Fusion HCI and you add additional 1.6 TB drives again, the newly added drives remain unutilized.

Procedure

1. Log in to IBM Fusion HCI user interface.
2. Click Services menu to go to the Services page.
Note: Alternatively, you can go to the Settings > Upgrades page and view the upgrade status and in progress upgrades. The Data Foundation goes into rolling upgrade. If you can run service upgrades in parallel in a non-disruptive manner, click Upgrade (<number of upgrades available>). If there are any errors found in the automatic prechecks, then click the service tile for more details about the error.
3. In the Installed section, click Upgrade from the ellipsis menu of Data Foundation.
Only if an upgrade is available for Data Foundation, the Upgrade option is displayed.
The Upgrade pre-check window gets displayed.
4. In the Upgrade pre-check window, monitor the progress of the pre-checks.
The IBM Fusion HCI runs prechecks to ensure that your system is ready for an upgrade.
If all the checks pass or there are some conditions in warning state, you can proceed with the upgrade. However, it is highly recommended to fix the warnings to prevent any potential impacts on the system during the upgrade process. Immediately address any blocker errors encountered during prechecks, as they require fixing before proceeding with the upgrade. After the completion of all pre-checks, a summary of total number of issues found gets displayed. If there are no blocker issues, go to step 6.
5. If there are blocker issues, do the following steps:
 - a. To know more about blockers or warnings, click View upgrade details link in the Services page. The IBM Fusion HCI user interface takes you to the Services page wherein a Upgrade pre-check report window displays all the Blocking issues and Issues (optional). Alternatively, click the service tile in error state in the Upgrade page to view the Upgrade pre-check report with Blocking issues and Issues (optional) issues.

- b. Click the corresponding BMYxxxxxx code to know more about how to fix the issue.
 - If you find error resources in the Resources section of the individual issues, you can click the resource link to know more details about it.
 - c. Fix all the blocking issues based on the guidance.
 - d. Return to the Services page of the IBM Fusion HCI user interface and click Upgrade.
6. After the pre-checks complete without any blocker issues, click Upgrade now.
To know more details about the upgrade that is progress, click View details in the notification tab of the Services page. A slide out pane displays the following details:
 - Progress percentage
 - Upgrade pre-check. As this is complete, a check mark appears and the status shows complete.
 - Upgrade in progress.
7. Wait for a minute or more for the upgrade to complete.
After the completion of upgrade, a success notification gets displayed.
To view the status of the upgrade, go to Settings > Upgrade or the Services page.

Important:

- If auto-upgrade is not enabled during installation, you may encounter a situation where some components of the Data Foundation operators do not upgrade as expected. To ensure all components are upgraded correctly, you must verify that all **InstallPlans** in the **openshift-storage** namespace are approved. For steps, see [Fusion Data Foundation operator upgrade is not initiated](#).
 - The upgrade consumes more time depending on the number of compute nodes in the rack.
8. When you upgrade Data Foundation from version 4.16.z to 4.17.z or 4.18.z or 4.19.z or 4.20.z, you must also upgrade the Local Storage Operator (LSO) to ensure that OpenShift Container Platform, Data Foundation, and LSO are on compatible versions.
If LSO is not upgraded automatically at the same OpenShift Container Platform level post OpenShift Container Platform upgrade, follow these steps to change the Update Channel and set the Update approval:
 - a. Change the Update Channel.
To upgrade LSO to a new minor (y-stream) version, update the channel as follows:
 - i. Go to Operators > Installed Operators > Local Storage > Subscription tab > Update Channel.
 - ii. Set the update channel to match your current OpenShift Container Platform version (For example, 4.19 or 4.20).
 - b. Set Update Approval:
If Update Approval is set to Automatic, the upgrade proceeds automatically.
If set to Manual, you must manually approve and apply the upgrade.

Upgrading Global Data Platform

Upgrade Global Data Platform service.

Before you begin

- Optionally, before you upgrade the Global Data Platform, enable kdump to save the core that gets created in the event of any IBM Storage Scale crash. You need the core dump for debugging and analysis. For the steps to enable kdump, see [Enabling kdump](#) in *Red Hat OpenShift Container Platform* documentation.
- Run the following command to check the pidslimits.

```
for node in `oc get nodes -o name`; do oc debug $node -- chroot /host grep podPidsLimit /etc/kubernetes/kubelet.conf; done
```

Example output:

```
for node in `oc get nodes -o name`; do oc debug $node -- chroot /host grep podPidsLimit /etc/kubernetes/kubelet.conf; done
Starting pod/compute-1-ru5rackm02mydomaincom-debug ...
To use host binaries, run `chroot /host`
"podPidsLimit": 12228,

Removing debug pod ...
Starting pod/compute-1-ru6rackm02mydomaincom-debug ...
To use host binaries, run `chroot /host`
"podPidsLimit": 12228,

Removing debug pod ...
Starting pod/compute-1-ru7rackm02mydomaincom-debug ...
To use host binaries, run `chroot /host`
"podPidsLimit": 12228,

Removing debug pod ...
```

Note: Ensure that the pidslimit is not lesser than 12228 for each node in any condition.

- If you plan to do a offline installation, mirror the Global Data Platform 6.0.0.3 images to your enterprise registry. For the procedure and images to download, see [Mirroring IBM Storage Scale images](#).
- Ensure no Backup & Restore jobs are running.

About this task

You can perform service upgrades from the Services page or the Settings > Upgrades page of the IBM Fusion user interface.
For more information about the storage version support, see [Support matrix](#).

Procedure

1. Log in to IBM Fusion HCI user interface.
2. Click Services menu to go to the Services page.
Note: Alternatively, you can go to the Settings > Upgrades page and view the upgrade status and in progress upgrades. The Global Data Platform goes into rolling upgrade. If you can run service upgrades in parallel in a non-disruptive manner, click Upgrade (<number of upgrades available>). If there are any errors found in the

- automatic prechecks, then click the service tile for more details about the error.
3. In the Installed section, click Upgrade from the ellipsis menu of Global data platform.
Only if an upgrade is available for Global data platform, the Upgrade option is displayed.
The Upgrade pre-check window gets displayed.
 4. In the Upgrade pre-check window, monitor the progress of the pre-checks.
The IBM Fusion HCI runs prechecks on conditions that impact the upgrade of the service. To know more about the prechecks and its coverage, see the user interface.
If all the checks pass or there are some conditions in warning state, you can proceed with the upgrade. However, it is highly recommended to fix the warnings to prevent any potential impacts on the system during the upgrade process. Immediately address any blocker errors encountered during prechecks, as they require fixing before proceeding with the upgrade. After the completion of all pre-checks, a summary of total number of issues found gets displayed. If there are no blocker issues, go to step [6](#).
 5. If there are blocker issues, do the following steps:
 - a. To know more about blockers or warnings, click View upgrade details link in the Services page. The IBM Fusion HCI user interface takes you to the Services page wherein a Upgrade pre-check report window displays all the Blocking issues and Issues (optional). Alternatively, click the service tile in error state in the Settings > Upgrades page to view the Upgrade pre-check report with Blocking issues and Issues (optional) issues.
You can also view the parallel upgrades from Settings > Upgrades page.
 - b. Click the corresponding BMYxxxxxx code to know more about how to fix the issue.
If you find error resources in the Resources section of the individual issues, you can click the resource link to know more details about it.
 - c. Fix all the blocking issues based on the guidance.
 - d. Return to the Services page or the Upgrade page of the IBM Fusion HCI user interface and click Upgrade.
 6. After the pre-checks complete without any blocker issues, click Upgrade now.
 7. When the upgrade is in progress, in the side panel, you can click view details link for advanced monitoring.
If you find error resources in the View details section of the individual sections, you can click the resource link to know more details about it.
 8. Wait for the upgrade to complete.
After the completion of the upgrade, a success notification gets displayed.
If you want to disable the kdump after a successful upgrade of Global data platform, see and follow the instructions for [Disabling kdump](#).
Note: The upgrade consumes more time depending on the number of compute nodes in the rack.
To view the status of the upgrade, go to Settings > Upgrade or the Services page.

If you see “Service upgrade has failed” message, see View details on the right pane for more details. If you are not able to fix the issue, contact [IBM support](#).

Upgrading Global Data Platform remote mount

Upgrade the Global Data Platform remote mount service in IBM Fusion HCI.

Before you begin

Important:

Check your Red Hat® OpenShift® Container Platform version before proceeding:

- **Version 4.20 or earlier:** Continue with this procedure.
- **Version 4.21:** See [Migrating Global Data Platform remote mount](#).
- **Version 4.22 or later:** Upgrading Fusion Data Foundation automatically triggers the Global Data Platform remote mount upgrade. No manual intervention is required.

Upgrading the Global Data Platform remote mount service triggers a MachineConfigPool (MCP) rollout. During the upgrade, the tile might briefly display Upgrade Available or Degraded. After the MCP rollout completes, the status returns to Running.

Ensure the following conditions are met before you begin the upgrade:

- If you plan to do an offline installation, mirror the Global Data Platform remote mount images to your enterprise registry. For the procedure and images to download, see [Mirroring IBM Storage Scale images](#).
- Ensure no Backup & Restore jobs are running.
- Ensure no MCP rollout is in progress.

About this task

On Red Hat OpenShift Container Platform version 4.20 and earlier, you can perform service upgrades from the Services page or the Settings > Upgrades page of the IBM Fusion HCI user interface.

For more information about the storage version support, see [Support matrix](#).

Procedure

1. Log in to the IBM Fusion HCI user interface.
2. Click the Services menu to go to the Services page.
Note: Alternatively, you can go to the Settings > Upgrades page and view the upgrade status and in-progress upgrades. The Global Data Platform goes into rolling upgrade. If you can run service upgrades in parallel in a non-disruptive manner, click Upgrade (<number of upgrades available>). If there are any errors found in the automatic pre-checks, click the service tile for more details about the error.
3. In the Installed section, click Upgrade from the ellipsis menu of the Global data platform Remote Mount tile.
The Upgrade option is displayed only when an upgrade is available for Global Data Platform.
The Upgrade pre-check window is displayed.
4. In the Upgrade pre-check window, monitor the progress of the pre-checks.
The IBM Fusion HCI runs pre-checks on conditions that impact the upgrade of the service. For more information about the prechecks and their coverage, see the user interface.

If all the checks pass or there are some conditions in warning state, you can proceed with the upgrade. Fix warnings before proceeding to prevent potential impacts on the system during the upgrade. Immediately address any blocker errors encountered during pre-checks, as they require fixing before you can proceed. After all pre-checks complete, a summary of the total number of issues found is displayed. If there are no blocker issues, go to step 6.

5. If there are blocker issues, complete the following steps:

- a. For more information about blockers or warnings, click View upgrade details in the Services page.

The IBM Fusion HCI user interface takes you to the Upgrade pre-check report window, which displays all Blocking issues and Issues (optional).

You can also view the parallel upgrades from Settings > Upgrades page.

- b. Click the corresponding BMYxxxxxx code to learn how to fix the issue.

If error resources are listed in the Resources section of the individual issues, click the resource link for more details.

- c. Fix all blocking issues based on the guidance.

- d. Return to the Services page or the Settings > Upgrades page and click Upgrade.

6. After the pre-checks complete without any blocker issues, click Upgrade now.

7. While the upgrade is in progress, click View details in the side panel for advanced monitoring.

If error resources are listed in the View details section, click the resource link for more details.

8. Wait for the upgrade to complete.

Note: The upgrade takes more time depending on the number of compute nodes in the rack.

Results

After the upgrade completes, a success notification is displayed. To view the status of the upgrade, go to Settings > Upgrade or the Services page.

If you see a Service upgrade has failed message, see View details on the right pane for more details. If you cannot fix the issue, contact [IBM support](#).

Upgrading Backup & Restore service

After a IBM Fusion operator upgrade, if a Backup & Restore upgrade is available, IBM Fusion automatically initiates prechecks and then proceeds with the upgrade.

Important: Do not upgrade the Backup & Restore service, AMQ Streams operator, or OADP operator from the OpenShift Container Platform (OCP) console. Service upgrades must be performed through the IBM Fusion user interface. Upgrading these components directly from the OCP console is not supported and may result in operational issues.

If you plan to do an offline installation in IBM Fusion 2.14.0, mirror the Backup & Restore 2.14.0 images to your enterprise registry for the automatic upgrade to initiate.

For the procedure and images to download, see [./install/sf_mirror_guardian_images.html](#).

To view the status of the upgrade, go to Settings > Upgrade or the Services page.

Important: When you upgrade to version 2.14.0, the Backup & Restore database is upgraded and the data is migrated to the new version of MongoDB. Ensure that the Backup & Restore storage class contains sufficient available capacity. The upgrade process requires an extra 60 GiB of storage temporarily to migrate the Backup & Restore database to the new version. After the migration is complete, the old Persistent Volume Claims (PVCs) are deleted, releasing the extra storage.

Upgrading IBM Data Cataloging service

Steps to upgrade IBM Data Cataloging service.

About this task

Sometimes, the IBM Data Cataloging service upgrade may not be available after you upgrade IBM Fusion. To know more about such issues and its resolutions, see [Troubleshooting Data Cataloging service upgrade issues](#).

Procedure

1. Log in to IBM Fusion HCI user interface.

2. Click Services menu to go to the Services page.

Note: Alternatively, you can go to the Settings > Upgrades page and view the upgrade status and in progress upgrades. If you can run service upgrades in parallel in a non-disruptive manner, click Upgrade (<number of upgrades available>). If there are any errors found in the automatic prechecks, then click the service tile for more details about the error.

3. In the Installed section, click Upgrade from the ellipsis menu of IBM Data Cataloging.

Only if an upgrade is available for IBM Data Cataloging, the Upgrade option is displayed.

The Upgrade pre-check window gets displayed.

4. In the Upgrade pre-check window, monitor the progress of the pre-checks.

The IBM Fusion HCI runs some common prechecks.

If all the checks pass or there are some conditions in warning state, you can proceed with the upgrade. However, it is highly recommended to fix the warnings to prevent any potential impacts on the system during the upgrade process. Immediately address any blocker errors encountered during prechecks, as they require fixing before proceeding with the upgrade. After the completion of all pre-checks, a summary of total number of issues found gets displayed. If there are no blocker issues, go to step 6.

5. If there are blocker issues, do the following steps:

- a. To know more about blockers or warnings, click View details link.

- b. The IBM Fusion HCI user interface takes you to the Services page wherein a Upgrade pre-check report window displays all the Blocking issues and Issues (optional). Alternatively, click the service tile in error state in the Settings > Upgrades page to view the Upgrade pre-check report with Blocking issues and Issues (optional) issues.

You can also view the parallel upgrades from Settings > Upgrades page.

- c. Click the corresponding BMYxxxxxx code to know more about how to fix the issue.
 - If you find error resources in the Resources section of the individual issues, you can click the resource link to know more details about it.
 - d. Fix all the blocking issues based on the guidance.
 - e. Return to the Services page of the IBM Fusion HCI user interface and click Upgrade.
6. After the pre-checks complete without any blocker issues, click Upgrade now.
 7. Wait for a minute or more for the upgrade to complete.
- After the completion of upgrade, a success notification gets displayed.
- Note: The upgrade consumes more time depending on the number of compute nodes in the rack.
- To view the status of the upgrade, go to Settings > Upgrade or the Services page.

If you see "Service upgrade has failed" message, see View details on the right pane for more details. If you are not able to fix the issue, contact [IBM support](#).

Upgrading Content-Aware Storage (CAS)

Steps to upgrade Content-Aware Storage (CAS) service.

Before you begin

Open the IBM Fusion user interface, go to the Services tab and check the current version of CAS in the Installed section.

Note: You cannot skip version when upgrading CAS to the latest version. For example, if CAS v1.0.4 is installed as your current version, upgrading to v1.1.0 requires an upgrade path of 1.0.4 > 1.0.5 > 1.0.6 > 1.0.7 > 1.1.0.

Procedure

1. Open the IBM Fusion user interface.
2. Go to the Services tab. In the Installed section, click Upgrade service in the ellipsis overflow menu of Content-Aware Storage.
Alternatively, you can go to the Settings > Upgrades page, and view the upgrade status and in progress upgrades. If you can run service upgrades in parallel in a non-disruptive manner, click Upgrade (<number of upgrades available>).
3. In the Upgrade service window, click Upgrade.
The upgrade starts and you can see the upgrade status. After the completion of upgrade, a success notification is displayed.
Note: Wait for a minute or more to see the upgrade status in the Services tab of the IBM Fusion user interface. You can also find the latest version in the Services tab when the upgrade completes.

Upgrade considerations for CAS v1.0.6 and earlier to v1.1.0

If you are upgrading from CAS v1.0.6 or earlier, start by upgrading to CAS v1.0.7 through the IBM Fusion user interface. After IBM Fusion initiates the upgrade, you must manually approve the process in OpenShift® before it can continue to CAS v1.1.0 by following these steps:

1. Manual approval that is required after CAS v1.0.7
After Fusion completes the upgrade to CAS v1.0.7, the next upgrade step (from v1.0.7 to v1.1.0) does not start automatically.

Before you continue, verify that the CAS subscription in OpenShift is configured as follows:
 - **Update approval: Manual**
 OpenShift path:

Operators > Installed Operators > Project: ibm-cas > Content Aware Storage > Subscription
2. Verify whether CAS v1.0.7 is installed correctly
Before you approve the upgrade to version 1.1.0, verify that the environment is ready. To confirm Kafka readiness for the next upgrade step, ensure that Kafka is running in KRaft mode.

```
oc get kafka -n ibm-cas -o yaml | yq '.items[0].status.kafkaMetadataState'
```

 Expected output:

```
KRaft
```

 When the value is **KRaft**, you can approve the next upgrade safely.
3. Approve upgrade to CAS v1.1.0
 - a. After confirming readiness, go to Operators > Installed Operators and select the project as ibm-cas.
 - b. Open Content Aware Storage, go to the Subscription tab, and click 1 requires approval.
 - c. Select Preview install plan.
 - d. Click Approve.
 The installation process of CAS v1.1.0 is triggered.

While the upgrade is waiting for manual approval in OpenShift, IBM Fusion displays the service status as Upgrading. This behavior is expected. IBM Fusion remains in this state until you approve the upgrade to version 1.1.0 in the OpenShift UI. After approval and installation are complete, IBM Fusion updates the version and marks the service as Healthy.

Upgrading Software Hub service

Steps to upgrade the Software Hub service.

Before you begin

Ensure that you met the following prerequisites for a successful upgrade of the Software Hub service.

- Before upgrading the Software Hub service, create the required image pull secret by following the instructions steps:
 1. Log in to the cluster using the `oc login` command.
 2. Create a `dockerconfig.json` file using your IBM Entitlement Key:

```
cat <<EOF > dockerconfig.json
{
  "auths": {
    "cp.icr.io": {
      "auth": "${IMAGE_PULL_CREDENTIALS}"
    },
    "icr.io": {
      "auth": "${IMAGE_PULL_CREDENTIALS}"
    }
  }
}
EOF
```

3. Create the `ibm-entitlement-key` secret in both the operator and instance namespaces.

```
oc create secret docker-registry ibm-entitlement-key \
--from-file ".dockerconfigjson=dockerconfig.json" \
--namespace=cpd-oeprator

oc create secret docker-registry ibm-entitlement-key \
--from-file ".dockerconfigjson=dockerconfig.json" \
--namespace=cpd-instance
```

Note:

- During upgrade, automated the backup and uninstalling of IBM cert manager operator.
- The Red Hat® cert manager latest version is installed as part of upgrade the Software Hub service.

Procedure

1. Log in to IBM Fusion HCI user interface.
2. Click Services menu to go to the Services page.
Note: Alternatively, you can go to the Settings > Upgrades page and view the upgrade status and in progress upgrades. The Software Hub goes into rolling upgrade. If you can run service upgrades in parallel in a non-disruptive manner, click Upgrade (<number of upgrades available>). If there are any errors found in the automatic prechecks, then click the service tile for more details about the error.
3. In the Installed section, click Upgrade from the ellipsis menu of Software Hub.
Only if an upgrade is available for Software Hub, the Upgrade option is displayed.
The Upgrade pre-check window gets displayed.
4. In the Upgrade pre-check window, monitor the progress of the pre-checks.
If an empty page for the upgrade precheck is displayed. To check the status of these prechecks, run the following command:

```
oc get softwarehubmanager ibm-softwarehub-service-instance \
-n ibm-software-hub-operator \
-o jsonpath='{.status.environmentReadiness}'
```

In the **Environment**

Readiness category, check the message type for each precheck. If the message type is **INFO**, the precheck is passed. If any precheck has a message type of **ERROR**, check the Events page for details on the failure.

5. After the prechecks complete without issues, click Upgrade.
6. During the upgrade, you can click the View details link in the side panel for advanced monitoring. If error resources are listed, click the resource link for more information.
7. Wait for the upgrade to complete. A success notification is displayed upon completion.
8. To view the status of the upgrade, go to Settings > Upgrade or the Services page.
If the service upgrade failed message is displayed, check the Events page for details. If you cannot resolve the issue, contact IBM Support.

- [Upgrading watsonx.ai service](#)
Steps to upgrade the watsonx.ai service.
- [Upgrading watsonx Orchestrate service](#)
Steps to upgrade the watsonx Orchestrate service.

Upgrading watsonx.ai service

Steps to upgrade the watsonx.ai service.

Before you begin

Ensure that you met the following prerequisites for a successful upgrade of the watsonx.ai service.

1. Before upgrading the Software Hub service, create the required image pull secret by following the instructions steps:
 - a. Log in to the cluster using the `oc login` command.
 - b. Create a `dockerconfig.json` file using your IBM Entitlement Key:

```
cat <<EOF > dockerconfig.json
{
  "auths": {
    "cp.icr.io": {
      "auth": "${IMAGE_PULL_CREDENTIALS}"
    }
  }
}
```

```

    },
    "icr.io": {
      "auth": "${IMAGE_PULL_CREDENTIALS}"
    }
  }
}
EOF

```

- c. Create the `ibm-entitlement-key` secret in both the operator and instance namespaces.

```

oc create secret docker-registry ibm-entitlement-key \
--from-file ".dockerconfigjson=dockerconfig.json" \
--namespace=cpd-operator

oc create secret docker-registry ibm-entitlement-key \
--from-file ".dockerconfigjson=dockerconfig.json" \
--namespace=cpd-instance

```

2. Ensure that you upgrade the Software Hub service to latest version before upgrading the watsonx.ai service.

Procedure

1. Log in to IBM Fusion HCI user interface.
2. Click Services menu to go to the Services page.
Note: Alternatively, you can go to the Settings > Upgrades page and view the upgrade status and in progress upgrades. The watsonx.ai goes into rolling upgrade. If you can run service upgrades in parallel in a non-disruptive manner, click Upgrade (<number of upgrades available>). If there are any errors found in the automatic prechecks, then click the service tile for more details about the error.
3. In the Installed section, click Upgrade from the ellipsis menu of Software Hub.
Only if an upgrade is available for watsonx.ai, the Upgrade option is displayed.
The Upgrade pre-check window gets displayed.
4. In the Upgrade pre-check window, monitor the progress of the pre-checks.
If an empty page for the upgrade precheck is displayed. To check the status of these prechecks, run the following command:

```

oc get watsonxaimanager ibm-watsonxai-service-instance \
-n ibm-software-hub-operator \
-o jsonpath='{.status.environmentReadiness}'

```

In the **Environment**

Readiness category, check the message type for each precheck. If the message type is **INFO**, the precheck is passed. If any precheck has a message type of **ERROR**, check the Events page for details on the failure.

5. After the prechecks complete without issues, click Upgrade.
6. During the upgrade, you can click the View details link in the side panel for advanced monitoring. If error resources are listed, click the resource link for more information.
7. Wait for the upgrade to complete. A success notification is displayed upon completion.
8. To view the status of the upgrade, go to Settings > Upgrade or the Services page.
If the service upgrade failed message is displayed, check the Events page for details. If you cannot resolve the issue, contact IBM Support.

Upgrading watsonx Orchestrate service

Steps to upgrade the watsonx Orchestrate service.

Before you begin

Ensure that you met the following prerequisites for a successful upgrade of the watsonx Orchestrate service.

1. Before upgrading the watsonx Orchestrate service, create the required image pull secret by following the instructions steps:
 - a. Log in to the cluster using the `oc login` command.
 - b. Create a `dockerconfig.json` file using your IBM Entitlement Key:

```

cat <<EOF > dockerconfig.json
{
  "auths": {
    "cp.icr.io": {
      "auth": "${IMAGE_PULL_CREDENTIALS}"
    },
    "icr.io": {
      "auth": "${IMAGE_PULL_CREDENTIALS}"
    }
  }
}
EOF

```

- c. Create the `ibm-entitlement-key` secret in both the operator and instance namespaces.

```

oc create secret docker-registry ibm-entitlement-key \
--from-file ".dockerconfigjson=dockerconfig.json" \
--namespace=cpd-operator

oc create secret docker-registry ibm-entitlement-key \
--from-file ".dockerconfigjson=dockerconfig.json" \
--namespace=cpd-instance

```

2. Ensure that you upgrade the Software Hub service to latest version before upgrading the watsonx Orchestrate service.

Procedure

1. Log in to IBM Fusion HCI user interface.
2. Click Services menu to go to the Services page.
Note: Alternatively, you can go to the Settings > Upgrades page and view the upgrade status and in progress upgrades. The watsonx Orchestrate goes into rolling upgrade. If you can run service upgrades in parallel in a non-disruptive manner, click Upgrade (<number of upgrades available>). If there are any errors found in the automatic prechecks, then click the service tile for more details about the error.
3. In the Installed section, click Upgrade from the ellipsis menu of Software Hub.
Only if an upgrade is available for watsonx Orchestrate, the Upgrade option is displayed.
The Upgrade pre-check window gets displayed.
4. In the Upgrade pre-check window, monitor the progress of the pre-checks.
If an empty page for the upgrade precheck is displayed. To check the status of these prechecks, run the following command:

```
oc get watsonxorchestratemanager ibm-watsonxorchestrate-service-instance \
-n ibm-software-hub-operator \
-o jsonpath='{.status.environmentReadiness}'
```

In the **Environment Readiness** category, check the message type for each precheck. If the message type is **INFO**, the precheck is passed. If any precheck has a message type of **ERROR**, check the Events page for details on the failure.
5. After the prechecks complete without issues, click Upgrade.
6. During the upgrade, you can click the View details link in the side panel for advanced monitoring. If error resources are listed, click the resource link for more information.
7. Wait for the upgrade to complete. A success notification is displayed upon completion.
8. To view the status of the upgrade, go to Settings > Upgrade or the Services page.
If the service upgrade failed message is displayed, check the Events page for details. If you cannot resolve the issue, contact IBM Support.

Upgrading Hosted Control Plane Fusion and its services

When IBM Fusion and services on the Hosted Control Plane cluster are installed using labels, they are automatically upgraded to the latest supported version available on the IBM Fusion hub.

It ensures that IBM Fusion and services versions (Fusion Data Foundation, Global Data Platform remote mount, and Backup & Restore) on the hub and the Hosted Control Plane cluster remains synchronized.

Note: When you upgrade HCP clusters on IBM Fusion HCI from version 2.13.x to 2.14.0, you must manually approve the **installplan** generated for the upgrade on respective HCP cluster.

- [Upgrading OpenShift Container Platform on Hosted Control Plane](#)
Upgrade the OpenShift® Container Platform version for Hosted Control Plane clusters by following the Red Hat® documentation and updating the NodePool custom resource to point to the mirrored release image for offline environments.

Upgrading OpenShift Container Platform on Hosted Control Plane

Upgrade the OpenShift Container Platform version for Hosted Control Plane clusters by following the Red Hat® documentation and updating the NodePool custom resource to point to the mirrored release image for offline environments.

To upgrade the OpenShift Container Platform version for Hosted Control Plane clusters, see the [Updating a control plane in a hosted cluster](#) in *Red Hat OpenShift Container Platform* documentation.

Note: For offline Hosted Control Plane clusters:

- If you are upgrading OpenShift Container Platform in an offline Hosted Control Plane cluster, first mirror the images for the target OpenShift Container Platform version. For more information, see [Mirroring OpenShift Container Platform release images to enterprise registry](#).
- In addition to the steps provided in the Red Hat documentation, make sure to update the **release-image** field in the **NodePool** custom resource (CR) to point to the mirrored OpenShift Container Platform release image.

Upgrading OpenShift Container Platform

Upgrade OpenShift in IBM Fusion HCI. For offline upgrades of OpenShift Container Platform, follow the Red Hat steps. However, follow the guidelines and versions that are specified in this section.

Before you begin

Important: If you are upgrading to OpenShift Container Platform 4.21 for the Fusion Data Foundation service and you selected Enable automatic updates during installation, disable automatic upgrades if the Global Data Platform remote mount service is installed or configured. Before you proceed with the upgrade, review the supported [migration](#) scenarios.

Important: Check the compatibility of your underlying storage before you proceed with the OpenShift Container Platform upgrade. For more information about the version support, see [Support matrix](#).

- Common prerequisites:
 - For OpenShift Container Platform upgrades, the following upgrade sequences are recommended by IBM and are validated with IBM Fusion Lab:
 - 4.18.22 > 4.19.9 > 4.20.z
 - 4.17.28 > 4.18.18 > 4.18.25

- 4.17.z > 4.18.25

Note: If you choose to use a different OpenShift upgrade path than those paths listed prior, you must plan the upgrade in coordination with Red Hat or by using the OpenShift Upgrade Planner tool: https://access.redhat.com/labs/ocpupgradegraph/update_path/

Important: The OpenShift Container Platform 4.14.x and 4.15.x versions are not supported from IBM Fusion HCI 2.12.0. Upgrade to any supported OpenShift Container Platform version before you upgrade IBM Fusion HCI.

- After every OpenShift Container Platform upgrade, check whether you have an installation of OpenShift virtualization operator. If it is available, then upgrade it. For more information, see [Updating Red Hat OpenShift Virtualization](#) in *Red Hat OpenShift Container Platform* documentation.
 - If you are using an offline method, see the following *Updating clusters* topics based on your version of OpenShift Container Platform:
 - [Red Hat OpenShift Container Platform 4.16 documentation](#)
 - [Red Hat OpenShift Container Platform 4.17 documentation](#)
 - [Red Hat OpenShift Container Platform 4.18 documentation](#)
 - [Red Hat OpenShift Container Platform 4.19 documentation](#)
 - [Red Hat OpenShift Container Platform 4.20 documentation](#)
 - [Red Hat OpenShift Container Platform 4.21 documentation](#)
 - Verify whether all services and OpenShift Container Platform are healthy.
 - Both high speed switches must be available, functional, and healthy.
- Note: Review the supported and allowed upgrade path on OpenShift Container Platform upgrade graph tool. Do this to avoid the upgrade to a version that does not have any further upgrade paths due to unavailability of stable channels. For more information about upgrade version details, see [Red Hat OpenShift Container Platform Update Graph](#).
- When the submariner auto upgrade fails or you observe any submariner issue during OpenShift Container Platform upgrade, contact IBM Support.
 - Ensure that the appropriate eviction strategy is configured for the virtual machine before starting the OpenShift Container Platform upgrade. For more information, see [Eviction strategies](#) in *Red Hat OpenShift Container Platform* documentation.

About this task

In the following procedure, version 4.18 is used as an example. Replace it with your version of OpenShift Container Platform.

Procedure

1. Run the following command to change the channel to stable 4.18 or higher.

```
oc patch clusterversion version --type merge -p '{"spec": {"channel": "stable-4.18"}}'
```

2. Upgrade OpenShift Container Platform to 4.18.18.

Important: When you upgrade OpenShift Container Platform from version 4.20 to 4.21, run the following command to acknowledge that the Sigstore signatures are mirrored and your cluster is ready update:

```
oc -n openshift-config patch configmap admin-acks --patch '{"data":{"ack-4.20-sigstore-in-4.21":"true"}}' --type=merge
```

3. Wait for upgrade to complete.
4. Verify whether all services and OpenShift Container Platform are healthy.

IBM Fusion HCI user interface:

- Go to the Services page and check the health of all services.
- Go to Infrastructure > Overview and check the health of all nodes and switches.

OpenShift Container Platform console:

Go to Operators > Installed operator in IBM Fusion namespace and check that the ISF operator shows in Succeed state.

OC commands

- Run the following command to check the ready state of the OpenShift Container Platform nodes:

```
oc get nodes
```

- Run the following command to check that all operators are available.

```
oc get co
```

Firmware upgrade

The firmware on all nodes, whether they are part of the base OpenShift® Container Platform cluster or Hosted Control Plane hosted nodes, is automatically updated each time the IBM Fusion operator is upgraded. Firmware updates are applied automatically in the background. Firmware updates for switches are orchestrated by IBM Fusion, but require a manual step to trigger the update.

For more information about automatic node firmware upgrade, see [Upgrading node firmware](#).

Note:

- Power operations must not be performed on any node in the cluster during a firmware upgrade.
- IBM Fusion HCI manages firmware upgrades for both switches and nodes in a rolling fashion, ensuring that there is a minimal impact to the Red Hat® OpenShift cluster during the upgrades. Firmware update for switches happens one at a time.

Upgrading Red Hat OpenShift Virtualization

Upgrading Red Hat OpenShift Virtualization on IBM Fusion HCI is done based on Red Hat® guidelines.

For the procedure to upgrade Red Hat OpenShift Virtualization, see [Updating Red Hat OpenShift Virtualization](#) in *Red Hat OpenShift Container Platform* documentation.

Important: If you created virtual machines on the OpenShift® Container Platform cluster by using the OpenShift virtualization, then the PVCs of the live migration VMs use Read Write Many (RWX) access modes. Otherwise, these VMs block drain during roll-outs, and you must manually force-drain the nodes and delete the VMs.

Upgrading the service node

Upgrade the service node to the latest version from the IBM Fusion UI.

Before you begin

Before you start the service node upgrade, ensure that the following prerequisites are met:

Version and system requirements

- The service node must be on the previous **major.minor** versions. For example, the service node must be on versions 2.12 or 2.13 before you upgrade to version 2.14.
- The service node must be running Red Hat® Enterprise Linux 9.6 or later.
- The service node must have a minimum of 80 GiB of available storage space.
- The service node firmware must be at the newest version. The compute operator manages the firmware update.

Credentials and access

- The correct Kubernetes-native Infrastructure (KNI) user credentials must be stored in the OpenShift® Container Platform secret. For example, the secret name can be **<rack>-servicenode-kni-secret**.
- The service node agent uses port 3001 on the service node during the upgrade.

Air-gapped environment requirements

- The upgrade image must be mirrored to the private registry. For more information, see [Mirroring IBM Fusion HCI images](#).
- The IDMS or ICSP configuration must be correct.

If all prerequisites are met and the KNI user secret is updated correctly, you can trigger the service node upgrade from the IBM Fusion UI.

Upgrade process

The service node upgrade process occurs in the following steps:

1. OpenShift Container Platform cluster operations
 - a. The user triggers the upgrade from the IBM Fusion UI.
 - b. The registry CA certificates are synchronized to the service node.
 - c. The upgrade image is resolved. In air-gapped environments, this phase includes IDMS or ICSP handling.
 - d. The upgrade image is downloaded to the service node, and the upgrade agent is extracted and started.
2. Service node operations
 - a. The upgrade agent upgrades the service node.
 - b. The upgrade agent installs additional software bundles such as AWX and Vault.
3. Populate and configure Vault. The Vault is configured and populated with the latest data.

Remember: For N-2 upgrade scenarios (for example, 2.12 to 2.14), the IBM Fusion dashboard displays a notification after the service node upgrade completes. Use the notification to download the **vault-secret**, **vault-login-secret**, and **servicenode-snuser-credentials** secrets. Store all three secrets securely and keep them accessible for future use.

The **servicenode-snuser-credentials** secret in the **ibm-spectrum-fusion-ns** namespace contains the credentials for the **snuser** account that you can use to connect to the service node.

Alternatively, you can download the secrets directly from the OpenShift Container Platform console as follows:

- a. Select the **ibm-spectrum-fusion-ns** namespace in the Projects drop-down, and go to Workloads > Secrets.
- b. Open the secret, go to the YAML section, and click Download.
- c. Repeat steps [3.a](#) and [3.b](#) for the **vault-login-secret** and **servicenode-snuser-credentials** secrets.
- d. Verify that you downloaded the YAML files for **vault-secret**, **vault-login-secret**, and **servicenode-snuser-credentials**.

Failure scenarios and troubleshooting

Pre-upgrade validation failures

- RHEL version check failed: The service node must be running RHEL 9.6.
- Insufficient storage: Free up the disk space so that at least 80 GiB is available.
- Firmware not at newest version: The compute operator automatically upgrades the service node firmware.

Connectivity failures

- Invalid credentials: Update the KNI user credentials in the OpenShift Container Platform secret.

Image download failures

- Image pull failed: Verify the pull secret, the IDMS or ICSP configuration for air-gapped environments, and the image specified in the **cr-version-cm** ConfigMap. In air-gapped environments, ensure that the image is mirrored correctly.
- Certificate issues: Ensure that **additionalTrustedCA** is configured for air-gapped environments.

Upgrade agent failures

- The agent does not respond: Collect the service node logs.
- Stage-specific failures: Check the upgrade status for specific stage errors.

- Maximum retry reached: After a failure, a **CRITICAL** event is raised. Fix the root cause and then retrigger the upgrade.

Vault-related failures during service node upgrade

If the service node upgrade fails, perform the following checks:

- Confirm that the service node is accessible with no network connectivity issues.
- Confirm that Vault is installed on the service node by running the **vault version** command.
- Verify whether the service node was restarted or powered off during the upgrade process.
- If the service node was restarted, check the Vault service status. Vault might start in a sealed or masked state after a node reboot or service interruption.
- If Vault is sealed, stopped, masked, or if the Vault readiness check fails, resolve the issue and retry the upgrade. For the recovery steps, see [Troubleshooting Vault](#).

Monitoring

You can monitor the service node upgrade from the IBM Fusion UI.

Events

- **INFO: BMYUP1136** - Service node upgrade triggered
- **INFO: BMYUP1172** - Service node upgrade completed
- **CRITICAL: BMYUP1141** - Service node upgrade failed

Logs

If a failure occurs, collect the service node log package for additional debugging.

Retry upgrade

After you fix the root cause of a failure, you can retry the upgrade directly from the IBM Fusion UI using the Retry upgrade button on the service node upgrade page.

Troubleshooting upgrade issues

Known upgrade issues for IBM Fusion HCI 2.14, categorized by symptom and component, with resolution steps.

Node cannot move to maintenance mode

Problem statement

The firmware upgrade fails because the node cannot move into maintenance mode. The following event is logged:

```

BMYCO0011: Failed to move node <node-name> into maintenance mode.
IBM Storage Fusion Data Foundation is not healthy.
Status: HEALTH_WARN

```

Cause

The upgrade fails when the storage subsystem health is in a Warning or Critical state. The node cannot move into maintenance mode until storage health is restored.

Resolution

1. Resolve the storage health issue that is causing the Warning or Critical state.
2. After storage health is restored, the node might automatically resume the upgrade.
3. If the node returns to the Upgrade Available state, trigger the firmware upgrade again from the IBM Fusion UI.

Node upgrade pending

When you use a rack as a service node and upgrade to version 2.11, you might see all nodes in the "Upgrade Pending" state on the Nodes page. It indicates that a firmware upgrade is in progress. Check the **computeinit** Custom Resource (CR) to identify the node that is currently undergoing the upgrade.

Restore failures post upgrade

Problem statement

After upgrade, you might encounter some restore failures. Check whether the job logs of the failed restore jobs contain the following error:

```

Invalid value: true: Privileged containers are not allowed, spec.containers[0].securityContext.capabilities.add: Invalid
value: "SYS_ADMIN": capability may not be added, provider "nonroot":

```

Resolution

Contact IBM Support to resolve this known issue.

Community operator catalog is shown as missing

Resolution

If the Community operator catalog is shown as missing, then create it before you attempt upgrade.

Machine config roll out error

Resolution

If an operation causes `machine config roll out` and gets stuck for a long time, then check whether the node to be updated is pingable and has an IP after restart. If there exist any DHCP or network issues that prevent the node from getting a hostname, then fix them and restart the node.

On-demand backup failures post upgrade

Problem statement

Post upgrade, on-demand backup failures might happen for existing applications.

Resolution

Do the following manual steps after you upgrade to avoid this problem:

1. Run the following command to display the phase status of the backup policies associated with all your applications:

```
oc get fpa -A
```

Example output:

```
oc get fpa -A
```

NAMESPACE	NAME	PROVIDER	APPLICATION	BACKUPPOLICY	DATAC
ibm-spectrum-fusion-ns	deptest2-azure-hourly-30	isf-ibmspp	deptest2	azure-hourly-30	
ibm-spectrum-fusion-ns	new-generic-1-azure-hourly-45	isf-ibmspp	new-generic-1	azure-hourly-45	
ibm-spectrum-fusion-ns	new-mongo-project-1-azure-hourly-15	isf-ibmspp	new-mongo-project-1	azure-hourly-15	
ibm-spectrum-fusion-ns	new-mongo-project-azure-hourly-30	isf-ibmspp	new-mongo-project	azure-hourly-30	

2. Verify whether your `policyassignment` CR corresponds to any application in `InitializeError` phase. In this example, the `new-mongo-project-1` application is in `InitializeError` phase.
3. Log in to IBM Fusion HCI user interface.
4. Go to Applications > Backups tab.
5. Unassign the backup policy that is assigned to the application in `InitializeError` phase and wait for its unassignment. In this example, unassign `azure-hourly-15` policy from `new-mongo-project-1` application.
6. Reassign the backup policy.

ImagePull failure

Resolution

If an `ImagePull` failure occurs due to intermittent network or registry issue during an upgrade, then restart the pod and retry. If the issue persists, contact [IBM support](#).

DeadlineExceeded error

Problem statement

IBM Cloud Paks foundational services operator ClusterServiceVersion (CSV) status shows Failed and its InstallPlan status shows Failed after the subscription gets created.

Resolution

If you notice that the operator installation or upgrade fails with `DeadlineExceeded error`, see [Operator installation or upgrade fails with DeadlineExceeded error](#).

watsonx.ai upgrade progress stalled at 60%

Problem statement

The watsonx.ai service upgrade is stalled at 60%. This issue occurs when the WML CR is fixed at 22.5%.

Resolution

Follow the steps to resolve the issue:

Note: In the following commands, `$instance_ns` represents the namespace where the watsonx.ai instance is installed.

1. Run the following command to verify the status of the WML custom resource:

```
oc describe wmlbases wml-cr -n $instance_ns | grep Progress
```

Example output:

```
Progress:          22.5%
Progress Message:  Waiting for dependency CCS to upgrade
Wml Status:       InProgress
```

If the WML CR is stuck at 22.5% with the previous message, continue to the next step.

2. Run the following command to verify that the CCS CR is completed successfully:

```
oc describe ccs ccs-cr -n $instance_ns | grep Progress
```

Example output:

```
Progress:          100%
Progress Message:  Last reconciliation succeeded
```

If the CCS CR progress is 100% and the WML CR is still stuck at 22.5%, then proceed with the following resolution steps.

3. To resolve the WML upgrade issues, follow the workaround instruction mentioned in the [Watson Machine Learning upgrade to version 5.3 fails with imagepull error](#).

4. Run the following command to verify whether the **WatsonxAIIFM** CR is stuck at 9%:

```
oc describe watsonxaiifm watsonxaiifm-cr -n $instance_ns | grep Progress
```

Example output:

```
Progress:          9%
Progress Message:  Waiting for CCS cr ccs-cr to be in 'Completed' state, before continuing with watsonxaiifm install or up
Watsonxaiifm Status: InProgress
```

If the CR is in this state, proceed to the next step.

5. To resolve the **WatsonxAIIFM** upgrade issue, follow the workaround instruction mentioned in the [Watson Machine Learning upgrade to version 5.3 fails with imagepull error](#).

watsonx Orchestrate upgrade progress stalled at 83%

Problem statement

The watsonx Orchestrate service upgrade is stalled at 83%. This issue occurs when watsonx Orchestrate **Kafka** resource does not enter the verifying state during upgrade..

Resolution

To resolve the issue, follow the workaround instruction mentioned in the [During upgrade watsonx Orchestrate Kafka is not in ready state](#).

BMYC00162 event persists after upgrading from 2.13

Problem statement

After upgrading from IBM Fusion HCI 2.13 or an earlier version, the following critical event remains active on the Events page and does not resolve automatically:

```
BMYC00162: Failed to install Self Node Remediation operator:
client rate limiter Wait returned an error: context canceled
```

Cause

On IBM Fusion HCI 2.13 and earlier versions, the compute operator does not handle a canceled context correctly when the operator pod restarts or scales down. The operator raises the **BMYC00162** event based on the context state of the previous container, not from an actual Self Node Remediation Operator installation failure. The event is a false positive.

The IBM Fusion HCI 2.14 code fix prevents new false events of this type from being generated. However, the fix does not automatically clear the stale event that the pre-upgrade container raised. Fresh installations of 2.14 are not affected.

Resolution

Manually mark the **BMYC00162** event as fixed once after the upgrade completes:

1. Log in to the IBM Fusion HCI user interface.
2. In the navigation menu, click Events.
3. Locate the **BMYC00162** event in the list.
4. Select the event row and choose Mark as fixed from the context menu.

The event moves to the resolved state. No further action is required. The same event does not reappear after this one-time action.

Troubleshooting and serviceability

The steps to troubleshoot an issue vary depending on the problem. To help make relevant information available to you as quickly as possible, the log files and other tools for troubleshooting problems are consolidated.

- [Contacting IBM Support Center](#)
The IBM® Support Center is available for various types of IBM hardware and software problems that IBM Fusion customers might encounter.
- [How to provide feedback](#)
Customers can submit feedback on the IBM Documentation platform and on product documentation using the "Was this topic helpful?" rating on every page.
- [Serviceability in IBM Fusion HCI](#)
The serviceability of IBM Fusion includes Call Home client, event manager, and log collector. They gather event logs to track down problematic events, help troubleshooting issues, and update relevant information in the support ticket automatically.
- [Events and error codes message references in IBM Fusion HCI](#)
This reference information provides a consolidated view of all the events or error messages that can be displayed when the IBM Fusion system might result in an event or an error.
- [Troubleshooting issues in IBM Fusion HCI](#)
This topic covers the most common issues and their workarounds, which you might encounter while you work with the IBM Fusion HCI appliance.

Contacting IBM Support Center

The IBM® Support Center is available for various types of IBM hardware and software problems that IBM Fusion customers might encounter.

Before you begin

Points to note when you contact the IBM Support Center:

1. For IBM Fusion HCI, ensure that you have your system's serial number and its associated account number.

2. Based on your issue, collect appropriate log files and diagnostic data.
3. IBM Support provides a time period within which IBM representative returns your call. Be sure that the person that you identified as your contact can be reached in the phone number.
4. An online case gets created to track the problem you are reporting. Note down the number for future reference and communication. If you need to make subsequent calls to discuss the problem, use the number to identify the problem.

About this task

If you enabled Call Home, then it connects your system to service representatives who can monitor issues and respond to problems efficiently and quickly to keep your system up and running. Enabling Call Home significantly improves your IBM Support experience. For more information about Call Home and Service level in Call Home, see [Enabling Call Home for IBM Fusion HCI](#).

If you have an IBM Hardware and Software Maintenance service contract, then use this procedure to open a case on IBM Support site.

The following table lists alternative ways of contacting IBM Support Center:

Your location	Method of contacting the IBM Support Center
In the United States	Call 1-800-IBM-SERV for support.
Outside the United States	Contact your local IBM Support Center or see the Directory of worldwide contacts (www.ibm.com/planetwide) .

If you do not have an IBM Software Maintenance service contract, then contact your IBM sales representative to find out how to proceed. For non-IBM failures, follow the problem-reporting procedures provided with that product.

Procedure

1. Log in to [IBM support page](#) by using your IBMid and click Continue.
2. In Let's troubleshoot, click Open a case tile.
3. In the Open a case page, enter the following details:
 - a. Select a value for the Type of support that you need.
 - b. Enter the Case title to describe your case. The maximum length of the case title is 255 characters.
 - c. Enter **IBM** in Product manufacturer.
 - d. Enter **Fusion** or **Fusion HCI Physical Appliance** for Product.
 - e. For **Fusion HCI Physical Appliance**, enter the Machine serial number.
 - f. Enter Product version.
 - g. Select Service Type.
 - h. Check Address where product is located.
 - i. Select Severity.
 - j. For **Fusion HCI Physical Appliance**, enter Machine Type Model.
Note: For **Fusion HCI Physical Appliance** the machine models are currently: 9155-C10, 9155-C14, 9155-G03, 9155-S01, 9155-S02, 9155-R42, 9155-TF5.
 - k. Enter System down (yes or no).
 - l. Enter Failing Component (Software or Hardware)
 - m. Enter Account name and Case description.
 - n. Enter Case contact phone number.
 - o. You can Add team members based on the need.

Note: If a diagnostic file is required for this case, you can upload it after you submit this case.
4. Go through the terms and conditions and click Submit case.

How to provide feedback

Customers can submit feedback on the IBM Documentation platform and on product documentation using the "Was this topic helpful?" rating on every page.

IBM customers can provide feedback on two levels: feedback on the the platform (IBM Documentation site) and feedback on your product's documentation.

How to provide feedback on IBM Documentation platform

To leave feedback about the IBM Documentation platform (website), use the "Was this topic helpful?" at the top of this page. When you rate the content with a thumbs up or thumbs down, a dialog appears where you can leave optional comments.

We welcome any feedback that you have. You will not receive a direct response to your feedback, but your comments help us improve your IBM Documentation experience.

How to provide feedback on your product's documentation

IBM Documentation provides a single standardized process to leave feedback on your product using "Was this topic helpful?", located at the top of every page. When you rate the content with a thumbs up or thumbs down, a dialog appears where you can leave optional comments. IBM Documentation automatically captures both the product and the URL of the page you are leaving your feedback on.

We welcome any feedback that you have, including comments on the clarity, accuracy, or completeness of the information. You will not receive a direct response to your feedback, but your comments help us improve our product documentation.

If you require support and a response to technical questions, visit IBM's [technical support site](#) to open a defect.

Serviceability in IBM Fusion HCI

The serviceability of IBM Fusion includes Call Home client, event manager, and log collector. They gather event logs to track down problematic events, help troubleshooting issues, and update relevant information in the support ticket automatically.

Call Home

The Call Home feature alerts you and IBM Support about hardware failures and potentially serious configuration or environmental events. It constantly monitors the health and availability of your storage so that you can address issues before they impact your business.

You can enable this feature to receive requests from any IBM Fusion source. For more information about benefits and how to enable, see [Benefits of enabling Call Home](#) and [Enabling Call Home for IBM Fusion HCI](#).

For more information about how to open a support ticket, see [Support ticket](#).

Event manager

The event manager contains the logic for servicing the basic event handling. Event Manager does basic checks for duplicate events and forwards them to Call Home Client. The expectation is that Call Home Client determines whether an event must be ignored or must open a Salesforce ticket.

You can work with the event manager from both IBM Fusion user interface and OpenShift® user interface:

For more information about how to filter events, see [Analyzing events in IBM Fusion HCI](#).

Log collector

The log collector collects and returns appliance logs dynamically at run time. You can configure and manage collection sets for the log collector by using both user interface and APIs. A list of all the appliance logs and collection sets that can be returned are maintained in related config maps.

For more information about logs in IBM Fusion HCI, see [Logs in IBM Fusion HCI](#).

- [Analyzing events in IBM Fusion HCI](#)
The Events page in IBM Fusion HCI gives you a consolidated view of system events across all components. Use it to identify issues, track their severity, and determine whether a support ticket is opened on your behalf.
- [Logs in IBM Fusion HCI](#)
The IBM Fusion HCI has in-built log capability to collect the logs. You can configure and manage the log package by using both the user interface and APIs.
- [Call Home in IBM Fusion](#)
IBM Fusion includes a built-in Call Home capability that automatically opens IBM support cases when issues are detected in your environment. The topic explains how Call Home works, what triggers it, and what happens when a ticket is created.
- [Remote support](#)
Remote support is a service that enables IBM Support representative to remotely access your rack and accomplish essential tasks, such as installation, maintenance, and troubleshooting.
- [Password rotation](#)
The password rotation feature automatically updates hardware (nodes) credentials at regular intervals to enhance system security and meet enterprise compliance requirements. It minimizes the risk of credential compromise by eliminating the need for manual password updates.
- [Custom certificate expiration alert](#)
This section provides information about custom certificate expiration monitoring and alerting for critical cluster components.
- [Configuring License Service Reporter for IBM Fusion](#)
Configure License Service Reporter to obtain a unified view of IBM Fusion licensing metrics. License Service Reporter supports this feature and can be extended to IBM Fusion. In addition to the IBM Fusion user interface, it provides an additional view of licensing metrics, offering deeper insights. It can also be configured across multiple clusters, enabling centralized monitoring and reporting of license usage in distributed environments.
- [Troubleshooting serviceability issues](#)
List of all troubleshooting and known issues in Events, Log collection, and Call Home.

Analyzing events in IBM Fusion HCI

The Events page in IBM Fusion HCI gives you a consolidated view of system events across all components. Use it to identify issues, track their severity, and determine whether a support ticket is opened on your behalf.

Before you begin

IBM Fusion HCI continuously monitors its components and records events as they occur. Understanding the event model before you start filtering helps you act on what you find.

Event severity levels

Severity	What it means	Retention
Critical	A failure or condition that requires immediate attention. A support ticket can be opened automatically.	14 days
Warning	A condition that might indicate a developing problem. Monitor and investigate if it persists.	7 days
Informational	A routine system activity. No action is typically required.	3–4 hours

Support tickets

For Critical events that are whitelisted for Call Home, IBM Fusion HCI automatically opens an IBM Support ticket. The Support ticket column on the Events page shows the ticket number when one is created. If no ticket number appears for a Critical event, the event is not whitelisted for Call Home. Automatic ticket creation is only triggered for qualifying (whitelisted) events, not for all Critical events.

Note: To check which events are whitelisted for Call Home, inspect the `isf-serviceability-operator-allow-tickets` ConfigMap in the IBM Fusion namespace. An event is eligible for automatic ticket creation only when both of the following conditions are true in the ConfigMap:

- The component has `allowed: true`
- The specific event ID within that component has `allowed: true`

For example:

```
isf-network-operator-controller-manager:  
  allowed: true
```

```
defaultlogs:
  loglevel101: isf-collection-sets:network
messages:
  BMYNW0009:
    allowed: true
```

In this example, event **BMYNW0009** from **isf-network-operator-controller-manager** triggers automatic ticket creation. An event from the same component with **allowed: false** (or absent from the ConfigMap) does not.

If you encounter a Critical event that is not whitelisted for Call Home but you believe that it requires attention, contact [IBM Support](#) directly with the event details.

Marking events as fixed

When a Warning or Critical event is resolved, you can mark it as fixed on the Events page. It changes the display state of the event in the IBM Fusion HCI user interface. It does not close or update the associated support ticket. Manage the ticket directly with IBM Support.

Kubernetes controllers in IBM Fusion HCI also mark events as fixed automatically when they detect that the underlying condition has cleared.

Viewing events from the IBM Fusion HCI user interface

1. Log in to the IBM Fusion HCI user interface.
2. In the navigation menu, click Events.
3. Use the Search field to filter events by keyword, or use the Severity and Category filters to narrow the list.

The Events page displays the following columns by default:

Column	What does it describe
Severity	How urgent the event is: Critical, Warning, or Informational.
Category	The system area affected. For example, Backup and restore, Compute, Network, Storage, or System.
Time	The time when the event occurred.
Description	A short summary of what happened.
Support ticket	The IBM Support ticket number associated with this event, if one was opened automatically. If empty for a Critical event, contact IBM Support .
Fixed	Whether the condition is resolved, either automatically by a Kubernetes controller or manually by an administrator.

Note: IBM Storage Scale controller names and **isf_node** labels can exceed 63 characters, which is the OpenShift® limit for label values. When this occurs, IBM Fusion truncates the name to 60 characters for display in the Description column and Call Home data. If you need the full name, retrieve it directly from the resource by using **oc describe** on the relevant object. For more information, see [Host name validation errors](#).

4. To adjust the display:
 - Use the settings icon to show or hide columns. Click Reset to default to restore the original column set.
 - Use the Items per page dropdown to control how many rows appear at once. Use the arrow controls or the page dropdown to navigate between pages.
5. To download a snapshot of recent events, use the downloads icon. The download includes all events that are recorded in the last 48 hours. For events older than 48 hours, see [Long-term event retention](#).

Result: You can now see all active events and identify which ones require attention based on their severity. Escalate Critical events with no support ticket number to [IBM Support](#).

Viewing events from the Red Hat® OpenShift Container Platform console

Use this method when you want to see lower-level Kubernetes events alongside IBM Fusion events, or when the IBM Fusion HCI user interface is not accessible.

1. Log in to the OpenShift console.
2. Go to Overview > Events.
3. Filter by resource type, event type, or enter a name or message in the search field.

Result: The OpenShift Events page shows all cluster-level events, including those generated by IBM Fusion components. This view includes events from all workloads on the cluster. Use the resource filter to narrow the scope.

Tip: You can enable proactive notifications for IBM Fusion events by using OpenShift Alertmanager. For setup instructions, see [IBM Fusion event alerts](#).

Viewing events from the command line

Use the **oc** CLI to query events directly. It is useful for scripting, automation, or when you need to export raw event data.

To list all IBM Fusion events, run the following command:

```
oc get event --field-selector reason=ISFEventManager -n ibm-spectrum-fusion-ns
```

To filter events for a specific IBM Fusion component, add the component's namespace and a label selector. For example:

```
oc get event -n <component-namespace> -l <label-key>=<label-value>
```

Replace **<component-namespace>** with the namespace of the component that you are investigating, and **<label-key>=<label-value>** with the appropriate label for that component.

Interpreting output

- If the command returns a list of events, review the **REASON**, **MESSAGE**, and **OBJECT** columns to identify the component and condition.
- If the command returns **No resources found**, then no events match that selector currently. It is expected when the system is healthy or when the filter is too narrow.
- If you are unsure whether the filter is correct, omit **--field-selector** to list all events in the namespace and then scan for **ISFEventManager** entries.

Acting on events

Responding to Critical events

1. Check the Support ticket column. If a ticket number is shown, IBM is notified automatically. You can reference the ticket number when contacting [IBM Support](#) for status.
2. If no ticket number appears, contact IBM Support directly and provide the event description, category, and timestamp.
3. After the condition is resolved, mark the event as fixed, select the event row and choose Mark as fixed. It does not close the support ticket. Close the ticket separately through IBM Support.

Responding to Warning events

1. Investigate the event description and the affected resource.
2. If you resolve the underlying condition, mark the event as fixed. If the condition clears automatically, IBM Fusion Kubernetes controllers mark it fixed.
3. If a Warning event persists or escalates to Critical, open a support case.

Long-term event retention

The Events page retains events for a maximum of 14 days (Critical). The 48-hour download is also limited to recent data.

For long-term visibility, forward IBM Fusion alerts to your operations team's alerting platform through OpenShift Alertmanager. It lets your team manage retention according to their own policies and integrate IBM Fusion events into existing incident workflows. For setup instructions, see [IBM Fusion event alerts](#).

Reference

For a complete list of IBM Fusion HCI events and error codes, see [Events and error codes message references in IBM Fusion HCI](#).

- [IBM Fusion event alerts](#)
Use these instructions to enable notifications of IBM Fusion events using OpenShift Container Platform **Alertmanager**.

IBM Fusion event alerts

Use these instructions to enable notifications of IBM Fusion events using OpenShift® Container Platform **Alertmanager**.

About this task

IBM Fusion supports notifications for **CRITICAL** and **WARNING** events, which are visible in the IBM Fusion user interface. By configuring supported receivers in the OpenShift Container Platform, notifications can be routed through preferred channels such as Slack, email, and webhooks. This setup simplifies incident management by delivering alerts directly to configured notification channels. Additionally, multiple IBM Fusion clusters can be configured with similar settings to centralize event notifications in a single location.

Procedure

1. Log in to the OpenShift Container Platform web console.
2. Go to Administration > Cluster Settings.
3. In the Configuration tab, select the Alertmanager.
4. In the Alertmanager, click Create Receiver.
The Create Receiver page opens.
5. Enter the Receiver name and select the channel that you prefer from the Receiver type drop-down list.
For example, if you select the Slack as a preferred channel. Ensure that you must update the following details.
 - a. Enter the Slack API URL.
 - b. Enter the Channel name to send the notifications.
 - c. Use Show advanced configuration drop-down to customize the Icon, Username, Title, and Text.
Important: You can use the following labels and annotations to customize your message:

```
Severity: {{ .CommonLabels.severity }}
Hardware Address: {{ .CommonLabels.hwAddr }}
Event Message: {{ .CommonLabels.alertMessage }}
Alert Summary: {{ .CommonAnnotations.summary }}
Alert Description: {{ .CommonAnnotations.description }}
```

 - Cluster - Add the cluster name manually.
 - Severity - **Critical** or **Warning**.
 - Address - Hardware address generating the event (cannot be present for software).
 - Event message - Description of the event.
 - Alert summary - Static string of **IBM Fusion Event Alert**.
 - Alert description - Static string **Alert sent from IBM Fusion Event Manager**.
 - d. Enter the label details in the Routing labels.
Important:
 - Ensure that you enter **source = ISFEventManager** label in the Routing labels.
 - Do not mark Send resolved alerts to this receiver? to true.
 Optionally, you can also add **severity = CRITICAL** or **severity = WARNING** labels.
6. Click Create.

What to do next

After the receiver is configured, you start receiving notifications for IBM Fusion events based on the routing label specified during setup.

By default, when the routing label source is set to **ISFEventManager**, the receiver is notified of all events with severity levels **WARNING** and **CRITICAL**. This setup ensures that important alerts are delivered promptly without needing extra filtering.

To streamline monitoring across multiple racks, you can apply the same receiver configuration to each rack. This enables centralized alerting, allowing all events to be routed to a common notification channel for unified visibility and management.

Note: The cluster name is not automatically detected, so it is recommended to manually specify the cluster name in the receiver configuration to ensure accurate identification and traceability of events.

Logs in IBM Fusion HCI

The IBM Fusion HCI has in-built log capability to collect the logs. You can configure and manage the log package by using both the user interface and APIs.

You can create your log package by using one or more component logs. IBM may also request you for logs from IBM Fusion HCI when troubleshooting a support case. You may be asked to collect a particular set of logs package and upload the log package to an IBM site. The IBM Fusion HCI gathers the current logs and includes them in a compressed archive file. For the procedure to collect log package, see [Collecting log packages for IBM Fusion HCI](#). Decompress the collected log zip file and use the sub-folders and files as diagnostic data to resolve issues or errors in IBM Fusion HCI. For more guidance on the download log package, see [Log package](#).

If you have enabled Call Home, then the system automatically collects appropriate log packages and raises a IBM Support ticket.

- [Collecting log packages for IBM Fusion HCI](#)
You can create your log package by using one or more component logs.
- [Log package](#)
A quick overview of the IBM Fusion HCI log packages.
- [Automatic cleanup of log packages](#)
This section describes the automatic cleanup feature for diagnostic log packages that are collected from the IBM Fusion environment.

Collecting log packages for IBM Fusion HCI

You can create your log package by using one or more component logs.

Procedure

1. From the title bar, click the help icon and select Support logs.
2. In the Support logs page, click Create.
The Create a log package page gets displayed.
3. In the Create a log package page, select one or more components to create the log package. The log package contains the folders, namespaces, and relevant files. For more guidance on the log package, see [Log package](#).
You can collect logs for individual nodes and switches. Click Add and select the nodes or switches that you want to collect the logs. Alternatively, you can download logs for the nodes and switches from the Nodes and Network menu on the IBM Fusion HCI user interface as follows:
 - a. Go to Infrastructure > Nodes.
 - b. In the ellipsis menu of the node, click Collect logs to get the logs of the node.

System logs

System logs contains the information about the operation, status, and potential issues of the system health and administration in the IBM Fusion HCI.

System health check

Use this option to collect logs that provide an overall assessment of the health of IBM Fusion HCI. This log package includes the following information:

- The health of the components that make up the IBM Fusion HCI.
- The health of IBM Fusion services such as the Global Data Platform and Backup & Restore.
- The health of the IBM Fusion HCI operator
- The Red Hat® OpenShift® configuration of Bare Metal hosts, machine sets, machines, and nodes.

Administration

Use this option to collect logs related to Red Hat OpenShift, administration, and audit logging.

Hardware logs

Hardware logs contains the information about the operation, status, and potential issues of the hardware components such as nodes, service node, and switches in the IBM Fusion HCI.

Nodes

Using this option to collect logs for the nodes in the IBM Fusion HCI appliance. Troubleshoot issues related to node health, firmware upgrades, storage configuration, Metro-DR, and Regional DR configurations. For example, issues like offline nodes and issues with firmware upgrade.

Network switches

Use this option to collect logs for the switches in the IBM Fusion HCI appliance. Troubleshoot issues related to the IBM Fusion HCI network. The logs that are collected in this package include information on the switches, Vlans, and links that make up the appliance network. For example, issues like network outages, degraded performance, connecting the IBM Fusion HCI appliance to the data center network, and problems related to Metro-DR recovery.

Attention: Network switches log collection package does not include the spine switches logs.

Software and services

Software and services logs contains the information about the operation, status, and potential issues of the services such as Global Data Platform, IBM Data Cataloging, Backup & Restore, and Data Foundation in the IBM Fusion HCI.

Global Data Platform

Important:

- Enable scale traces before you collect the Global Data Platform logs. For more information about how to enable traces, see [Generating GPFS trace reports](#).

Use this option to collect logs related to the physical storage configuration of IBM Fusion HCI and Global Data Platform. These logs are used to troubleshoot storage issues. For example, issues like loss of storage access, problems with CSI provisioning, problems related to disaster recovery (Metro-DR and Regional DR), problems with the overall health of the Global Data Platform.

Backup & Restore

Use this option to collect logs related to the Backup & Restore service. These logs are used to troubleshoot issues that are related to setup, backup, and restore. These logs contain mainly the **ibm-backup-restore** namespace resources.

For Backup & Restore service, you can also select logs for the specific clusters as follows:

- a. In the Summary slide out pane, click edit icon next to Backup & Restore.
The Select spoke clusters page gets displayed with all the available clusters.
- b. Select the spoke clusters that you want to include in the log package.
Important:
 - You can collect logs for spokes from Hub by selecting the spoke clusters from the Hub IBM Fusion HCI user interface.
 - The logs can also be collected from the individual Spoke clusters.

Backup & Restore agent

Use this option to collect logs related to the Backup & Restore service on the spoke cluster. These logs are used to troubleshoot issues that are related to setup, backup, and restore. These logs contain mainly the **ibm-backup-restore** namespace resources.

IBM Data Cataloging

Use this option to collect logs that are related to the IBM Data Cataloging service. These logs contain mainly the **ibm-data-cataloging** namespace resources.

Data Foundation

Use this option to collect logs that are related logs related to Kubernetes resources of openshift-local-storage, openshift-storage-client, openshift-lvm-storage, and openshift-storage.

Important: If a service is not enabled, the user interface does not display the service component in the log collection.

4. Click Create.

The created log package gets added to the log list with status as Creating. After the collection is complete, the status changes to Success.

The log package creation might take several minutes and the amount of time might vary based on the type of logs collected. You can view the progress of the log package creation in the table that is shown on the Support logs page.

The Support logs page lists all created log packages with the following details:

Name

The name of the log package.

Note: The name of the log package consists of two parts: component name and timestamp. For example, in a nodes package, the file name must be `cn-20220324124442`. The name of the log package change for every component.

- **Global Data Platform: gdp**
- **System health check: sh**
- **Administration: ad**
- **Network: nw**
- **Data foundation: odf**

Contents

It contains details of which component logs comprise the log package.

Status

The values of the status field are Collecting, Success, and Partial.

Note: The Partial status means that some of the requested logs are collected successfully, but there are error messages that are generated in the process.

Created

The date and time of the creation of the log package.

Expires

The expiry date and time of the log set.

Note: The collected log packages are auto-deleted after 24 hours.

5. After a log package is successfully added to the log list, you can upload it to IBM directly by using the Call Home feature, download it to your local, or delete it.

Upload the collected log package to IBM Support

If Call Home is enabled, you can use the IBM Fusion HCI user interface to automatically upload logs to a ticket. For steps to enable call home, see [Enabling Call Home for IBM Fusion HCI](#).

- a. Click the ellipsis menu of the log record and click Upload.
The Upload log package window gets displayed. The collected logs get uploaded so that the IBM Support team can use for diagnosis.
- b. In the Upload log package window, choose whether you want to create a new support case or attach to an existing case.
- c. If it is an existing case, then enter the Ticket number.
Note: A log collection package can be uploaded only once to any ticket through this user interface page.
- d. Click Upload log.

Download collected log package

Click the ellipsis menu of the log record and click Download. The Downloading log package window gets displayed indicating that the download is in progress.

Delete a log package

- a. Click the ellipsis menu of the log record and click Delete.
- b. In the Confirm delete log package window, click Delete.

If you did not enable Call Home, then download the log package and upload it to an IBM site. In the table of log packages, click the ellipsis menu for the log package that you want to upload and select the Download action. It triggers the download of the log package file in your web browser. The user interface provides three

methods of uploading logs to IBM.

FTP transfer

This option is the fastest approach to upload logs to IBM. It uses FTP to upload logs to the IBM Enhanced Customer Data Repository (ECUREP) site.

Browser upload

Using the browser upload option, upload the log package from your web browser. This option is limited to files that are smaller than 200 MiB.

Blue Diamond

HIPPA customers designated as Blue Diamond must upload logs to the IBM Blue Diamond site.

What to do next

1. After a log package is successfully completed, you can check the folders, namespaces, and relevant files of the log package to read and troubleshoot. See [Log package](#).

Log package

A quick overview of the IBM Fusion HCI log packages.

The following log packages are available in the Logs page:

- [Fusion core](#)
- [Nodes](#)
- [Network switches](#)
- [Global Data Platform](#)
-
- [Backup and Restore](#)
- [Data Cataloging](#)
- [Data Foundation](#)
- [Red Hat OpenShift Virtualization](#)

Fusion core

The Fusion core package is selected by default and contains the IBM Fusion-related components that are present in the cluster. The Fusion core log package mainly contains the folders for the following namespaces:

- **ibm-spectrum-fusion-ns**
- **ums-fusion**
- **openshift-machine-api**
- **openshift-marketplace**
- **openshift-operator-lifecycle-manager**

Note: It includes the Kubernetes events that are associated with the resource. If any resource does not exist, then skip it.

Fusion core log package contains the namespace service account manifests and the corresponding **oc ns inspect** output. The inspect output includes the namespace resources, events, configuration, and other diagnostic data, providing a comprehensive snapshot of the namespace for validation, troubleshooting, and recovery.

The package includes platform diagnostic data such as:

Audit logs

Audit logs contain the Control-O-rack, Kube, OAuth, and OpenShift folders with the relevant log files.

ocp-must-gather

It contains cluster-wide OpenShift® diagnostic data such as operator status, cluster resources, node information, namespace resource dumps, events, and pod details used for troubleshooting.

system-info

It contains a cluster-wide system inventory snapshot, including cluster identity, topology, IBM Fusion and OpenShift versions, upgrade history, installed operator and service versions, storage configuration, and switch firmware details.

The Fusion core log package contains custom resources for IBM Fusion platform services, serviceability components, infrastructure configuration, data protection workflows, storage integrations, and platform extensions that are present in the cluster.

Nodes

Logs related to compute nodes, service node, firmware upgrades, and node health. The nodes log package mainly contains the folders for the following namespace:

openshift-user-workload-monitoring

This directory contains the namespace service account manifests and the corresponding **oc ns inspect** output. The inspect output includes the namespace resources, events, configuration, and other diagnostic data, providing a comprehensive snapshot of the namespace for validation, troubleshooting, and recovery.

Note: It includes the Kubernetes events that are associated with the resource. If any resource does not exist, then skip it.

IMM-logs

Important: The IMM logs package is collected only for the Lenovo Gen 1 and Gen 2 nodes.

The bmc-logs logs folder contains the IMM_NAME.ffdc and IMM_NAME.inventory files for every IMM.

Note: The log contents vary based on the Node vendor **imm** logs for Lenovo and Support Assist package for Dell.

Dell Support Assist logs

Important: The Dell Support Assist logs package is collected only for the Dell nodes.
The Dell support assist logs contain the debug logs, hardware logs, and storage logs for the Dell nodes.

Lenovo BMC Assist logs

Important: The Lenovo BMC Assist logs package is collected only for the Lenovo Gen 3 nodes.
The node-logs folder contains a folder with the node name, which contains a nodename_diagnostic_log subfolder with the log package. The Lenovo Gen 3 BMC diagnostic logs contain system, hardware, and BMC diagnostic data for Lenovo nodes.

OCP must gather

The folder contains OpenShift Container Platform must-gather logs for analysis.

Service node logs

The service node logs contain diagnostic information from the service node to help troubleshooting and system diagnostics. These include Baseboard Management Controller (BMC) logs and retrieval of operating system (OS) logs from the service node.

OS files and directories collected by default

- /home/kni/isfLogs/
- /opt/fusion/remote-support/challengeManagerClient.log.*
- /var/opt/ibm/trc/target/*.log
- /var/opt/ibm/trc/target/profiles/lightsoutprofile.properties
- /home/kni/logs
- /etc/ibmtrct.conf
- /var/log/fusion
- /var/vault_logs/vault_audit.log

Diagnostic command outputs

The command-output or directory contains outputs from system diagnostic commands:

- System information (**uname -a**)
- Operating system details (**cat /etc/os-release**)
- Hostname and system information (**hostnamectl**)
- Disk space usage (**df -h**)
- Memory usage (**free -h**)
- System uptime and load average (**uptime**)

Vault must gather logs

It retrieves vault status details and diagnostic logs to assist with troubleshooting internal vault issues.

Error logging

- **error.log** - Lists any files or directories that failed to be collected due to permission issues, file not found, or other issues. This log is created only if errors occur.
Note:
 - If a file or directory path is not found, it is logged in **error.log** but does not mark the log collection as partial. The log collection is marked as partial only if a file or directory exists but cannot be retrieved due to permission issues or other access-related issues.
 - If a directory path exists but contains no content, it does not appear in the collected log package.
- **stderr.log** - Contains error output from diagnostic commands. This log is created only if commands fail.

Important:

- Service node logs are collected only if a service node is present in the rack.
- All files and directories must have read permission for the **kni** user on the service node.
- Additional custom paths can be specified through the **isf-serviceability-operator-collection-sets** ConfigMap.

Network switches

Logs related to appliance network errors and connectivity. The network switches log package mainly contains the folders for the following namespaces:

openshift-monitoring

It contains the namespace service account manifests and the corresponding **oc ns inspect** output. The inspect output includes the namespace resources, events, configuration, and other diagnostic data, providing a comprehensive snapshot of the namespace for validation, troubleshooting, and recovery.

Note: It includes the Kubernetes events that are associated with the resource. If any resource does not exist, then skip it.

Switch logs

The switch log packages include directories that contain the actual switch logs. These packages are organized by switch type, and each package includes the following directories:

- Cumulus switches
 - cumulus-switch-logs
 - clncl
 - gencl

Global Data Platform

Logs related to storage availability. The Global Data Platform log package mainly contains the folders for the following namespaces:

- **ibm-spectrum-scale**
- **ibm-spectrum-scale-csi**
- **ibm-spectrum-scale-operator**
- **ibm-spectrum-scale-dns**

Note: It includes the Kubernetes events that are associated with the resource. If any resource does not exist, then skip it.

Global Data Platform log packages contain both the custom resources (**scalemanagers** and **scaleclusters**) and cluster resources. This log package contains the namespace service account manifests and the corresponding **oc ns inspect** output. The inspect output includes the namespace resources, events, configuration, and other diagnostic data, providing a comprehensive snapshot of the namespace for validation, troubleshooting, and recovery.

Follow the steps to collect **Velero** namespace logs:

1. On the Global Data Platform service, manually add the **Velero** namespace under the namespaces in the serviceability section of the **FusionServiceDefinition** instance.
2. It ensures that the **Velero** namespace logs are collected as part of log collection for the Global Data Platform service.
3. The **Velero** namespace is specified in **ramen-dr-cluster-operator-config** configmap in the **ibm-spectrum-fusion-ns** namespace.

It also includes the GPFS snap logs and must-gather that is related to IBM Storage Scale.

Important: To obtain GPFS logs, gather them from IBM Fusion HCI user interface and not from OpenShift Container Platform.

Backup and Restore

Logs related to the backup and restore of your workload applications. The backup and restore log package mainly contains the folders for the following namespaces:

ibm-backup-restore

It contains the namespace service account manifests and the corresponding **oc ns inspect** output. The inspect output includes the namespace resources, events, configuration, and other diagnostic data, providing a comprehensive snapshot of the namespace for validation, troubleshooting, and recovery.

Note: It includes the Kubernetes events that are associated with the resource. If any resource does not exist, then skip it.

If Cloud Pak for Data (CPD) is installed and custom resource (CR) is created, the backup and restore log packages also include backup and restore-specific CPD logs, which contain log data from all CPD-related namespaces.

Note: The CPD log collection process might fail to collect logs for Velero backup and restore operations. The failure occurs when the CPD script is unable to validate or recognize self-signed TLS certificates configured for the backup storage location. To prevent this, ensure that a properly configured and trusted TLS certificate is associated with the backup storage location.

Data Cataloging

Logs related to the IBM Data Cataloging service. The IBM Data Cataloging log package mainly contains the folders for the following namespace:

ibm-data-cataloging

It contains the namespace service account manifests and the corresponding **oc ns inspect** output. The inspect output includes the namespace resources, events, configuration, and other diagnostic data, providing a comprehensive snapshot of the namespace for validation, troubleshooting, and recovery.

Note: It includes the Kubernetes events that are associated with the resource. If any resource does not exist, then skip it.

Data Foundation

Logs related to storage availability. The Red Hat® OpenShift Data Foundation log package mainly contains the folders for the following namespaces:

- **openshift-local-storage**
- **openshift-lvm-storage**
- **openshift-storage**

Note: It includes the Kubernetes events that are associated with the resource. If any resource does not exist, then skip it.

Red Hat OpenShift Data Foundation log packages contains both custom and cluster resources. It includes custom resources such as **odfmanagers**, **odfclusters**, **storageclusters**, **cephclusters**, **localvolumediscoveries**, **localvolumediscoveryresults**, and **localvolumesets**.

This log package contains the namespace service account manifests and the corresponding **oc ns inspect** output. The inspect output includes the namespace resources, events, configuration, and other diagnostic data, providing a comprehensive snapshot of the namespace for validation, troubleshooting, and recovery.

Follow the steps to collect **Velero** namespace logs:

1. On the Data Foundation service, manually add the **Velero** namespace under the namespaces in the serviceability section of the **FusionServiceDefinition** instance.
2. It ensures that the **Velero** namespace logs are collected as part of log collection for the Data Foundation service.
3. The **Velero** namespace is specified in **ramen-dr-cluster-operator-config** ConfigMap in the **ibm-spectrum-fusion-ns** namespace.

It also includes the **Openshift Data Foundation must-gather** folder with the relevant log files.

Note: Though Data Foundation log status shows partial due to the unavailability of one or more namespaces, you can still upload and download partial logs.

Red Hat OpenShift Virtualization

Logs related to virtual machine management and virtualization infrastructure. The Red Hat OpenShift Virtualization log package mainly contains the folders for the following components:

Inspect namespace (**openshift-cnv**)

The **cnv-inspect** folder contains logs and object definition files for major resources in the core virtualization namespace. This includes:

- Core and workload resources, including pods, deployments, DaemonSets, and CronJobs
- Storage and routing resources, including routes, persistent volumes, and config maps
- Custom virtualization resources, including **hco.kubevirt.io**, **cdi.kubevirt.io**, **kubevirt.io**, and **snapshot.kubevirt.io**

Note: It includes the Kubernetes events that are associated with the resource. If any resource does not exist, then skip it.

Must gather

The must-gather folder contains common control-plane data that is collected across the virtualization infrastructure for advanced debugging.

The tool always collects all control-plane logs and information. This includes:

- **apiservices**, which contains API routing definitions for `kubevirt.io`, `cdi.kubevirt.io`, and `ssp.kubevirt.io`
- **cluster-scoped-resources**, which contains cluster-wide configuration, including `cdiconfigs`, `cdis`, `nmstate.io`, and `virtualmachineclusterinstancetypes`
- **nodes**, which contains node-specific configuration and health logs for control plane and compute nodes
- **webhooks**, which contains mutating and validating webhook configurations

Automatic cleanup of log packages

This section describes the automatic cleanup feature for diagnostic log packages that are collected from the IBM Fusion environment.

After a log package collection completes, the system automatically removes or sanitizes sensitive information before the package is available to download. This behavior protects sensitive data and supports compliance with enterprise security and data-protection requirements.

Key benefits

- Protects sensitive information by removing or masking confidential data.
- Supports compliance with data-protection and privacy requirements.
- Enables safe sharing of log packages with IBM Support.
- Operates automatically without requiring additional user actions.
- Preserves diagnostic information that is needed for analysis and troubleshooting.

Protected information

The log cleanup process removes or obfuscates sensitive data in collected log packages.

Removed data

- Kubernetes secrets, including `secret` resources and `secret.yaml` files
- Credentials such as passwords, tokens, and API keys
- Authentication files, including `kubeconfig`, pull secrets, and service account tokens
- Private keys, including SSH keys and TLS private keys (`.key`, `.pem`)
- Certificate files, including SSL and TLS certificates (`.crt`)

Masked or obfuscated data

- IP addresses are replaced with consistent placeholder values
- MAC addresses are replaced with consistent placeholder values
- Internal domain names are obfuscated
- Credentials (API keys) and tokens are obfuscated
- PEM certificate content found in files

Unchanged content

The cleanup process removes or obfuscates only sensitive information. All logs, resources, and configuration data that is required for debugging remain intact.

User experience

By default, automatic log cleanup is enabled and requires no manual intervention.

1. Collect logs by using the IBM Fusion UI.
2. The system automatically sanitizes sensitive data in the log package.
3. Download the clean and secure log package.

Configuration

When to change the configuration (optional)

The default configuration is secure and recommended for all environments. Disable automatic log cleanup only in the following scenarios:

- Logs remain strictly within the organization for internal debugging
- IBM Support explicitly requests for unsanitized log packages

Disabling automatic log package cleanup

To disable automatic log package sanitization by using the OpenShift® console:

1. Log in to the OpenShift web console.
2. Switch to Project `<FusionNamespace>` (typically `ibm-spectrum-fusion-ns`).
3. Go to Workloads > ConfigMaps, locate the `appliance-info` ConfigMap, and open it in YAML view.
4. Search for `platformconfigCM` and locate it in the `rackType: base` entry.

```

1 kind: ConfigMap
2 apiVersion: v1
3 metadata:
4   name: appliance-info
5   namespace: ibm-spectrum-fusion-ns
6   uid: 68b876ab-bb8c-410b-949b-873f2b1a42b2
7   resourceVersion: '281859498'
8   creationTimestamp: '2026-01-14T11:49:32Z'
9   annotations:
10    kubectl.kubernetes.io/last-applied-configuration: |
11      {"apiVersion":"v1","data":{"F55L020":{"rackType":"base","rackID":"1","rackSerial":"F55L020","kickstartCM":"kickstart-f55l020","kickstartF
12    managedFields:--
13  data:
14    F55L020: '{"rackType":"base","rackID":"1","rackSerial":"F55L020","kickstartCM":"kickstart-f55l020","kickstartFile":"kickstart-f55l020.json","userconfigSecret":"userc
34

```

5. Save the **platformconfigCM** key value.

```

1
2
3
4
5
6
7
8
9
10
11 serconfigFile": "\user_config.json", "rackName": "F55L020", "rackInfoCM": "rackinfoconfig", "rackInfoFile": "rackinfoconfig.json"}\n"), "kind": "ConfigMa
12
13 >
14
15
16
17
18
19
20
21
22
23
24
25
26
27
28
29
30
31
32
33 nfoCM":"rackinfoconfig","rackInfoFile":"rackinfoconfig.json","platformconfigCM":"platformconfig-f55l020","platformconfigFile":"platformconfig-f55l020.json"}'
34

```

6. Return to Workloads > ConfigMaps, search for **platformconfig** ConfigMap along with its value from the previous step, and open it in YAML view.
7. Locate the **logCollectorConfig** entry in the ConfigMap and update it with the following configuration. If the **logCollectorConfig** entry does not exist, add the following entry to the JSON content of the key **<platform-config-name>.json** (retrieved in step 4):

```
"logCollectorConfig": {"disableLogCleanup": true},
```

8. Save the changes.
The automatic log package cleanup is now disabled.

Call Home in IBM Fusion

IBM Fusion includes a built-in Call Home capability that automatically opens IBM support cases when issues are detected in your environment. The topic explains how Call Home works, what triggers it, and what happens when a ticket is created.

Overview

Call Home is a proactive serviceability feature that monitors your IBM Fusion cluster and notifies [IBM Support](#) when a significant hardware or software issue is detected. Instead of waiting for you to report a problem manually, Call Home sends diagnostic information (along with relevant logs) directly to IBM's support systems (IBM Electronic Problem Determination, Inter-Enterprise Process Director or Salesforce). A support case is opened, and IBM Support can begin working on the problem with full context already in hand.

Call Home operates in two complementary modes:

Mode	What triggers it	How it works
Event-based	An IBM Fusion component detects a hardware or software fault.	Event Manager receives the event from the IBM Fusion component and forwards it to the Callhome Client for ticket creation.
Alert-based	A Prometheus alert defined by an IBM Fusion squad fires in AlertManager.	AlertManager delivers the alert to the Callhome Client through a webhook, and a ticket is created if the alert is in the allowlist.

Both modes share same microservice and ultimately open the same type of IBM Support case. They complement each other: Event-based Call Home covers discrete faults that are raised by IBM Fusion components, and alert-based Call Home covers metric-driven conditions that are monitored by Prometheus.

Event-based Call Home

Event Manager is the entry point for event-based Call Home. IBM Fusion components (storage, compute, networking, and other application operators) send events to Event Manager's API, enriched with structured labels and annotations. Event Manager validates and normalizes these events, then forwards qualifying events to the Callhome Client.

Alert-based Call Home

Alert-based Call Home extends the existing feature to handle Prometheus alerts from OpenShift® AlertManager. It enables ticket creation for metric-driven conditions that do not necessarily produce discrete Kubernetes events. When a critical firing alert occurs on the cluster, the integration automatically formats the alert payload and creates an IBM Support Call Home ticket. For supported alerts, diagnostic log packages are automatically gathered and attached to the support ticket to accelerate problem resolution.

Key capabilities and features

IBM Fusion's Serviceability Operator automatically manages integration with OpenShift AlertManager without requiring manual cluster monitoring configuration:

- Receiver name: **fusion-callhome-alerts**
- Target endpoint: Internal secure service endpoint
https://callhomeclient.<namespace>.svc.cluster.local:<port>/api/v1/callhomeclient/alertmanager/alerts
- Alert matching rule: Captures alerts with **severity = critical**.
- Non-disruptive routing: Configured with **continue: true** in AlertManager route specifications, ensuring that existing notification channels (for example, Slack, Email, PagerDuty) and cluster routing rules continue to operate without interruption.
- Automatic reconciliation: The operator continuously maintains the receiver and route configuration within the **alertmanager-main** secret (**openshift-monitoring** namespace) to safeguard against accidental deletion or configuration drift.
- Alert status handling: Firing alerts are evaluated for ticket creation. Resolved alerts update the local resolution state, which is required before a new ticket can open for the same alert instance. Any other status is silently skipped.

- Fingerprint-scoped deduplication: Each alert is tracked by its **alertname** and AlertManager **fingerprint**. A new ticket is only opened when no creation is in progress, the prior instance is resolved, the prior Salesforce case is confirmed closed through IBM Support APIs. This prevents duplicates for ongoing conditions and premature re-opening after a brief resolution.
- No UI provided: No graphical user interface is exposed in the IBM Fusion user interface for configuring, viewing, or interacting with this feature.

Call Home alerts for Data Foundation service

The following table lists the supported Call Home alerts for the Data Foundation service:

Alert name	Category or component	Message	Documentation
CephClusterCriticallyFull	IBM Storage Ceph Cluster	Storage cluster is critically full and needs immediate expansion.	Troubleshooting
CephMgrIsAbsent	IBM Storage Ceph Manager	Storage metrics collector service is no longer available.	Troubleshooting
CephClusterErrorState	IBM Storage Ceph Cluster	Storage cluster is in an error state.	Troubleshooting
CephMonQuorumLost	IBM Storage Ceph Monitor	Storage is offline when mon quorum is lost. Immediate attention is needed to resolve the mon quorum.	Troubleshooting
CephOSDFlapping	IBM Storage Ceph OSD	Storage daemon osd.x has restarted 5 times in the last 5 minutes. Check the pod events or Ceph status to find out the cause.	Troubleshooting
OdfMirrorDaemonStatus	Red Hat® OpenShift Data Foundation Mirroring	Mirror daemon is unhealthy.	Troubleshooting
NooBaaDatabaseStorageFull	NooBaa Database	NooBaa database on pod noobaa-db-pg-cluster-1 or noobaa-db-pg-cluster-2 is using over 90% of its PVC capacity.	Troubleshooting
CephClusterReadOnly	IBM Storage Ceph Cluster	Storage cluster is read-only and needs immediate data deletion or cluster expansion.	Troubleshooting

- **Benefits of enabling Call Home**
Configure and enable the call home feature as it improves the user experience when IBM Fusion is used.
- **Data privacy with Call Home**
A licensee can configure the IBM Fusion to automatically send specific cluster information to the IBM® support team by using the Call Home feature.
- **Enabling Call Home for IBM Fusion HCI**
You can enable Call Home and remote access from the Support settings page.
- **Configuring Call Home with proxy**
You can configure Call Home to use a proxy server for outbound connectivity to IBM Support.
- **IBM Fusion Call Home Telemetry**
IBM Fusion Call Home Telemetry enhances supportability by providing IBM with valuable insights into system configuration and performance. Telemetry data is collected from various components and securely transmitted to IBM, helping support teams proactively identify issues and optimize system behavior based on real-world usage.
- **Custom Certificate Authority (CA) support for Call Home**
Support for custom Certificate Authority (CA) for IBM Fusion Call Home.

Benefits of enabling Call Home

Configure and enable the call home feature as it improves the user experience when IBM Fusion is used.

The call home feature when enabled provides the following benefits:

1. Improves customer service response time
 - **Scheduled data uploads:**
If the Call Home feature is enabled, then the IBM® support representatives can start with the analysis of the issue that is reported without any delay. The IBM support team can use the cluster data from the Call Home scheduled uploads to do an immediate analysis of the issue. For more information, see [Logs in IBM Fusion HCI](#).

However, if the Call Home feature is not enabled, then the IBM support team first collects debugging data from the IBM Fusion user interface. The whole process takes time to request, collect, and deliver the data, which might cause a delay in resolving the issue on the site.
 - **Selected failure events trigger automatic Call Home uploads:**
If the Call Home feature is enabled, then the event-based uploads feature automatically collects the relevant component-specific information and uploads it to the IBM ECuRep server. The uploaded data enables the IBM support team to immediately find the root cause of the issue that is reported on the customer site.
2. Proactively detects issues
 - Detects violations against best practices and common misconfiguration.
 - Finds out which specific customer site is affected by the reported issue by using tools like High Impact Programming Error Authorized Program Analysis Report (HIPER APARs).
 - Constantly extends the list of automatically detected issues, best practice violations, and common misconfiguration over time.

Note: IBM Fusion user interface displays the list of events.
3. Improves customer support experience in areas of consumability and ease of usage
 - **Uploads gpfs snaps directly from the IBM Fusion system:**
If the Call Home feature is enabled, then a customer can find out the customer number. The requested debugging data is transferred from the customer site cluster or node to the IBM support team by raising a service ticket. For more information, see [Enabling Call Home for IBM Fusion HCI](#).
4. Creates service tickets automatically for reported failures
If the call home feature is enabled, then the system automatically creates Salesforce service tickets for any hardware failures that are reported on customer sites.
Note: A user can configure the Call Home settings on the IBM Fusion user interface.

Data privacy with Call Home

A licensee can configure the IBM Fusion to automatically send specific cluster information to the IBM® support team by using the Call Home feature.

When a licensee enables the Call Home feature, the licensee provides the support contact information, such as names, phone numbers, or email addresses, which are needed during the Call Home feature configuration and activation process.

By default, when a licensee decides to activate and use the Call Home feature, the licensee agrees to allow IBM and its subsidiaries to store and use the licensee's support contact information. This information is processed and used with IBM business relationship and might be shared with third-parties under the direction of IBM. For example, IBM support center representatives or assignees of IBM and its subsidiaries.

The support contact information can be used for processing business orders, business promotions, problem determination, or market research.

When the call home feature is configured and activated, the IBM Fusion collects all monitoring information that is related to system utilization, performance, capacity planning, and service maintenance. The service information includes system failure logs, part numbers, machine serial number, software version, maintenance levels, installed patches, and configuration values.

When the Call Home feature is enabled, the licensee allows IBM to use and share the data, which is gathered from system monitoring functions, within IBM and with IBM business partners and third-parties, such as IBM support centre sub-contractors or assignees. The shared data is used only under the direction of IBM for the following defined purposes:

- Determining a problem.
- Assisting licensee with performance and capacity planning.
- Assisting IBM to enhance IBM products and services.
- Notifying licensee about the licensee's system status and available solutions.

Note: The licensee information excludes the collection and transmission of licensee's financial, statistical, and personal data, and licensee's business plans.

When the Call Home feature is enabled, a licensee agrees to the fact that the licensee's support contact information can be transferred to countries that might not be a member of the European Union. A licensee can disable the Call Home feature at any time.

Enabling Call Home for IBM Fusion HCI

You can enable Call Home and remote access from the Support settings page.

Before you begin

- Ensure that the [Firewall sites](#) are configured for Call Home.
- If your environment requires a proxy, confirm the proxy details and credentials before you proceed.

Note: Telemetry is no longer configured as a separate option. When you enable Call Home, telemetry collection and transmission are enabled automatically. For more information, see [IBM Fusion Call Home Telemetry](#).

About this task

Support status banner

A yellow banner might appear at the header of the Support settings page with messages similar to:

- Support features disabled. Call Home or other support features are not enabled. Review support settings to restore full support capabilities.
This banner is an expected behavior in the following case:
 - Call Home and/or telemetry is disabled
- Support disconnected. One or more support features are not functioning. Review your support settings to restore full support capabilities.
This banner is an expected behavior in the following cases:
 - Call Home or telemetry is enabled but in a failed or degraded state
 - Required contact information is missing or incomplete

After Call Home is successfully enabled and connectivity is restored, the banner clears automatically.

Procedure

1. Open Support settings.

In the IBM Fusion user interface, go to Support > Support settings.

Note: If contact information is not configured, the page displays a warning: `Contact details must be provided before enabling any support settings`. The Enable button for Call Home is disabled until this information is added.

2. Add contact information.

- a. In the Contact information section, click Add.

- b. Enter contact information:

In the Contact information dialog, provide the primary support contact details:

- i. Enter Company name.
- ii. Enter Customer number.
- iii. Enter Primary contact name.
- iv. Enter Primary email address.
- v. Enter Primary phone number:
 1. Select the country code.
 2. Enter the phone number.

- c. Provide the data center location:

In the Data center section, enter the physical location details:

- i. Enter Address line 1.

- ii. Enter Address line 2 (optional).
 - iii. Enter City.
 - iv. Enter State/Province/Region.
 - v. Enter Zip/Postal code.
 - vi. Select the appropriate Country from the drop-down list.
 - d. Click Add to save the information.
 - After you save the information, the warning message is cleared and the Call Home and remote access options become available.
 3. Enable Call Home.
 - a. In the Call Home section, click Enable.
 - b. Select a connection type:
 - Direct connection
 - Proxy connection, if your network requires a proxy
 - c. If you use a proxy, enter the proxy configuration details:
 - Host and port
 - Authentication details or certificates, if required
 - d. Click Test connection to validate connectivity.
 - If the test succeeds, a success confirmation is displayed and Call Home is enabled.
 - If the test fails, an error message explains the issue, for example, a proxy authentication failure or connectivity error. Correct the configuration and test again.
 4. Optional: Enable remote access.
 - a. In the Remote access section, click Enable.
 - b. Confirm the action when prompted.
- Remote access is enabled and ready for use when IBM Support assistance is required.

Note: Enabling remote access does not start a support session automatically. Sessions are initiated only with customer approval.

What to do next

After successful configuration:

- The Call Home section shows an enabled status.
- Any connectivity or configuration issues are surfaced directly on the Support settings page.

These steps ensure that Call Home is correctly enabled and ready to support proactive monitoring and faster issue resolution.

Configuring Call Home with proxy

You can configure Call Home to use a proxy server for outbound connectivity to IBM Support.

About this task

Call Home supports both HTTP and HTTPS proxies, including HTTP, HTTPS (TLS), and HTTPS with mutual TLS (mTLS). Select the connection type based on your environment's ability to allow outbound internet access.

Call Home supports direct connectivity and different proxy configurations to align with common enterprise network and security models.

Important: The Proxy host field must include the protocol: **http://** or **https://**. A hostname without the protocol prefix is not accepted. For example: **http://proxy.example.com** or **https://proxy.example.com**.

Procedure

1. In the IBM Fusion user interface, go to Settings > Support.
2. Review and complete the contact information.
3. In the Call Home section, click Edit.
4. Select a connection type.

Choose the appropriate connection type based on your network configuration:

 - Direct connection**

Use a direct connection when the system can reach IBM Support endpoints directly without routing through a proxy. No additional fields are required for this option.
 - Open proxy**

Use an open proxy when outbound traffic must pass through a proxy that does not require authentication. This option supports both HTTP and HTTPS proxies. Provide a Certificate Authority (CA) certificate only if the proxy uses a non-public CA.
 - Basic authentication**

Use basic authentication when the proxy requires a username and password for access. This option supports HTTP and HTTPS proxies. If HTTPS is used and a private CA issues the proxy certificate, a CA certificate must be provided.
 - Certificate authentication**

Use Certificate authentication when the proxy uses certificate-based security. This option supports TLS and mutual TLS (mTLS), allowing configuration of the CA certificate for server validation and, when required, a client certificate and private key. It is typically used in environments with stricter security or compliance requirements. If required by the proxy, username and password can also be provided.
5. Configure the proxy details as required.

The following fields apply whenever a proxy is configured, regardless of authentication type:

Field	Required	Description
Proxy host	Yes (for proxy connections)	Fully qualified proxy URL. It must start with http:// or https:// .

Field	Required	Description
Port	Yes (for proxy connections)	Network port on which the proxy listens (for example, 8080 or 3128).
Username	Optional	Proxy username, if required by the proxy configuration.
Password	Optional	Proxy password, if required by the proxy configuration.
CA certificate	Conditional	Certificate Authority (CA) is used to validate the proxy server certificate. Required when the proxy uses HTTPS (TLS or mTLS) with a private or internal CA. Supported formats: <code>.crt</code> , <code>.cer</code> , <code>.cert</code> , <code>.ca</code>
Client certificate	Conditional	A client certificate is presented to the proxy during mutual TLS (mTLS). Required only when the proxy enforces client certificate authentication. Supported formats: <code>.crt</code> , <code>.cer</code> , <code>.cert</code> , <code>.ca</code>
Client key	Conditional	Private key corresponding to the client certificate. Required only for mTLS authentication. Supported formats: <code>.pem</code> , <code>.key</code> , <code>.crt</code> , <code>.cer</code> , <code>.cert</code> , <code>.ca</code>

6. Save and test the configuration.

- Click Save to apply the configuration.
- Click Test connection to validate the configuration.
 - If the test succeeds, a success confirmation is displayed and Call Home is configured with the proxy settings.
 - If the test fails, an error message explains the issue. Verify the proxy configuration and test again.

IBM Fusion Call Home Telemetry

IBM Fusion Call Home Telemetry enhances supportability by providing IBM with valuable insights into system configuration and performance. Telemetry data is collected from various components and securely transmitted to IBM, helping support teams proactively identify issues and optimize system behavior based on real-world usage.

Telemetry automatically collects and transmits the data from IBM Fusion components, such as software applications or hardware devices. Also, it is used to gather information about system configuration, usage patterns, and performance metrics. For steps to enable call home telemetry, see [Enabling Call Home for IBM Fusion HCI](#). Note: The system uploads Call Home telemetry data every 24 to 26 hours.

The following details are collected and uploaded as part of call home telemetry support:

IBM Fusion cluster details

Collects statistical insights into IBM Fusion resources, such as the number of pods, deployments, and other key components, along with version and health status details for both OpenShift® and IBM Fusion. Also, it collects node storage consumption details for OpenShift.

IBM Fusion license data

Collects IBM Fusion licensing data. For more information on licensing metrics, see [Understanding the IBM Fusion license report](#).

IBM Fusion events data

Collects the summary of IBM Fusion events by severity and event ID.

IBM Fusion Services

Collects the details such as name, version, health, and upgrade details of different fusion services installed in the cluster. If Backup & Restore service is installed, then it shows the success % of backups and restores.

Hosted clusters

Collects basic count and health status of hosted clusters that are deployed.

Virtual machines

Collects basic count and health status of virtual machines that are created on cluster.

Basic rack details

Collects configuration details including serial number, model, storage type, multi-rack setup, proxy enablement, Disaster Recovery (DR) enablement, IBM serial number, and other IBM Fusion HCI rack-specific parameters.

Node and switch health monitoring

Collects hardware and health details for nodes and switches, including name, vendor, model, firmware, and type. Also, it captures component-level stats such as memory, processors, fans, GPU nodes, cards, power supplies (for nodes), and relevant metrics for switches.

Custom Certificate Authority (CA) support for Call Home

Support for custom Certificate Authority (CA) for IBM Fusion Call Home.

Overview

IBM Fusion Call Home supports custom Certificate Authorities (CAs) to enable seamless operation in enterprise environments that use TLS-intercepting proxies. This support allows Call Home to establish secure connections to IBM support services even when your network uses non-standard certificate authorities.

Importance of custom CA support for Call Home

In many enterprise environments, standard TLS certificates do not meet security policy or network architecture requirements. Custom CA support addresses these challenges by enabling Call Home to trust certificates signed by your organization's certificate authorities.

Use cases and scenarios

Custom CA support is required in the following scenarios:

TLS-intercepting proxies

Many organizations use security proxies that intercept outbound HTTPS connections to inspect traffic for threats. These proxies decrypt the original connection, inspect the content, and then re-encrypt it using an enterprise certificate before forwarding to the destination.

Example flow:

```
Call Home → Corporate proxy → IBM support
            (intercepts and
             re-signs with
             enterprise CA)      (esupport.ibm.com)
```

Without custom CA support, Call Home rejects the re-signed certificates as untrusted, which prevents communication with IBM support services.

Private certificate authorities

Organizations that use private Certificate Authorities sign certificates for internal services and infrastructure. When Call Home communicates through infrastructure secured by these private CAs, it must trust the certificate chain to establish secure connections.

Custom CA integration behavior

Call Home integrates with OpenShift® cluster-wide CA configuration through an automated process:

- Automatic discovery: Call Home automatically detects and uses custom CAs configured at the OpenShift cluster level.
- Dynamic updates: When cluster administrators update CA configurations, Call Home automatically receives and applies these changes.
- Zero configuration: Call Home does not require manual CA configuration.
- Operator-managed: The ISF serviceability operator manages CA injection and updates.

Remote support

Remote support is a service that enables IBM Support representative to remotely access your rack and accomplish essential tasks, such as installation, maintenance, and troubleshooting.

When you contact [IBM Support](#) teams with an issue or question, the support team can initiate a remote connection for problem determination and resolution provided you enable the remote support feature. For the procedure to configure remote support, see [Enabling remote support](#).

Remote support uses the latest security technology to protect the data exchanged during a remote session. All transferred information, including screen views, file transfer data, and identities, are encrypted. Encryption and decryption are from end-to-end, so data cannot be intercepted during transit and can be viewed only from the console of the remote support team. For more information about security considerations, see [Security considerations](#).

Benefits of the remote support

Use remote support to reduce disruptions, optimize workflows, and save time and resources. It leads to an overall enhancement in efficiency and cost savings.

Key benefits of remote support are as follows:

Faster problem solving

You can contact technical experts in your support region to help resolve problems and do not have to wait for data, such as logs, memory dumps, and traces. As a result, problems can be solved faster.

Connection with a worldwide network of experts

IBM Technical support team can call on other worldwide subject experts available through chat, phone, email, or remote assistance to assist with problem determination.

Closer monitoring and enhanced collaboration

You can monitor the activities and join conference calls with IBM Support teams to discuss the next steps.

Save time and money

Many of your problems can be solved without sending an IBM Support representative to your site.

Troubleshooting remote support: Access provisioning

When the IBM support team needs to troubleshoot cluster-level issues in your OpenShift® environment, provide the minimum level of access that is required for the troubleshooting activity.

Tip: Always use **Read-only** access unless the support engineer explicitly requires cluster modifications or deep infrastructure access, such as node-level debugging, CRD manipulation, or operator configuration changes.

Step 1: Create a support user

1. Use a cluster administrator account and log in to the OpenShift web console.
2. Create an **HTPasswd** identity provider for the support engineer. Follow the instructions in the [Red Hat documentation](#).

Step 2: Assign a role

After creating the support user account, grant the user permission to access resources. Choose the role based on the level of access required. Replace **<new-user>** with the username that you created in Step 1.

Access level	Role	Command	When to use
Read-only	cluster-reader	<code>oc adm policy add-cluster-role-to-user cluster-reader <new-user></code>	Inspect resources, view logs, check events
Full admin	cluster-admin	<code>oc adm policy add-cluster-role-to-user cluster-admin <new-user></code>	Cluster modifications, operator restarts, structural configuration changes

Step 3: Obtain and share the login command

The support engineer can authenticate by using either username and password credentials or an OpenShift-issued token.

Option A: Username and password

Use the following command, replacing the variables with the appropriate values:

```
SERVER=$(oc whoami --show-server)
oc login -u <new_user> -p <new_user_password> --server="$SERVER"
```

Option B: Obtain a token from the OpenShift web console

1. Use the newly created support account and log in to the OpenShift web console.
2. In the upper-right corner, click the username dropdown.
3. Select Copy login command.
4. Click Display Token.
5. Copy the complete `oc login --token=... --server=...` command.
6. Share the command with the support engineer by using an approved secure communication channel.

Warning: Treat the login command and token as credentials. Do not send them through public channels, email distribution lists, tickets, or other unapproved communication methods.

Step 4: Revoke the role

After the support engineer completes the troubleshooting session, you can revoke the role that you assigned in Step 2 by running the following command:

```
oc adm policy remove-cluster-role-from-user <cluster-role-name> <username>
```

- [Security considerations](#)
Security considerations information to help you to create for a remote support connection.
- [Enabling remote support through user interface](#)
Enable remote support connection so that IBM Support representatives can remotely access your service node and storage system.
- [Enabling remote support manually](#)
Enable remote support connection manually when the IBM Fusion HCI user interface is not available.
- [Forwarding additional ports for remote support](#)
By default, port 22 is used for SSH based command line access to the service node using remote support. You can configure additional ports to let IBM Service Support Representative access other services like installation stage 2 user interface.

Security considerations

Security considerations information to help you to create for a remote support connection.

Remote support uses the latest security technology to ensure that the data exchanged between support teams and clients is secure. The identities are verified and protected with industry standard authentication technology, and remote support connection sessions are kept secure and private with the use of randomly generated session keys and advanced encryption.

The following are the some key security aspects:

Authorization and access Control

Remote support maintains multiple-level internal authorizations for any privileged access to the IBM Fusion HCI components. Only approved IBM service personnel can gain access to the tools that provide the security codes for IBM Fusion service node command-line access. Remote support sessions can only be initiated by a customer.

After a session is ended, then the support can no longer connect to the service node. Client needs to set timeout in hours while starting a remote support session. Starting a remote support session is considered as a consent from the client for support engineer to connect to the system remotely. The timeout to automatically stop remote support session prevents customers from accidentally keeping connections open.

Strong password protection

Remote support sessions are protected by strong password authentication. Support engineers are authenticated using a challenge and response password exchange. Multi factor authentication ensures that auditing can be achieved at a greater level. Additionally challenge response authentication can be used to grant different level of access to different support engineers.

Advanced Encryption

Remote support implements outbound connections protected by 128-bit MARS or TLS encryption to prevent intruder access to the information exchanged during all remote support sessions. Chat, screen viewing, screen sharing and file transfer data are encrypted end to end, and packets are never decrypted in transit by the communication servers.

Uncompromising firewalls and proxy

Remote support works seamlessly with most firewalls and the connections are possible without any firewall reconfiguration. It requires access to outbound ports at both ends of a connection, so no need to open holes in firewalls. It also supports configuring a proxy for communication.

For more information about how to collect audit logs that includes record of all activities related a remote support session, see [Audit logs](#).

- [Audit logs](#)
Audit logs track and record all activities related to remote access and actions taken during remote support session.

Audit logs

Audit logs track and record all activities related to remote access and actions taken during remote support session.

Audit logs in a remote support connection provides a detailed record of activities, mainly related to security, system operations, and system actions. It tracks all the activities performed by the IBM support representative and customer. The audit logs mainly consists the service node, OpenShift® Container Platform, and node audit details.

Service node audit

The service node audit contains utilities such as **Rsyslog**, **Auditd** (**Audit Daemon**), and **Logrotate** are used which come by default in RHEL.

Rsyslog

Rsyslog is used as a logging utility to generate log files for the commands directly executed only by the IBM support representative in the shell. For example:

```
$ ls /var/log/fusion/
```

Example output:

```
audit.log  audit.log.1  audit.log-20241013
```

The latest logs are stored in the **audit.log** file. Only users with **sudo** access to service node can read these files.

Auditd (Audit Daemon)

The **Auditd** is configured to track all system calls that users execute. It provides detailed audits and tracks the ones that may not be run directly from the command line. This detailed audit captures even the implicit commands that SSR might run from a script. To reduce manual steps, a wrapper script (**fusion-audit**) is provided. The utility asks for start and end date time as a parameter lists the output, and saves the detailed output to a file.

For example:

```
[kni@tc1lgen2001svcnod ~]$ fusion-audit
*****
Welcome to IBM Fusion - Audit Daemon
This utility facilitates the generation of an audit report actions
performed by IBM support during the specified time filter.
*****

Your current date in locale-specific format is as follows:
10/15/2024

Enter start date (in above format) and time, eg: DATE<space>HH:MM:SS
10/11/2024

Enter End date and time in similar format. Leave it blank for current time.

Current time is taken for end time filter

COMMAND: sudo ausearch -sc execve -ts 10/11/2024 -te now -ga ibmsupport -i

*****
Output Summary from 10/11/2024 to now
*****
type=PROCTITLE msg=audit(10/11/2024 18:09:45.548:10668) : proctitle=bash
type=PROCTITLE msg=audit(10/11/2024 18:09:45.634:10684) : proctitle=basename /usr/bin/bash
type=PROCTITLE msg=audit(10/11/2024 18:10:40.713:10694) : proctitle=oc get pods
type=PROCTITLE msg=audit(10/11/2024 18:10:43.984:10697) : proctitle=ls --color=auto
type=PROCTITLE msg=audit(10/11/2024 18:10:48.146:10702) : proctitle=ssh
*****
Detailed Ausearch output saved as AuditReport_2024-10-15_05-45-04.log
[kni@tc1lgen2001svcnod ~]$
```

Logrotate

Multiple files available in this folder as a log rotation rule is applied for this file. By default, weekly rotation is configured. If you want to change it, then see the [Linux man page](#) documentation.

For example:

```
$ cat /etc/logrotate.d/fusion
/var/log/fusion/audit.log {
    weekly
    rotate 7
    compress
    delaycompress
    missingok
    notifempty
    create 0640 root adm
    postrotate
        /bin/systemctl reload rsyslog > /dev/null
    endscrip
}
```

OpenShift Container Platform audit

OpenShift Container Platform provides various logging profiles based on the needs. For more information on profile and the level of content that gets logged, see [Configuring the audit log policy](#) in *Red Hat OpenShift Container Platform* documentation.

For more information on how these logs can be queried based on filters, see [Viewing audit logs](#) in *Red Hat OpenShift Container Platform* documentation.

Node audit

Node audit logs of compute hardware contains the record of actions performed by the user or services on the hardware. It helps you with ensuring accountability, traceability, and regulatory compliance for data access, modification, and security within the IBM Fusion HCI.

Follow the steps to download the node audit logs:

1. Go to Events in the IBM Fusion HCI.
2. Enter the text **CEUSER** in the search description.

It lists all the alerts raised for the actions performed by the IBM support representative .

3. Click Download.
4. For any further auditing of actions performed on the node, collect system health check logs and contact IBM Support. For steps download logs, see [Collecting log packages for IBM Fusion HCI](#)

Enabling remote support through user interface

Enable remote support connection so that IBM Support representatives can remotely access your service node and storage system.

About this task

From the Support settings page of the user interface, enter the contact information, optional proxy server details, and enable the remote support option. After you enable the remote support, you can start or stop remote sessions.

Procedure

1. From the IBM Fusion HCI user interface, go to Settings > Support.
The Support settings page gets displayed.
2. In the Contact information section, enter the following information.

Company
Enter the name of your organization.

Customer number
Enter the IBM ID assigned to your organization.

Primary name
Enter the primary name of your contact.

Primary phone
Enter the phone number of your primary contact.

Primary email
Enter the official email address of your primary contact.
3. Click Save.
A success message for successfully saving the contact information is displayed.
Note: The Configure button in the Proxy settings section and the Remote access disabled toggle button in the Remote support section are enabled only after the contact information is saved successfully.
4. Optional (required for offline environments): In the Proxy settings section, click Configure and enter the following Proxy settings information. If your environment does not have direct connectivity to the IBM Remote Support endpoint, you must configure a proxy server to route the remote support traffic.

Host address
Enter the host address.

Port
Enter the port details.

Username (optional)
Enter the username of the server.

Password (optional)
Enter the password of the server.

The username and password fields are optional.
Note: You can skip proxy configuration if your environment has direct internet access to the Remote Support endpoint. If direct connectivity is not available (offline deployments), you must configure a proxy server to establish the remote support connection.
5. Click Save
6. In the Remote support section, click the toggle to enable the remote support connection.
The Start session is visible in the user interface after you click the Remote support toggle button.
7. If you want to initiate a remote session, then click Start session.
The Start remote support session window gets displayed.
8. Enter the Session time and click Start session.
The IBM support team can log in to the service node after starting the remote support session. Share necessary credentials with the IBM Support, such as OpenShift® token, login details for switch and nodes.
9. The Stop session button gets displayed instead of the Start session. The session automatically closes after the scheduled time. Alternatively, you can choose to end the session anytime with the Stop session button. If you enabled the session during installation, you can click Stop session button in the Remote support bar that is located near to the title bar.

Enabling remote support manually

Enable remote support connection manually when the IBM Fusion HCI user interface is not available.

About this task

The following instructions can be used to configure and start remote support session in case the IBM Fusion HCI user interface is not available. The following steps are to be run only when necessary as it requires manual steps, which can be error prone. If your environment does not have direct connectivity to the IBM Remote Support endpoint (for example, in offline deployments), you must configure a proxy server as part of this procedure.

To forward additional ports for remote support, see [Forwarding additional ports for remote support](#).

Important: As this is a manual procedure, be sure to explicitly stop the session after you are done; otherwise, it continues to remain active.

Procedure

1. Log in to the service node with **kni** user details.
2. Optional (required for offline environments): Configure proxy. If your deployment does not have direct internet access to the Remote Support endpoint, you must configure a proxy server to establish the remote support connection.

- a. Update the `/etc/ibmtrct.conf` file.

- b. Ensure you update the **ProxyURL** field.

Example of **ProxyURL** filed with username and password:

```
ProxyURL= dummyuser:dummyspassword@9.23.x.x:xx
```

Example of **ProxyURL** filed without username and password:

```
ProxyURL= 9.23.x.x:xx
```

3. Configure remote support.
 - a. Edit the `/var/opt/ibm/trc/target/profiles/lightoutprofile.properties` file.
 - b. Ensure you update the following fields:

```
Custom.CustNumber=<IBM_assigned_customer_number>
Custom.CustName=<Company_name >
ProfileEnabled flag set to "true"
```

4. Run the following command to restart the service.

```
sudo service ibmtrct restart
```

5. Validate the logs.

The logs are available in the `/var/opt/ibm/trc/target` directory. The log files are collected on a daily basis and you find the log file for each day in the `trc_base_Day.log` format.

For example:

```
[kni@servicenode-1 target]$ ls trc_base_*.log
```

Example output:

```
trc_base_Fri.log trc_base_Mon.log trc_base_Sat.log trc_base_Sun.log trc_base_Tue.log trc_base_Wed.log
```

6. Set flag to false to stop the remote support session.

.

```
Custom.CustNumber=<IBM_assigned_customer_number>
Custom.CustName=<Company_name >
ProfileEnabled flag set to "false"
```

7. Restart the service for the changes to take effect.

```
sudo service ibmtrct restart
```

Forwarding additional ports for remote support

By default, port 22 is used for SSH based command line access to the service node using remote support. You can configure additional ports to let IBM Service Support Representative access other services like installation stage 2 user interface.

About this task

All remote support communication is conducted over HTTPS, with no need to open any additional ports.

Procedure

1. Log in to the service node with **kni** user details.
2. Edit the `/var/opt/ibm/trc/target/profiles/lightoutprofile.properties` file.
3. Update the **TunnelList** field.

For example:

```
Old value: TunnelList = command_line\tcp@localhost\:22
New value: TunnelList = command_line\tcp@localhost\:22,install_ui\tcp@localhost\:3000
```

4. Save and close the properties file.

Note: If there is an ongoing remote support session, then stop and the start session for the changes to take effect.

Password rotation

The password rotation feature automatically updates hardware (nodes) credentials at regular intervals to enhance system security and meet enterprise compliance requirements. It minimizes the risk of credential compromise by eliminating the need for manual password updates.

The system manages password rotation internally and applies it to supported hardware components without affecting normal operations. The system securely stores updated credentials and allows only authorized components to access them.

The system logs all password rotation activities to support auditing and traceability. It ensures that administrators can monitor credential changes and verify adherence to security policies.

- [Enabling password rotation for IBM Fusion HCI system](#)
Steps to configure and manage password rotation for hardware credentials in the IBM Fusion HCI system.
- [External secret rotation](#)
This section describes how to integrate an external vault or any other external secret management solution.

Enabling password rotation for IBM Fusion HCI system

Steps to configure and manage password rotation for hardware credentials in the IBM Fusion HCI system.

Before you begin

- Ensure that you have the required administrative privileges to modify cluster configuration.
- If you plan to use an external Vault, ensure that the Vault is installed, configured, and accessible from the cluster.

About this task

Password rotation feature is introduced with multiple configurable strategies to enhance security and meet enterprise compliance requirements.

You can configure password rotation by updating the `credentialRotation` section in the `platformconfig` ConfigMap. The system supports internal management, external secret management integration, or disabling the feature entirely.

Procedure

1. Log in to the cluster by using the OpenShift® CLI or user interface.
2. Go to the `ibm-spectrum-fusion-ns` namespace.
3. Edit the `platformconfig` ConfigMap for the base rack.
4. In the `credentialRotation` section, choose one of the following strategies:
 - Internal (default):
 - Internal strategy is supported only on service node rack.
 - Passwords are stored on the service node rack.
 - Credentials are automatically rotated every 90 days.
 - The system fully manages the rotation.

Example configuration:

```
"credentialsPolicy": {
  "strategy": {
    "type": "internal",
    "kmsProvider": {
      "name": "k8sSecret",
    },
    "rotationPeriod": 90
  },
  "sshKeyRotationPeriod": 90
}
```

- External:
 - Enables integration with an external secret management system. As of now, HashiCorp vault is supported. To configure your own secret management system, you must adhere to the requirements stated in [External secret rotation](#).
 - The external vault manages the password rotation based on its policies.

Example configuration:

```
"credentialsPolicy": {
  "strategy": {
    "type": "external"
  },
  "sshKeyRotationPeriod": 90
}
```

- None:
 - Disables password rotation completely.

Example configuration:

```
"credentialsPolicy": {
  "strategy": {
    "type": "none"
  }
}
```

The password rotation configuration is applied to the system based on the selected strategy.

SSH key rotation

- SSH key rotation is supported for the KNI user.
- It is internally managed and operates independently of password rotation.
- If the **none** strategy is selected, SSH key rotation is also disabled.

External Vault configuration

To use an external Vault, configure and integrate the HashiCorp Vault with the system.

Important: When mapping secrets from the external Vault, ensure that the Vault secret contains the same key-value pairs as the original secret, and that the values are stored in plain text. The password must strictly comply with the [hardware complexity requirements](#).
Example configuration:

```
apiVersion: secrets.hashicorp.com/v1beta1
kind: VaultStaticSecret
metadata:
  name: <vss-name>
  namespace: <fusion-ns>
spec:
  type: kv-v2
  mount: kv
  path: <secret-path>
  destination:
    name: <rotation-secret-name>
    create: false
  refreshAfter: 30s
  vaultAuthRef: <static-auth-name>
```

Important: The **destination.name** field must follow this format: **<original-secret-name>-rotation**

Troubleshooting password rotation

You can monitor and troubleshoot password rotation issues in IBM Fusion HCI by using events, metrics, and the **SpectrumFusion** custom resource (CR). The status of password rotation is reported for each node in the CRs. For node-specific details, see the **ComputeMonitoring** CR.

Monitoring password rotation

- Track events and metrics to verify that rotation operations are proceeding as expected.
- Check the **SpectrumFusion** CR for the final status of password rotation.
- For compute nodes, consult the **ComputeMonitoring** CR for rotation status specific to each node.
- For service node SSH key, consult the **SpectrumFusion** CR for rotation.

Common issues and resolution

- Node is down:
 - Symptom: Rotation status shows failure for a node.
 - Resolution: Ensure that the affected node is up and operational. Resolve any hardware or network issues before attempting rotation again.
- Password does not meet [hardware complexity requirements](#):
 - Symptom: Rotation fails for a specific component or node.

- Resolution: Update the password configuration to comply with the hardware complexity rules. Ensure that the new password matches the hardware-defined rotation policy.
- Internal Vault update issues:
 - Symptom: IBM Fusion HCI console shows events indicating a Vault secret update failure.
 - Resolution: Verify that the Vault service is running on the service node. If the service is not running, wait approximately 15 minutes for Vault to become fully operational. Once Vault reaches an active and unsealed state, the failed secret rotation is reattempted. If Vault is still not active and unsealed after 15 minutes, perform the manual recovery steps to restore Vault to an active and unsealed state. For more information about Vault issues and their resolutions, see [Troubleshooting Vault](#).
- External Vault integration issues:
 - Symptom: Rotation fails when you use an external vault.
 - Resolution: Verify that the Vault connection is valid, the secret exists, and key-value pairs match the required format. Ensure that the `VaultStaticSecret` resource is correctly configured.

External secret rotation

This section describes how to integrate an external vault or any other external secret management solution.

Overview

You can integrate an external vault or any other external secret management solution to manage periodic credential rotation. You can also implement a custom process to rotate secrets at regular intervals.

Important: Externally rotated secrets or custom-managed secrets must follow the required format.

- Use the prescribed secret naming convention
- Preserve the exact key-value structure of the original secret

Failure to comply with these requirements might result in rotation or integration failures.

Requirements and constraints

- The rotation secret name must use the original secret name with the `-rotation` suffix. For example: `<original-secret-name>-rotation`
- All values must be Base64 encoded.
- The secret must use the same keys as the original secret.
- Do not add fields and do not remove fields.
- The namespace must match the IBM Fusion namespace, for example, `ibm-spectrum-fusion-ns`.
- The password must strictly comply with the [hardware complexity requirements](#).

Secret template

Use the following template when you update a rotation secret:

```
apiVersion: v1
kind: Secret
metadata:
  name: <rotation-secret-name>          # Format: <original-secret-name>-rotation
  namespace: <namespace>
type: Opaque
data:
  ceUserGroup: <base64-ce-user-group>
  ceUserName: <base64-ce-user-name>
  ceUserNumber: <base64-ce-user-number>
  ceUserPasswrd: <base64-ce-user-password>

  defaultUserGroup: <base64-default-user-group>
  defaultUserName: <base64-default-user-name>
  defaultUserNumber: <base64-default-user-number>
  defaultUserPasswrd: <base64-default-user-password>

  isfmgmtUserGroup: <base64-isfmgmt-user-group>
  isfmgmtUserName: <base64-isfmgmt-user-name>
  isfmgmtUserNumber: <base64-isfmgmt-user-number>
  isfmgmtUserPasswrd: <base64-isfmgmt-user-password>
```

Password hardware complexity requirements

Length: Exactly 15 characters

Required character types (minimum 1 each)

- Uppercase letters (A–Z)
- Lowercase letters (a–z)
- Numbers (0–9)
- Special characters from: `_ - @`

Critical rules

- The first character must be a letter (cannot be a number or special character).
- Only these special characters are allowed: `_ - @`

Note: Password complexity requirements can vary depending on the hardware model and firmware version.

Custom certificate expiration alert

This section provides information about custom certificate expiration monitoring and alerting for critical cluster components.

About this task

The certificate expiration alert feature proactively monitors the validity of custom certificates used by critical cluster services such as the API server, cluster proxy, and ingress, and generates alerts before certificates expire to help prevent service disruptions.

When you enable this feature, the system periodically checks certificate validity and raises warning and critical alerts based on configurable thresholds. It ensures that you can take timely action to renew certificates and maintain uninterrupted cluster operations.

The monitoring process is lightweight and does not affect system performance or availability. The system logs all alert events to support auditing, observability, and operational tracking.

Components monitored

The system generates alerts for certificate expiration of the following components:

- API server
- Cluster proxy
- Ingress

Configuration of custom certificate expiration alerts

Certificate expiration monitoring is configured in the `platformconfig` ConfigMap for the base rack by using the `certificateExpiryCheck` section. You can enable or disable this feature and define alert thresholds for warning and critical events.

Example configuration:

```
"certificateExpiryCheck": {
  "enable": true,
  "warningEventPeriod": 120,
  "criticalEventPeriod": 90
}
```

- **warningEventPeriod**: Number of days before certificate expiration when the system generates a warning alert. In the prior example, the system raises a warning 120 days before expiration.
- **criticalEventPeriod**: Number of days before certificate expiration when the system generates a critical alert. In the prior example, the system raises a critical alert 90 days before expiration.

Procedure

Updating the configuration

1. Edit the `platformconfig` ConfigMap in the base rack.
2. Modify the `certificateExpiryCheck` section as required.
 - Set **enable** to **true** or **false** to enable or disable monitoring.
 - Adjust **warningEventPeriod** and **criticalEventPeriod** thresholds based on your operational requirements.
3. Save and apply the changes.

Results

The updated configuration takes effect after you apply it. The system begins monitoring certificate expiration based on the configured thresholds.

Alerts or event IDs

The system generates the following event IDs for certificate expiration monitoring:

Event ID	Severity	Description	Parameters
BMYSVC2004	Warning	Custom certificate for component %s expiring in %d days.	• %s: Component name (API server, cluster proxy, or ingress)
BMYSVC3003	Critical	Custom certificate for component %s expiring in %d days.	• %d: Number of days until expiration

Configuring License Service Reporter for IBM Fusion

Configure License Service Reporter to obtain a unified view of IBM Fusion licensing metrics. License Service Reporter supports this feature and can be extended to IBM Fusion. In addition to the IBM Fusion user interface, it provides an additional view of licensing metrics, offering deeper insights. It can also be configured across multiple clusters, enabling centralized monitoring and reporting of license usage in distributed environments.

Before you begin

- Ensure that the newest version of License Service Reporter is installed, with support for Usage Metering Operator as a data source.
- Review the prerequisites for IBM License Service Reporter in the [Installing and configuring License Service Reporter](#) section.

Install and configure License Service Reporter

Ensure that the IBM License Service Reporter is installed on the cluster. If it is not installed, follow the instructions in the [Installing License Service Reporter from public container registry](#) section.

Configure a connection to the License Service Reporter

Follow the steps in the [Configuring a connection to License Service Reporter by using the OpenShift® console](#) section to connect the Usage Metering Operator in the Fusion namespace to License Service Reporter.

Use the following high-level steps and documentation links to simplify the setup process for IBM Fusion.

Create the following resources in the namespace where IBM Fusion is installed:

Create the ConfigMap

Edit the following YAML to match your environment. Use the URL and certificate that is provided by License Service Reporter.

```
kind: ConfigMap
apiVersion: v1
metadata:
  name: <name>
data:
  url: '<License Service Reporter URL>'
  tls.crt: |
    <License Service Reporter certificate>
```

For more information on obtaining the License Service Reporter's URL and certificate, see [Creating the ConfigMap](#).

Create the secret

To create the secret that is used to configure the connection to the License Service Reporter, update the following YAML to be in line with your environment:

```
kind: Secret
apiVersion: v1
metadata:
  name: <name>
data:
  token: <License Service Reporter token>
type: Opaque
```

For more information on retrieving the License Service Reporter token, see [Creating the secret](#).

Create the configuration Custom Resource (CR)

1. Log in to the OpenShift console of the cluster where IBM Fusion is deployed.
2. Open the IBM Fusion namespace.
3. Go to Operators > Installed Operators.
4. Select IBM Usage Metering Operator and open the IBM Usage Metering tab.
5. Click ibm-usage-metering-fusion and open the YAML tab.
6. Add the following content to the **spec** section and save:

```
spec:
  sender:
    reporter:
      configMapName: <Name of the ConfigMap>
      secretName: <Name of the secret>
```

Note: The **configMapName** and **secretName** are the names of the ConfigMap and secret that are created in the previous steps.

Results

After completing the configuration, a connection is set and the Usage Metering Operator begins sending data to License Service Reporter. It enables a unified view of IBM Fusion licensing metrics.

Example of the unified view of IBM Fusion Licensing metrics in License Service Reporter.

- **Usage metering operator setup**

• License Service Reporter setup

License Usage

Licensing data is from the following clusters: `ibm-spectrum-fusion-ns.apps.f36f016.fusion.tadn.ibm.com`

Download audit snapshot

Time period: October 2025

Select metrics to display: All metrics

Select clusters to display: ibm-spectrum-fusion-ns.apps.f36f016.fusion.tadn.ibm.com

Product	Peak usage	Percent of threshold	Threshold	License usage metric	Peak usage date
IBM Fusion	1	—	Not set	Backup Restore Service	13 October 2025
IBM Fusion	3165	—	Not set	Backup Storage Gb	13 October 2025
IBM Fusion	0	—	Not set	Data Cataloging Service	13 October 2025
IBM Fusion	0	—	Not set	Ibm Gas Service	13 October 2025
IBM Fusion	2	—	Not set	Node Smt Max	13 October 2025
IBM Fusion	384	—	Not set	Processor Core	13 October 2025
IBM Fusion	57231	—	Not set	Storage Fdb	13 October 2025

What to do next

To log in to License Service Reporter console, follow these steps:

- For more information on getting the console route, see [Retrieving License Service Reporter console route](#).
- For more information on how to retrieve the credentials to login, see [Retrieving credentials for basic authentication](#).

Troubleshooting serviceability issues

List of all troubleshooting and known issues in Events, Log collection, and Call Home.

IBM Fusion licensing audit snapshot is unavailable

Problem statement

The IBM Fusion licensing audit snapshot is unavailable .

Resolution

Follow the steps to resolve the issue:

1. Run the following steps to check the IBM Fusion license service configuration:
 - a. Log in to the OpenShift® Container Platform web console.
 - b. Go to Workloads > CronJobs.
 - c. Select the Licensig-CronJob and go to Jobs tab.
 - d. Ensure that the cronjob is set up and running successful.
 - e. If the cronjob is in a failed state, then create a new job by selecting Start Job under Actions drop-down.
 - f. If the issue still persists after creating a new job, then contact [IBM support](#).
2. Run the following steps to check for UMS state:
 - a. Log in to the OpenShift Container Platform web console.
 - b. Switch to Project **ums-fusion**.
 - c. Go to Installed Operators.
 - d. Check whether IBM Usage Metering Operator status is Succeeded.
 - e. Go to Workloads > Pods and make sure that one pod of **ibm-usage-metering-operator** (with prefix **ibm-usage-metering-operator**) is in a running state.
 - f. Switch to Project **<fusion-namespace>** and make sure that one pod of **ibm-usage-metering-instance** is in a running state.

Log collector does not work in IBM Fusion without primary storage

Run the following commands to start logcollector without persistent storage.

```
oc patch isflcdep logcollector --type=merge -p '{"spec":{"storageclass":"","replicas":1}}'
oc delete deployment logcollector
```

Note: New pods are created within a few minutes, after which log collection becomes available.

Unable to delete proxy config from IBM Fusion user interface

Problem statement

Unable to delete proxy configurations available on the IBM Fusion user interface.

Resolution

Follow the steps to resolve the issue:

1. Important: Ensure that you disable the remote support connection before you update or delete the proxy configuration.
Disable remote support connection from the IBM Fusion HCI user interface as follows:
 - a. From the IBM Fusion HCI user interface, go to Settings > Support.
The Support settings page gets displayed.
 - b. In the Remote support section, click the toggle button to disable the remote support connection.
Note: Disable the remote support connection only if it is enabled.
2. Log in to the service node as a **kni** user.
3. Remove the proxy credential from pass tool on the service node.

```
pass rm -f remoteSupport
```

4. Clean up the proxy details related to remote support from **/home/kni/isf-ui/conf/proxydata.json** on the service node.

```
jq 'del(.remoteSupport)' /home/kni/isf-ui/conf/proxydata.json > temp.json && mv temp.json /home/kni/isf-ui/conf/proxydata.json
```

5. Refresh the IBM Fusion HCI or install user interface.

Events that go through the trap server do not get created in IBM Fusion

Problem statement

Sometimes, events that go through the trap server do not get created in IBM Fusion.

Resolution

If you see the following details in the trapserver logs, follow the steps as a workaround:

```
Listening for traps on 0.0.0.0:31620
[fd8c:215d:178e:c0de:a94:efff:fe3:35cd]:41493 byte array parsed in is not a sequence

```

- Restart the trapserver pod in the **ibm-spectrum-fusion-ns**.
- Run the following command to delete all the **ComputeMonitoring** CRs that are present in the **ibm-spectrum-fusion-ns** namespace.

```
oc delete cmo --all -n ibm-spectrum-fusion-ns
```

Wait for the custom resource instances to get recreated.

- Restart BMC of all the compute nodes by executing **resetbmc** command from the BMC command line.

Log status shows complete for downloaded log file with 0-bytes size

Problem statement

The Log status shows complete for downloaded log file with 0-bytes size. The status should be failed if logs are not collected, but it shows completed with 0-bytes size.

Cause

1. Pods get evicted because of a lack of storage space.
2. The ongoing jobs are taking time to get storage space, but if it takes more time, then they are marked as stale and automatically get cleaned up.

Resolution

There are two methods to resolve this issue:

Method 1

1. Delete the unnecessary logs through the IBM Fusion HCI user interface to get storage space. For more information, see [Delete a log package](#).
2. Delete the on going jobs that are taking a long time and retry the job again.

Important: Method 2 is applicable only when the log collector is using PV.

Method 2

- You can increase the log collector PVC size by following the steps:
 1. Log in to the Red Hat® OpenShift Container Platform web console.
 2. Go to Storage > PersistentVolumeClaims.
The PersistentVolumeClaims page gets displayed.
 3. Select the log collector PVC that you want to modify.
 4. Click the ellipsis icon and select Expand PVC.
The Expand PersistentVolumeClaims page gets displayed.
 5. Set the PVC value that you want and click Expand.

Log collector deployment fails with CrashLoopBackOff due to Init container failure

Problem statement

When using Global Data Platform storage in an IBM Fusion HCI cluster, the **init** container of the log collector pod may fail to set permissions on the logs directory. As a result **init** container fails and the log collector pod enters a **CrashLoopBackOff** state.

Resolution

Follow the steps to resolve the issue:

1. Delete the log collector deployment and wait for it to be automatically recreated by the serviceability operator.
Note: It may take 5 minutes for the deployment to get recreated.
2. Important: If step 1 does not fix the problem and the pod is still in the **CrashLoopBackOff** state, try this step:
If the issue persists, verify the presence of the **init-set-ownership** **init** container and patch the deployment as follows:
 - a. Run the following command to check for the **init** container.

```
oc get pod <log-collector-pod> -n ibm-spectrum-fusion-ns -o jsonpath='{.spec.initContainers[*].name}'
```

- b. If present, apply the patch using the command for your operating system:

For Linux or macOS:

Use the following command:

```
oc patch deployment logcollector -n ibm-spectrum-fusion-ns -p '{"spec":{"template":{"spec":{"initContainers":[{"name":"init-set-ownership","securityContext":{"capabilities":{"add":["CHOWN"]}}}]}}}}'
```

For windows:

Use the following command:

```
oc patch deployment logcollector -n ibm-spectrum-fusion-ns -p '{"spec":{"template":{"spec":{"initContainers":[{"name":"init-set-ownership","securityContext":{"capabilities":{"add":["CHOWN"]}}}]}}}}'
```

This patch allows the **init** container to change ownership of the logs directory, ensuring the log collector starts successfully.

3. If the issue still persists, then [IBM support](#).

Known issues

- In the Logs page of the IBM Fusion user interface, if you select System Health Check option during log collection, then it takes longer than usual time to complete. It is observed that the log collection process might take 20 to 25 minutes. In some cases, it can be due to many directories and multiple IMM log file collection process.
- For IBM Storage Scale warning events, the fixed status might be incorrect.
- Sometimes, in the Events page, the Source column of the events list might be incorrect.
- Events are not created for IBM Storage Scale events with entity_name fields that do not conform to the URL path components (^([A-Za-z0-9](-A-Za-z0-9_)]*)?[A-Za-z0-9])?\$).
- Call Home ticket creation can have a failed state when the system is not entitled or the Call Home server does not respond with the ticket number. Click Verify connection to check the test connection.
- To prevent a deadlock condition, the event manager must be restarted every 24 hours. Run the following command to restart the event manager:

```
oc rollout restart deployment eventmanager
```

- Sometimes, the automatic upload of logs might not happen and the Call Home would fail. In such cases, manually upload the logs.
- If you power off a control node wherein the trap server pod is running, then the migration of trap server pods to a different node fails. As a result, the trap server pod may get stuck in the terminating state, and some SNMP trap events may fail to capture and display.
- In rare scenarios, the Events page comes up as empty because of a backend error due to a load with a 504 Gateway error. Generally, this page comes up after sometime automatically as the system recovers. Try again after some time.
- One possible reason is log collector pod runs out of space and no space is available on it. This can happen when too many logs are collected in short period. The solution is to delete already collected logs from Fusion UI which are no longer required.

Workaround

- From the title bar, click the help icon and select Support logs.
- Identify and delete logs through ellipsis menu in the Support logs page.
- If Data Foundation log collection request or requests for multiple log packages collected simultaneously fails or stuck for more than 6 hours, then update the pod memory to 12000MiB instead of 6000MiB in the log collector deployment at `spec.containers[0].resources.limits.memory` and then attempt the log collection again one by one.
- Sometimes, an intermittent partial log collection error occurs for node log packages in case of multi-rack set up.

Workaround

- Retry to collect node logs again. For steps, see [Collecting log packages for IBM Fusion HCI](#).
- If the issue persists, then contact IBM team to get the commands (FFDC) to collect the individual node logs.

Events and error codes message references in IBM Fusion HCI

This reference information provides a consolidated view of all the events or error messages that can be displayed when the IBM Fusion system might result in an event or an error.

About event or error messages

When you encounter an event or error message in a log or on other parts of the IBM Fusion user interface, look up the event or error message by its prefix to find more information. Use the events and error messages to diagnose and solve problems when you troubleshoot the IBM Fusion system.

Message prefix format

A message number format denotes the type of message and with which component it is associated with. The default prefix starts as **BMX** in the code, which is followed by one of these tags:

- The compute node-related events tag is associated with **CO** in the message code.
- The installation-related events tag is associated with **IN** in the message code.
- The backup and restore-related events tag is associated with **BR** in the message code.
- The network-related events tag is associated with **NW** in the message code.
- The upgrade-related events tag is associated with **UP** in the message code.
- The call home related events tag is associated with **CH** in the message code.
- The disaster recovery-related events tag is associated with **DR** in the message code.
- The hardware-related events tag is associated with **XC** in the message code.
- The 4 digits after the tag denote the number of the event or error message. For example, **0000**.
- The Cumulus Network Switch events tag is associated to **BMXCUxxxx** in the message code.
- The list of hardware trap events that can open tickets tag is associated to **BMXXC** and **BMXDL** in the message code.

An example of a message prefix format is **BMXCO0001**.

Message severity tag

A severity tag is a one-character alphabetic code, followed by a message. You can determine the message severity by examining the text or by contacting the IBM® Support. To collect logs, see [Collecting log packages for IBM Fusion HCI](#).

Table 1. Message severity tags

Severity tag	Message type	Meaning
C	CRITICAL	Indicates a critical condition that must be corrected immediately. The system discovered an internal inconsistency of some kind. The system functioning might be halted or the system might attempt to continue despite the inconsistency. Report these errors to IBM® Support.
I	INFORMATIONAL	Indicates normal operation. This message by itself indicates that nothing is wrong; no action is required.
W	WARNING	Indicates a problem, but the system functioning continues. The problem can be a transient inconsistency. It can be that the action skipped some operations on some objects, or is reporting an irregularity that could be of interest.

Hardware events and error codes

IBM Fusion HCI supports Lenovo and Dell servers. It monitors these servers for hardware events such as CPU, DIMM, drive, and fan issues, as well as BMC-related events like misconfigurations and firmware errors. Event IDs start with BMXDL for Dell and BMXXC for Lenovo.

Install events and error codes

List of all the events that you might encounter during installation.

Upgrade events and error codes

List of all the events that you might encounter during upgrade.

Compute events and error codes

List of all the events that you might encounter in compute nodes.

Network events error codes

List of all the events that you might encounter in network node.

Metro-DR events and error codes

List of all the events and error codes that you might encounter in Metro-DR setup.

- [Global Data Platform events and error codes](#)
List of all the events and error codes that you might encounter while you work with storage.
- [Data foundation events and error codes](#)
List of all the events and error codes that you might encounter while you work with Data Foundation storage.
- [High availability cluster events and error codes](#)
List of all the events that you might encounter during High availability cluster setup.
- [IBM Data Cataloging events and error codes](#)
List of all the events that you might encounter while you work with IBM Data Cataloging for the IBM Fusion HCI .
- [Backup & Restore events and error codes](#)
List of all the events that you might encounter during Backup & Restore for the IBM Fusion HCI.
- [Connection services events and error codes](#)
List of all the events that you might encounter during connection service for the IBM Fusion HCI .
- [Content-Aware Storage events and error codes](#)
List of all the events that you might encounter while you work with CAS for the .
- [Serviceability events and error codes](#)
List of all the events that you might encounter that related to serviceability.
- [Hosted Control Plane events and error codes](#)
List of all the events that you might encounter that related to Hosted Control Plane.
- [Virtualization events and error codes](#)
List of all the events that you might encounter that are related to Red Hat OpenShift Virtualization on ROKS clusters.
- [Software Hub events and error codes](#)
List of all the events and error codes that you might encounter while you work with storage.

Hardware events and error codes

IBM Fusion HCI supports Lenovo and Dell servers. It monitors these servers for hardware events such as CPU, DIMM, drive, and fan issues, as well as BMC-related events like misconfigurations and firmware errors. Event IDs start with BMYDL for Dell and BMYXC for Lenovo.

Refer to the respective vendor documentation for detailed descriptions and recommended actions.

- [Events and error codes for Dell hardware](#)
Hardware events or alerts raised for Dell hardware failures.
- [Events and error codes for Lenovo hardware](#)
Hardware events or alerts raised for Lenovo hardware failures.

Events and error codes for Dell hardware

Hardware events or alerts raised for Dell hardware failures.

Hardware trap events

IBM Fusion HCI converts Dell hardware trap events into IBM Fusion events for streamlined observability. Each event includes a **Reference ID (RefID)** matching the original Dell event identifier. Search for the **RefID** within the following Dell documentation for detailed information on the specific error or alert: [Dell error and event reference guide](#).

Call Home events

- [BMYDL2153](#)

CPU arg1 has a thermal trip (over-temperature) event.

BMYDL2153

Fan arg1 RPM is less than the lower critical threshold.

Severity

Critical

Problem description

It indicates the fan is not performing optimally. The fan may be installed improperly or may be failing. Fan speeds may have increased to protect the system.

User actions

Do the following steps to diagnose the error:

1. If you have enabled Call Home feature, then the system automatically collects system health check collection set logs and raises a Call Home ticket.
2. If you have not enabled Call Home feature, collect the [Nodes and System health check](#) logs and contact [IBM support](#).

BMYDL2161

The system board arg1 temperature is less than the lower critical threshold.

Severity

Critical

Problem description

It indicates the Ambient air temperature is too cool.

User actions

Do the following steps to diagnose the error:

1. If you have enabled Call Home feature, then the system automatically collects system health check collection set logs and raises a Call Home ticket.
2. If you have not enabled Call Home feature, collect the [Nodes and System health check](#) logs and contact [IBM support](#).

BMYDL2185

Power supply arg1 failed.

Severity

Critical

Problem description

It indicates the power supply is failed.

User actions

Do the following steps to diagnose the error:

1. If you have enabled Call Home feature, then the system automatically collects system health check collection set logs and raises a Call Home ticket.
2. If you have not enabled Call Home feature, collect the [Nodes and System health check](#) logs and contact [IBM support](#).

BMYDL2225

The system board battery is absent.

Severity

Critical

Problem description

It indicates the system settings may be preserved if input power is not removed from the power supplies.

User actions

Do the following steps to diagnose the error:

1. If you have enabled Call Home feature, then the system automatically collects system health check collection set logs and raises a Call Home ticket.
2. If you have not enabled Call Home feature, collect the [Nodes and System health check](#) logs and contact [IBM support](#).

BMYDL2265

Multi-bit memory errors are detected on the memory device at location(s) arg1. Immediately replace the DIMM.

Severity

Critical

Problem description

It indicates the memory has an uncorrectable error. System performance may be degraded and the operating system and/or applications may fail as a result of this.

User actions

Do the following steps to diagnose the error:

1. If you have enabled Call Home feature, then the system automatically collects system health check collection set logs and raises a Call Home ticket.
2. If you have not enabled Call Home feature, collect the [Nodes and System health check](#) logs and contact [IBM support](#).

BMYDL2297

The drive is removed from the drive bay.

Severity

Critical

Problem description

It indicates the controller detected that the drive is removed.

User actions

Do the following steps to diagnose the error:

1. If you have enabled Call Home feature, then the system automatically collects system health check collection set logs and raises a Call Home ticket.

2. If you have not enabled Call Home feature, collect the [Nodes and System health check](#) logs and contact [IBM support](#).

BMYDL2417

A bus time-out was detected on a component at bus arg1 device arg2 function arg3.

Severity

Critical

Problem description

It indicates the system performance may be degraded. The device has failed to respond to a transaction (source/ target abort or completion timeout).

User actions

Do the following steps to diagnose the error:

1. If you have enabled Call Home feature, then the system automatically collects system health check collection set logs and raises a Call Home ticket.
2. If you have not enabled Call Home feature, collect the [Nodes and System health check](#) logs and contact [IBM support](#).

BMYDL2497

CPU Exception Type 0x00: Divide by Zero (Software).

Severity

Critical

Problem description

It indicates the fan is not performing optimally. The fan may be installed improperly or may be failing. Fan speeds may have increased to protect the system.

User actions

Do the following steps to diagnose the error:

1. If you have enabled Call Home feature, then the system automatically collects system health check collection set logs and raises a Call Home ticket.
2. If you have not enabled Call Home feature, collect the [Nodes and System health check](#) logs and contact [IBM support](#).

BMYDL3249

The air Filter in the bezel has a connectivity issue.

Severity

Critical

Problem description

It indicates the air Filter in the bezel has a connectivity issue.

User actions

Do the following steps to diagnose the error:

1. If you have enabled Call Home feature, then the system automatically collects system health check collection set logs and raises a Call Home ticket.
2. If you have not enabled Call Home feature, collect the [Nodes and System health check](#) logs and contact [IBM support](#).

BMYDL5604

CPU arg1 has a thermal trip (over-temperature) event.

Severity

Critical

Problem description

It indicates that the processor temperature increased beyond the operational range. Thermal protection shut down the processor. Factors external to the processor may have induced this exception.

User actions

Do the following steps to diagnose the error:

1. If you have enabled Call Home feature, then the system automatically collects system health check collection set logs and raises a Call Home ticket.
2. If you have not enabled Call Home feature, collect the [Nodes and System health check](#) logs and contact [IBM support](#).

2. If you have not enabled Call Home feature, collect the [System health check](#) logs and contact [IBM support](#).

BMXXC0050

The component mentioned in the error message is in critical or unhealthy state.

Severity

Critical

User actions

Do the following steps to diagnose the error:

1. If you have enabled Call Home feature, then the system automatically collects compute and system health check collection set logs and raises a Call Home ticket.
2. If you have not enabled Call Home feature, collect the [Nodes and System health check](#) logs and contact [IBM support](#).

BMXXC0021

OS timeout value exceeded.

Severity

Informational

User actions

No action is required.

BMXXC0022

Refer to error conditions for a specific condition.

Error conditions

The error message can be for the following conditions:

1. The operating System status changed to offline.
2. The server is restarted with a chassis control command.
3. The server is powered with a chassis control command.
4. User LXPM has mounted the file tdm_image.img from local.
5. The port 1 of the PCIe device Intel I350 1GbE RJ45 4-port OCP Ethernet Adapter onboard is linked down.
6. Disk related errors. For example, disk removal, addition, rebuild, hot spare and so on.
7. User password modified by user from at IP address.

Severity

Informational, warning, or critical

Note: The critical severity occurs whenever there are disk related errors.

User actions

Do the following steps to diagnose the error:

1. Error conditions one, two, three, four, and seven are informational messages, and no action is required.
2. For error condition five, ensure that you check the network cable and power cable connectivity to the respective ports.
3. For error condition six, collect the [System health check and Nodes logs](#) and contact [IBM support](#).

Critical or warning or informational

User actions

Do the following steps to diagnose the error:

1. Note down the **IBM-MTM: 9155-xxx** model number and **EVENT ID: xxxxx** details of the BMYXC9999.
2. Check the following table to get details of the IBM MTMs with their respective Lenovo server model and publications details.

Table 1. IBM and Lenovo server model Mapping

Description	IBM MTM	Lenovo server model	Publication
IBM Fusion HCI Compute Server	9155-C00	SR645	SR645 publication
IBM Fusion HCI Compute/Storage Server	9155-C01	SR645	SR645 publication
IBM Fusion HCI Compute Server	9155-C04	SR645	SR645 publication
IBM Fusion HCI Compute/Storage Server	9155-C05	SR645	SR645 publication
IBM Fusion HCI AFM Server	9155-F01	SR630	SR630 publication
IBM Fusion HCI GPU Server	9155-G01	SR665	SR665 publication
IBM Fusion HCI GPU Server	9155-G02	SR650v3	SR650v3 publication
IBM Fusion HCI GPU Server	9155-G03	SR675v3	SR675v3 publication
IBM Fusion HCI Compute/Storage Server	9155-C10	SR630v3	SR630v3 publication
IBM Fusion HCI Compute/Storage Server	9155-C14	SR630v3	SR630v3 publication

3. To get workaround steps or more information about the event, click and open the Lenovo server model publication based on your IBM MTM model number and search with the event id.

Backup & Restore server instance is unhealthy.
- [BMYP6045](#)
Backup & Restore agent instance is unhealthy.
- [BMYP6076](#)
The DNS resolution for the node failed.
- [Configuration error](#)
Message: Encountered a configuration error. Red Hat® OpenShift Container Platform installation did not start successfully.
- [Timed out creating bootstrap VM](#)
Message: Bootstrap VM creation on provisioner node (also known as service node) has not started.
- [Bootstrap VM creation did not complete](#)
Message: Bootstrap VM creation on the provisioner node (also known as service node) did not complete within the expected time.
- [Failed control nodes inspection](#)
Message: Inspection failed for one or more control nodes.
- [Control nodes creation failed](#)
Message: Failed to create the Red Hat OpenShift Container Platform cluster control nodes.
- [Cluster bootstrapping failed](#)
Cluster bootstrapping fails when one or more control nodes do not boot during installation of Red Hat OpenShift Container Platform.
- [Catalog source pod is healthy](#)
Message: IBM Fusion catalog source pod is not found or is not healthy.
- [Operator subscription isf-subscription not found](#)
Message: Subscription for IBM Fusion operator not found.
- [Failed to save vault secret configuration](#)
Message: Failed to save the vault secret configuration.
- [Failed to save vault login secret configuration](#)
Message: Failed to save the vault login secret configuration.
- [Failed to create and configure service node user](#)
Message: Failed to create and configure the service node user.
- [Failed to save secrets inside Vault](#)
Message: Failed to save the secrets inside Vault.
- [Failed to unseal Vault](#)
Message: Failed to unseal the Vault.
- [Failed to log in to Vault](#)
Message: Failed to log in to the Vault.
- [Failed to find or process kickstart files for Vault storage](#)
Message: Failed to find or process kickstart files for Vault storage.
- [Failed to save secrets to Vault after 5 attempts](#)
Message: Failed to save secrets to the Vault after 5 attempts.
- [Failed to read SSH keypair](#)
Message: Failed to read the SSH keypair.
- [Bootstrap VM is not pingable](#)
A temporary bootstrap VM is created on provisioner node to create Red Hat OpenShift Container Platform control plane.
- [Configuration error](#)
The certificate does not contain a wildcard domain for cluster.
- [Failed to install CSV for isf-operator](#)
When you install IBM Fusion, the installation fails with "Failed to install CSV for ifs-operator" error.
- [Failed to install IBM Fusion operator](#)
Failed to install the IBM Fusion operator. Check the log file `/home/kni/logs/installoperator_playbook.log` for more details.
- [The catalogsource pod for Red Hat operators is not running](#)
The `catalogsource` pod for `redhat-operators` is not running in `openshift-marketplace` namespace. Check the log file `%s` for more details.
- [Failed to deploy nmstate-operator](#)
Failed to deploy `nmstate-operator`. Check the log file `/home/kni/logs/installoperator_playbook.log` for more details.
- [Failed to install CSV for kubernetes-nmstate-operator](#)
While installing IBM Fusion HCI, the installation fails with the error message `Failed to install CSV for kubernetes-nmstate-operator`. Check log file `/home/kni/logs/installoperator_playbook.log` for more details.
- [Delete files from provisioned node](#)
The provisioner node, also known as service node, remains intact after IBM Fusion HCI initialization. For security reasons, all the configuration files are deleted from the service node.

Install Call Home events and error codes

List of Call Home events that you might encounter in the install.

Install Call Home events

If you have enabled Call Home feature, then the system automatically collects relevant log package and raises a Call Home ticket.

If you have not enabled Call Home feature, collect the relevant log package and contact [IBM support](#).

User actions

Collect [Backup and Restore logs](#) and contact [IBM support](#).

BMYIN3115

OpenShift® node did not transition to the **Ready** state.

Severity

Critical

User actions

Do the following steps to diagnose the error:

1. Run the following command to verify the pending certificates.

```
oc get csr --no-headers | grep -i pending
```

2. Run the following command to approve the pending certificates.

```
for i in `oc get csr --no-headers | grep -i pending | awk '{ print $1 }'`; do oc adm certificate approve $i; done
```

3. Restart the node.

```
oc debug node/<NODE_NAME>
chroot /host
reboot
```

4. If the problem persists, then collect Administration logs and contact [IBM support](#).

BMYIN3116

Service is Unhealthy.

Severity

Critical

User actions

Do the following steps to diagnose the error:

1. Go to OpenShift® Container Platform web console and check the FusionServiceInstance for the specific service and check the conditions section to find the error.
2. If the issue persists, run the following oc command, and check the status section and debug the error.

```
oc get fusionserviceinstance <instance-name-of-service> -o yaml
```

3. If this occurs during installation or post service installation, collect logs for the corresponding service that shows as unhealthy and contact [IBM support](#). Follow the steps to collect logs from IBM Fusion.
 - Go to Services page in IBM Fusion user interface.
 - Click the ellipses menu for the corresponding service.
 - Select the Collect logs button. It downloads all the necessary logs.

BMYIN3117

Service Catalog source creation is failed.

Severity

Critical

User actions

Do the following steps to diagnose and report the problem:

1. Run the following command and try to debug the results.

```
oc describe catalogsource <catalogsource-name> -n openshift-marketplace
```

2. If the result says Username/Password missing, manually update the secret for the required registry.

3. If the issue persists, contact the [IBM support](#).

BMYIN3118

A node might contain an invalid hostname (local host).

Severity

Critical

User actions

Do the following steps to diagnose the error:

1. Correct the DHCP configuration of the affected node.
2. Contact [IBM support](#) for local host node clean up.

BMYIN3119

Service installation failed.

Severity

Critical

User actions

Do the following steps to diagnose the error:

1. Go to OpenShift® Container Platform web console and check the FusionServiceInstance for the specific service and check the conditions section to find the error.
2. If the issue persists, run the following oc command, and check the status section and debug the error.

```
oc get fusionserviceinstance <instance-name-of-service> -o yaml
```
3. If this occurs during installation or post service installation, collect logs for the corresponding service that shows as unhealthy and contact [IBM support](#). Follow the steps to collect logs from IBM Fusion.
 - Go to Services page in IBM Fusion user interface.
 - Click the ellipses menu for the corresponding service.
 - Select the Collect logs button. It downloads all the necessary logs.

BMYIN3129

Failed to taint the node.

Severity

Critical

User actions

Do the following steps to diagnose the error:

1. Update taint based on node type when the underlying storage is Global Data Platform only.
2. Run the following commands to update the taint for the AFM node.

```
oc adm taint nodes <NODE_NAME> isf.ibm.com/noworkload:NoSchedule
oc adm taint nodes <NODE_NAME> afm.isf.ibm.com/noworkload:NoSchedule
```
3. Run the following commands to update the taint for the other nodes.

```
oc adm taint nodes <NODE_NAME> isf.ibm.com/noworkload:NoSchedule
```

BMYIN3130

Failed to update the cluster scheduler.

Severity

Critical

User actions

Do the following steps to diagnose the error:

1. Run the following command to update the cluster scheduler.

```
oc edit schedulers.config.openshift.io cluster
```

2. set `mastersSchedulable` field to true and save.

```
mastersSchedulable: true
```

Critical

Problem description

The `VaultUnSealStatusCheckFailed` event indicates that the system failed to unseal the internal vault for a requested operation. The event message uses the following format:

`Failed to unseal internal vault for %s operation.`

The `%s` placeholder is filled with the operation name. The following table lists the possible values:

Operation name	Resulting event description
Secret Rotation	Failed to unseal internal vault for Secret Rotation operation.
Vault Health Check	Failed to unseal internal vault for Vault Health Check operation.
Vault Sync	Failed to unseal internal vault for Vault Sync operation.

Severity

Informational

Problem description

It indicates that the related storage service is already installed on this setup.

User actions

No action is required.

BMYPIN4104

`StorageClassPrereqNotFound`

Severity

Informational

Problem description

It indicates that the `StorageClass` is not present to install this service.

User actions

Check the availability of the storage class specified in the FSD/FSI.

BMYPIN4105

`OCPVersionPrereqNotFound`

Severity

Informational

Problem description

It indicates that the OpenShift® Container Platform version is not in line with the service to be installed.

User actions

Upgrade the current OpenShift Container Platform version if services are supported on higher version than the current version.

BMYPIN4106

`CRDMissingPrereqNotFound`

Severity

Informational

Problem description

It indicates that Custom Resource Definition (CRD) is not present on the setup to install the service.

User actions

Check with IBM Support for CRD.

BMYPIN4107

DataJSONKeyNotFoundInCM

Severity

Informational

Problem description

It indicates that the ConfigMap information is invalid to install the service.

User actions

Validate whether the ConfigMap is present on the setup and its values are valid, which are specified in the FSD.

BMYPIN4108

SkipServiceInSpectrumFusionCRTrue

Severity

Informational

Problem description

It indicates that the service installation is skipped in the **Spectrum Fusion** CR.

User actions

If you want to install the service, you can remove the **skipService** list values from the **Spectrum Fusion** CR.

BMYPIN4110

PrereqServiceNotInstalled

Severity

Informational

Problem description

It indicates that a dependent service is not installed on this setup.

User actions

Install the dependent service first. After the dependent service is installed successfully, the **prereq** service can be deployed.

BMYPIN5001

Cluster operator is available but is in progress state.

Severity

Warning

Problem description

It indicates that the specified OpenShift® cluster operator is available but not all replicas are available. Do not start any upgrade until all cluster operators are available and are not in progress or degraded state.

User actions

Do the following steps to resolve the issue:

1. Check whether a machine configuration rollout is in progress, as it might be the reason for an unhealthy cluster operator. In such a case, wait for the machine configuration rollout to complete and the cluster operator to turn healthy.

2. After you resolve the health and status of the cluster operator, the upgrade precheck detects the fix and resumes the upgrade operation automatically.

BMYPE5002

A **MachineConfigPool** is updating.

Severity

Error or warning

Problem description

It indicates that a **MachineConfigPool** update is in progress. It impacts the upgrade as the next machine configuration rollout in the queue fails because of its dependency on the successful rollout of the ongoing change.

For example, an ongoing rollout is for a registry auth change for all the nodes. This change must get rolled out to all nodes before you start the upgrade so that no pod failures due to image pullback errors cause upgrade failures.

User actions

Do the following steps to resolve the issue:

1. The issue might occur for a short duration whenever the Machine config rollout, OpenShift® Container Platform, and Global Data Platform operations are in progress. Wait for these operations to complete, then check that the **MachineConfigPool** is healthy and available.
2. If a pool remains in a degraded state for a long time, then use the following command to find the root cause.

```
oc describe machineconfigpool <poolname>
```

3. Check for the problems indicated in the description, and debug further to identify the root cause. The following are some possible reasons:
 - If a node is stuck in a **NotReady** state, restart the node to fix the issue.
 - Though the node completes the roll out, it might not be in a schedulable state. Compare the required and current configurations. If the configurations are the same, manually remove taint of the unscheduleable state.

After the **MachineConfigPool** is available and up to date, the upgrade precheck detects the fix and resumes upgrade automatically.

BMYPE5004

A pod PodDisruptionBudget (PDB) is set to zero.

Severity

Warning

Problem description

It indicates that the PodDisruptionBudget (PDB) of a pod is zero. During the upgrade, each node restarts in a rolling fashion. Any pod with a PDB set to zero blocks the node restarts because of the incomplete node drain operation. It might cause the upgrade to get stuck until you delete the pod manually. The upgrade operation restarts after the pod gets deleted and the node drains completely.

User actions

Do the following steps to resolve the issue:

1. To avoid this issue, delete the pod and set the PDB to zero.
2. If you proceed with the upgrade without deleting the pod, the upgrade gets stuck during the node restart where the pod is running. Delete the pod whenever the IBM Fusion user interface shows the upgrade as blocked.
3. Select a method based on how disruptive the pod deletion is for its associated workloads. If you can tolerate a pod in unscheduled state during the upgrade, then pod deletion before the upgrade causes it to run unblocked.
4. If you require active replicas of the pod throughout the upgrade, then you must manually manage the upgrade.
5. Every time the upgrade gets blocked because a nod drain is in progress, delete the pod that causes the issue and allow it to reschedule on another node.

The upgrade restarts after the pod deletion and node drain operations are complete.

BMYPE5005

Virtual machine is using PVC with non-RWX access mode.

Severity

Warning

Problem description

It indicates that a virtual machine is using PVCs with RWO access mode. It blocks the upgrade by preventing nodes from restarting that is necessary for machine configuration rollout and firmware upgrade.

User actions

Do the following steps to resolve the issue:

1. Manually stop the virtual machine until the upgrade is complete.
2. Manually stop the virtual machine before you start the upgrade or wait for the node on the virtual machine to drain completely.
3. If you choose to wait, then the upgrade can be paused while draining the node, and the upgrade should not proceed until you stop the virtual machine.
4. It is always recommended to migrate all virtual machines to use RWX PVC by cloning the existing RWO PVC. It prevents issues with upgrades and also enables virtual machines to take advantage of live migration.

Continue with the upgrade operation after you migrate all virtual machines to use RWX PVC by cloning the existing RWO PVC.

BMYPC5006

A pod in the `openshift-operator-lifecycle-manager` namespace is unhealthy.

Severity

Error

Problem description

It indicates that pod in the `openshift-operator-lifecycle-manager` namespace is not ready. Pods in the `openshift-operator-lifecycle-manager` namespace are responsible for managing catalogs, packages, and operator lifecycle in the OpenShift®. If pods are not running or have errors, then it can cause operator upgrade failure in the IBM Fusion HCI.

User actions

Do the following steps to resolve the issue:

1. Check for the events of the failed pods and logs to find the root cause of failure and take an appropriate action to fix the issues. Restarting the pod might also solve the problem.
2. After all the pods in the `openshift-operator-lifecycle-manager` namespace are ready, the upgrade precheck detects the fix and resumes upgrade automatically.

BMYPC5010

IBM Fusion operator installation is in progress.

Severity

Error

Problem description

The IBM Fusion operator is in `installready` or `installing` or `pending` state, which indicates that the operator install is in progress. It can block the ability of IBM Fusion operator or other IBM Fusion components ability to install, upgrade, or function.

User actions

Do the following steps to resolve the issue:

1. Check for IBM Fusion operator CSV events and conditions to find the root cause for this state. Some of the common reasons for the `Pending` state of the IBM Fusion operator are as follows:
 - Check whether IBM Fusion operator is installing or upgrading.
 - Some changes might corrected in any deployment spec in CSV for IBM Fusion operator. It recreates pods and reconciles to succeeded state in some time.
 - One of the IBM Fusion operator pod is not running. It might be due to an OOM killed error where the pod is requesting more memory than its set limit. To resolve this, update the memory limit for that deployment in CSV.
 - A pod might be in a `crashloopbackoff` due to another reason. Check the pod log and events to find the root cause and take an appropriate action.
 - It is possible that a `Custom Resource Definition` is missing due to an accidental deletion. In such case, contact [IBM support](#) to get the CRD YAML and create it in the cluster.

You can continue with the upgrade operation after the IBM Fusion operator is successful.

BMYPC5013

Unable to check DNS resolution for the registry.

Severity

Warning

Problem description

Unable to determine whether the DNS resolution for the image registry is successful or not. It might block the upgrade due to image pull failures.

User actions

Do the following steps to resolve the issue:

1. Check whether the image registry is used to host images for either IBM Fusion or any of its data service services or firmwares.
2. If the image registry hosts any of images, then manually verify that each cluster node can resolve registry hostname to its IP since this registry will be used to pull images during upgrade and upgrade fails if registry hostname cannot be resolved.
3. If any node cannot resolve the hostname, fix that issue.

BMYPC5027

The OpenShift® Container Platform is currently operating at the latest version that is supported by IBM Fusion.

Severity

Warning

User actions

Do not upgrade OpenShift Container Platform to the next minor version as it is not supported by the IBM Fusion.

BMYPC5028

A virtual machine is configured with PCI pass-through.

Severity

Warning

Problem description

It indicates that a virtual machine is configured with PCI pass-through and it blocks OpenShift® node draining and upgrades of Global Data Platform service, OpenShift and compute nodes.

User actions

Stop the virtual machine mentioned in the precheck so that it does not block draining of nodes.

If the issue still persists, then go to virtual machines YAML definition, and under the `spec` field, add `evictionStrategy: LiveMigrateIfPossible`. Save the YAML file and restart the virtual machine so that the draining of the nodes cannot be blocked once the virtual machine is up.

BMYPC5029

The OpenShift® Container Platform is currently operating at the latest version that is supported by Fusion Data Foundation.

Severity

Warning

User actions

Do not upgrade OpenShift Container Platform to the next minor version as it is not supported by the Fusion Data Foundation service.

BMYPC6001

Cluster operator is not healthy.

Severity

Error

Problem description

It indicates that the specified OpenShift® cluster operator is not available or degraded. It can impact the upgrade because different cluster operators are responsible for the various functions in the OpenShift cluster. If any function is not working due to an unavailable cluster operator, it might result in an upgrade failure.

User actions

Do the following steps to resolve the issue:

1. Check whether a machine configuration rollout is in progress as it can be a reason for the health status of the cluster operator. In this case, wait for machine configuration rollout to complete and cluster operator to turn healthy.
2. Check whether a node is in a **NotReady** state as it be a reason for the health status of the cluster operator. Debug the reason for **NotReady** state and check that it is a part of the machine configuration rollout progress. If it is a part of the machine configuration rollout, then wait for the roll out to complete.
3. If a node remains in a **NotReady** state for more than 30 minutes, then check the network for the node by pinging the IPv4 address or hostname. In case the node does not respond, then restart the node.
4. If node is in a **Ready** state but scheduling is disabled, then it might be due to a machine configuration rollout, node in a maintenance mode, or ongoing firmware upgrade. Wait for the operation to complete for the node to become schedulable. After the cluster operator is available and not degraded, the upgrade precheck detects the fix and resumes upgrade automatically.

If you want to override the prechecks that are blocking the upgrade, do the following steps:

It converts the **Error** prechecks to **Warning** prechecks and triggers the upgrade.

Note: Before using the **precheck-acks** configmap to override the pre-checks, ensure that the unhealthy resource does not affect the upgrade.

1. Run the following command and export IBM Fusion namespace as an environmental variable.

```
export FUSION_NS="namespace-where-fusion-is-installed"
```

2. Run the following command to create a **precheck-acks** configmap in the namespace where the IBM Fusion is installed.

```
oc create configmap precheck-acks -n $FUSION_NS
```

3. In the **precheck-acks** config map, add the key **ClusterOperatorHealth** and set the value to **true**.

```
oc patch configmap precheck-acks -n $FUSION_NS --type merge -p '{"data": {"ClusterOperatorHealth": "true"}}'
```

BMYPC6002

A **MachineConfigPool** is degraded.

Severity

Error

Problem description

It indicates that a **MachineConfigPool** is in a degraded state in the OpenShift® cluster. It can impact the upgrade because the different IBM Fusion component upgrades also start machine configuration roll outs and they might not succeed if **MachineConfigPool** is in a degraded state. A new machine configuration must be rolled out when all **MachineConfigPool** are healthy.

User actions

Do the following steps to resolve the issue:

1. The issue might occur for a short duration whenever the Machine config rollout, OpenShift Container Platform, and Global Data Platform operations are in progress. Wait for these operations to complete, then check that the **MachineConfigPool** is healthy and available.
2. If a **MachineConfigPool** remains in a degraded state for a long time, then use following command to find the root cause.

```
oc describe machineconfigpool <poolname>
```

3. Check for the problems indicated in the description, and debug further to identify the root cause. The following are some possible reasons:
 - A node is stuck in a **NotReady** state, then restart the node to fix the issue.
 - Though the node completes the roll out, it might not be in a schedulable state. Compare the required and current configurations. If the configurations are the same, manually remove taint of the unschedulable.
4. After the **MachineConfigPool** is available and up to date, the upgrade precheck detects the fix and resumes upgrade automatically.

BMYPC6003

A node is not ready or unschedulable.

Severity

Error

Problem description

It indicates that a node is not ready or unschedulable. Ensure that all nodes are available before you proceed with the upgrade.

User actions

Do the following steps to resolve the issue:

1. Check whether the node is placed in a maintenance mode for a planned work. In this case, bring the node out of the maintenance mode after the planned work is complete.
2. If a machine configuration roll out is in progress, then wait for the roll out to complete and the node to return to a ready state.
3. If the node is in a **Notready** state for more than 30 minutes, then it might be an error with the node in the joining cluster. Do the following steps to resolve issues that are related to the joining cluster:
 - a. Run the following command to check for the pending CSRs.

```
oc get csr | grep -i pending
```

- b. If you find any pending CSRs, then run the following command to approve them.

```
oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve
```

- c. If you do not find any pending CSRs, then restart the node.
- d. Connect to the node by using the core OS private SSH key and run the following command.

```
ip a
```

- e. Recover the node during the following scenarios:
 - IPv4 address assigned to the bond0 interface
 - **br-ex** interface not created

You can continue with the upgrade operation after the node is in a **Ready** state.

BMYPC6006

A pod in the **openshift-operator-lifecycle-manager** namespace is not ready.

Severity

Error

Problem description

It indicates that pod in the **openshift-operator-lifecycle-manager** namespace is not ready. Pods in the **openshift-operator-lifecycle-manager** namespace are responsible for managing catalogs, packages, and operator lifecycle in the OpenShift®. If pods are not running or have errors, then it can cause operator upgrade failure in the IBM Fusion HCI.

User actions

Do the following steps to resolve the issue:

1. Check for the events of the failed pods and logs to find the root cause of failure and take an appropriate action to fix the issue. Pod restart can also resolve the problem.
2. After all the pods in the **openshift-operator-lifecycle-manager** namespace are ready, the upgrade precheck detects the fix and resumes upgrade automatically.

If you want to override the prechecks that are blocking the upgrade, do the following steps:

It converts the **Error** prechecks to **Warning** prechecks and triggers the upgrade.

Note: Before using the **precheck-acks** configmap to override the pre-checks, ensure that the unhealthy resource does not affect the upgrade.

1. Run the following command and export IBM Fusion namespace as an environmental variable.

```
export FUSION_NS="namespace-where-fusion-is-installed"
```

2. Run the following command to create a **precheck-acks** configmap in the namespace where the IBM Fusion is installed.

```
oc create configmap precheck-acks -n $FUSION_NS
```

3. In the `precheck-acks` config map, add the key `OpenShiftLifeCycleManagementPodStatus` and set the value to `true`.

```
oc patch configmap precheck-acks -n $FUSION_NS --type merge -p '{"data": {"OpenShiftLifeCycleManagementPodStatus": "true"}}'
```

BMYPC6007

A `CatalogSource` is not ready.

Severity

Error

Problem description

It indicates that a `CatalogSource` in the OpenShift® is either not ready or not healthy. It is required for any operator lifecycle management operation, such as installation or upgrade to function. All catalog sources in the OpenShift cluster must be healthy and ready. Any unhealthy catalog source impacts the OLM functions in the cluster.

User actions

Do the following steps to resolve the issue:

- Some of the possible reasons with diagnostic steps for a catalog source to not work are as follows:
 1. Invalid image name in the catalog source:
 - Check the pod for the given catalog source in its dedicated namespace or `openshift-marketplace` namespace.
 - Run the following command to describe the pod.

```
oc describe pod <pod name> -n <namespace>
```
 - If you find an error with the message `invalid image reference` under events section, then fix the image field in the catalog source YAML. Wait for the catalog source to turn healthy.
 2. Missing images in the registry for disconnected setup:
 - Check the pod for the given catalog source in its dedicated namespace or `openshift-marketplace` namespace.
 - Run the following command to describe the pod.

```
oc describe pod <pod name> -n <namespace>
```
 - If you find an error with the message `unknown manifest` under events section, mirror images to enterprise registry and wait for catalog source to turn healthy.
 3. Missing `ImageContentSourcePolicy` for disconnected set up:
 - Check the pod for the given catalog source in its dedicated namespace or `openshift-marketplace` namespace.
 - Run the following command to describe the pod.

```
oc describe pod <pod name> -n <namespace>
```
 - If you find an error with the messages `unknown manifest` and `Mirrors failed` under events section, then review the `imagecontentsourcepolicy` applied for any incorrect paths or ports or spelling mistakes. Fix them and wait for catalog source to turn healthy.
 4. Missing credentials for the registry in the global pull-secret of the `openshift-config` namespace. Check the credentials in the global pull-secret in the `openshift-config` namespace:
 - Check the pod for the given catalog source in its dedicated namespace or `openshift-marketplace` namespace.
 - Run the following command to describe the pod.

```
oc describe pod <pod name> -n <namespace>
```
 - If you find an error with the messages `Unknown desc = unable to retrieve auth token: invalid` and `username/password: unknown: Authentication is required` under events section, then review the `pull-secret` in `openshift-config` namespace for correct credentials for registry where the image is referenced. Fix auth for registry in secret and wait for catalog source to turn healthy.
 5. Connection error to the registry. Ensure that the firewall and proxy do not block registry and port access.
 - Check the pod for the given catalog source in its dedicated namespace or `openshift-marketplace` namespace.
 - Run the following command to describe the pod.

```
oc describe pod <pod name> -n <namespace>
```
 - If you find an error with the messages `pinging container registry registry.redhat.io: Get` and `"https://<registryhost>": dial tcp <registryip>: connect: connection refused` under events section, then review the firewall and proxy settings to make sure that registry access is allowed to the cluster and wait for catalog source to turn healthy.

After the `CatalogSource` is in a ready state, the upgrade precheck detects the fix and resumes the upgrade operation automatically.

If you want to override the prechecks that are blocking the upgrade, do the following steps:

It converts the **Error** prechecks to **Warning** prechecks and triggers the upgrade.

Note: Before using the `precheck-acks` configmap to override the pre-checks, ensure that the unhealthy resource does not affect the upgrade.

1. Run the following command and export IBM Fusion namespace as an environmental variable.

```
export FUSION_NS="namespace-where-fusion-is-installed"
```

2. Run the following command to create a **precheck-acks** configmap in the namespace where the IBM Fusion is installed.

```
oc create configmap precheck-acks -n $FUSION_NS
```

3. In the **precheck-acks** config map, add the key **CatalogSourceStatus** and set the value to **true**.

```
oc patch configmap precheck-acks -n $FUSION_NS --type merge -p '{"data": {"CatalogSourceStatus": "true"}}'
```

BMYPC6008

Inaccessible registry.

Severity

Warning

Problem description

It indicates that the specified image registry is not accessible from one or more cluster nodes. It blocks the upgrade because image pulls might fail. It also causes other issues outside of upgrades as newly scheduled or rescheduled pods are unable to access their images.

For the registries that have non-empty auth specified in the pull-secret in the **openshift-config** namespace, check for the connectivity to make sure that the images are pulled successfully for IBM Fusion components and the OpenShift® Container Platform. If you fail to address the registry access might result in pods can get into an **ImagePullBackOff** error.

User actions

Do the following steps to resolve the issue:

1. Check the network connectivity between the OpenShift cluster and the image registry.
2. A firewall can prevent the access to the registry.
3. After the connectivity issue is resolved, the upgrade precheck detects the fix and resumes upgrade automatically.

BMYPC6010

IBM Fusion operator is in a **Failed** state or not found.

Severity

Error

Problem description

It indicates that the IBM Fusion operator is in a **Failed** state or not found. It can block the ability of the IBM Fusion operator or other IBM Fusion components ability to install, upgrade, or do other function.

User actions

Do the following steps to resolve the issue:

1. Check for IBM Fusion operator CSV events and conditions to find the root cause for this state. Some of the common reasons for the **Failed** state of the IBM Fusion operator are as follows:
 - One of the IBM Fusion operator pod is not running. It might be due to an OOM killed error where the pod is requesting more memory than its set limit. To resolve this, update the memory limit for that deployment in CSV.
 - A pod might be in a **crashloopbackoff** due to another reason. Check the pod log and events to find the root cause and take an appropriate action.
 - It is possible that a **Custom Resource Definition** is missing due to an accidental deletion. In this case, contact [IBM support](#) to get the CRD YAML and create it in the cluster.

You can continue with the upgrade operation after the IBM Fusion operator is successful.

If you want to override the prechecks that are blocking the upgrade, do the following steps:

It converts the **Error** prechecks to **Warning** prechecks and triggers the upgrade.

Note: Before using the **precheck-acks** configmap to override the pre-checks, ensure that the unhealthy resource does not affect the upgrade.

1. Run the following command and export IBM Fusion namespace as an environmental variable.

```
export FUSION_NS="namespace-where-fusion-is-installed"
```

2. Run the following command to create a **precheck-acks** configmap in the namespace where the IBM Fusion is installed.

```
oc create configmap precheck-acks -n $FUSION_NS
```

3. In the **precheck-acks** config map, add the key **FusionOperatorStatus** and set the value to **true**.

```
oc patch configmap precheck-acks -n $FUSION_NS --type merge -p '{"data": {"FusionOperatorStatus": "true"}}'
```

BMYPC6013

The DNS resolution for image registry failed.

Severity

Error

Problem description

It indicates that the hostname resolution specified for the image registry failed for one or more cluster nodes. It blocks the upgrade because of image pull failure. It can also cause other issues outside of the upgrade because the newly scheduled or rescheduled pods cannot access the images.

The registries can have a non-empty auth specified in the pull-secret of the `openshift-config` namespace. Check the connectivity for successful image pulls of IBM Fusion components and the OpenShift® Container Platform. Failure to address the registry access can result in an `ImagePullBackOff` error of the pod.

User actions

Do the following steps to resolve the issue:

1. Check the DNS settings for the image registry.
2. A firewall can prevent the access to the registry
3. After the DNS resolution issue is resolved, the upgrade precheck detects the fix and resumes upgrade automatically.

If you want to override the prechecks that are blocking the upgrade, do the following steps:

It converts the **Error** prechecks to **Warning** prechecks and triggers the upgrade.

Note: Before using the `precheck-acks` configmap to override the pre-checks, ensure that the unhealthy resource does not affect the upgrade.

1. Run the following command and export IBM Fusion namespace as an environmental variable.

```
export FUSION_NS="namespace-where-fusion-is-installed"
```

2. Run the following command to create a `precheck-acks` configmap in the namespace where the IBM Fusion is installed.

```
oc create configmap precheck-acks -n $FUSION_NS
```

3. In the `precheck-acks` configmap, add the key `DNSResolution` and set the value to `true`.

```
oc patch configmap precheck-acks -n $FUSION_NS --type merge -p '{"data": {"DNSResolution": "true"}}'
```

BMYPC6014

Global Data Platform service upgrade is in progress.

Severity

Error

Problem description

It indicates that the Global Data Platform upgrade is in progress. The upgrades for compute nodes firmware, switch firmware and OpenShift® should not be triggered when the Global Data Platform service upgrade is in progress as the nodes get rebooted in a rolling pattern during the Global Data Platform upgrade.

User actions

Wait until the Global Data Platform service upgrade to be complete before triggering the upgrades for compute nodes, switches, or OpenShift.

BMYPC6015

It is a switch upgrade precheck error. STP is enabled on the high-speed switches.

Severity

Error

Problem description

It indicates that the STP is enabled on the high-speed switches. For the switch upgrade, the STP needs to be disabled.

User actions

Collect [Network switches logs](#) and contact [IBM support](#).

BMYPC6023

`pidslimit` on the nodes is less than 12228.

Severity

Error

Problem description

The node `pidslimits` is set to a value less than 12228, which is the minimum required value for the Global Data Platform to run on IBM Fusion HCI. It results in a non-functional storage cluster that impacts the applications that require storage.

User actions

Do the following steps to resolve the issue:

1. Follow steps [1](#) to [4](#) to apply `kubeletconfig`. It ensures the `pidslimits` are as expected on nodes.
2. After the `pidslimit` is set correctly, the upgrade precheck detects the fix and resumes upgrade automatically.

BMYPC6040

Backup & Restore agent instance not found.

Severity

Error

Problem description

It indicates that there is no Backup & Restore agent instance on the cluster. This can occur if the `DataProtectionAgent` CR is deleted from the cluster.

User actions

Contact [IBM support](#) to resolve this issue.

BMYPC6042

The Subscription is missing the `CatalogSource`.

Severity

Error

Problem description

It indicates that the listed subscription is missing in the `CatalogSource`. This can occur if the `CatalogSource` is missing from the subscription CR, or if the `CatalogSource` listed in the subscription CR is missing on the cluster.

User actions

Do the following steps to resolve the issue:

1. Check the `CatalogSource` required by the subscription exists on the cluster and create the `CatalogSource` if it does not exist
2. If you want to override the prechecks that are blocking the upgrade, do the following steps:
Note: Before using the `precheck-acks configmap` to override the prechecks, ensure that the unhealthy resource does not affect the upgrade.
 - a. Run the following command and export IBM Fusion namespace as an environmental variable.

```
export FUSION_NS="namespace-where-fusion-is-installed"
```
 - b. Run the following command to create a `precheck-acks configmap` in the namespace where the IBM Fusion is installed.

```
oc create configmap precheck-acks -n $FUSION_NS
```

c. In the `precheck-acks` configmap, add the key `BNRSubscriptionCatalogs` and set the value to true.

```
oc patch configmap precheck-acks -n $FUSION_NS --type merge -p '{"data": {"BNRSubscriptionCatalogs": "true"}}'
```

BMYPC6044

Backup & Restore server instance is unhealthy.

Severity

Error

Problem description

It indicates that the Backup & Restore server instance is unhealthy. This can occur if one or more services listed the `DataProtectionServer` CR contain issues.

Recommended actions

Contact [IBM support](#).

BMYPC6045

Backup & Restore agent instance is unhealthy.

Severity

Error

Problem description

It indicates that the Backup & Restore agent instance is unhealthy. This can occur if one or more services listed the `DataProtectionServer` CR contain issues.

Recommended actions

Contact [IBM support](#).

BMYPC6076

The DNS resolution for the node failed.

Severity

Error

Problem description

It indicates that the hostname resolution failed for the specified node.

User actions

Follow the steps described in the [Setting up DNS](#) section to verify the DNS configuration of the affected node.

After you correct the DNS configuration, the node addition process proceeds successfully.

Configuration error

Message: Encountered a configuration error. Red Hat® OpenShift® Container Platform installation did not start successfully.

Diagnosis

1. As a kni user on a provisioner node (also known as service node), review the log file `/home/kni/logs/install_<timestamp>.log`.

2. Scroll to end of file and check whether it reports any failure. Following is an example of a successful run, however, if you find value for **failed** not equal to 0, then check the log for a step that failed.

```
PLAY RECAP *****
localhost                : ok=68   changed=3   unreachable=0   failed=0   skipped=45   rescued=0   ignored=0
```

Next actions

1. Take appropriate action to resolve the reported problem in the log.
2. In the installation user interface, click **Retry** to restart the installation.

Timed out creating bootstrap VM

Message: Bootstrap VM creation on provisioner node (also known as service node) has not started.

Diagnosis

1. As a kni user, on the provisioner node, review the log file `/home/kni/clusterconfigs/.openshift_install.log`.
2. Rectify the reported problem.

Next actions

In the installation user interface, click **Retry** to restart the installation.

If problem persists, collect all files in `/home/kni/logs` and `/home/kni/clusterconfigs`, and contact [IBM support](#).

Bootstrap VM creation did not complete

Message: Bootstrap VM creation on the provisioner node (also known as service node) did not complete within the expected time.

Diagnosis

1. As a kni user, on the provisioner node, review the log file `/home/kni/clusterconfigs/.openshift_install.log`.
2. Rectify the reported problem.

Next actions

In the installation user interface, click **Retry** to restart the installation.

If problem persists, do the following steps:

1. Collect all files from `/home/kni/logs`, `/home/kni/clusterconfigs`, and `/home/kni/install/results.json`.
2. Contact [IBM support](#).

Failed control nodes inspection

Message: Inspection failed for one or more control nodes.

Diagnosis

Note: Run all commands as a **kni** user from provisioner node.

1. Check the `.openshift_install.log` for errors.
2. If the logs do not provide the necessary information, then continue the steps in this procedure for further diagnostics.
3. Ping node by using the IP and hostname that are reserved for the node in DHCP.
4. If ping does not work, then do the following steps to access the IMM user interface of the Baremetal node:
Find IPv6 or IPv4 address of node and debug by using the following command:

```
oc get bmh -A -o wide | grep control
openshift-machine-api control-1-ru2 OK externally provisioned isf-rackae4-2bztv-master-0
ipmi://[fd8c:215d:178e:c0de:a94:efff:fefe:2f95]:623 unknown true 3h28m
openshift-machine-api control-1-ru3 OK externally provisioned isf-rackae4-2bztv-master-1
ipmi://[fd8c:215d:178e:c0de:a94:efff:fefc:cecd]:623 unknown true 3h28m
openshift-machine-api control-1-ru4 OK externally provisioned isf-rackae4-2bztv-master-2
ipmi://[fd8c:215d:178e:c0de:a94:efff:fefe:3031]:623 unknown true 3h28m
```

5. Note down the IPv6 or IPv4 address of the node you are checking.
6. Go to `/home/kni/isfconfig` folder and open `kickstart-.json` file to find the password of the IMM user **USERID** of node.
7. Open the file and look for the string **OCProle** with value equal to hostname (for example, control-1-ru3) of the node.

Sample section for IPv6:

```
"ipv6ULA": "XXXXXXXXXXXXXXXXXXXX",
"ipv6LLA": "XXXXXXXXXXXX",

    ],
    "uuid": "uuid"
  }
],

```

8. Run the following command to create a tunnel to the IMM of the node:

```
ssh -N -f -L :1443:[IPv6 or IPv4 address of IMM]:443 -L :3900:[IPv6 or IPv4 address of IMM]:3900 root@localhost
```

9. To access the IMM user interface using the provisioner node IP address, open your browser and access the following IP.

```
https://<provisioner ip>:1443
```

- user - Enter **USERID**.
- password - Use the value obtained in the previous step.

10. From the IMM user interface page, open the remote console and check whether the node is up and shows a valid hostname prompt.

- If the console shows localhost, then review your DHCP/DNS settings to ensure whether correct reservation is made for the node.
- If the node shows a Red Hat® Linux login prompt instead of Core OS, then it infers that the node Base management controller (BMC) is not responsive.

Do the following steps to resolve the issue:

a. Identify IMM of the missing node. Here is mapping of nodes to IMM:

```

control-1-ru2 ==> imm_ru2
control-1-ru3 ==> imm_ru3
control-1-ru4 ==> imm_ru4

```

- b. For node(s) that did not show up in the previous steps, run the following sample IMM command to connect to their IMM: For example, if node **control-1-ru3** did not show up, then from RU7/provisioner (compute-1-ru7), run the **imm_ru3** command as a **kni** user.
- c. Wait for the successful connection to IMM. c. In the system prompt, run the **resetsp** on IMM prompt.
- d. Wait for 10 minutes.

Next actions

In the installation user interface, click the Retry to restart the installation.

Control nodes creation failed

Message: Failed to create the Red Hat® OpenShift® Container Platform cluster control nodes.

Diagnosis

Note: Run all commands as a **kni** user from provisioner node.

1. Check the **.openshift_install.log** for errors.
2. If the logs do not provide the necessary information, then continue next steps in this procedure for further diagnostics.
3. As a kni user, run **oc get nodes** on the provisioner (service node).
4. Check whether the following three ready nodes are not listed in the output:

NAME	STATUS	ROLES	AGE	VERSION
control-1-ru2.rackm03.<domainname>	Ready	control-plane,master,worker	55m	v1.27.3+4aaeac
control-1-ru3.rackm03.<domainname>	Ready	control-plane,master,worker	56m	v1.27.3+4aaeac
control-1-ru4.rackm03.<domainname>	Ready	control-plane,master,worker	56m	v1.27.3+4aaeac

5. Identify the node that is not booted. If you do not see these three nodes, then note down the missing node(s) from the output.
6. Identify the IMM of the missing node. Here is mapping of nodes to IMM:

```

control-1-ru2 ==> imm_ru2
control-1-ru3 ==> imm_ru3
control-1-ru4 ==> imm_ru4

```

7. For node(s) that did not show up in the step 4 output, then run the corresponding IMM command to connect to its IMM. For example, if node **control-1-ru3** did not show up, then from RU7/provisioner (compute-1-ru7), run the **imm_ru3** command as a **kni** user.
8. Run **resetsp** command on the IMM prompt.
9. Wait for 10 minutes and retry the installation.
10. If issue persists, ping the control nodes by using the IP and hostname that are reserved for the node in DHCP.
11. If ping is not working, then do the following steps to access the IMM user interface of the Baremetal node:
 - a. Run the following command to find the IPv6 or IPv4 address of the node to debug:

```
oc get bmh -A -o wide |grep control
```

Example output:

openshift-machine-api	control-1-ru2	OK	externally provisioned	isf-rackae4-2bztv-master-0
ipmi://[fd8c:215d:178e:c0de:a94:efff:fefe:2f95]:623		unknown	true	3h28m
openshift-machine-api	control-1-ru3	OK	externally provisioned	isf-rackae4-2bztv-master-1
ipmi://[fd8c:215d:178e:c0de:a94:efff:fefe:ced]:623		unknown	true	3h28m
openshift-machine-api	control-1-ru4	OK	externally provisioned	isf-rackae4-2bztv-master-2
ipmi://[fd8c:215d:178e:c0de:a94:efff:fefe:3031]:623		unknown	true	3h28m

- Note down the IPv6 or IPv4 address of the node you are checking.
- Go to `/home/kni/isfconfig/` and open the `kickstart-.json`
- Find the password for the IMM user (USERID) of the node and search for the string `OCPRole` with value equal to hostname (for example control-1-ru3) of node.

```

- g. From the IMM user interface page, open the remote console and check whether the node is up and shows a valid hostname prompt.
- If the console shows localhost, then review your DHCP/DNS settings to ensure whether correct reservation is made for the node.
 - If the node shows a Red Hat linux login prompt instead of Core OS, then it infers that the node Base management controller (BMC) is not responsive.

Do the following steps to resolve the issue:

- i. Identify IMM of the missing node. Here is mapping of nodes to IMM:

```
control-1-ru2 ==> imm_ru2
control-1-ru3 ==> imm_ru3
control-1-ru4 ==> imm_ru4
```

- ii. For node(s) that did not show up in the previous steps, run the following sample IMM command to connect to their IMM: For example, if node **control-1-ru3** did not show up, then from RU7/provisioner (compute-1-ru7), run the following command as a **kni** user: **imm_ru3**
- iii. Wait for the successful connection to IMM.
- iv. In the system prompt, run the **resetsp** on IMM prompt.
- v. Wait for 10 minutes.

Next actions

In the installation user interface, click the Retry to restart the installation.

Cluster bootstrapping failed

Cluster bootstrapping fails when one or more control nodes do not boot during installation of Red Hat® OpenShift® Container Platform.

Message: Bootstrapping failed for Red Hat OpenShift Container Platform cluster.

Diagnosis

Note: Run all commands as a **kni** user from provisioner node.

1. Check the **.openshift_install.log** for errors.
2. If the logs do not provide the necessary information, then continue the steps in this procedure for further diagnostics.
3. As a kni user, run **oc get nodes** on the provisioner (service node).
4. Check whether the following three ready nodes are not listed in output:

NAME		STATUS	ROLES	AGE	VERSION
control-1-ru2.rackm03.<domainname>	Ready		control-plane,master,worker	55m	v1.27.3+4aaeaeec
control-1-ru3.rackm03.<domainname>	Ready		control-plane,master,worker	56m	v1.27.3+4aaeaeec
control-1-ru4.rackm03.<domainname>	Ready		control-plane,master,worker	56m	v1.27.3+4aaeaeec

5. Identify the node that is not booted. If you do not see the listed three nodes, then note down the missing node(s) from the output.

6. Identify the IMM of the missing node. Here is mapping of nodes to IMM:

```
control-1-ru2 ==> imm_ru2
control-1-ru3 ==> imm_ru3
control-1-ru4 ==> imm_ru4
```

7. For node(s) that did not show up in output in step 4, run the corresponding IMM command to connect to its IMM. For example, if node `control-1-ru3` did not show up, then from the RU7/provisioner (compute-1-ru7), run the `imm_ru3` command as `kni` user. Wait for the successful connection to IMM.
8. In the system prompt, run the `resetsp` on IMM prompt.
9. Wait for 10 minutes and retry installation.
10. If none of the nodes show up, ping the control nodes by using the IP and hostname that are reserved for the node in DHCP.
11. If ping does not work, then do the following steps to access the IMM user interface of the Baremetal node:
- Find IPv6 or IPv4 address of node to debug using the following command:

```
oc get bmh -A -o wide |grep control
```

Example output:

```
openshift-machine-api control-1-ru2 OK externally provisioned isf-rackae4-2bztv-master-0
ipmi://[fd8c:215d:178e:c0de:a94:efff:fefe:2f95]:623 unknown true 3h28m
openshift-machine-api control-1-ru3 OK externally provisioned isf-rackae4-2bztv-master-1
ipmi://[fd8c:215d:178e:c0de:a94:efff:fefd:cecd]:623 unknown true 3h28m
openshift-machine-api control-1-ru4 OK externally provisioned isf-rackae4-2bztv-master-2
ipmi://[fd8c:215d:178e:c0de:a94:efff:fefe:3031]:623 unknown true 3h28m
```

- Note down the IPv6 or IPv4 address of the node you are checking.
- Go to `/home/kni/isfconfig` folder and open `kickstart-.json` file to find the password of the IMM user `USERID` of node
- Open the file and look for the string `OCPRole` with value equal to hostname (for example, `control-1-ru3`) of the node.

Sample section for IPv6:

```
"ipv6ULA": "XXXXXXXXXXXXXXXXXXXX", "ipv6LLA": "XXXXXXXXXXXX", "serialNum": "J1025PXX", "mtm": "7D2XCTO1WW",
"ibmSerialNumber": "rackae402", "ibmMTM": "9155-C01", "type": "storage", "OCPRole": "control-1-ru3", "location":
"RU2", "name": "IMM_RU2", "bootDevice": "/dev/sda", "users": [ { "user": "CEUSER", "password": "XXXXX", "group":
"Administrator", "number": 2 }, { "user": "ISFUSER", "password": "XXXXXX", "group": "Administrator", "number": 3 }, {
"user": "USERID", "password": "XXXXXX", "group": "Administrator", "number": 1 }
```

Sample section for IPv4:

```
"ipv4": 165.253.1.7", "serialNum": "J1025PXX", "mtm": "7D2XCTO1WW", "ibmSerialNumber": "rackae402", "ibmMTM": "9155-
C01", "type": "storage", "OCPRole": "control-1-ru3", "location": "RU2", "name": "IMM_RU2", "bootDevice": "/dev/sda",
"users": [ { "user": "CEUSER", "password": "XXXXX", "group": "Administrator", "number": 2 }, { "user": "ISFUSER",
"password": "XXXXXX", "group": "Administrator", "number": 3 }, { "user": "USERID", "password": "XXXXXX", "group":
"Administrator", "number": 1 }
```

- Run the following command to create a tunnel to the IMM of the node:

```
ssh -N -f -L :1443:[IPv6 or IPv4 address of IMM]:443 -L :3900:[IPv6 or IPv4 address of IMM]:3900 root@localhost
```

- Access the IMM user interface using the provisioner node IP address, open your browser and access the following IP.

```
https://<provisioner ip>:1443
```

- User - Enter ``USERID``.
- Password - Use the value obtained in the previous step.

12. From the IMM user interface page, open the remote console and check whether the node is up and shows a valid hostname prompt.
- If the console shows `localhost`, then review your DHCP/DNS settings to ensure whether correct reservation is made for the node.
 - If the node shows a Red Hat linux login prompt instead of Core OS, then it infers that the node Base management controller (BMC) is not responsive.

Do the following steps to resolve the issue:

- Identify IMM of the missing node. Here is mapping of nodes to IMM:

```
control-1-ru2 ==> imm_ru2
control-1-ru3 ==> imm_ru3
control-1-ru4 ==> imm_ru4
```

- For node(s) that did not show up in the previous steps, run commands to connect to their IMM. For example, if node ``control-1-ru3`` did not show up, then from RU7/provisioner (compute-1-ru7), run `imm_ru3` command as a `kni` user:
- Wait for the successful connection to IMM.
- In the system prompt, run the ``resetsp`` on IMM prompt.
- Wait 10 minutes.

Next actions

In the installation user interface, click the Retry to restart the installation.

Catalog source pod is healthy

Message: IBM Fusion catalog source pod is not found or is not healthy.

Diagnosis

Note: Run all commands as a `kni` user from the provisioner node.

- Run the following command to verify whether the `catalogsource` exists or not.

```
oc -n openshift-marketplace get catsrc
```

Sample output:

NAME	DISPLAY	TYPE	PUBLISHER	AGE
certified-operators		Certified	Operators	grpc Red Hat 11d
community-operators		Community	Operators	grpc Red Hat 11d
fusion-catalog		IBM Fusion	Catalog	grpc IBM 11d
isf-data-foundation-catalog		Data Foundation	Catalog	grpc IBM 9d
redhat-marketplace		Red Hat	Marketplace	grpc Red Hat 11d
redhat-operators		Red Hat	Operators	grpc Red Hat 11d

From the output, check for catalog source with name **fusion-catalog** exists.

2. If catalog source exists, then run the following command to check for the next **catalogsource** pod:

```
oc -n openshift-marketplace get po
```

3. Check for a pod that starts with **fusion-catalog-** and is in **Running** state with 1/1 containers in **READY** field.

For example

```
oc -n openshift-marketplace get po
```

Sample output:

NAME	READY	STATUS	RESTARTS	AGE
certified-operators-ztp8f			1/1	Running 0 14h
community-operators-78vrd			1/1	Running 0 14h
fusion-catalog-kbw6h			1/1	Running 0 2d12h
isf-data-foundation-catalog-tv6pc			1/1	Running 0 19h
marketplace-operator-f84d7df4f-f2zrg			1/1	Running 0 2d11h
redhat-marketplace-8dgwp			1/1	Running 0 2d11h
redhat-operators-qj6pk			1/1	Running 0 14h

4. If the pod is in **ImagePullBackOff** or **ErrImagePull** state, then describe pod to check the exact reason.

- If describe shows timeout in pulling image, then check network bandwidth.
- Offline installation:
 - If the listed error is related to an image manifest not known, then check whether the image is present in the enterprise registry.
 - If describe shows authentication error, then check whether the secret **pull-secret** in namespace **openshift-configs** has the correct credentials for the enterprise registry.

Next actions

Take corrective measures based on the diagnostics and rerun the installation.

Operator subscription isf-subscription not found

Message: Subscription for IBM Fusion operator not found.

Diagnosis

Note: Run all commands as a kni user from provisioner node.

1. Run the following command and in the output check whether the subscription with name **isf-subscription** exists.

```
oc get sub -n ibm-spectrum-fusion-ns
```

Sample output:

NAME	PACKAGE	SOURCE	CHANNEL
grafana-operator	grafana-operator	community-operators	v4
isf-subscription	isf-operator	isf-catalog	v2.0

2. If subscription does not exist, then go to **/home/kni/logs** and check the log file that starts with **installoperator** for any errors:

Next actions

Take corrective measures based on the diagnostics and rerun installation. If issue is not resolved, contact IBM support with all logs from **/home/kni/** and archive that is downloaded from installation user interface.

Failed to save vault secret configuration

Message: Failed to save the vault secret configuration.

Problem description

The installer cannot create or apply the Vault Kubernetes secret by using the `vault_secret.j2` template during the persist-configuration phase. This secret stores the Vault root token and unseal keys as a Kubernetes Secret object. The failure occurs when the `k8s` module cannot delete the pre-existing secret or create the new one. Common causes include a Kubernetes API connectivity issue, an invalid or malformed template, or insufficient RBAC permissions for the `kni` user's kubeconfig.

Recommended actions

1. Review `~/logs/persistconfig_playbook.log` for the precise `k8s` module error message.
2. Verify that `KUBECONFIG` is valid and the cluster API server is reachable from the provisioner node.
3. Confirm that the target namespace exists and the service account has `create` and `delete` permissions on Secrets.
4. Check that the `vault_secret.j2` template renders correctly and all required variables (root token, unseal keys) are populated.
5. Inspect Vault key files under `/home/kni/` to ensure that they are present, readable, and Base64-encoded correctly.

Failed to save vault login secret configuration

Message: Failed to save the vault login secret configuration.

Problem description

The installer cannot create the Vault login Kubernetes secret, which stores the Vault username and password credentials that are derived from the `vaultLoginFile`. This task reads a Base64-encoded colon-separated credential file, decodes it, extracts the username and password, and renders them into a Kubernetes Secret through the `vault_login_secret.j2` template. Failure can occur if the login file is missing or malformed, the Base64 decoding produces unexpected content, or the Kubernetes API rejects the secret creation request.

Recommended actions

1. Review `~/logs/persistconfig_playbook.log` for detailed task output.
2. Confirm that the Vault login file referenced by `vaultLoginFile` exists and is valid Base64-encoded content in `username:password` format.
3. Verify that the Kubernetes cluster API is reachable and the kubeconfig is valid.
4. Check that the target namespace exists and permissions allow Secret creation.
5. If [INS0074F](#) triggers first, resolve that error before attempting again, as both tasks depend on the same Kubernetes connectivity.

Failed to create and configure service node user

Message: Failed to create and configure the service node user.

Problem description

The installer encounters an error while executing `create_snuser.yml`, the task responsible for provisioning and configuring the service node (SN) user on the cluster. This step runs only on service node deployments where `isServiceNode == True`. The error means the installer cannot create the dedicated service node OS user, configure its home directory, or set its permissions correctly. This user is required for later operational access.

Recommended actions

1. Review `~/logs/status_playbook.log` for the specific failure point within `create_snuser.yml`.
2. Confirm that the provisioner node has SSH access to the service node hosts listed in the inventory.
3. Check that the remote host has sufficient disk space and that `useradd` and `usermod` commands are available.
4. Ensure that no OS-level restrictions such as SELinux policies or locked accounts that prevent user creation are present.
5. Verify that the `isServiceNode` variable is correctly set. This block is skipped entirely for non-service-node deployments.

Failed to save secrets inside Vault

Message: Failed to save the secrets inside Vault.

Problem description

This is a top-level catch-all error for the entire Vault secret-saving workflow (`save_secrets_in_vault.yml`). The outer rescue block for the Vault storage phase raises it when an unexpected error occurs that is not already handled by the more specific error codes [INS0080F](#) through [INS0084F](#). In practice, this error can occur if the Vault service is unreachable before any individual operation begins, if a pre-condition check fails, or if a task outside of the guarded sub-blocks raises an unhandled exception. This outer catch fires only when the current results file does not already record a specific Vault sub-error (status codes -80 through -84).

Recommended actions

1. First check whether a more specific error code ([INS0080F](#) through [INS0084F](#)) is recorded. [INS0078F](#) is a fallback and the root cause usually points to one of those codes.
2. Review `~/logs/status_playbook.log` for the full traceback.
3. Confirm that the Vault service is running: `systemctl status vault.service`.
4. Ensure that the `VAULT_ADDR` environment variable is correctly configured and the Vault address is reachable from the provisioner node.
5. Check that all required Vault key files exist under `/home/kni/` and are readable by the `kni` user.

Failed to unseal Vault

Message: Failed to unseal the Vault.

Problem description

The installer cannot unseal the HashiCorp Vault instance by using the configured unseal keys. The Vault uses a Shamir secret-sharing scheme requiring 3 out of 5 unseal keys. The installer applies keys 1, 2, and 3 sequentially using `vault operator unseal`. This error fires if any of those three unseal operations returns a non-zero exit code, or if the subsequent `vault status` verification confirms that the Vault is still sealed. Common causes include corrupted or incorrect unseal key files, a Vault instance that is not yet started, or a network or TLS issue preventing communication with the Vault API.

Recommended actions

1. Verify that the Vault service is running on the provisioner node:

```
systemctl status vault.service
```
2. Confirm that the unseal key files (for example, `vaultUnsealKeys1File` through `vaultUnsealKeys3File`) exist, are readable, and contain valid Base64-encoded unseal keys.
3. Attempt manual unsealing: run `vault operator unseal <key>` with `VAULT_ADDR` and `VAULT_SKIP_VERIFY` set appropriately.
4. Check Vault logs:

```
journalctl -u vault.service --no-pager -n 100
```
5. Ensure that the Vault storage backend (filesystem or raft) is healthy and not out of disk space.

Failed to log in to Vault

Message: Failed to log in to the Vault.

Problem description

After successfully unsealing Vault, the installer cannot authenticate by using the Vault root token. The login is performed by piping the decoded root token to `vault login -`. A non-zero return code from this command triggers this error. Typical causes include a missing or corrupted root token file, a token that is revoked or expired, or a Vault instance that is unsealed but not yet fully initialized and ready to accept login requests.

Recommended actions

1. Confirm that the root token file (referenced by `vaultRootToken`) exists and contains a valid Base64-encoded Vault token.
2. Verify that the token is not revoked by checking Vault audit logs or running `vault token lookup <token>` manually.
3. Ensure that the Vault is fully operational after unsealing by running `vault status` and confirming `Sealed: false`.
4. Check `~/logs/status_playbook.log` for any Vault API error responses around the login task.
5. If the token is lost or revoked, Vault might need re-initialization, which is a destructive operation. Consult [IBM Support](#) before proceeding.

Failed to find or process kickstart files for Vault storage

Message: Failed to find or process kickstart files for Vault storage.

Problem description

The installer is unable to locate or parse the kickstart JSON configuration files that are required to populate Vault with provisioner, switch, and CNIMM (Cluster Node Infrastructure Management Module) data. The installer searches for files matching `kickstart-*.json` in `/home/kni/isfconfig/`. This error fires if no matching files are found, if a file is unreadable, or if the JSON content cannot be parsed and aggregated into the expected `provisioners`, `switches`, and `cnimm` data structures that are written to `/tmp/extracted_*.json` for subsequent Vault storage.

Recommended actions

1. Verify that at least one `kickstart-*.json` file exists in `/home/kni/isfconfig/` and is readable by the `kni` user.
2. Validate the JSON syntax of the kickstart files:

```
python3 -m json.tool /home/kni/isfconfig/kickstart-*.json
```
3. Confirm that the file is correctly generated during the PreparingInstallation phase. If that phase has errors, the kickstart file might be incomplete or absent.
4. Review `~/logs/status_playbook.log` to determine which specific task within the kickstart processing block fails.
5. Check disk space and filesystem permissions on `/home/kni/isfconfig/` and `/tmp/`.

Failed to save secrets to Vault after 5 attempts

Message: Failed to save secrets to the Vault after 5 attempts.

Problem description

All five automatic retry attempts to write secrets to Vault through the REST API (using `store_secrets_to_vault.yml`) fail. Between each attempt the installer runs `ensure_vault_healthy.yml` to recover the Vault service, reunseal it, and reauthenticate before retrying. After exhausting the maximum retry count (`vault_storage_max_retries = 5`) the installer sets this terminal error code. Causes include persistent Vault instability, storage backend I/O failures, insufficient permissions for the KV secrets engine path, or network interruptions between the provisioner and the Vault API endpoint.

Recommended actions

1. Review `~/logs/status_playbook.log` for the per-attempt failure messages and the specific Vault API error on each try.
2. Confirm that the Vault KV secrets engine is enabled and mounted at the expected path.
3. Check the Vault storage backend for errors:

```
journalctl -u vault.service --no-pager -n 200
```
4. Manually test a Vault write operation after logging in:

```
vault kv put secret/test value=ping
```
5. Ensure that the provisioner node has stable network connectivity to the Vault API (`VAULT_ADDR`) with no intermittent packet loss.
6. If Vault is running out of disk space on its storage backend, free up the space before retrying the installation.

Failed to read SSH keypair

Message: Failed to read the SSH keypair.

Problem description

The installer is unable to read the ECDSA SSH keypair for the `kni` user from `/home/kni/.ssh/id_ecdsa` (private key) and `/home/kni/.ssh/id_ecdsa.pub` (public key). These keys are required to populate the `ProvisionerPubPrivKeySecret` entry in Vault, which IBM Fusion uses for subsequent provisioner-to-node SSH authentication. The key type is `ecdsa` rather than `ed25519` to ensure FIPS compliance. This error fires if either file does not exist, is not readable by the `kni` user, or the `slurp` module encounters a permissions error.

Recommended actions

1. Confirm that both files exist:

```
ls -la /home/kni/.ssh/id_ecdsa /home/kni/.ssh/id_ecdsa.pub
```
2. Ensure that the files are owned by and readable by the `kni` user. Permissions must be `600` for the private key and `644` for the public key.
3. If the keypair does not exist, regenerate it:

```
ssh-keygen -t ecdsa -b 521 -f /home/kni/.ssh/id_ecdsa -N ""
```

Note: `ed25519` keys do not satisfy this step. The installer explicitly expects ECDSA keys for FIPS compliance. Do not substitute a different key algorithm.
4. After regenerating the keypair, ensure that the new public key is distributed to all managed nodes in the cluster before running the installation again.

Bootstrap VM is not pingable

A temporary bootstrap VM is created on provisioner node to create Red Hat® OpenShift® Container Platform control plane.

Message: Either bootstrap VM is not created or did not receive hostname and IP from DHCP.

Diagnosis

Note: Run all commands from the provisioner node as a **kni** user.

1. Run the following command on the provisioner node as a **kni** user to check whether the bootstrap VM is created:

```
sudo virsh list
```

2. Empty output of previous command indicates that bootstrap VM is not created. To debug further, check the log file `/home/kni/clusterconfigs/.openshift_install.log` for errors.

```
sudo virsh list
setlocale: No such file or directory
Id   Name   State
-----
```

3. If output from first command is not empty. Example when bootstrap VM is created.

```
sudo virsh list
setlocale: No such file or directory
Id   Name   State
-----
1    isf-rackae4-2bztv-bootstrap  running
```

4. If VM is listed in step 3, then run the following command to connect to it and check whether it has a valid hostname assigned.

```
ping bootstrap.<subdomain>
```

Here, subdomain is your `<cluster name>.<basedomain name>`.

- If bootstrap is not pinging, then verify your DHCP and DNS setting for bootstrap VM.
- An IP reservation in DHCP server must be made for bootstrap VM with correct MAC address as received in TDA sheet.
- Lookup and reverse lookup records in DNS server for bootstrap VM.
- Rectify the identified problems.

Next actions

In the installation user interface, click **Retry** to restart the installation.

Configuration error

The certificate does not contain a wildcard domain for cluster.

Diagnosis

1. Provided ingress certificate does not have a wildcard sub-domain of the OpenShift® cluster.
2. Provided certificate must adhere to guidelines from OpenShift outlined here - [Understanding the default ingress certificate](#) in *Red Hat OpenShift Container Platform* documentation.

Next actions

1. Obtain a new certificate with valid wildcard OpenShift subdomain in it.
2. In the installation user interface, click Back and provide a new certificate with a private key. The installation restarts with the new certificate.

Failed to install CSV for isf-operator

When you install IBM Fusion, the installation fails with "Failed to install CSV for ifs-operator" error.

For more information, check the log file `/home/kni/logs/installoperator_playbook.log`.

Diagnosis

Run all the commands as a **kni** user from the provisioner node.

1. Open the log file `/home/kni/logs/installoperator_playbook.log` and search for the string `"Wait for CSV isf-operator to get installed"` for errors to find the root cause.

- If the previous logs do not contain details of the root cause, then continue with next steps for further diagnostics.
- Run `oc get csv -n ibm-spectrum-fusion-ns` on the provisioner (also known as RU7 or compute-1-ru7 node). Example output:

NAME	DISPLAY	VERSION	REPLACES	PHASE
isf-operator.v2.8.0-13104160	IBM Storage Fusion	2.8.0	isf-operator.v2.7.1	Failed

- Check which pods are not in **Running** or **Completed** state by using the following command:

```
oc get pods -n ibm-spectrum-fusion-ns | grep -ivE 'Running|Completed'
```

Sample output with one pod in **ImagePullBackOff** error:

NAME	READY	STATUS	RESTARTS	AGE
isf-application-operator-controller-manager-7578464c4b-tld5w	0/2	ImagePullBackOff	0	116m
logcollector-5cf49dbc55-jzczf	0/1	Pending	0	116m
logcollector-5cf49dbc55-pjgl5	0/1	Pending	0	116m

- Run the following describe command to view the details of pod:

```
oc describe pod <POD NAME> -n ibm-spectrum-fusion-ns
```

- Scroll the output and examine the **Events** section of the output.
Example output:

Events:				
Type	Reason	Age	From	Message
Normal	Scheduled	98m	default-scheduler	Error: ImagePullBackOff

- If error from the describe command indicates authorisation or authentication error, then check whether the credentials you provided during the stage2 installation are correct.
 - For online installation, it is the entitlement key that you provided. In this case, the user is always **cp**.
 - For online installation, also check whether the specified entitlement key includes an IBM Fusion HCI entitlement.
 - For installation from enterprise registry, check the provided credentials for your enterprise registry (for both multiple and single repositories).
 - Try to pull the image manually on one OpenShift® Container Platform node by connecting to the node from provisioner by using `oc debug node/<NODE-NAME>`.
- If the error from the previous describe command indicates manifest unknown error, then do the following checks:
 - For installation from enterprise registry, check whether your enterprise registry is configured properly and reachable from provisioner (RU7).
 - For installation from enterprise registry, make sure that the IBM Fusion HCI images are mirrored correctly.
 - Ensure that the user mirror images with right digest to right path exist in the enterprise registry.

Next actions

Take corrective actions and click Retry in the installation user interface.

Failed to install IBM Fusion operator

Failed to install the IBM Fusion operator. Check the log file `/home/kni/logs/installoperator_playbook.log` for more details.

Diagnosis

Run all commands as a kni user from the provisioner node.

- Run the following command to check whether the catalogsource exists:

```
oc get catsrc -n openshift-marketplace
```

- Verify whether the catalog source with name **isf-catalog** exists.
Sample output:

NAME	DISPLAY	TYPE	PUBLISHER	AGE
certified-operators	Certified Operators	grpc	Red Hat	3d9h
community-operators	Community Operators	grpc	Red Hat	3d9h
ibm-operator-catalog	IBM Operator Catalog	grpc	IBM	3d2h
isf-data-foundation-catalog	Data Foundation Catalog	grpc	IBM	3d5h
isf-catalog		grpc		8h
redhat-marketplace	Red Hat Marketplace	grpc	Red Hat	3d9h
redhat-operators	Red Hat Operators	grpc	Red Hat	3d9h

- Run the following command to check whether the **catalogsource** pod exists:

```
oc get pods -n openshift-marketplace
```

- Check whether a pod that starts with **isf-catalog** exists with the **Status** as **Running** and **Ready** as **1/1**.
Example:

NAME	READY	STATUS	RESTARTS	AGE
isf-catalog-wh8zn	1/1	Running	0	8h
marketplace-operator-dd4dff8f-jxwm4	1/1	Running	0	32h
redhat-marketplace-d9dl8	1/1	Running	0	32h
redhat-operators-gzk4q	1/1	Running	0	32h

- If you find that the pod is not in running status, then run the following command to view the details:

```
oc describe pod <POD NAME> -n openshift-marketplace
```

6. Scroll to the bottom and examine the **Events** section of the output.

```
Events:
  Type      Reason      Age   From              Message
  ----      -
Normal      Scheduled    98m   default-scheduler Error: ImagePullBackOff
```

7. If error from the describe command indicates authorisation or authentication error, then check whether the credentials you provided during the stage2 installation are correct.

- For online installation, it is the entitlement key that you provided. In this case, the user is always **cp**.
- For online installation, also check whether the specified entitlement key includes an IBM Fusion HCI entitlement.
- For installation from enterprise registry, check the provided credentials for your enterprise registry (for both multiple and single repositories).
- Try to pull the image manually on one OpenShift® Container Platform node by connecting to the node from provisioner by using **oc debug node/<NODE-NAM>**.

8. If the error from the previous describe command indicates manifest unknown error, then do the following checks:

- For installation from enterprise registry, check whether your enterprise registry is configured properly and reachable from provisioner (RU7).
- For installation from enterprise registry, make sure that the IBM Fusion HCI images are mirrored correctly.
- Ensure that the user mirror images with right digest to right path exist in the enterprise registry.

9. If **isf-catalog** pod is running successfully, then run the following command to check for IBM Fusion HCI namespace:

```
oc get namespace | grep ibm-spectrum-fusion-ns
```

Sample output:

```
ibm-spectrum-fusion-ns          Active   3d9h
```

If the command **oc get namespace | grep ibm-spectrum-fusion-ns** gives a blank output, then it means that the IBM Fusion HCI namespace is not created. Check the log file `/home/kni/logs/installoperator_playbook.log` for the following message:

```
message":"etcdserver: request timed out","code":500}\n", "reason": "Internal
Server Error", "status": 500}
```

The failure indicates that this API issue is caused by the network bandwidth or any other latency. If the installation retries fail, contact IBM Support. Even if you do not find any API related issue in your logs, then contact IBM Support.

10. If the namespace is created, then run the following command to check for IBM Fusion **operator group**:

```
oc get og -n ibm-spectrum-fusion-ns
```

Sample output:

```
NAME      AGE
isf-og    3d9h
```

If the previous **oc get og -n ibm-spectrum-fusion-ns** command gives a blank output, then it means that the operator group is not created. Check the log file `/home/kni/logs/installoperator_playbook.log` for the following message:

```
message":"etcdserver: request timed out","code":500}\n", "reason": "Internal
Server Error", "status": 500}
```

The failure indicates that this API issue is caused by the network bandwidth or any other latency. If the installation retries fail, contact IBM Support. Even if you do not find any API related issue in your logs, then contact IBM Support.

11. If the operator group is created, then run the following command to check for IBM Fusion **subscription**:

```
oc get sub -n ibm-spectrum-fusion-ns
```

Sample output:

```
NAME              PACKAGE      SOURCE          CHANNEL
isf-subscription  isf-operator iso-catalog-new v2.0
```

12. If the previous **oc get og -n ibm-spectrum-fusion-ns** command gives a blank output, then it means that the operator group is not created. Check the log file `/home/kni/logs/installoperator_playbook.log` for the following message:

```
message":"etcdserver: request timed out","code":500}\n", "reason": "Internal
Server Error", "status": 500}
```

The failure indicates that this API issue is caused by the network bandwidth or any other latency. If the installation retries fail, contact IBM Support. Even if you do not find any API related issue in your logs, then contact IBM Support.

13. If subscription is created, then run the following command to check for IBM Fusion **install plan**:

```
oc get ip -n ibm-spectrum-fusion-ns
```

Sample output:

```
NAME           CSV              APPROVAL  APPROVED
install-bcqb4  isf-operator.v2.8.0-13321732  Manual    true
```

If the command **oc get ip -n ibm-spectrum-fusion-ns** gives a blank output, then it means that the install plan is not created.

14. If **install plan** is not found, then run the following commands to check jobs:

```
oc get job -n openshift-marketplace
```

Example output:

NAME	COMPLETIONS	DURATION	AGE
0308d219fbaf8eeca9372a4314df5af975f06f2ff3cd55c8fc33489e88deb346	1/1	9s	3d2h

f31ed4a99e495429a1d47697faef595eb7a0f59b40d43617f8f3e2018bd1842	1/1	7s	3d6h

15. If any job does not have COMPLETION as 1/1, then run the following command to check for errors:

```
oc get jobname -n openshift-marketplace
```

Next actions

Take corrective actions and click Retry in the installation user interface.

The catlogsource pod for Red Hat® operators is not running

The **catlogsource** pod for **redhat-operators** is not running in **openshift-marketplace** namespace. Check the log file %s for more details.

Diagnosis

Run all commands as a kni user from the provisioner node.

1. Run the following command to verify whether the **catalogsource** exists or not.

```
oc -n openshift-marketplace get catsrc
```

2. Verify whether the catalog source with name **redhat-operators** exists.

Sample output:

NAME	DISPLAY	TYPE	PUBLISHER	AGE
certified-operators	Certified Operators	grpc	Red Hat	3d22h
community-operators	Community Operators	grpc	Red Hat	3d22h
ibm-operator-catalog	IBM Operator Catalog	grpc	IBM	3d12h
isf-catalog	IBM Fusion Catalog	grpc	IBM	3d21h
opencloud-operators	IBMCS Operators	grpc	IBM	3d12h
redhat-marketplace	Red Hat Marketplace	grpc	Red Hat	3d22h
redhat-operators	Red Hat Operators	grpc	Red Hat	3d22h

3. If the catalog source exists, then run the following command to check for **catalogsource** pod:

```
oc -n openshift-marketplace get po
```

4. Check whether a pod that starts with **redhat-operators-** exists with the **Status** as **Running** and **Ready** as **1/1**.

Example:

NAME	READY	STATUS	RESTARTS	AGE
certified-operators-2j2jx	1/1	Running	0	3d11h
community-operators-9wxc	1/1	Running	0	14h
ibm-operator-catalog-d768c	1/1	Running	0	3d10h
isf-catalog-d972s	1/1	Running	0	3d21h
marketplace-operator-84558d7577-9nmdj	1/1	Running	0	3d21h
opencloud-operators-bghhj	1/1	Running	0	3d12h
redhat-marketplace-czb2z	1/1	Running	0	3d21h
redhat-operators-49nf8	1/1	Running	0	142m

5. If the pod is in **ImagePullBackOff** or **ErrImagePull** state, then describe pod to check the exact reason:

- If describe shows timeout in pulling image, then check the network bandwidth.
- If error listed is the image manifest is not known and it is an offline installation, then check whether the image is present in enterprise registry.
- If describe shows authentication error and it is an offline installation, then check the secret **pull-secret** in namespace **openshift-config** for correct enterprise registry credentials.

Next actions

Take corrective actions and rerun installation.

Failed to deploy nmstate-operator

Failed to deploy **nmstate-operator**. Check the log file /home/kni/logs/installoperator_playbook.log for more details.

Diagnosis

Run all commands as a kni user from the provisioner node.

1. Run the following command to check whether the `catalogsource` exists or not:

```
oc get catsrc -n openshift-marketplace
```

2. Verify whether the catalog source with name `redhat-operators` exists.

NAME	DISPLAY	TYPE	PUBLISHER	AGE
certified-operators	Certified Operators	grpc	Red Hat	3d9h
community-operators	Community Operators	grpc	Red Hat	3d9h
ibm-operator-catalog	IBM Operator Catalog	grpc	IBM	3d2h
isf-data-foundation-catalog	Data Foundation Catalog	grpc	IBM	3d5h
isf-catalog.		grpc		8h
redhat-marketplace	Red Hat Marketplace	grpc	Red Hat	3d9h
redhat-operators	Red Hat Operators	grpc	Red Hat	3d9h

3. If catalog source exists, then run the following command to check for `catalogsource` pod:

```
c get pods -n openshift-marketplace
```

4. Verify a pod starting with `redhat-operators-` is present and is in **Running** state with **1/1** containers in **READY** field. For example:

NAME	READY	STATUS	RESTARTS	AGE
isf-catalog-wh8zn	1/1	Running	0	8h
marketplace-operator-dd4dff8f-jxwm4	1/1	Running	0	32h
redhat-marketplace-d9dl8	1/1	Running	0	32h
redhat-operators-gzk4q	1/1	Running	0	32h

5. If the pod is not running, then run the following command to see the details of pod:

```
oc describe pod <POD NAME> -n openshift-marketplace
```

6. Scroll and examine the **Events** section of the output.

Type	Reason	Age	From	Message
Normal	Scheduled	98m	default-scheduler	Error: ImagePullBackOff

7. If error from the describe command in authorisation or authentication error, then check the credentials you provided in stage2 installation GUI page:

- For online installation, check your pull-secret that you provided.
- For installation from enterprise registry, check the provided credentials for your enterprise registry (for both multiple and single repositories).
- Try to pull the image manually on one OpenShift® Container Platform node by connecting to the node from provisioner by using `oc debug node/<NODE-NAM>`.

8. If error from the describe command in step 3 indicated manifest unknown error then make sure the following checks:

- For installation from enterprise registry, check whether your enterprise registry is configured properly and reachable from provisioner (RU7).
- For installation from enterprise registry, make sure that the `kubernetes-nmstate-operator` images are mirrored correctly.
- Ensure that the user mirror images with right digest to right path exist in the enterprise registry.

9. If the `redhat-operators` pod is running successfully, then run the following command to check the namespace `openshift-nmstate`:

```
oc get namespace | grep openshift-nmstate
```

Sample output:

```
openshift-nmstate          Active    4dlh
```

If the previous `oc get og -n openshift-nmstate` command gives a blank output, then it means that the operator group is not created. Check the log file `/home/kni/logs/installoperator_playbook.log` for the following message:

```
message":"etcdserver: request timed out","code":500}\n", "reason": "Internal Server Error", "status": 500}
```

The failure indicates that this API issue is caused by the network bandwidth or any other latency. If the installation retries fail, contact IBM Support. Even if you do not find any API related issue in your logs, then contact IBM Support.

10. If namespace is created, then check for the operator group with name `openshift-nmstate`:

```
oc get og -n openshift-nmstate
```

Sample output:

NAME	AGE
openshift-nmstate	4d2h

If the previous `oc get og -n openshift-nmstate` command gives a blank output, then it means that the operator group is not created. Check the log file `/home/kni/logs/installoperator_playbook.log` for the following message:

```
message":"etcdserver: request timed out","code":500}\n", "reason": "Internal Server Error", "status": 500}
```

The failure indicates that this API issue is caused by the network bandwidth or any other latency. If the installation retries fail, contact IBM Support. Even if you do not find any API related issue in your logs, then contact IBM Support.

11. If the operator group is created, then run the following command to check for `kubernetes-nmstate-operator` subscription:

```
oc get sub -n openshift-nmstate
```

Sample output:

NAME	PACKAGE	SOURCE	CHANNEL
kubernetes-nmstate-operator	kubernetes-nmstate-operator	redhat-operators	stable

If the previous `oc get og -n openshift-nmstate` command gives a blank output, then it means that the operator group is not created. Check the log file `/home/kni/logs/installoperator_playbook.log` for the following message:

```
message":"etcdserver: request timed out","code":500}\n", "reason": "Internal Server Error", "status": 500}
```

The failure indicates that this API issue is caused by the network bandwidth or any other latency. If the installation retries fail, contact IBM Support. Even if you do not find any API related issue in your logs, then contact IBM Support.

12. If the subscription is created, then check for `kubernetes-nmstate-operator` installplan:

```
oc get ip -n openshift-nmstate
```

Sample output:

NAME	CSV	APPROVAL	APPROVED
install-kz5sb	kubernetes-nmstate-operator.4.14.0-202311021650	Automatic	true

13. If the `oc get ip -n openshift-nmstate` command gives a blank output, then it means that the install plan is not created. If `install plan` is not found, check jobs by running the command `oc get job -n openshift-marketplace`.

NAME	COMPLETIONS	DURATION	AGE
0308d219fbaf8eec9372a4314df5af975f06f2ff3cd55c8fc33489e88deb346	1/1	9s	3d2h

d68f3512c112308d77831d6c2765ee4c8e8d1960661a33dad59f0419e9fd732	1/1	9s	3d3h
f31ed4a99e495429a1d47697faef595eb7a0f59b40d43617f8f3e2018bd1842	1/1	7s	3d6h

14. If any job does not have COMPLETION as '1/1', then run the `oc get jobname -n openshift-marketplace` comment and check for errors.

Next actions

Take corrective actions and rerun installation.

Failed to install CSV for kubernetes-nmstate-operator

While installing IBM Fusion HCI, the installation fails with the error message `Failed to install CSV for kubernetes-nmstate-operator`. Check log file `/home/kni/logs/installoperator_playbook.log` for more details.

Diagnosis

Run all commands as a kni user from the provisioner node.

1. See log file `/home/kni/logs/installoperator_playbook.log` and search for the following string:

```
Wait for CSV kubernetes-nmstate-operator to get installed on second attempt
```

2. If the logs do not give enough information, then continue further diagnostics.
3. As a kni user, run `oc get csv -n openshift-nmstate` on the provisioned (also known as RU7 or compute-1-ru7 node). Check for 'Failed' status.

NAME	DISPLAY	VERSION	REPLACES	PHASE
kubernetes-nmstate-operator.4.14.0-202311021650	Kubernetes NMState Operator	4.14.0-202311021650		Failed

4. Check which pods are not **Running** or in **Completed** state:

```
oc get pods -n openshift-nmstate
```

See the sample output for pods that are not in 'Running' STATUS:

NAME	READY	STATUS	RESTARTS	AGE
nmstate-cert-manager-64474fd576-v75sq	1/1	Running	0	2d2h
nmstate-console-plugin-5bb9bbf97c-ssjff2	1/1	Running	0	2d2h
nmstate-handler-2x16x	1/1	Running	4 (4d1h ago)	4d1h
nmstate-handler-8xktl	1/1	Running	0	4d2h
nmstate-handler-97pzc	1/1	Running	3 (4d1h ago)	4d1h
nmstate-handler-ggbpt	1/1	Running	0	4d2h
nmstate-handler-p9wsn	1/1	Running	0	4d2h
nmstate-handler-pjjdr	1/1	Running	3 (4d1h ago)	4d1h
nmstate-operator-c89955d9-snmh4	1/1	Running	0	2d2h
nmstate-webhook-69477dbc4f-6v719	1/1	Running	0	2d2h
nmstate-webhook-69477dbc4f-mqwmq	1/1	Running	0	2d2h

5. See the details of pod which are not in 'Running' STATUS:

```
oc describe pod <POD NAME> -n openshift-nmstate
```

6. Scroll and examine the **Events** section of the output:

```
Events:
  Type            Reason            Age   From                      Message
  ----            -
  Normal          Scheduled          98m   default-scheduler        Error: ImagePullBackOff
```

7. If error from the describe command indicates authorisation or authentication error, then check whether the credentials you provided during the stage2 installation are correct.

- For online installation, check pull-secret that you provided.
- For installation from enterprise registry, check the provided credentials for your enterprise registry (for both multiple and single repositories).
- Try to pull the image manually on one OpenShift® Container Platform node by connecting to the node from provisioner by using `oc debug node/<NODE-NAME>`.

8. If the error from the previous describe command indicates manifest unknown error, then do the following checks:

- For installation from enterprise registry, check whether your enterprise registry is configured properly and reachable from provisioner (RU7).
- For installation from enterprise registry, make sure that the **redhat** **kubernetes-nmstate-operator** images are mirrored correctly.
- Ensure that the user mirror images with right digest to right path exist in the enterprise registry.

Next actions

Take corrective actions and rerun installation.

Delete files from provisioned node

The provisioner node, also known as service node, remains intact after IBM Fusion HCI initialization. For security reasons, all the configuration files are deleted from the service node.

Diagnostics

Note: Run all commands as kni user from the provisioner node.

1. Check `/home/kni/logs/servicenode_cleanup_playbook.log` for more details.
2. Scroll to end of file and check if it reports a failure.

The following example shows a successful run:

```
PLAY RECAP *****
localhost                : ok=68   changed=3    unreachable=0    failed=0    skipped=45    rescued=0    ignored=0
```

If you find a failed value that is not equal to 0, then review the log to identify the step that failed.

Next actions

1. Log in to service node using kni user.
2. Check for `/home/kni/install/cleanup_files_manually.json`
3. Delete all the service node files manually, which are listed in the `cleanup_files_manually.json`.

BMYP1172

Service node upgrade completed.

Severity

Informational

User actions

No action is required.

BMYP2106

Firmware update Job failed for the compute node.

Error conditions

The error message can be for the following conditions:

- Failed to put the node in maintenance mode for firmware update.
- Failed to move the node out of maintenance after firmware update attempt.
- Power operation of graceful restart of the node failed after firmware update attempt.
- Firmware update failed on the node, not reflecting the latest version after the node restart and IMM reset.
- Firmware update operation timed out on the compute node.
- Scale cluster did not turn healthy post firmware update on the node.

Note: If the storage is configured with Data Foundation, then also the message shows that `Scale cluster did not turn healthy post firmware update on the node` in the IBM Fusion user interface because of a typographical error in the event message.

Severity

Critical

User actions

Do the following steps to diagnose and report the problem:

1. Check whether any other node is in maintenance mode. Ensure that all the nodes must be up and in a ready state to perform firmware update operations.
2. An administrator needs to move the node out of maintenance mode by using the OpenShift® or IBM Fusion user interface.
3. The administrator should power-off and power-on the node, and after it gets completed successfully, move the node out of maintenance mode manually. This issue might get resolved on its own. This issue happens mostly when power operation takes longer than expected.
4. Run the OC Command to check whether the scale cluster is healthy.

```
oc -n ibm-spectrum-fusion-ns get scales storagemanager -oyaml | grep storageClusterStatus
```

5. Run the OC Command to check whether the Data Foundation cluster is healthy.

```
oc get odcluster odcluster -o yaml -n ibm-spectrum-fusion-ns | grep odcluster.cephClusterHealth
```

6. Retrigger firmware update if compute CR shows `upgradeRequired=true`. If the firmware update fails again, contact [IBM Support](#).
7. The administrator should collect the [Nodes logs](#) and then retrigger the firmware update on the node after ensuring all the prerequisites are met. If the retrigger fails again, contact [IBM Support](#).
8. The firmware update timed out. The administrator should collect the [Nodes logs](#) and retrigger the firmware update after some time. If the firmware update continues to fail, contact the [IBM Support](#).
9. Collect the [Nodes logs](#). Perform a power-off and power-on of the target node. See [Administering the node](#).
10. After successfully powering on the node, wait 15 minutes to see whether the scale cluster state changed to healthy. If the scale cluster remains in a DEGRADED state, contact the [IBM Support](#).

BMYP2107

Firmware Update of the switch has failed.

Severity

Critical

User actions

Collect [Network switches logs](#) and contact [IBM support](#).

BMYP2108

Failed to login to the switch with default user credentials after firmware upgrade.

Severity

Warning

User actions

Do the following steps to diagnose and report the problem:

1. Run the following command to get the switch IP address.

```
oc get switch mgmt1-rackag5 -o yaml | grep switchIpAddress
```

Example output:

```
switchIpAddress: fd8c:215d:178e:c0de:e69d:73ff:fe69:b400
```

2. Check connectivity to the switch from one of the compute node using the following steps:
 - a. Run the following command to get the node details.

```
oc get node
```

Example output:

NAME	STATUS	ROLES	AGE	VERSION
compute-1-ru27.rackag5.mydomain.com	Ready	worker	5d14h	v1.25.14+bc9a60
compute-1-ru6.rackag5.mydomain.com	Ready, SchedulingDisabled	worker	9d	v1.25.14+bc9a60
compute-1-ru7.rackag5.mydomain.com	Ready, SchedulingDisabled	worker	9d	v1.25.14+bc9a60
control-1-ru2.rackag5.mydomain.com	Ready	control-plane,master	9d	v1.25.14+bc9a60
control-1-ru3.rackag5.mydomain.com	Ready	control-plane,master	9d	v1.25.14+bc9a60
control-1-ru4.rackag5.mydomain.com	Ready	control-plane,master	9d	v1.25.14+bc9a60

- b. Run the following command to log in to node.

```
oc debug node/compute-1-ru27.rackag5.mydomain.com
```

Example output:

```
Temporary namespace openshift-debug-svms is created for debugging node...
Starting pod/compute-1-ru27rackag5mydomaincom-debug ...
To use host binaries, run `chroot /host`
Pod IP: 172.88.55.32
If you don't see a command prompt, try pressing enter.
sh-4.4# ping fd8c:215d:178e:c0de:e69d:73ff:fe69:b400
PING fd8c:215d:178e:c0de:e69d:73ff:fe69:b400 (fd8c:215d:178e:c0de:e69d:73ff:fe69:b400) 56 data bytes

2 packets transmitted, 2 received, 0% packet loss, time 1002ms
rtt min/avg/max/mdev = 0.464/2.971/5.478/2.507 ms
sh-4.4#
```

3. If ping to switch IP is not working, then collect [Network switches logs](#) and contact [IBM support](#).
4. If ping to switch IP works, then run the following commands to get the default username and password.

```
oc get secret mgmt1-rackag5-secret -o yaml | grep defaultUserName
oc get secret mgmt1-rackag5-secret -o yaml | grep defaultUserPasswrd
```

5. Decode the username and password obtained from the previous step.

```
echo <username/password> | base64 --decode
```

6. Try to SSH from one of the compute node using the default credentials.

```
ssh cumulus@fd8c:215d:178e:c0de:e69d:73ff:fe69:b400
```

Example output:

```
The authenticity of host 'fd8c:215d:178e:c0de:e69d:73ff:fe69:b400 (fd8c:215d:178e:c0de:e69d:73ff:fe69:b400)' can't be established:

Do the following steps to diagnose and report the problem:

1. Ensure that you performed the before you begin steps of [Implementing a comprehensive upgrade procedure](#).
2. If the issue persists, contact [IBM support](#).

BMYP3104

Service upgrade is failing.

Severity

Critical

User actions

Do the following steps to diagnose and report the problem:

1. Go to OpenShift® Container Platform web console and check the FusionServiceInstance for the specific service and check the conditions section to find the error.
2. If the issue persists, run the following oc command, and check the status section and debug the error.

```
oc get fusionserviceinstance <instance-name-of-service> -o yaml
```

3. If this occurs during installation or post service installation, collect logs for the corresponding service that shows as unhealthy and contact [IBM support](#). Follow the steps to collect logs from IBM Fusion.
 - Go to Services page in IBM Fusion user interface.
 - Click the ellipses menu for the corresponding service.
 - Select the Collect logs button. It downloads all the necessary logs.

BMYP3105

Operator Upgrade Failed.

Severity

Critical

User actions

Do the following steps to diagnose the error:

1. Go to OpenShift® Container Platform web console and check the FusionServiceInstance for the specific service and check the conditions section to find the error.
2. If the issue persists, run the following oc command to check the status section and try to debug the error.

```
oc get fusionserviceinstance <instance-name-of-service> -o yaml
```

3. If the issue still persists, do the following:
 - If this occurs during Data Cataloging upgrade, Collect [Data Cataloging logs](#) and contact [IBM support](#).
 - If this occurs during Backup and Restore upgrade, Collect [Backup and Restore logs](#) and contact [IBM support](#).

BMYPEC4083

Bare Metal network bond contains sufficient port availability.

Severity

Informational

User actions

No action is required.

BMYPEC4085

Node firmware is currently in progress with current state as %s.

Severity

Problem description

It indicates that the node firmware is currently in progress with current state as %s.

User actions

Follow the steps to resolve the issue:

1. Check the reason for failure and take appropriate action to resolve the issue.
2. If the issue persists, contact [IBM support](#) to resolve this issue.

BMYPC5055

One AMQ subscription on the cluster is not at a version that is compatible with the Backup & Restore upgrade.

Severity

Warning

Problem description

It indicates that there is an AMQ subscription found outside the Backup & Restore namespace is not at a compatible version. For Backup & Restore version 2.10, the AMQ version must be at 2.9.x. If there is an AMQ operator that is installed outside the Backup & Restore namespace is not at 2.9.x, then it can cause conflicts and failures as Backup & Restore try to upgrade its own AMQ to 2.9.0.

User actions

Upgrade the other AMQ to 2.9.x version.

BMYPC5056

Multiple AMQ subscriptions on the cluster are not at a version compatible with the Backup & Restore upgrade.

Severity

Warning

Problem description

It indicates that there are multiple AMQ subscriptions found outside of the Backup & Restore namespace that are not at a compatible version. For Backup & Restore version 2.10, the AMQ version must be at 2.9.x. If there is an AMQ operator installed outside of the Backup & Restore namespace that is not at 2.9.x, then it can cause conflicts and failures as Backup & Restore try to upgrade its own AMQ to 2.9.0.

User actions

Upgrade the other AMQ installation to the version 2.9.x.

BMYPC5057

One other OADP subscription on the cluster is not at a version compatible with the Backup & Restore upgrade.

Severity

Warning

Problem description

It indicates that there is an OADP subscription found outside of the Backup & Restore namespace that is not at a compatible version. For Backup & Restore version 2.10, the OADP version must be at 1.4.x. If there is an OADP operator installed outside of the Backup & Restore namespace that is not at 1.4.x, then it can cause conflicts and failures as Backup & Restore try to upgrade its own OADP to 1.4.0.

User actions

Upgrade the other OADP installation to the version 1.4.x.

BMYP5058

Multiple OADP subscriptions on the cluster are not at a version compatible with the Backup & Restore upgrade. Proceeding with the upgrade may cause issues with backup functionality.

Severity

Warning

Problem description

It indicates that there are multiple OADP subscriptions found outside of the Backup & Restore namespace that are not at a compatible version. For Backup & Restore version 2.10, the OADP version must be at 1.4.x. If there is an OADP operator installed outside of the Backup & Restore namespace that is not at 1.4.x, then it can cause conflicts and failures as Backup & Restore try to upgrade its own OADP to 1.4.0.

User actions

Upgrade the other OADP installation to the version 1.4.x.

BMYP6016

It is a switch upgrade precheck error. One of the high-speed switches is not healthy.

Severity

Error

Problem description

It indicates that one of the high-speed switches is not healthy. The issue causes because the IBM Fusion network operator is unable to log in to the respective switch. Reason for unsuccessful login might be as follows:

1. Switch down
2. Switch IP removed on the switch
3. Switch credentials changed.

User actions

Collect [Network switches logs](#) and contact [IBM support](#).

BMYP6017

It is a switch upgrade precheck error. No redundancy for uplink port.

Severity

Error

Problem description

It indicates that no redundancy for uplink port. The uplink port of one of the high-speed switches is either down or not configured. An upgrade in such scenarios could cause network connectivity issues.

User actions

Collect [Network switches logs](#) and contact [IBM support](#).

BMYP6020

OpenShift® Container Platform upgrade is in progress.

Severity

Error

Problem description

It indicates that the OpenShift Container Platform upgrade is in progress. The upgrades for compute nodes firmware, switch firmware and Global Data Platform service should not be triggered when the OpenShift Container Platform upgrade is in progress since nodes are rebooted in a rolling pattern.

User actions

Wait until the OpenShift Container Platform service upgrade to be complete.

BMYPC6021

Compute nodes firmware upgrade is in progress.

Severity

Error

Problem description

It indicates that the upgrade for the compute node firmwares are in progress. In such case, the upgrades for OpenShift® cluster, switches, and Global Data Platform service must not be triggered because the firmware upgrade requires rolling restart of OpenShift nodes.

User actions

Wait until the compute nodes silent upgrades to finish.

BMYPC6022

Compute node reboot is in progress.

Severity

Error

Problem description

It indicates that the compute node reboot is in progress. In such case, the upgrades for OpenShift® cluster, switches, and Global Data Platform service should not be triggered.

User actions

Wait until the compute node reboot to finish.

BMYPC6034

It is a switch upgrade precheck error. One of the switches contains misconfiguration.

Severity

Error

Problem description

It indicates that one of the switches contains misconfiguration. The missing configuration might be a VLAN not tagged on the required ports on the switch. It causes if a VLAN is added during manual configuration of the switches.

User actions

Do the following steps to diagnose and report the problem:

1. Run the following command to see the VLANs that are not tagged on the required ports on the switch.

```
oc get switch -o yaml | grep -A 2 "is not tagged"
```

2. If the issue persists, collect the [Network switches logs](#) and contact [IBM support](#).

BMYPE6035

Switch is healthy.

Severity

Informational

User actions

No action is required.

BMYPE6036

Ports related to the uplink are up and running for the mentioned switch.

Severity

Informational

User actions

No action is required.

BMYPE6037

SNMP exporter pod for the mentioned switch is up and running.

Severity

Informational

User actions

No action is required.

BMYPE6038

It is a switch upgrade precheck error. Unable to monitor the SNMP exporter pod.

Severity

Error

Problem description

It indicates that unable to monitor the SNMP exporter pod. It occurs if the SNMP export pod for the related switch is not created.

User actions

Collect [Network switches logs](#) and contact [IBM support](#).

BMYPE6039

All the configurations on the switches are in a consistent state.

Severity

Informational

User actions

No action is required.

BMYPE6047

Storage VLAN is tagged on the required ports on the high-speed switches.

Severity

Informational

User actions

No action is required.

BMYPE6048

It is a switch upgrade precheck error.

Severity

Error

Problem description

It indicates that the storage VLAN is not tagged on the required ports of the switch on one of the high-speed switches. It blocks the triggering of the switch upgrade.

User actions

Collect the [Network switches logs](#) and contact [IBM support](#).

BMYPE6049

Custom VLAN is tagged on the required ports on the high-speed switches.

Severity

Informational

User actions

No action is required.

BMYPE6050

It is a switch upgrade precheck error.

Severity

Error

Problem description

It indicates that one of the custom VLAN is not tagged on the required ports of the switch on one of the high-speed switches. It blocks the triggering of the switch upgrade.

User actions

Collect the [Network switches logs](#) and contact [IBM support](#).

BMYPC6051

OpenShift® VLAN is tagged on the required ports on the high-speed switches.

Severity

Informational

User actions

No action is required.

BMYPC6052

It is a switch upgrade precheck error.

Severity

Error

Problem description

It indicates that OpenShift® VLAN is not tagged on the required ports of the switch on one of the high-speed switches. It blocks the triggering of the switch upgrade.

User actions

Collect the [Network switches logs](#) and contact [IBM support](#).

BMYPC6053

Switch firmware upgrade is in progress.

Severity

Error

Problem description

It indicates that the switch firmware upgrade is in progress. In such a case, the upgrades for OpenShift® cluster, Global Data Platform, and compute firmware must not be triggered.

User actions

Wait until the switch upgrade to finish.

BMYPC6054

Found a failed OLM job in namespace.

Severity

Error

Problem description

It indicates that there is a failed OLM job is identified in the namespace and it might cause issues when you upgrade the service.

User actions

Investigate and resolve the cause of job failure and then delete the configmap of each job linked in the event message. Each failed job contains a corresponding configmap in the same namespace with the same name, and removing the configmap also removes its related job.

BMYPE6055

Found multiple failed OLM jobs in the namespace.

Severity

Error

Problem description

It indicates that there are multiple failed OLM jobs identified in the namespace and it might cause issues when you upgrade the service.

User actions

Investigate and resolve the cause of job failures and then delete the configmaps of each job linked in the event message. Each failed job contains a corresponding configmap in the same namespace with the same name, and removing these configmaps also removes their related jobs.

BMYPE6072

Kickstart entry is incorrect.

Severity

Error

Problem description

It indicates that there is an incorrect entry in the kickstart and reported keys are missing.

User actions

Follow the steps to resolve the issue:

1. Check and update the missing keys in the kickstart file.
2. If the issue persists, contact [IBM support](#) to resolve this issue.

BMYPE6073

Node health is not normal.

Severity

Error

Problem description

It indicates that the node health is not normal because of the reported issues.

User actions

Follow the steps to resolve the issue:

1. Restart service processor on the BMC or IDrac.
2. If the issue persists, contact [IBM support](#) to resolve this issue.

BMYPE6074

Kickstart entry is correct.

Severity

Informational

User actions

No action is required.

BMYPC6075

Node health is normal.

Severity

Informational

User actions

No action is required.

BMYPC6076

The DNS resolution for the node failed.

Severity

Error

Problem description

It indicates that the hostname resolution failed for the specified node.

User actions

Follow the steps described in the [Setting up DNS](#) section to verify the DNS configuration of the affected node.

After you correct the DNS configuration, the node addition process proceeds successfully.

BMYPC6080

PXE port status with address is not up.

Severity

Error

Problem description

It indicates that the PXE status with address is not up.

User actions

Follow the steps to resolve the issue:

1. Check the Ports tab in the IBM Fusion UI under the node monitoring page to verify the status of the first port of the 1G adapter. Also, confirm the status of the connected switch port.
2. If the issue persists, contact [IBM support](#) to resolve this issue.

BMYPC6082

Node adapters are missing.

Severity

Error

Problem description

It indicates that the node adapters are missing.

User actions

Follow the steps to resolve the issue:

1. Check the BMC or iDRAC and reseal the adapter or any loose connection.
2. If the issue persists, contact [IBM support](#) to resolve this issue.

BMYP6083

All ports %s of Bare Metal network bond are down.

Severity

Error

Problem description

It indicates that the all ports of the Bare Metal network bond are down.

User actions

Follow the steps to resolve the issue:

1. Check the cable connectivity, switch port configuration.
2. If the issue persists, contact [IBM support](#) to resolve this issue.

BMYP6085

Node firmware is currently not in progress or already up-to-date.

Severity

Informational

User actions

No action is required.

Compute events and error codes

Compute Call Home events and error codes

List of Call Home events that you might encounter in the compute.

Compute Call Home events

If you have enabled Call Home feature, then the system automatically collects compute log package and raises a Call Home ticket.

If you have not enabled Call Home feature, collect the [Nodes logs](#) and contact [IBM support](#).

- [BMYC00003](#)
A critical failure occurred while the compute operator was reading monitoring data from the node BMC (Baseboard Management Controller), or the node hardware health transitioned to a Critical state.
- [BMYC00006](#)
A critical BMC configuration (set) operation failed on a compute node.
- [BMYC00009](#)
Firmware upgrade failures
- [BMYC00013](#)
A compute operator software error occurred during node configuration, discovery, initialization, rack information import, system-board replacement, or location processing.
- [BMYC00023](#)
Failed to upsize the node.
- [BMYC00024](#)
The compute operator cannot access the remote support API server on the service node associated with the specified compute node.

BMYC00003

A critical failure occurred while the compute operator was reading monitoring data from the node BMC (Baseboard Management Controller), or the node hardware health transitioned to a Critical state.

Severity

Critical

Error conditions

This event is raised for the following conditions:

- BMC, iDRAC, Redfish, or IMM connection refused, timed out, or credentials rejected (**Connect Failed**).
- Node hardware health is Critical — one or more hardware components (processor, memory, storage, PCIe) are in a failed state as reported by the BMC (**Hardware Critical**).
- BMC monitoring data could not be retrieved during a monitoring cycle (**Monitoring Failed**).

Note: The event message identifies the specific sub-condition. Check the Fusion UI Infrastructure > Nodes page or the ComputeMonitoring CR status for the exact sub-state. All of the conditions have built-in retries. If the condition is transient, the operator recovers automatically. If the event persists, IBM Support is engaged.

User actions

Perform the following steps to diagnose the error:

1. Check the Fusion UI Infrastructure > Nodes page. The node status column shows the current sub-state:
 - **Connect Failed** — the BMC is not reachable.
 - **Critical** — the node hardware is in a failed state.
 - **Monitoring Failed** — BMC monitoring data retrieval failed.
2. For **Connect Failed**:
 - a. Verify BMC network reachability from the management network.
 - b. Check the IMM credential Secret for the node:

```
oc get secret -n ibm-spectrum-fusion-ns -l node=<node-name>
```
 - c. If credentials are correct and network is reachable, attempt a BMC restart from the Fusion UI (Infrastructure > Nodes > node action menu > Restart BMC).
3. For **Hardware Critical**:
 - a. Review the active hardware events listed on the node in the Fusion UI.
 - b. If event BMYPC6060 is also active for this node, use that event detail for the specific hardware fault description (for example, memory DIMM error or PCIe failure).
 - c. Inspect the physical hardware based on the fault description.
4. For **Monitoring Failed**:
 - a. Attempt a BMC restart from the Fusion UI (Infrastructure > Nodes > node action menu > Restart BMC).
 - b. Wait one monitoring cycle (approximately 60 seconds) and check whether the event clears.
5. If the event persists after completing the steps above, collect the [Nodes logs](#) and contact [IBM Support](#).

BMYC00006

A critical BMC configuration (set) operation failed on a compute node.

Severity

Critical

Error conditions

This event is raised when a BMC configuration (set) operation fails during compute-node configuration. The error message can be for the following conditions:

- Unable to change first time password
- Configuring IPv6 or IPv4 address failed with output
- IMM's new IPv6 or IPv4 address configured is not reachable - Onecli config set failed with output (Boot order and System Boot Mode)
- Onecli failed to clear SysInfoProdIdentifier for SR645 with output
- Onecli failed to set Processors.PreferredIOBus=Preferred
- Onecli failed to set Processors.PreferredIOBusNumber
- Configuring ports failed with output
- Configuring alertentries failed with output
- Configuring power restoration policy failed
- Configuring snmp failed
- Configuring snmpAlerts failed with output
- Configuring password complexity failed with output
- Adding user %s failed with output
- Clearing existing raid config failed for controller
- Unable to config drv mkgood for node
- Unable to config drive mkgood for node
- Error clearing mvstor for node
- Configuring disks in raid mode failed with output
- Configuring disks in raid mode failed with output
- Enabling IPMI over VLAN failed with output
- Onecli config set failed with output (Settling Network Link Type to Ethernet)
- Failed to set Mellanox Network Adapter NetworkLinkType to Ethernet
- Other BMC configuration (set) operations failed.

Note: All of the error conditions have built-in retries. However, there shall be support tickets to check the appliance if the event persists for a longer duration. If the condition is transient, it recovers automatically. Otherwise, IBM Support checks the appliance.

User actions

Perform the following steps to diagnose the error:

1. Check the event message to identify the specific BMC configuration step that failed:

```
oc get computemonitoring -n ibm-spectrum-fusion-ns -o yaml
```
2. If the event is recent (less than 5 minutes old), monitor for automatic recovery. The operator retries all configuration steps.
3. For **RAID or disk configuration failures**: verify the node disk state from the Fusion UI (Infrastructure > Nodes > node > Storage tab).
4. For **network or IP configuration failures**: verify the management network is reachable and the node network settings match the expected configuration in the **appliance-info** ConfigMap:

```
oc get configmap appliance-info -n ibm-spectrum-fusion-ns -o yaml
```
5. If the event persists, collect the [Nodes logs](#) and contact [IBM Support](#).

BMYC00009

Firmware upgrade failures

Severity

Critical

Error conditions

The error message can be for the following conditions:

- The system components on the server fail to upgrade, resulting in a silent flashing failure.
- After rebooting, a firmware mismatch occurs because the new firmware version is not applied.

User actions

Do the following steps to diagnose the error:

1. If you have enabled Call Home feature, then the system automatically collects compute collection set logs and raises a Call Home ticket.
2. If you have not enabled Call Home feature, collect the [Nodes logs](#) and contact [IBM support](#).

BMYC00013

A compute operator software error occurred during node configuration, discovery, initialization, rack information import, system-board replacement, or location processing.

Severity

Critical

Note: The event severity shown in the user interface can vary by the operation that raised the event. If the severity appears inconsistent with the operation, collect the Nodes logs and contact IBM Support.

Error conditions

This event can be raised for compute operator errors during node configuration, discovery, initialization, rack information import, system-board replacement, or location processing. The event message can be a resource-related message or the underlying error text from the failed operation.

Examples of resource-related errors

- The `appliance-info`, `kickstart`, or `rackinfo` ConfigMap cannot be read, is missing, empty, or is malformed.
- The rack serial number is not found in the `appliance-info` ConfigMap.
- Rack details or rack ID cannot be read from the `appliance-info` ConfigMap.
- Management switch information cannot be retrieved from the `kickstart` ConfigMap.

Secret errors

- The IMM or BMC credential Secret for the node is missing or inaccessible.
- Management switch credentials cannot be retrieved from the Secret.

Examples of node discovery and location errors

- The location of a new node cannot be determined from the `rackinfo` ConfigMap.
- IBM serial number or asset tag is not set for the node at the specified rack unit.

Examples of ComputeInit lifecycle errors

- A Kubernetes operation failed during node initialization (create, update, or read of a ComputeInit CR).
- A post-disk-upsize Scale CR update failed.
- NVMe detection failed after performing a reset of the service processor.
- A power operation on the node failed.

Important:

If the event message reads **API server on service node is not reachable**, that condition has its own dedicated event code from ISF 2.14.0 onwards. See [BMYC00024](#).

If the event message describes a node upsize or scale-out failure, see [BMYC00023](#).

All conditions have built-in retries. If the condition is transient, the operator recovers automatically (the matching recovery event BMYC00014 appears). If the event persists, IBM Support is engaged.

User actions

Perform the following steps to diagnose the error:

1. Read the specific error message attached to this event in the Fusion UI Events page or run:

```
oc get computemonitoring -n ibm-spectrum-fusion-ns -o yaml
```

The message can identify the affected resource or contain the underlying error text from the failed operation.

2. When the message identifies a **ConfigMap error** (**appliance-info**, **kickstart**, or **rackinfo**):

```
oc get configmap appliance-info kickstart rackinfo -n ibm-spectrum-fusion-ns
```

Verify the ConfigMaps exist and contain the expected fields for all racks.

3. When the message identifies a **Secret error** (IMM or BMC credentials):

```
oc get secret -n ibm-spectrum-fusion-ns -l node=<node-name>
```

Verify the credential Secret exists and contains valid **ceUserName** and **ceUserPasswrd** fields.

4. When the message identifies a **node location or rackinfo error** (for example, a **rackSerial** field is missing): check the **appliance-info** ConfigMap for the correct **rackSerial** value and verify it matches the physical rack serial number. Correct the value and monitor for the recovery event BMYCO0014.
5. For an underlying error message that does not identify a ConfigMap, Secret, or rack data, collect the [Nodes logs](#) and contact [IBM Support](#).
6. If the event persists after the above steps, collect the [Nodes logs](#) and contact [IBM Support](#).

BMYCO0023

Failed to upsize the node.

Severity

Critical

User actions

Do the following steps to diagnose the error:

1. If you have enabled Call Home feature, then the system automatically collects compute collection set logs and raises a Call Home ticket.
2. If you have not enabled Call Home feature, collect the [Nodes logs](#) and contact [IBM support](#).

BMYCO0024

The compute operator cannot access the remote support API server on the service node associated with the specified compute node.

Severity

Critical

Error condition

The service node provides remote management capabilities required for hardware health monitoring and BMC operations. This event fires when the compute operator cannot access the remote support API server on the service node associated with the specified compute node:

```
Remote support API server on service node <node-name> is inaccessible.  
Please check if the remote support API service is active.
```

Note: Prior to ISF 2.14.0, this condition was reported under [BMYCO0013](#). From ISF 2.14.0 onwards, it has its own dedicated event code to allow targeted diagnosis and alerting. All occurrences have built-in retries. The operator re-checks service node reachability on each monitoring cycle (approximately every 60 seconds).

User actions

Perform the following steps to diagnose the error:

1. Check the service node pod status:

```
oc get pods -n ibm-spectrum-fusion-ns
```

2. If the pod is not in **Running** state, describe it to review events:

```
oc describe pod -n ibm-spectrum-fusion-ns <service-node-pod-name>
```

3. Check service node logs for errors:

```
oc logs -n ibm-spectrum-fusion-ns <service-node-pod-name> --tail=100
```

4. Verify that the service node hostname shown in the event message is DNS-resolvable from within the cluster:

```
oc exec -n ibm-spectrum-fusion-ns <any-compute-operator-pod> -- \\\nslookup <service-node-hostname>
```

5. If the pod is healthy and DNS resolves correctly but the event persists, restart the service node pod:

```
oc delete pod -n ibm-spectrum-fusion-ns <service-node-pod-name>
```

- Wait one monitoring cycle (approximately 60 seconds) and confirm the event clears.
6. If the event persists after the above steps, collect the [Nodes logs](#) and contact [IBM Support](#).

BMYC00001

Unable to login, unable to ping, invalid credentials.

Error conditions

The error message can be for the following conditions:

IMM

- Failed to connect to IMM for changing the default user's password.
- Unable to login to IMM of new node.
- Unable to connect or log in to the IMM of new node.
- Unable to create remote OneCli connection with IMM.
- Unable to create remote OneCli connection with IMM using LLA.
- Connected the cable to an empty port of the management switch 1 that is not configured.

Node

Failed to change the default user's password after node configuration.

Other messages

- Onecli executable not found.
- Unable to fetch link local.
- Failed detect system type.

Severity

Critical

User actions

Do the following steps to diagnose the error:

1. Do a visual inspection of the physical network connectivity.
2. Check that the cables are connected and LEDs show a connected state for the network interface of the node.
3. Check whether any device is connected to an empty port of the management switch 1 that is not configured.
4. If the issue persists, collect the [Nodes and Network switches logs](#) and contact [IBM support](#).

BMYC00004

Hardware monitoring data, including BIOS configuration data, could not be retrieved from the node BMC (Baseboard Management Controller).

Severity

Warning

Error conditions

This warning event is raised when the compute operator cannot retrieve hardware monitoring data, including BIOS configuration data, from the node BMC during a monitoring cycle.

User actions

Do the following steps to diagnose the error:

1. This is a temporary error and it gets resolved on its own.
2. If the issue persists for a longer period, collect the compute-monitoring CR status and [Nodes logs](#), and contact [IBM support](#).

BMYC00005

The system board hardware is replaced on the existing node located at RU.

Severity

Informational

User actions

No action is required.

BMYC00007

Failed to set and update Processors.

Error conditions

The error message can be for the following conditions:

- Failed to update Processors. PreferredIOBus to be Preferred.
- Failed to set Processors. PreferredIOBusNumber for the node.

Severity

Warning

User actions

Do the following steps to diagnose the error:

1. Reboot the node manually.
2. If the issue persists after rebooting the node, then collect the [Nodes logs](#) and contact [IBM support](#).

BMYC00008

Default password successfully reset to a complex password upon first login.

Severity

Informational

User actions

No action is required.

BMYC00010

Firmware upgrade success.

Severity

Informational

User actions

No action is required.

BMYC00011

Unable to put the node into maintenance mode as scale cluster status is not healthy.

Severity

Critical

Error conditions

The error message can be for the following conditions:

- Failed to move node out of maintenance
- Failed to move the node into maintenance mode because the node cordoning not succeeded
- Failed to move the node into maintenance mode because the node exists in maintenance mode.
- Failed to move node into maintenance mode because the cluster status might not be retrieved.
- Failed to move the node into maintenance mode as because the IBM Fusion Data Foundation cluster status is not healthy.
- Failed to move the node into maintenance mode as because the IBM Storage Scale cluster status is not healthy.
- Unable to move node to maintenance mode. Some other process may be preventing the node from draining, such as an open file handle, an open pod login, or a workload with a Pod Disruption Budget set to zero.
- Failed to move node into maintenance because the MCO rollout is in progress on the cluster.
- Multiple nodes cannot be put in maintenance mode simultaneously, if a node exists in maintenance mode.
- Maintenance mode success.

Note: This is an informational message and no action is required for this message.

User actions

Do the following steps to diagnose the error:

1. Check whether any node exists in maintenance mode.
2. Move the node out of maintenance and retry.
3. Run the `oc` command to check whether the scale cluster is healthy.

```
oc -n ibm-spectrum-fusion-ns get scales storagemanager -oyaml | grep storageClusterStatus
```

4. If the Scale cluster is not healthy, check and bring it to a healthy state.
5. Run the `oc` command to check whether the Data Foundation cluster is healthy.

```
oc -n ibm-spectrum-fusion-ns get odflcluster odflcluster -o yaml | grep status
```

6. If the Data Foundation cluster is not healthy, check and bring it to a healthy state.

BMYC00014

IBM Fusion software error recovery.

Error conditions

The error message can be for the following conditions:

- Unable to read port status from any switch to validate the cabling.
- Provided RU number is invalid because it is not sequentially incremental New node should be stacked up in bottom up direction. Last used RU is <RU number>.

Severity

Informational

User actions

No action is required.

BMYC00015

Hardware validation error.

Error conditions

The error message can be for the following conditions:

Hardware validation

- The new node model is not recognized.
- The provided RU number is invalid because it is not sequentially incremental. Stack up the new node in a bottom-up direction.
- Provide a valid RU.
- Unable to read network CRS, internal runtime error".
- Unable to create remote OneCli connection with IMM using LLA.
- Management switch port is not up for the switch. If the port is not up even after 20 minutes, check cable connectivity.
- Unable to read port status from any switch to validate the cabling.
- High speed switch port is not up for the switch hence retrying connectivity. If the port is not up even after 20 minutes, check cable connectivity.
- Unable to read the port status of switch.
- Unable to read port status from any switch to validate the cabling.

- Unable to read/parse user_config secret.

Severity

Critical

User actions

Collect [Nodes logs](#) and contact [IBM support](#).

BMYC00016

Informational event for updating user about upsize success.

Severity

Informational

User actions

No action is required.

BMYC00017

Discovered a new node at RU, link-locations and rack serials or failed to get the location of a new node from rackinfo configmap.

Severity

Informational

User actions

This is an informational event when a new node is discovered on a rack. No action is required.

BMYC00019

Power operation (on, off) does not succeed within the stipulated time of 75 seconds.

Severity

Critical

User actions

Check the power state of the node on the IBM Fusion HCI nodes page and perform the operation manually. If the issue persists, collect the [Nodes logs](#) and contact [IBM support](#).

BMYC00020

Successfully performed power operation [Gracefulshutdown/GracefulRestart] on the node.

Severity

Warning

User actions

No action is required.

BMYC00021

Successfully performed power operation [On] on the node.

Severity

Informational

User actions

No action is required.

BMYC00022

The compute operator failed to configure user privilege settings on the node BMC (Baseboard Management Controller).

Severity

Warning

Error conditions

This event is raised for the following condition:

- Failed to set the privilege of a user on the BMC.

Note: All occurrences have built-in retries. The operator re-attempts user privilege configuration during the next monitoring cycle. If the condition is transient, it recovers automatically.

User actions

Perform the following steps to diagnose the warning:

1. Check the event message to identify the specific BMC user and failure reason:

```
oc get computemonitoring -n ibm-spectrum-fusion-ns -o yaml
```

2. If the event message indicates a credential or BMC connectivity issue, verify that the credential Secret for the node exists and that the BMC is reachable:

```
oc get secret -n ibm-spectrum-fusion-ns -l node=<node-name>
```

3. If the BMC is reachable, attempt a BMC restart from the Fusion UI (Infrastructure > Nodes > node action menu > Restart BMC).
4. Wait one monitoring cycle (approximately 60 seconds) and check whether the warning clears.
5. If the event persists after completing the steps above, collect the [Nodes logs](#) and contact [IBM Support](#).

BMYC00048

Contact [IBM support](#).

BMYC00069

Password complexity validation failed for the node.

Severity

Critical

User actions

Contact [IBM support](#).

BMYC00070

Failed to unseal the internal vault for the node addition operation.

Severity

Critical

User actions

Contact [IBM support](#).

BMYC00210

Power off warning about successful power operation execution on the node.

Severity

Warning

User actions

Do the following steps to diagnose the error:

1. Check the power connection.

2. Check whether the node is down.
3. To proceed, check and re-power.

BMYC00150

Workload Failover Enabled.

Description

It indicates that the workload failover is successfully enabled for this compute node, and the system is now monitoring the nodes for failures.

Severity

Information

User actions

No action.

BMYC00151

Workload Failover Disabled.

Description

It indicates that the workload failover is successfully disabled.

Severity

Information

User actions

No action.

BMYC00161

Self Node Remediation Operator Installed

Description

It indicates that the SNR Operator is successfully installed in the cluster, and the failover remediation component is ready.

Severity

Information

User actions

No action.

BMYC00162

The Self Node Remediation Operator installation failed.

Description

The compute operator cannot complete the installation of the Self Node Remediation Operator.

Important: If you upgraded from IBM Fusion HCI 2.13 or an earlier version, this event might appear as a stale critical event that does not resolve automatically. The compute operator generates the event from a canceled context in the previous container before the upgrade. The underlying installation failure is not present in 2.14. Fresh installations of 2.14 are not affected. You must go to the Events page in the IBM Fusion HCI user interface and mark this event as fixed once after upgrading. For details, see [BMYC00162 event persists after upgrading from 2.13](#).

Severity

Critical

User actions

If you upgraded from IBM Fusion HCI 2.13 or an earlier version

Manually mark the event as fixed once from the IBM Fusion HCI user interface:

1. Log in to the IBM Fusion HCI user interface.
2. In the navigation menu, click Events.
3. Locate the **BMYC00162** event in the list.
4. Select the event row and choose Mark as fixed from the context menu.

The event moves to the resolved state and does not reappear.

If you are on a fresh 2.14 installation

Complete the following steps to investigate the installation failure:

1. Check OLM logs and ensure all required permissions and catalog sources are available.
2. Check whether the CatalogSource is available and healthy.
OLM fetches operator metadata from a CatalogSource.

```
oc get catalogsource -n openshift-marketplace
```

3. Check the Subscription:

```
oc get subscription self-node-remediation -n openshift-workload-availability -o yaml
```

BMYC00171

SelfNodeRemediationConfig Updated

Description

SelfNodeRemediationConfig successfully updated and synchronized with the desired specification.

Do the following steps to diagnose the error:

1. Run the following command to check whether node feature discovery CR is present on the cluster:

```
oc get nodefeaturediscovery nfd-instance -o yaml -n openshift-nfd
```

2. If the issue persists, then contact [IBM support](#).

BMYC00304

NFD CR is not in a required state.

Severity

Warning/Critical

User actions

Do the following steps to diagnose the error:

1. If NFD CR is in degraded state.
 - a. Run the following command to check if pods are running or not in the namespace `openshift-nfd`.

```
oc get pods -n openshift-nfd
```
 - b. Run the following command to check events for the pods that are not running:

```
oc describe pod <pod-name> -n openshift-nfd
```
2. If NFD CR is in progressing state.
 - a. Run the following command to check if pods are running or not in the namespace `openshift-nfd`.

```
oc get pods -n openshift-nfd
```
 - b. Run the following command to check events for the pods that are not running:

```
oc describe pod <pod-name> -n openshift-nfd
```
3. If NFD CR is in unknown state.
 - Run the following command to check the status of NFD CR.

```
oc get nodefeaturediscovery nfd-instance -o json -n openshift-nfd | jq '.status'
```
4. If the issue persists, then contact [IBM support](#).

BMYC00305

NFD CR is in **Ready** state.

Severity

User actions

Do the following steps to diagnose the error:

1. Check the status of the `nvidia-driver-daemonset` pods in the `nvidia-gpu-operator` namespace.
2. Look for pods in states like `ImagePullBackOff`, `CrashLoopBackOff`, or `Error`.
3. Use `kubectl describe pod -n nvidia-gpu-operator` to get detailed event logs and error messages.
4. If the `daemonset` pods are running, then execute one of them and run `nvidia-smi` to confirm successful driver installation and GPU detection.

```
oc exec -it <nvidia-driver-daemonset-pod> -n nvidia-gpu-operator -- nvidia-smi
```

5. If the issue persists, then contact [IBM support](#).

BMYC00358

GPU cluster policy `gpu-cluster-policy` is in **Disabled** state.

Severity

Critical

User actions

Do the following steps to diagnose the error:

1. Check the status of the `nvidia-driver-daemonset` pods in the `nvidia-gpu-operator` namespace.
2. Look for pods in states like `ImagePullBackOff`, `CrashLoopBackOff`, or `Error`.
3. Use `kubectl describe pod -n nvidia-gpu-operator` to get detailed event logs and error messages.
4. If the `daemonset` pods are running, then execute one of them and run `nvidia-smi` to confirm successful driver installation and GPU detection.

```
oc exec -it <nvidia-driver-daemonset-pod> -n nvidia-gpu-operator -- nvidia-smi
```

5. If the issue persists, then contact [IBM support](#).

BMYC00359

GPU cluster policy `gpu-cluster-policy` is in **Unknown** state.

Severity

Warning

User actions

Do the following steps to diagnose the error:

1. Check the status of the `nvidia-driver-daemonset` pods in the `nvidia-gpu-operator` namespace.
2. Look for pods in states like `ImagePullBackOff`, `CrashLoopBackOff`, or `Error`.
3. Use `kubectl describe pod -n nvidia-gpu-operator` to get detailed event logs and error messages.
4. If the `daemonset` pods are running, then execute one of them and run `nvidia-smi` to confirm successful driver installation and GPU detection.

```
oc exec -it <nvidia-driver-daemonset-pod> -n nvidia-gpu-operator -- nvidia-smi
```

5. If the issue persists, then contact [IBM support](#).

BMYC00360

NVIDIA driver `DaemonSet` check failed.

Severity

Critical

User actions

Do the following steps to diagnose the error:

1. Run the following command to get the NVIDIA driver `DaemonSet` deployed by the GPU operator.

```
oc get daemonset -n nvidia-gpu-operator -l openshift.driver-toolkit
```

Example output:

```
oc get daemonset -n nvidia-gpu-operator -l openshift.driver-toolkit
NAME                                DESIRED    CURRENT    READY    UP-TO-DATE    AVAILABLE    NODE SELECTOR
nvidia-driver-daemonset-416.94.202502260030-0  1          1          1        1             1            feature.node.kubernetes.i
```

2. Verify that the values are equal:

```
DESIRED = CURRENT
CURRENT = READY
```

3. If the issue persists, then contact [IBM support](#).

BMYC00361

NVIDIA driver `DaemonSet` pods check failed.

Severity

Critical

User actions

Do the following steps to diagnose the error:

1. Run the following command to get the expected number of scheduled pods from the NVIDIA driver **DaemonSet**:

```
oc get daemonset -n nvidia-gpu-operator -l openshift.driver-toolkit -o jsonpath='{.items[0].status.desiredNumberScheduled}'
```

2. Run the following command to get the list of pods created by the NVIDIA driver **DaemonSet**:

```
oc get pods -n nvidia-gpu-operator | grep nvidia-driver-daemonset
```

Example output:

```
oc get pods -n nvidia-gpu-operator | grep nvidia-driver-daemonset  
nvidia-driver-daemonset-416.94.202502260030-0-6x6dd 2/2 Running 0 4d16h
```

3. Compare the number of running pods (from the output in step 2) with the **desiredNumberScheduled** value (from step 1).
4. If both numbers match, it confirms that all expected NVIDIA driver pods are up and running as intended.
5. If the issue persists, then contact [IBM support](#).

BMYC00362

GPU cluster policy **gpu-cluster-policy** status not yet initialized (pending). Cluster policy status is not initialized yet. Waiting for the operator to update the status.

Severity

Informational

Severity

Warning

User actions

Do the following steps to diagnose the error:

1. Run the following command to check if the cluster policy status is updated:

```
oc get clusterpolicy -n nvidia-gpu-operator
```

2. After the status shows as ready, describe the cluster policy to confirm conditions:

```
oc describe clusterpolicy gpu-cluster-policy -n nvidia-gpu-operator
```

3. If it is still in pending state, wait for the operator to complete initialization and ensure the **gpu-operator** deployment pod is running.

```
oc get pods -n nvidia-gpu-operator
```

BMYC00363

All pods in NVIDIA GPU operator namespace not running.

Severity

Warning

User actions

Do the following steps to diagnose the error:

1. Run the following command to verify whether all pods in the NVIDIA GPU operator namespace are running:

```
oc get pods -n nvidia-gpu-operator
```

2. Run the following command to get the events of pods which are not in running state.

```
oc describe pod nvidia-operator-validator-k5dvn -n nvidia-gpu-operator | grep -A5 -i "Events:"
```

3. If the issue persists, then contact [IBM support](#).

BMYC00364

The NVIDIA GPU Operator upgrade is in progress, following an update to the operator subscription to enable automatic approval on the stable channel.

Severity

Warning

User actions

Do the following steps to diagnose the error:

1. Run the following command to verify the NVIDIA GPU operator subscription configuration:

```
oc get subscription gpu-operator-certified -n nvidia-gpu-operator -o yaml
```

Ensure that the subscription uses automatic approval and the stable channel.

2. Run the following command to verify the current installed and target CSV versions:

```
oc get subscription gpu-operator-certified -n nvidia-gpu-operator -o jsonpath='{.status.installedCSV}{"\n"}{.status.currentCSV}{"\n"}'
```

If the installed CSV and current CSV are different, then an upgrade is still in progress.

3. Run the following command to check pod health in the NVIDIA GPU operator namespace:

```
oc get pods -n nvidia-gpu-operator
```

4. If pods are not progressing to **Running** or **Completed** state, inspect operator logs:

```
oc logs -n nvidia-gpu-operator deploy/gpu-operator-controller-manager
```

5. If the issue persists, then contact [IBM support](#).

BMYC00365

NVIDIA GPU operator upgrade failed.

Severity

Warning

User actions

Do the following steps to diagnose the error:

1. Run the following command to verify the NVIDIA GPU operator subscription configuration exists:

```
oc get subscription gpu-operator-certified -n nvidia-gpu-operator
```

If the subscription is missing, then the NVIDIA GPU operator is not installed successfully.

2. Run the following command to inspect the subscription configuration:

```
oc get subscription gpu-operator-certified -n nvidia-gpu-operator -o yaml
```

Verify that `spec.installPlanApproval` is set to `Automatic`, `spec.channel` is set to `stable`, and `spec.startingCSV` is empty.

3. Run the following command to inspect related operator lifecycle manager resources:

```
oc get installplan,csv -n nvidia-gpu-operator
```

4. If there are failed install plans or unhealthy CSV resources, inspect their details using the following commands:

```
oc describe installplan -n nvidia-gpu-operator
oc describe csv -n nvidia-gpu-operator
```

5. If the issue persists, then contact [IBM support](#).

BMYC00366

Failed to read NVIDIA DCGM exporter dashboard JSON configuration.

Severity

Critical

User actions

Do the following steps to diagnose the error:

1. Verify that the operator image or deployment contains the DCGM exporter dashboard asset expected by the controller:

```
oc logs -n ibm-spectrum-fusion-ns deploy/isf-compute-operator-controller-manager -c manager | grep -i "DCGM Exporter Dashboard JSON"
```

If the log shows a file read or embedded asset error, the dashboard JSON resource may be missing or corrupted in the operator build.

2. Restart the operator pod after confirming the deployment image is correct:

```
oc rollout restart deploy/isf-compute-operator-controller-manager -n ibm-spectrum-fusion-ns
```

3. Check the operator logs again for repeated dashboard read failures:

```
oc logs -n ibm-spectrum-fusion-ns deploy/isf-compute-operator-controller-manager -c manager
```

4. If the issue persists, then contact [IBM support](#).

BMYC00368

Failed to apply required labels to configmap `nvidia-dcgm-exporter-dashboard` for NVIDIA DCGM exporter dashboard.

Severity

Critical

User actions

Do the following steps to diagnose the error:

1. Run the following command to inspect the configmap labels:

```
oc get configmap nvidia-dcgm-exporter-dashboard -n openshift-config-managed --show-labels
```

Verify that the following labels are present and set to `true`:

- `console.openshift.io/dashboard=true`
- `console.openshift.io/odc-dashboard=true`

2. If the labels are missing, inspect the full configmap definition:

```
oc get configmap nvidia-dcgm-exporter-dashboard -n openshift-config-managed -o yaml
```

3. Verify that the operator has permission to patch configmaps in the target namespace:

```
oc auth can-i patch configmaps -n openshift-config-managed --as system:serviceaccount:ibm-spectrum-fusion-ns:isf-compute-operator-controller-manager
```

4. Check operator logs for the patch error:

```
oc logs -n ibm-spectrum-fusion-ns deploy/isf-compute-operator-controller-manager -c manager
```

5. If the issue persists, then contact [IBM support](#).

BMYC00367

Failed to create configmap `nvidia-dcgm-exporter-dashboard` for NVIDIA DCGM exporter dashboard.

Severity

Critical

User actions

Do the following steps to diagnose the error:

1. Run the following command to verify whether the target configmap already exists:

```
oc get configmap nvidia-dcgm-exporter-dashboard -n openshift-config-managed
```

2. If the configmap already exists, inspect it for conflicts or invalid data:

```
oc get configmap nvidia-dcgm-exporter-dashboard -n openshift-config-managed -o yaml
```

3. Verify that the operator has permission to create configmaps in the target namespace:

```
oc auth can-i create configmaps -n openshift-config-managed --as system:serviceaccount:ibm-spectrum-fusion-ns:isf-compute-operator-controller-manager
```

4. Check the operator logs for the exact create failure returned by the Kubernetes API:

```
oc logs -n ibm-spectrum-fusion-ns deploy/isf-compute-operator-controller-manager -c manager
```

5. If the issue persists, then contact [IBM support](#).

BMYC00400

NMO installation started and is in progress in cluster in the specified namespace.

No action is required.

BMYFW0001E

Failed to put a node into maintenance mode for the firmware update.

It indicates that a node could not be moved into maintenance mode for the firmware upgrade. Check the diagnostic messages that are available on the IBM Fusion user interface and take an appropriate action before you retry the firmware upgrade operation on other nodes.

Severity

Error

Diagnosis and resolution

Do the following steps to diagnose and resolve the issue:

1. Check whether the node is placed in a maintenance mode for a planned work. In this case, bring the node out of maintenance mode after the planned work is complete.
2. If a machine configuration roll out is in progress, then wait for the roll out to complete and the node to return to a ready state.
3. If the node is in a **Notready** state for more than 30 minutes, then it might be an error with the node in the joining cluster. Do the following steps to resolve the issues that are related to the joining cluster:

- a. Run the following command to check for the pending CSRs.

```
oc get csr | grep -i pending
```

- b. If you find any pending CSRs, then run the following command to approve them:

```
oc get csr -o go-template='{range .items}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve
```

- c. If you do not find any pending CSRs, then restart the node.
- d. Connect to the node by using the core OS private SSH key and run the following command.

```
ip a
```

- e. Recover the node during the following scenarios:
 - IPv4 address assigned to the bond0 interface
 - **br-ex** interface not created
4. The storage cluster health can be degraded. Check the current storage cluster type.
 - If the storage cluster type is IBM Storage Scale or IBM Storage Scale ECE, then see [IBM Storage Scale documentation](#) to resolve the issue.
 - If the storage cluster type is Data Foundation, then see [Fusion Data Foundation](#) documentation to resolve the issue.

BMYFW0002E

Failed to move a node out of maintenance mode after the firmware upgrade.

It indicates that the node cannot be moved out of maintenance mode. It can happen whenever the **ComputeMaintenance** CR instance deletion does not succeed.

Severity

Error

Diagnosis and Resolution

Check whether the instance of a **ComputeMaintenance** CR is present in the **ibm-spectrum-fusion-ns** namespace and delete it manually. After the **ComputeMaintenance** CR is deleted successfully, the node comes out of the maintenance mode automatically.

BMYFW0012E

Firmware update operation timed out on the compute node.

It indicates that a node firmware upgrade workflow is taking more than expected time to complete the upgrade. Some of the possible reasons for this issue are as follows:

- Moving a node into maintenance might be taking more time than expected due to pending pods for eviction.
- Firmware flash operation might be taking more time to complete than expected.

Severity

Error

Diagnosis and Resolution

Do the following steps to diagnose and resolve the issue:

1. Cancel the firmware upgrade operation. For steps to cancel, see [Upgrading node firmware](#).
2. Wait for firmware upgrade message on the IBM Fusion user interface.
3. On the IBM Fusion user interface, check the timeout reason in the status and take appropriate action.

BMFW0013E

Storage cluster does not turn healthy after a node firmware upgrade.

It indicates that the storage cluster (Data Foundation or IBM Storage Scale ECE) state is unhealthy after the node rejoined the OpenShift® Container Platform cluster because of a firmware upgrade.

Severity

Error

Diagnosis and resolution

Do the following steps to diagnose and resolve the issue:

1. Wait for the storage cluster to turn healthy.
2. Check the current storage cluster type.
 - If the storage cluster type is IBM Storage Scale or IBM Storage Scale ECE, then see [IBM Storage Scale documentation](#) to resolve the issue.
 - If the storage cluster type is Data Foundation, then see [Fusion Data Foundation](#) documentation to resolve the issue.

BMFW0016E

Firmware upgrade stalled.

If a user triggers a node or cluster reboot, the upgrade can fail if the node is unable to drain pods before the reboot occurs.

Severity

Error

User action

As a resolution, drain the pods manually and then resume the upgrade. For more information about draining the pods, see [Remediating a maintenance drain failure](#).

BMFW0032E

Failed to move a node into maintenance mode as the storage cluster status is unhealthy.

It indicates that the storage cluster status is unhealthy and IBM Fusion cannot move a node to maintenance mode. Proceed with node maintenance or firmware upgrade only when the storage cluster is healthy.

Severity

Error

Diagnosis and Resolution

Do the following steps to diagnose and resolve the issue:

1. Check the current storage cluster type.
 - If the storage cluster type is IBM Storage Scale or IBM Storage Scale ECE, then see [IBM Storage Scale documentation](#) to resolve the issue.
 - If the storage cluster type is Data Foundation, then see [Fusion Data Foundation](#) documentation to resolve the issue.
2. Retry the firmware upgrade after the storage cluster turns to a healthy state.

BMFW0036E

Unable to move a node to a maintenance mode due to an unsafe IBM Storage Scale core pod eviction.

It indicates that the node maintenance did not succeed because the eviction of a IBM Storage Scale core pod on the node did not occur. Firmware upgrade workflow continues to drain the pods from the node until workflow timeout. You cannot cancel it because of the following reasons:

- Workflow is in an in-progress state
- Firmware upgrade cannot be initiated on any other node

The pod eviction might succeed because the workflow continuously retries to drain the pod from the node.

Severity

Error

Diagnosis and resolution

Check the reason for the pod eviction. To know more information about the error and debug steps, see [IBM Storage Scale documentation](#). After successful eviction of a scale core pod, the firmware upgrade operation resumes automatically.

BMFW0037E

Failed to move a node into a maintenance mode because an MCO rollout is in progress on the cluster.

It indicates that a **MachineConfigPool** update is in progress. It impacts the upgrade as the next machine configuration rollout in the queue fails because of its dependency on the successful rollout of the ongoing change.

For example, an ongoing rollout is for a registry auth change that is applicable for all the nodes. This change must get rolled out to all nodes before you start the upgrade so that no pod failures due to image pullback errors cause upgrade failures.

Severity

Error

Diagnosis and resolution

Do the following steps to diagnose and resolve the issue:

1. The issue might occur for a short duration whenever the following operations are in progress:
 - Machine config rollout
 - OpenShift® Container Platform upgrade
 - Global Data Platform upgrade

Wait for these operations to complete, then check whether the **MachineConfigPool** is healthy and available.

2. If a pool remains in a degraded state for a long time, then use the following command to find the root cause.

```
oc describe machineconfigpool <poolname>
```

3. Check for the problems indicated in the description, and debug further to identify the root cause. The following are some of the possible reasons:
 - A node is stuck in a **NotReady** state, restart the node to fix the issue.
 - Though the node completes the roll out, it might not be in a schedulable state. Compare the required and current configurations. If the configurations are the same, manually remove taint of the unschedulable.
4. After the **MachineConfigPool** is available and up to date, the firmware upgrade workflow detects the fix and resumes upgrade automatically.

BMFW0041E

Unable to move a node into maintenance mode. Failed to evict the workload pods from a node.

It indicates that the node maintenance did not succeeds because there are pods pending for eviction.

Severity

Error

Diagnosis and resolution

Do the following steps to diagnose and resolve the issue:

1. Check the list of pods pending for eviction.
2. If the application pods are safe to drain, manually drain them.
3. After the manual draining of the pods, if the firmware upgrade status is still in progress, then the upgrade proceeds automatically.
4. If the firmware upgrade fails, reattempt the failed firmware upgrade.

Note: You can modify the pod drain threshold timeout value by updating the field **MaintenanceWarningTimeout** in the **configmap** and **compute-operator-config** under the **ibm-spectrum-fusion-ns** namespace. The possible value can be between 5 to 40 and the default time units are in minutes. The modified value is applicable for the fresh firmware upgrade only and not applicable for the upgrade operation that is in progress.

BMYP5030

The node is degraded due to an active event.

It indicates that the node health is in a warning state.

The reason can be due to the warning state of any of the following hardware components or the loss of redundancy associated with the component.

- Cooling devices
- Power modules
- Local storage
- Processors
- Memory
- System

It is recommended not to start node firmware upgrade until the node status turns healthy.

Severity

Warning

User actions

Collect the [System health check logs](#) and contact [IBM support](#).

BMYP6030

Node hardware is not reachable.

It indicates that the node is not reachable because of the following reasons:

- Fault in the network
- Loss of power supply
- Hardware failure

Do not to start node firmware upgrade until the node is reachable.

Severity

Error

User actions

Collect the [System health check logs](#) and contact [IBM support](#).

BMYP6060

The node is in a critical state due to an active event.

Critical state of the node indicates that node is in the verge of failure, immediate attention is required. The reason might be the failure of any of the following hardware components:

- Cooling devices
- Power modules
- Local storage
- Processors
- Memory
- System

It is recommended not to start the node firmware upgrade until node status turns healthy.

Severity

Critical

User actions

Collect the [System health check logs](#) and contact [IBM support](#).

BMYP6061

Bond1 IP address is missing from the node.

This condition indicates that the Bond1 IP address is missing on a node in the OpenShift® cluster. The IP address must be configured and present to ensure proper network functionality and to avoid undefined or unexpected behavior.

Severity

Error

User actions

Complete the following steps to resolve the issue:

1. Ensure that the node is in the Ready state. Then log in to the node by running the following command:

```
oc debug node/<node-name>
```

2. After logging in to the node, switch to the host filesystem within the node:

```
chroot /host
```

3. Run the following commands sequentially:

```
nmcli conn down bond1
```

```
nmcli conn up bond1
```

4. To verify whether the Bond1 IP address is restored, run:

```
ip a s bond1
```

The Bond1 IP address must now be visible on the node, and the pre-check must clear within a few minutes. If the IP address is still not assigned, contact [IBM support](#) for further assistance.

Network events error codes

List of all the events that you might encounter in network node.

For Call Home events, see [Network Call Home events and error codes](#).

Informational

User actions

No action is required.

BMYNW0003

Switch interface down.

Severity

Warning

User actions

This can be a hardware problem. Do the following steps to diagnose the problem:

1. Check whether ports 31 and 32 are down.
2. Do a physical examination of their cables and switches.
3. If the problem is not resolved, collect the [Network switches logs](#) and contact [IBM support](#).

BMYNW0005

<switch-name:switch IBM Serial Number>: Fan is not OK

Error conditions

The error message can be for the following conditions:

- <switch-name:switch IBM Serial Number>: Fan1 Tray 1 Not OK
- <switch-name:switch IBM Serial Number>: Fan2 Tray 1 Not OK
- <switch-name:switch IBM Serial Number>: Fan3 Tray 2 Not OK
- <switch-name:switch IBM Serial Number>: Fan4 Tray 2 Not OK
- <switch-name:switch IBM Serial Number>: Fan5 Tray 3 Not OK
- <switch-name:switch IBM Serial Number>: Fan6 Tray 3 Not OK
- <switch-name:switch IBM Serial Number>: Fan7 Tray 4 Not OK
- <switch-name:switch IBM Serial Number>: Fan8 Tray 4 Not OK
- <switch-name:switch IBM Serial Number>: PSU1 Fan1 Not OK
- <switch-name:switch IBM Serial Number>: PSU2 Fan1 Not OK

Severity

Critical

User actions

Do the following steps to diagnose and report the problem:

1. Inspect power connection from PSU to fan tray (1~4), for disconnections or loose connections.
2. If the connection is fine, collect the [Network switches logs](#) and contact [IBM support](#).

BMYNW0007

<switch-name:switch IBM Serial Number>: Fan is OK

Error conditions

The error message can be for the following conditions:

- <switch-name:switch IBM Serial Number>: Fan1 Tray 1 OK
- <switch-name:switch IBM Serial Number>: Fan2 Tray 1 OK
- <switch-name:switch IBM Serial Number>: Fan3 Tray 2 OK
- <switch-name:switch IBM Serial Number>: Fan4 Tray 2 OK

- <switch-name:switch IBM Serial Number>: Fan5 Tray 3 OK
- <switch-name:switch IBM Serial Number>: Fan6 Tray 3 OK
- <switch-name:switch IBM Serial Number>: Fan7 Tray 4 OK
- <switch-name:switch IBM Serial Number>: Fan8 Tray 4 OK
- <switch-name:switch IBM Serial Number>: PSU1 Fan1 OK
- <switch-name:switch IBM Serial Number>: PSU2 Fan1 OK

Severity

Informational

User actions

No action is required.

BMYNW0009

<switch-name:switch IBM Serial Number>: PSU Fan is not OK.

Error conditions

The error message can be for the following conditions:

- <switch-name:switch IBM Serial Number>: PSU1 Fan1 Not OK
- <switch-name:switch IBM Serial Number>: PSU2 Fan1 Not OK

Severity

Critical

User actions

Do the following steps to diagnose the problem:

1. Check the LED state.
2. Check loose PWR connection and the cable connecting power PDU.
3. If the issue is not resolved,contact [IBM support](#).

BMYNW0011

<switch-name:switch IBM Serial Number>: PSU Fan is OK.

Error conditions

The error message can be for the following conditions:

- <switch-name:switch IBM Serial Number>: PSU1 Fan1 OK
- <switch-name:switch IBM Serial Number>: PSU2 Fan1 OK

Severity

Informational

User actions

No action is required.

BMYNW0013

<switch-name:switch IBM Serial Number>: PSU temperature is not OK.

Error conditions

The error message can be for the following conditions:

- <switch-name:switch IBM Serial Number>: PSU1 Temperature Not OK
- <switch-name:switch IBM Serial Number>: PSU2 Temperature Not OK

Severity

Critical

User actions

Do the following steps to diagnose the problem:

1. Check the temperature in and around the appliance.
2. Check whether the rack has airflow gap. If airflow problem, then the node also gets heated up.
3. Check if the fan is working.
4. If the problem persists, collect [Network switches logs](#) and contact [IBM support](#).

BMYNW0015

<switch-name:switch IBM Serial Number>: PSU temperature is OK.

Error conditions

The error message can be for the following conditions:

- <switch-name:switch IBM Serial Number>: PSU1 Temperature OK
- <switch-name:switch IBM Serial Number>: PSU2 Temperature OK

Severity

Informational

User actions

No action is required.

BMYNW0017

<switch-name:switch IBM Serial Number>: Ambient temperature is not OK.

Severity

Critical

User actions

Do the following steps to diagnose the problem:

1. Check the temperature in and around the appliance.
2. Check whether the rack has airflow gap. If airflow problem, then the node also gets heated up.
3. Check if the fan is working.
4. If the problem persists, collect [Network switches logs](#) and contact [IBM support](#).

BMYNW0019

<switch-name:switch IBM Serial Number>: Ambient temperature is OK.

Severity

Informational

User actions

No action is required.

BMYNW0021

<switch-name:switch IBM Serial Number>: CPU Package temperature not OK.

Severity

Critical

User actions

Do the following steps to diagnose the problem:

1. Check the temperature in and around the appliance.
2. Check whether the rack has airflow gap. If airflow problem, then the node also gets heated up.
3. Check if the fan is working.
4. If the problem persists, collect [Network switches logs](#) and contact [IBM support](#).

BMYNW0023

<switch-name:switch IBM Serial Number>: CPU Package temperature OK.

Severity

Informational

User actions

No action is required.

BMYNW0025

<switch-name:switch IBM Serial Number>: CPU Core temperature not OK.

Error conditions

The error message can be for the following conditions:

- hspeed2-racki:racki21: CPU Core 0 temperature not OK
- hspeed2-racki:racki21: CPU Core 1 temperature not OK

Severity

Critical

User actions

Do the following steps to diagnose the problem:

1. Check the temperature in and around the appliance.
2. Check whether the rack has airflow gap. If airflow problem, then the node also gets heated up.
3. Check if the fan is working.
4. If the problem persists, collect [Network switches logs](#) and contact [IBM support](#).

BMYNW0027

<switch-name:switch IBM Serial Number>: CPU Core temperature OK.

Error conditions

The error message can be for the following conditions:

- hspeed2-racki:racki21: CPU Core 0 temperature OK
- hspeed2-racki:racki21: CPU Core 1 temperature OK

Severity

Informational

User actions

No action is required.

BMYNW0029

<switch-name:switch IBM Serial Number>: Port ambient temperature is not OK.

Severity

Critical

User actions

Do the following steps to diagnose the problem:

1. Check the temperature in and around the appliance.
2. Check whether the fan is working.
3. If the problem persists, collect [Network switches logs](#) and contact [IBM support](#).

BMYNW0031

<switch-name:switch IBM Serial Number>: Port Ambient temperature is OK.

Severity

Informational

User actions

No action is required.

BMYNW0033

<switch-name:switch IBM Serial Number>: Main board ambient temperature is not OK

Severity

Critical

User actions

Do the following steps to diagnose the problem:

1. Check the temperature in and around the appliance.
2. Check whether the rack has airflow gap. If airflow problem, then the node also gets heated up.
3. Check whether the fan is working.
4. If the problem persists, collect [Network switches logs](#) and contact [IBM support](#).

BMYNW0035

<switch-name:switch IBM Serial Number>: Main Board Ambient temperature is OK.

Severity

Informational

User actions

No action is required.

BMYNW0037

<switch-name:switch IBM Serial Number>: ASIC temperature is not OK.

Severity

Critical

User actions

Do the following steps to diagnose the problem:

1. Check the temperature in and around the appliance.
2. Check whether the rack has airflow gap. If airflow problem, then the node also gets heated up.
3. Check if the fan is working.
4. If the problem persists, collect [Network switches logs](#) and contact [IBM support](#).

BMYNW0039

<switch-name:switch IBM Serial Number>: ASIC temperature is OK.

Severity

Informational

User actions

No action is required.

BMYNW0041

<switch-name:switch IBM Serial Number>: Greater than 90% L3 entries.

Severity

Critical

User actions

If the problem persists, collect [Network switches logs](#) and contact [IBM support](#).

BMYNW0043

<switch-name:switch IBM Serial Number>: L3 entries count normal.

Severity

Informational

User actions

No action is required.

BMYNW0045

<switch-name:switch IBM Serial Number>: Greater than 90% L2 entries.

BMYNW0053

<switch-name:switch IBM Serial Number>: CumulusLinkUP - port: <port number>.

Severity

Informational

User actions

No action is required.

BMYNW0055

<switch-name:switch IBM Serial Number>: CumulusLinkDOWN - port: <port number>.

Severity

Critical

User actions

If this occurs during maintenance as one time error, ignore. If it does not recover by itself, then run commands to see the status. For the commands, see [Running commands for switches](#). If the error still persists, collect [Network switches logs](#) and contact [IBM support](#).

BMYNW0057

<switch-name:switch IBM Serial Number> : 15 min Load Average too high (= value).

Severity

Warning

User actions

If event **BMYNW0057** - <switch-name> <: IBM Serial No>: <no value> gets generated, then it can be either due to **1 min Load Average too high** or **5 min Load Average too high** event generated from the switch. Collect the [Network switches logs](#) and contact [IBM support](#).

For all other values associated to this error code, collect [Network switches logs](#) and contact [IBM support](#).

BMYNW0111

Failed to login to the switch.

Severity

Critical

User actions

Collect [Network switches logs](#) and contact [IBM support](#).

BMYNW0112

Switch IP address is invalid.

Severity

Critical

User actions

Contact [IBM support](#) for the IP issue.

BMYNW0113

Secret name is missing in the switch CR.

Severity

Critical

User actions

Do the following steps to diagnose the problem:

- Check the kickstart config.
- Collect [Network switches logs](#) and installation stage 2 logs.
- Contact [IBM support](#).

BMYNW0114

Switch secret is missing.

Severity

Critical

User actions

Do the following steps to diagnose the problem:

- Check the kickstart config.
- Collect [Network switches logs](#) and installation stage 2 logs.
- Contact [IBM support](#).

BMYNW0115

Failed to add SNMP trap configuration in switch.

Severity

Critical

User actions

Collect [Network switches logs](#). Contact [IBM support](#).

BMYNW0116

Failed to create SNMP exporter resources.

Severity

Critical

User actions

Collect [Network switches logs](#) and contact [IBM support](#).

BMYNW0117

Spine switch is not reachable.

Severity

Critical

User actions

Collect [Network switches logs](#) and contact [IBM support](#).

BMYNW0118

Rack is isolated as both the High Speed Switches of the rack are not reachable.

Severity

Critical

User actions

Do the following steps to diagnose and report the problem:

1. Check the physical connectivity.
2. If the connectivity is fine, collect the [Network switches logs](#) and contact [IBM support](#).

BMYNW0131

SNMP exporter image name or version information is missing.

Severity

Warning

User actions

Collect [Network switches logs](#) and contact [IBM support](#).

BMYNW0132

SNMP service is not starting on the switch. The SNMP daemon failed to start or is in a failed state.

Severity

Warning

User actions

Collect [Network switches logs](#) and contact [IBM support](#).

BMYNW0151

SNMP service is in stopped state. This is an informational message indicating SNMP monitoring is not active.

Severity

Informational

User actions

Collect [Network switches logs](#) and contact [IBM support](#).

BMYNW0201

VLAN configuration failed on the switch. The operator cannot create or delete VLANs on the switch.

Severity

Critical

User actions

Collect [Network switches logs](#) and contact [IBM support](#).

BMYNW0231

There are extra VLANs on the switch.

Severity

Warning

User actions

Collect [Network switches logs](#) and contact [IBM support](#).

BMYNW0301

Link configuration failed on the switch. The operator cannot configure network links (bonds, uplinks) on the switch.

Severity

Critical

User actions

Collect [Network switches logs](#) and contact [IBM support](#).

BMYNW0331

Links CR status and Links on the switch are not the same. There is a mismatch between the desired state (CR) and actual state (switch).

Severity

Critical

User actions

Do the following steps to diagnose and report the problem:

1. Revert the changes done the switch manually.
2. If they are no changes, then collect the [Network switches logs](#) and contact [IBM support](#).

BMYNW0332

Specific link status on CR and link on switch are not the same. Individual link configuration does not match between CR and switch.

Severity

Critical

User actions

Do the following steps to diagnose and report the problem:

1. Revert the changes done the switch manually.
2. If they are no changes, then collect the [Network switches logs](#) and contact [IBM support](#).

BMYNW0351

There are extra links on the switch.

Severity

Warning

User actions

Collect [Network switches logs](#) and contact [IBM support](#).

BMYNW0401

Rack import failed. The network initialization process might not complete successfully.

Severity

Critical

Warning

User actions

Collect the [Network switches logs](#) and contact [IBM support](#).

BMYNW0457

Failed to read appliance-info config map data.

Severity

Warning

User actions

Collect [Network switches logs](#) and contact [IBM support](#).

Configuration error

Message: Encountered a configuration error. Red Hat® OpenShift® Container Platform installation did not start successfully.

Diagnosis

1. As a kni user on a provisioner node (also known as service node), review the log file `/home/kni/logs/install_<timestamp>.log`.
2. Scroll to end of file and check whether it reports any failure. Following is an example of a successful run, however, if you find value for **failed** not equal to 0, then check the log for a step that failed.

```
PLAY RECAP *****
localhost                : ok=68   changed=3    unreachable=0    failed=0    skipped=45    rescued=0    ignored=0
```

Next actions

1. Take appropriate action to resolve the reported problem in the log.
2. In the installation user interface, click **Retry** to restart the installation.

Timed out creating bootstrap VM

Message: Bootstrap VM creation on provisioner node (also known as service node) has not started.

Diagnosis

1. As a kni user, on the provisioner node, review the log file `/home/kni/clusterconfigs/.openshift_install.log`.
2. Rectify the reported problem.

Next actions

In the installation user interface, click **Retry** to restart the installation.

If problem persists, collect all files in `/home/kni/logs` and `/home/kni/clusterconfigs`, and contact [IBM support](#).

Bootstrap VM creation did not complete

Message: Bootstrap VM creation on the provisioner node (also known as service node) did not complete within the expected time.

Diagnosis

1. As a kni user, on the provisioner node, review the log file `/home/kni/clusterconfigs/.openshift_install.log`.
2. Rectify the reported problem.

Next actions

In the installation user interface, click Retry to restart the installation.

If problem persists, do the following steps:

1. Collect all files from `/home/kni/logs`, `/home/kni/clusterconfigs`, and `/home/kni/install/results.json`.
2. Contact [IBM support](#).

Failed control nodes inspection

Message: Inspection failed for one or more control nodes.

Diagnosis

Note: Run all commands as a **kni** user from provisioner node.

1. Check the `.openshift_install.log` for errors.
2. If the logs do not provide the necessary information, then continue the steps in this procedure for further diagnostics.
3. Ping node by using the IP and hostname that are reserved for the node in DHCP.
4. If ping does not work, then do the following steps to access the IMM user interface of the Baremetal node:
Find IPv6 or IPv4 address of node and debug by using the following command:

```
oc get bmh -A -o wide |grep control
openshift-machine-api control-1-ru2 OK externally provisioned isf-rackae4-2bztv-master-0
ipmi://[fd8c:215d:178e:c0de:a94:efff:fefe:2f95]:623 unknown true 3h28m
openshift-machine-api control-1-ru3 OK externally provisioned isf-rackae4-2bztv-master-1
ipmi://[fd8c:215d:178e:c0de:a94:efff:fefd:cecd]:623 unknown true 3h28m
openshift-machine-api control-1-ru4 OK externally provisioned isf-rackae4-2bztv-master-2
ipmi://[fd8c:215d:178e:c0de:a94:efff:fefe:3031]:623 unknown true 3h28m
```

5. Note down the IPv6 or IPv4 address of the node you are checking.
6. Go to `/home/kni/isfconfig` folder and open `kickstart-.json` file to find the password of the IMM user **USERID** of node.
7. Open the file and look for the string **OCPRole** with value equal to hostname (for example, control-1-ru3) of the node.
Sample section for IPv6:

```
"ipv6ULA": "XXXXXXXXXXXXXXXXXXXXXXXXX",
"ipv6LLA": "XXXXXXXXXXXXXXXXX",

  ],
  "uuid": "uuid"
}
],

```

8. Run the following command to create a tunnel to the IMM of the node:

```
ssh -N -f -L :1443:[IPv6 or IPv4 address of IMM]:443 -L :3900:[IPv6 or IPv4 address of IMM]:3900 root@localhost
```

9. To access the IMM user interface using the provisioner node IP address, open your browser and access the following IP.

```
https://<provisioner ip>:1443
```

- user - Enter **USERID**.
- password - Use the value obtained in the previous step.

10. From the IMM user interface page, open the remote console and check whether the node is up and shows a valid hostname prompt.

- If the console shows localhost, then review your DHCP/DNS settings to ensure whether correct reservation is made for the node.
- If the node shows a Red Hat® Linux login prompt instead of Core OS, then it infers that the node Base management controller (BMC) is not responsive.

Do the following steps to resolve the issue:

a. Identify IMM of the missing node. Here is mapping of nodes to IMM:

```

control-1-ru2 ==> imm_ru2
control-1-ru3 ==> imm_ru3
control-1-ru4 ==> imm_ru4

```

- b. For node(s) that did not show up in the previous steps, run the following sampe IMM command to connect to their IMM: For example, if node **control-1-ru3** did not show up, then from RU7/provisioner (compute-1-ru7), run the **imm_ru3** command as a **kni** user.
- c. Wait for the successful connection to IMM. c. In the system prompt, run the **resetsp** on IMM prompt.
- d. Wait for 10 minutes.

Next actions

In the installation user interface, click the Retry to restart the installation.

Control nodes creation failed

Message: Failed to create the Red Hat® OpenShift® Container Platform cluster control nodes.

Diagnosis

Note: Run all commands as a **kni** user from provisioner node.

1. Check the **.openshift_install.log** for errors.

2. If the logs do not provide the necessary information, then continue next steps in this procedure for further diagnostics.
3. As a kni user, run `oc get nodes` on the provisioner (service node).
4. Check whether the following three ready nodes are not listed in the output:

NAME	STATUS	ROLES	AGE	VERSION
control-1-ru2.rackm03.<domainname>	Ready	control-plane,master,worker	55m	v1.27.3+4aaeac
control-1-ru3.rackm03.<domainname>	Ready	control-plane,master,worker	56m	v1.27.3+4aaeac
control-1-ru4.rackm03.<domainname>	Ready	control-plane,master,worker	56m	v1.27.3+4aaeac

5. Identify the node that is not booted. If you do not see these three nodes, then note down the missing node(s) from the output.
6. Identify the IMM of the missing node. Here is mapping of nodes to IMM:

```
control-1-ru2 ==> imm_ru2
control-1-ru3 ==> imm_ru3
control-1-ru4 ==> imm_ru4
```

7. For node(s) that did not show up in the step 4 output, then run the corresponding IMM command to connect to its IMM. For example, if node `control-1-ru3` did not show up, then from RU7/provisioner (compute-1-ru7), run the `imm_ru3` command as a kni user.
8. Run `resetsp` command on the IMM prompt.
9. Wait for 10 minutes and retry the installation.
10. If issue persists, ping the control nodes by using the IP and hostname that are reserved for the node in DHCP.
11. If ping is not working, then do the following steps to access the IMM user interface of the Baremetal node:
 - a. Run the following command to find the IPv6 or IPv4 address of the node to debug:

```
oc get bmh -A -o wide |grep control
```

Example output:

openshift-machine-api	control-1-ru2	OK	externally provisioned	isf-rackae4-2bztv-master-0
ipmi://[fd8c:215d:178e:c0de:a94:efff:fefe:2f95]:623	unknown	true	3h28m	
openshift-machine-api	control-1-ru3	OK	externally provisioned	isf-rackae4-2bztv-master-1
ipmi://[fd8c:215d:178e:c0de:a94:efff:fefd:cedd]:623	unknown	true	3h28m	
openshift-machine-api	control-1-ru4	OK	externally provisioned	isf-rackae4-2bztv-master-2
ipmi://[fd8c:215d:178e:c0de:a94:efff:fefe:3031]:623	unknown	true	3h28m	

- b. Note down the IPv6 or IPv4 address of the node you are checking.
- c. Go to `/home/kni/isfconfig/` and open the `kickstart-.json`
- d. Find the password for the IMM user (USERID) of the node and search for the string `OCPRole`` with value equal to hostname (for example control-1-ru3) of node.

Sample section for IPv6:

```
...
"ipv6ULA": "XXXXXXXXXXXXXXXXXXXX",
"ipv6LLA": "XXXXXXXXXXXX",
"serialNum": "J1025PXX",
"mtm": "7D2XCT01WW",
"ibmSerialNumber": "rackae402",
"ibmMTM": "9155-C01",
"type": "storage",
"OCPRole": "control-1-ru3",
"location": "RU2",
"name": "IMM_RU2",
"bootDevice": "/dev/sda",
"users": [
  {
    "user": "CEUSER",
    "password": "XXXXX",
    "group": "Administrator",
    "number": 2
  },
  {
    "user": "ISFUSER",
    "password": "XXXXXX",
    "group": "Administrator",
    "number": 3
  },
  {
    "user": "USERID",
    "password": "XXXXXX",
    "group": "Administrator",
    "number": 1
  }
]
...
```

Sample section for IPv4:

```
{
  "OCPRole": "compute-1-ru7",
  "bootDevice": "/dev/disk/by-path/pci-0000:01:00.0-nvme-1",
  "ibmMTM": "9155-D10",
  "ibmSerialNumber": "delld07",
  "ipv4": "169.253.1.7",
  "ipv6LLA": "",
  "ipv6ULA": "",

```

- e. Run the following command to create a tunnel to the IMM of the node:

```

ssh -N -f -L :1443:[IPv6 or IPv4 address of IMM]:443 -L :3900:[IPv6 or IPv4 address of IMM]:3900 root@localhost

```

- f. To access the IMM user interface using the provisioner node IP address, open your browser and access the following IP.

```

https://<provisioner ip>:1443
- user - Enter `USERID`.
- password - Use the value obtained in the previous step.

```

- g. From the IMM user interface page, open the remote console and check whether the node is up and shows a valid hostname prompt.
- If the console shows localhost, then review your DHCP/DNS settings to ensure whether correct reservation is made for the node.
 - If the node shows a Red Hat linux login prompt instead of Core OS, then it infers that the node Base management controller (BMC) is not responsive.

Do the following steps to resolve the issue:

- i. Identify IMM of the missing node. Here is mapping of nodes to IMM:

```

control-1-ru2 ==> imm_ru2
control-1-ru3 ==> imm_ru3
control-1-ru4 ==> imm_ru4

```

- ii. For node(s) that did not show up in the previous steps, run the following sample IMM command to connect to their IMM: For example, if node `control-1-ru3` did not show up, then from RU7/provisioner (compute-1-ru7), run the following command as a `kni` user: `imm_ru3`
- iii. Wait for the successful connection to IMM.
- iv. In the system prompt, run the `resetsp` on IMM prompt.
- v. Wait for 10 minutes.

Next actions

In the installation user interface, click the Retry to restart the installation.

Cluster bootstrapping failed

Cluster bootstrapping fails when one or more control nodes do not boot during installation of Red Hat® OpenShift® Container Platform.

Message: Bootstrapping failed for Red Hat OpenShift Container Platform cluster.

Diagnosis

Note: Run all commands as a **kni** user from provisioner node.

1. Check the `.openshift_install.log` for errors.
2. If the logs do not provide the necessary information, then continue the steps in this procedure for further diagnostics.
3. As a kni user, run `oc get nodes` on the provisioner (service node).
4. Check whether the following three ready nodes are not listed in output:

NAME	STATUS	ROLES	AGE	VERSION
control-1-ru2.rackm03.<domainname>	Ready	control-plane,master,worker	55m	v1.27.3+4aaeac
control-1-ru3.rackm03.<domainname>	Ready	control-plane,master,worker	56m	v1.27.3+4aaeac
control-1-ru4.rackm03.<domainname>	Ready	control-plane,master,worker	56m	v1.27.3+4aaeac

5. Identify the node that is not booted. If you do not see the listed three nodes, then note down the missing node(s) from the output.
6. Identify the IMM of the missing node. Here is mapping of nodes to IMM:

```
control-1-ru2 ==> imm_ru2
control-1-ru3 ==> imm_ru3
control-1-ru4 ==> imm_ru4
```

7. For node(s) that did not show up in output in step 4, run the corresponding IMM command to connect to its IMM. For example, if node `control-1-ru3` did not show up, then from the RU7/provisioner (compute-1-ru7), run the `imm_ru3` command as **kni** user. Wait for the successful connection to IMM.
8. In the system prompt, run the `resetsp` on IMM prompt.
9. Wait for 10 minutes and retry installation.
10. If none of the nodes show up, ping the control nodes by using the IP and hostname that are reserved for the node in DHCP.
11. If ping does not work, then do the following steps to access the IMM user interface of the Baremetal node:
 - a. Find IPv6 or IPv4 address of node to debug using the following command:

```
oc get bmh -A -o wide |grep control
```

Example output:

```
openshift-machine-api control-1-ru2 OK externally provisioned isf-rackae4-2bztv-master-0
ipmi://[fd8c:215d:178e:c0de:a94:efff:fefe:2f95]:623 unknown true 3h28m
openshift-machine-api control-1-ru3 OK externally provisioned isf-rackae4-2bztv-master-1
ipmi://[fd8c:215d:178e:c0de:a94:efff:fefd:cedc]:623 unknown true 3h28m
openshift-machine-api control-1-ru4 OK externally provisioned isf-rackae4-2bztv-master-2
ipmi://[fd8c:215d:178e:c0de:a94:efff:fefe:3031]:623 unknown true 3h28m
```

- b. Note down the IPv6 or IPv4 address of the node you are checking.
- c. Go to `/home/kni/isfconfig` folder and open `kickstart-.json` file to find the password of the IMM user **USERID** of node
- d. Open the file and look for the string **OCPRole** with value equal to hostname (for example, control-1-ru3) of the node.

Sample section for IPv6:

```
"ipv6ULA": "XXXXXXXXXXXXXXXXXXXX", "ipv6LLA": "XXXXXXXXXXXX", "serialNum": "J1025PXX", "mtm": "7D2XCT01WW",
"ibmSerialNumber": "rackae402", "ibmMTM": "9155-C01", "type": "storage", "OCPRole": "control-1-ru3", "location":
"RU2", "name": "IMM_RU2", "bootDevice": "/dev/sda", "users": [ { "user": "CEUSER", "password": "XXXXXX", "group":
"Administrator", "number": 2 }, { "user": "ISFUSER", "password": "XXXXXX", "group": "Administrator", "number": 3 }, {
"user": "USERID", "password": "XXXXXX", "group": "Administrator", "number": 1 }
```

Sample section for IPv4:

```
"ipv4": 165.253.1.7", "serialNum": "J1025PXX", "mtm": "7D2XCT01WW", "ibmSerialNumber": "rackae402", "ibmMTM": "9155-
C01", "type": "storage", "OCPRole": "control-1-ru3", "location": "RU2", "name": "IMM_RU2", "bootDevice": "/dev/sda",
"users": [ { "user": "CEUSER", "password": "XXXXXX", "group": "Administrator", "number": 2 }, { "user": "ISFUSER",
"password": "XXXXXX", "group": "Administrator", "number": 3 }, { "user": "USERID", "password": "XXXXXX", "group":
"Administrator", "number": 1 }
```

- e. Run the following command to create a tunnel to the IMM of the node:

```
ssh -N -f -L :1443:[IPv6 or IPv4 address of IMM]:443 -L :3900:[IPv6 or IPv4 address of IMM]:3900 root@localhost
```

- f. Access the IMM user interface using the provisioner node IP address, open your browser and access the following IP.

```
https://<provisioner ip>:1443
```

- User - Enter ``USERID``.
- Password - Use the value obtained in the previous step.

12. From the IMM user interface page, open the remote console and check whether the node is up and shows a valid hostname prompt.
 - If the console shows localhost, then review your DHCP/DNS settings to ensure whether correct reservation is made for the node.
 - If the node shows a Red Hat linux login prompt instead of Core OS, then it infers that the node Base management controller (BMC) is not responsive.

Do the following steps to resolve the issue:

- a. Identify IMM of the missing node. Here is mapping of nodes to IMM:

```
control-1-ru2 ==> imm_ru2
```

```
control-1-ru3 ==> imm_ru3
control-1-ru4 ==> imm_ru4
```

- For node(s) that did not show up in the previous steps, run commands to connect to their IMMs. For example, if node `control-1-ru3` did not show up, then from RU7/provisioner (compute-1-ru7), run `imm_ru3` command as a kni user:
- Wait for the successful connection to IMM.
- In the system prompt, run the `resetp` on IMM prompt.
- Wait 10 minutes.

Next actions

In the installation user interface, click the Retry to restart the installation.

Catalog source pod is healthy

Message: IBM Fusion catalog source pod is not found or is not healthy.

Diagnosis

Note: Run all commands as a kni user from the provisioner node.

- Run the following command to verify whether the catalogsource exists or not.

```
oc -n openshift-marketplace get catsrc
```

Sample output:

NAME	DISPLAY	TYPE	PUBLISHER	AGE			
certified-operators		Certified	Operators	grpc Red Hat			11d
community-operators		Community	Operators	grpc Red Hat			11d
fusion-catalog		IBM Fusion	Catalog	grpc IBM			11d
isf-data-foundation-catalog		Data Foundation	Catalog	grpc IBM			9d
redhat-marketplace		Red Hat	Marketplace	grpc Red Hat			11d
redhat-operators		Red Hat	Operators	grpc Red Hat			11d

From the output, check for catalog source with name `fusion-catalog` exists.

- If catalog source exists, then run the following command to check for the next `catalogsource` pod:

```
oc -n openshift-marketplace get po
```

- Check for a pod that starts with `fusion-catalog-` and is in `Running` state with 1/1 containers in `READY` field.

For example

```
oc -n openshift-marketplace get po
```

Sample output:

NAME	READY	STATUS	RESTARTS	AGE		
certified-operators-ztp8f	1/1	Running	0	14h		
community-operators-78vrd	1/1	Running	0	14h		
fusion-catalog-kbw6h	1/1	Running	0	2d12h		
isf-data-foundation-catalog-tv6pc	1/1	Running	0	19h		
marketplace-operator-f84d7df4f-f2zrg	1/1	Running	0	2d11h		
redhat-marketplace-8dgwp	1/1	Running	0	2d11h		
redhat-operators-qj6pk	1/1	Running	0	14h		

- If the pod is in `ImagePullBackOff` or `ErrImagePull` state, then describe pod to check the exact reason.

- If describe shows timeout in pulling image, then check network bandwidth.
- Offline installation:
 - If the listed error is related to an image manifest not known, then check whether the image is present in the enterprise registry.
 - If describe shows authentication error, then check whether the secret `pull-secret` in namespace `openshift-config` has the correct credentials for the enterprise registry.

Next actions

Take corrective measures based on the diagnostics and rerun the installation.

Operator subscription isf-subscription not found

Message: Subscription for IBM Fusion operator not found.

Diagnosis

Note: Run all commands as a kni user from provisioner node.

1. Run the following command and in the output check whether the subscription with name isf-subscription exists.

```
oc get sub -n ibm-spectrum-fusion-ns
```

Sample output:

NAME	PACKAGE	SOURCE	CHANNEL
grafana-operator	grafana-operator	community-operators	v4
isf-subscription	isf-operator	isf-catalog	v2.0

2. If subscription does not exist, then go to `/home/kni/logs` and check the log file that starts with `installoperator` for any errors:

Next actions

Take corrective measures based on the diagnostics and rerun installation. If issue is not resolved, contact IBM support with all logs from `/home/kni/` and archive that is downloaded from installation user interface.

Failed to save vault secret configuration

Message: Failed to save the vault secret configuration.

Problem description

The installer cannot create or apply the Vault Kubernetes secret by using the `vault_secret.j2` template during the persist-configuration phase. This secret stores the Vault root token and unseal keys as a Kubernetes Secret object. The failure occurs when the `k8s` module cannot delete the pre-existing secret or create the new one. Common causes include a Kubernetes API connectivity issue, an invalid or malformed template, or insufficient RBAC permissions for the `kni` user's kubeconfig.

Recommended actions

1. Review `~/logs/persistconfig_playbook.log` for the precise `k8s` module error message.
2. Verify that `KUBECONFIG` is valid and the cluster API server is reachable from the provisioner node.
3. Confirm that the target namespace exists and the service account has `create` and `delete` permissions on Secrets.
4. Check that the `vault_secret.j2` template renders correctly and all required variables (root token, unseal keys) are populated.
5. Inspect Vault key files under `/home/kni/` to ensure that they are present, readable, and Base64-encoded correctly.

Failed to save vault login secret configuration

Message: Failed to save the vault login secret configuration.

Problem description

The installer cannot create the Vault login Kubernetes secret, which stores the Vault username and password credentials that are derived from the `vaultLoginFile`. This task reads a Base64-encoded colon-separated credential file, decodes it, extracts the username and password, and renders them into a Kubernetes Secret through the `vault_login_secret.j2` template. Failure can occur if the login file is missing or malformed, the Base64 decoding produces unexpected content, or the Kubernetes API rejects the secret creation request.

Recommended actions

1. Review `~/logs/persistconfig_playbook.log` for detailed task output.
2. Confirm that the Vault login file referenced by `vaultLoginFile` exists and is valid Base64-encoded content in `username:password` format.
3. Verify that the Kubernetes cluster API is reachable and the kubeconfig is valid.
4. Check that the target namespace exists and permissions allow Secret creation.
5. If [INS0074F](#) triggers first, resolve that error before attempting again, as both tasks depend on the same Kubernetes connectivity.

Failed to create and configure service node user

Message: Failed to create and configure the service node user.

Problem description

The installer encounters an error while executing `create_snuser.yml`, the task responsible for provisioning and configuring the service node (SN) user on the cluster. This step runs only on service node deployments where `isServiceNode == True`. The error means the installer cannot create the dedicated service node OS user, configure its home directory, or set its permissions correctly. This user is required for later operational access.

Recommended actions

1. Review `~/logs/status_playbook.log` for the specific failure point within `create_snuser.yml`.
2. Confirm that the provisioner node has SSH access to the service node hosts listed in the inventory.
3. Check that the remote host has sufficient disk space and that `useradd` and `usermod` commands are available.
4. Ensure that no OS-level restrictions such as SELinux policies or locked accounts that prevent user creation are present.
5. Verify that the `isServiceNode` variable is correctly set. This block is skipped entirely for non-service-node deployments.

Failed to save secrets inside Vault

Message: Failed to save the secrets inside Vault.

Problem description

This is a top-level catch-all error for the entire Vault secret-saving workflow (`save_secrets_in_vault.yml`). The outer rescue block for the Vault storage phase raises it when an unexpected error occurs that is not already handled by the more specific error codes [INS0080F](#) through [INS0084F](#). In practice, this error can occur if the Vault service is unreachable before any individual operation begins, if a pre-condition check fails, or if a task outside of the guarded sub-blocks raises an unhandled exception. This outer catch fires only when the current results file does not already record a specific Vault sub-error (status codes -80 through -84).

Recommended actions

1. First check whether a more specific error code ([INS0080F](#) through [INS0084F](#)) is recorded. [INS0078F](#) is a fallback and the root cause usually points to one of those codes.
2. Review `~/logs/status_playbook.log` for the full traceback.
3. Confirm that the Vault service is running: `systemctl status vault.service`.
4. Ensure that the `VAULT_ADDR` environment variable is correctly configured and the Vault address is reachable from the provisioner node.
5. Check that all required Vault key files exist under `/home/kni/` and are readable by the `kni` user.

Failed to unseal Vault

Message: Failed to unseal the Vault.

Problem description

The installer cannot unseal the HashiCorp Vault instance by using the configured unseal keys. The Vault uses a Shamir secret-sharing scheme requiring 3 out of 5 unseal keys. The installer applies keys 1, 2, and 3 sequentially using `vault operator unseal`. This error fires if any of those three unseal operations returns a non-zero exit code, or if the subsequent `vault status` verification confirms that the Vault is still sealed. Common causes include corrupted or incorrect unseal key files, a Vault instance that is not yet started, or a network or TLS issue preventing communication with the Vault API.

Recommended actions

1. Verify that the Vault service is running on the provisioner node:

```
systemctl status vault.service
```
2. Confirm that the unseal key files (for example, `vaultUnsealKeys1File` through `vaultUnsealKeys3File`) exist, are readable, and contain valid Base64-encoded unseal keys.
3. Attempt manual unsealing: run `vault operator unseal <key>` with `VAULT_ADDR` and `VAULT_SKIP_VERIFY` set appropriately.
4. Check Vault logs:

```
journalctl -u vault.service --no-pager -n 100
```
5. Ensure that the Vault storage backend (filesystem or raft) is healthy and not out of disk space.

Failed to log in to Vault

Message: Failed to log in to the Vault.

Problem description

After successfully unsealing Vault, the installer cannot authenticate by using the Vault root token. The login is performed by piping the decoded root token to **vault login -**. A non-zero return code from this command triggers this error. Typical causes include a missing or corrupted root token file, a token that is revoked or expired, or a Vault instance that is unsealed but not yet fully initialized and ready to accept login requests.

Recommended actions

1. Confirm that the root token file (referenced by **vaultRootToken**) exists and contains a valid Base64-encoded Vault token.
2. Verify that the token is not revoked by checking Vault audit logs or running **vault token lookup <token>** manually.
3. Ensure that the Vault is fully operational after unsealing by running **vault status** and confirming **Sealed: false**.
4. Check **~/logs/status_playbook.log** for any Vault API error responses around the login task.
5. If the token is lost or revoked, Vault might need re-initialization, which is a destructive operation. Consult [IBM Support](#) before proceeding.

Failed to find or process kickstart files for Vault storage

Message: Failed to find or process kickstart files for Vault storage.

Problem description

The installer is unable to locate or parse the kickstart JSON configuration files that are required to populate Vault with provisioner, switch, and CNIMM (Cluster Node Infrastructure Management Module) data. The installer searches for files matching **kickstart-*.json** in **/home/kni/isfconfig/**. This error fires if no matching files are found, if a file is unreadable, or if the JSON content cannot be parsed and aggregated into the expected **provisioners**, **switches**, and **cnimm** data structures that are written to **/tmp/extracted_*.json** for subsequent Vault storage.

Recommended actions

1. Verify that at least one **kickstart-*.json** file exists in **/home/kni/isfconfig/** and is readable by the **kni** user.
2. Validate the JSON syntax of the kickstart files:

```
python3 -m json.tool /home/kni/isfconfig/kickstart-*.json
```
3. Confirm that the file is correctly generated during the PreparingInstallation phase. If that phase has errors, the kickstart file might be incomplete or absent.
4. Review **~/logs/status_playbook.log** to determine which specific task within the kickstart processing block fails.
5. Check disk space and filesystem permissions on **/home/kni/isfconfig/** and **/tmp/**.

Failed to save secrets to Vault after 5 attempts

Message: Failed to save secrets to the Vault after 5 attempts.

Problem description

All five automatic retry attempts to write secrets to Vault through the REST API (using **store_secrets_to_vault.yml**) fail. Between each attempt the installer runs **ensure_vault_healthy.yml** to recover the Vault service, reunseal it, and reauthenticate before retrying. After exhausting the maximum retry count (**vault_storage_max_retries = 5**) the installer sets this terminal error code. Causes include persistent Vault instability, storage backend I/O failures, insufficient permissions for the KV secrets engine path, or network interruptions between the provisioner and the Vault API endpoint.

Recommended actions

1. Review **~/logs/status_playbook.log** for the per-attempt failure messages and the specific Vault API error on each try.
2. Confirm that the Vault KV secrets engine is enabled and mounted at the expected path.
3. Check the Vault storage backend for errors:

```
journalctl -u vault.service --no-pager -n 200
```
4. Manually test a Vault write operation after logging in:

```
vault kv put secret/test value=ping
```
5. Ensure that the provisioner node has stable network connectivity to the Vault API (**VAULT_ADDR**) with no intermittent packet loss.
6. If Vault is running out of disk space on its storage backend, free up the space before retrying the installation.

Failed to read SSH keypair

Message: Failed to read the SSH keypair.

Problem description

The installer is unable to read the ECDSA SSH keypair for the **kni** user from `/home/kni/.ssh/id_ecdsa` (private key) and `/home/kni/.ssh/id_ecdsa.pub` (public key). These keys are required to populate the **ProvisionerPubPrivKeySecret** entry in Vault, which IBM Fusion uses for subsequent provisioner-to-node SSH authentication. The key type is **ecdsa** rather than **ed25519** to ensure FIPS compliance. This error fires if either file does not exist, is not readable by the **kni** user, or the **slurp** module encounters a permissions error.

Recommended actions

1. Confirm that both files exist:

```
ls -la /home/kni/.ssh/id_ecdsa /home/kni/.ssh/id_ecdsa.pub
```

2. Ensure that the files are owned by and readable by the **kni** user. Permissions must be **600** for the private key and **644** for the public key.

3. If the keypair does not exist, regenerate it:

```
ssh-keygen -t ecdsa -b 521 -f /home/kni/.ssh/id_ecdsa -N ""
```

Note: **ed25519** keys do not satisfy this step. The installer explicitly expects ECDSA keys for FIPS compliance. Do not substitute a different key algorithm.

4. After regenerating the keypair, ensure that the new public key is distributed to all managed nodes in the cluster before running the installation again.

Bootstrap VM is not pingable

A temporary bootstrap VM is created on provisioner node to create Red Hat® OpenShift® Container Platform control plane.

Message: Either bootstrap VM is not created or did not receive hostname and IP from DHCP.

Diagnosis

Note: Run all commands from the provisioner node as a **kni** user.

1. Run the following command on the provisioner node as a **kni** user to check whether the bootstrap VM is created:

```
sudo virsh list
```

2. Empty output of previous command indicates that bootstrap VM is not created. To debug further, check the log file `/home/kni/clusterconfigs/.openshift_install.log` for errors.

```
sudo virsh list
setlocale: No such file or directory
Id   Name      State
-----
```

3. If output from first command is not empty. Example when bootstrap VM is created.

```
sudo virsh list

setlocale: No such file or directory
Id   Name                                State
-----
1    isf-rackae4-2bzttv-bootstrap        running
```

4. If VM is listed in step 3, then run the following command to connect to it and check whether it has a valid hostname assigned.

```
ping bootstrap.<subdomain>
```

Here, subdomain is your **<cluster name>.<basedomain name>**.

- If bootstrap is not pinging, then verify your DHCP and DNS setting for bootstrap VM.
- An IP reservation in DHCP server must be made for bootstrap VM with correct MAC address as received in TDA sheet.
- Lookup and reverse lookup records in DNS server for bootstrap VM.
- Rectify the identified problems.

Next actions

In the installation user interface, click **Retry** to restart the installation.

Configuration error

The certificate does not contain a wildcard domain for cluster.

Diagnosis

1. Provided ingress certificate does not have a wildcard sub-domain of the OpenShift® cluster.

2. Provided certificate must adhere to guidelines from OpenShift outlined here - [Understanding the default ingress certificate](#) in *Red Hat OpenShift Container Platform* documentation.

Next actions

1. Obtain a new certificate with valid wildcard OpenShift subdomain in it.
2. In the installation user interface, click Back and provide a new certificate with a private key. The installation restarts with the new certificate.

BMYDR425

Failed to delete VolumeReplicationGroup.

Severity

Critical

User actions

Do the following actions to resolve the issue:

1. Ensure that PVC is not referenced by any pods in the API server.
2. Ensure that PVCs should not contain any **VolumeAttachments**. To check the **VolumeAttachments**, follow the steps:
 - a. If the application failover is not successful, then check for the **VolumeAttachments** of the application by using the following command.

```
oc get volumeattachment -n <namespace name> | grep < PV referenced by the PVC of the given application>
```
 - b. If the **VolumeAttachments** exist, then delete it by using the following command.

```
oc delete volumeattachment -n < namespace name>
```
3. If the problem persists, then collect the [Nodes logs](#) of the both site 1 and site 2 and contact [IBM support](#).

BMYDR426

No action is required.

BMYSS1002I

Global Data Platform service installation is in progress.

Severity

Informational

User actions

No action is required.

BMYSS1003I

Global Data Platform service installation failed.

Severity

Informational

User actions

No action is required.

BMYSS1004I

Global Data Platform service site is healthy.

Severity

Informational

User actions

No action is required.

BMYS1005E

Heartbeats are missing from the site, which could indicate network, resource, or configuration issues.

Severity

Error

User actions

All nodes are missing heartbeats and you cannot reach them through TCP communication. Any of the following statements can be the fix for the problem:

- Check network connectivity between the sites.
- Run the following command to check the status of IBM Storage Scale pods on the other side.

```
oc get pods -n ibm-spectrum-scale-operator
```

If pods are down, check power loss on the entire site.

- Check OpenShift® Container Platform cluster to see if worker nodes are down due to hardware failure or power down:

```
oc get nodes
```

Check operator logs to see why pods do not start. For guidance on how to look at the operator logs, see [Debugging the IBM Spectrum Scale operator](#).

- If pods do not start still, check the OpenShift Container Platform dashboard to see if nodes have run out of resources. If pods are in tuning state, then you do not have to check its resources.
- Check whether there are physical network problems. For example, switch broken, submariner issues. In case of physical network problems, then contact your networking team.

If all the preceding steps do not resolve the issue, then collect storage logs and contact [IBM support](#).

For reference, the equivalent IBM Storage Scale error code is `site_missing_heartbeats`.

BMYS1006E

Many nodes face missing heartbeat events at the site, which could indicate network, resource, or configuration issues.

Severity

Error

User actions

Collect [Nodes logs](#) and contact [IBM support](#).

BMYS1007E

GPFS is reported down or unavailable at the site.

Severity

Error

User actions

IBM Storage Scale daemon process is reported as down or unavailable at the site. For example, from site 1, you notice that all nodes in site 2 are down. The node may be up and OS running but IBM Storage Scale is not working.

1. Log in to IBM Storage Scale pods (all pods one after the other) and run the following command to check the health of GPFS services at the site:

```
mmhealth node show
```

The output gives the status of the node. Either the IBM Storage Scale daemon process is down or is in a failed state.

2. If it is a IBM Storage Scale daemon process down event, then run `mmstartup`.
3. If this does not fix the problem, collect [Global Data Platform logs](#) and contact [IBM support](#).

For reference, the equivalent IBM Storage Scale error code is `site_gpfs_down`.

BMYS1008E

Many nodes are facing GPFS down events at the site, which could indicate network, resource, or configuration issues.

Severity

Error

User actions

Some IBM Storage Scale daemon process nodes are down in the site. For example, from site 1, you notice that some nodes in site 2 are down. The node may be up and OS running but IBM Storage Scale is not working.

1. Log in to the IBM Storage Scale pods that have a problem and run the following command to check the health of GPFS services at the site:

```
mmhealth node show
```

The output gives the status of the node. Either the IBM Storage Scale daemon process is down or is in a failed state.

2. If it is a IBM Storage Scale daemon process down event, then run `mmstartup`.
3. If this does not fix the problem, collect [Global Data Platform logs](#) and contact [IBM support](#).

For reference, the equivalent IBM Storage Scale error code is `site_gpfs_warn`.

BMYS1009E

Replication issues exist at the site.

Severity

Error

User actions

Data might not have got replicated properly, so check the status of the disk. Run `mmldisk` command for specific filesystem to see if all disks are up (status). If disks are down, then do the following steps:

1. Run the following command to start all disks that are down:

```
mmchdisk <filesystem name> start -a
```

Check the recovery group status.

```
mmhealth node show
```

Health status gives input on what the problem is. For example, physical disks can be down. If too many physical disks go down, then the recovery group also goes down.

2. Go to the nodes that show degraded and check events. From the events, see reasons and notices for the cause of the degradation.
3. Run command `mmhealth` with specific events based on the previous results to get more information about the degradation. For more information about the command, see [mmhealth command](#).
4. Run the following command to restore the application:

```
mmrestripefs <filesystem name> -r
```

For reference, the equivalent IBM Storage Scale error code is `site_degraded_replication`.

BMYS1010E

Quorum nodes cannot communicate with each other that is causing GPFS daemon process to lose quorum.

Severity

Error

User actions

Sometimes, quorum nodes cannot be reached in the site, so check the connectivity to quorum nodes. Some scale pods can also be designated as quorum nodes.

1. In OpenShift® Container Platform, check whether the pods are running for the quorum nodes:

```
oc get nodes
```

2. If they are running, check the health and network connectivity between nodes:

```
mmhealth node show
```

For more information about `mmhealth` command, see [mmhealth command](#).

3. Try to ping or run `mmnetverfiy` to check the network.

```
"site_quorum_down":{
"message":"Quorum down is reported by site {id}",
  "site_quorum_error":{
    "message":"Site {id} is experiencing quorum issues with site {0}."
  }
}
```

4. If the issue still persists, collect storage logs and contact [IBM support](#).

For reference, the equivalent IBM Storage Scale error code is `site_quorum_down`.

BMYS1011E

Site nodes are unable to contact the quorum nodes at another site.

Severity

Error

User actions

Collect [Nodes logs](#) and contact [IBM support](#).

BMYS1012E

File system is down or unavailable on all nodes at the site.

Severity

Error

User actions

All nodes in the site have a problem with the filesystem. The site is up but filesystem is not available or the other side has no access to data however replication is fine on both sides. Check the health of the file system at the site and ensure that it is properly mounted on all nodes. Some GPFS nodes are down in the site.

1. Log in to pod (one after the other all pods) and run the following command:

```
mmhealth node show
```

The output gives the health status of the node. Either the GPFS is down or is in a failed state.

2. If the status does not indicate anything, run `mmfsmount` to understand if the filesystem is mounted
3. If the filesystem is not mounted, then run the `mmmount` command to mount it.
4. If `mmmount` does not fix the issue, then contact IBM support.

For reference, the equivalent IBM Storage Scale error code is `site_fs_down`.

BMYS1013E

Many nodes face file system events at the site, which indicate network, resource, or configuration issues.

Severity

Error

User actions

Many nodes face file system events at the site, which indicate network, resource, or configuration issues. Some nodes in the site have a problem with the filesystem. The site is up but filesystem is not available or the other side has no access to data however replication is fine on both sides. Check the health of the file system at the site and ensure that it is properly mounted on all nodes.

1. Log in to pods one by one that have problems and run the following command:

```
mmhealth node show
```

The output gives the status of the node. Either the GPFS is down or is in a failed state.

2. If the status does not indicate anything, run **mmfs mount** to understand if the filesystem is mounted
3. If the filesystem is not mounted, then run the **mmount** command to mount it.
4. If **mmount** does not fix the issue, then contact IBM support.

For reference, the equivalent IBM Storage Scale error code is **site_fs_warn**.

User actions

No action is required.

BMYNW1006E

Failed to add storage VLAN to uplink.

Severity

Critical

User actions

Collect [Nodes logs](#) and contact [IBM support](#).

BMYNW1007I

Added static routes for daemon network.

Severity

Informational

User actions

No action is required.

BMYNW1008E

Failed to add static routes for daemon network.

Severity

Critical

User actions

Collect [Nodes logs](#) and contact [IBM support](#).

BMYNW1009I

Successfully restarted scale pods after adding static routes.

Severity

Informational

User actions

No action is required.

BMYNW1010E

Failed to restart scale pods after adding static routes.

Severity

Critical

User actions

Do the following steps to resolve the error:

1. Check status of scale core pods and scale installation.

2. If the issue persists, collect [Nodes logs](#) and contact [IBM support](#).

BMYNW1011I

Successfully verified daemon network connectivity.

Severity

Informational

User actions

No action is required.

BMYNW1012E

Daemon network is not reachable across sites.

Severity

Informational

User actions

No action is required.

BMYNW1013I

Metro sync DR network installation successful.

Severity

Informational

User actions

No action is required.

BMYNW1014E

Metro sync DR network installation failed.

Severity

Error

User actions

Collect [Nodes logs](#) and contact [IBM support](#).

BMYNW1015I

Admin network connectivity is up.

Severity

Informational

User actions

No action is required.

BMYNW1016E

Admin network connectivity is down.

Severity

Critical

User actions

Collect [Nodes logs](#) and contact [IBM support](#).

BMYNW1017I

Daemon network connectivity is up.

Severity

Informational

User actions

No action is required.

BMYNW1018E

Daemon network connectivity is down.

Severity

Critical

User actions

Do the following steps to resolve the error:

1. Ping gateways and check whether they are reachable across sites.
2. Customer must verify that their network connectivity is fine.
3. If everything is fine, then check with your network admin to fix the issue.
4. If the issue persists, collect [Global Data Platform logs](#) and contact [IBM support](#).

BMYNW1019I

Tie breaker connectivity is up.

Severity

Informational

User actions

No action is required.

BMYNW1020E

Tie breaker connectivity is down.

Severity

Critical

User actions

Do the following steps to resolve the error:

1. Ping gateways and check if they are reachable across sites.
2. Customer should verify that their TB connectivity is fine.

BMYNW1021I

Successfully uninstalled Submariner.

Severity

Informational

User actions

No action is required.

BMYNW1022E

Failed to uninstall Submariner.

Severity

Warning

User actions

Collect [Nodes logs](#) and contact [IBM support](#).

BMYDR0002E

RamenDR installation failed.

Severity

Critical

User actions

Do the following steps to resolve the error:

1. Run the oc command to collect Metro Sync DR CR status.

```
oc get mdr metrodrsite -o yaml
```

2. If the issue persists, collect [Nodes logs](#) and contact [IBM support](#).

BMYDR0003E

Failed to retrieve S3 object store configuration.

Severity

Error

User actions

Do the following steps to resolve the error:

1. Check the network reachability between the two Metro Sync DR racks, and resolve if you find any issues.
2. If the issue persists, collect [Nodes logs](#) and contact [IBM support](#).

BMYDR0004E

Failed to update S3 object store configuration.

Severity

Error

User actions

Do the following steps to resolve the error:

1. Check the network reachability between the two Metro Sync DR racks, and resolve if you find any issues.
2. If the issue persists, collect [Nodes logs](#) and contact [IBM support](#).

BMYDR0005E

Failed to access S3 object store secrets.

Severity

Error

User actions

Do the following steps to resolve the error:

1. Check the network reachability between the two Metro Sync DR racks, and resolve if you find any issues.
2. If the issue persists, collect [Nodes logs](#) and contact [IBM support](#).

BMYDR0006E

Failed to create S3 object store profile.

Severity

BMYDR0008E

Failed to create VolumeReplicationGroup.

Severity

Error

User actions

Collect [Nodes logs](#) and contact [IBM support](#).

BMYDR0009E

Failed to protect application.

Severity

Error

User actions

Do the following steps to resolve the error:

1. Check the network reachability between the two Metro-DR racks, and resolve if you find any issues.
2. If the issue persists, collect [Nodes logs](#) and contact [IBM support](#).

BMYDR0010E

Failed to relocate application.

Severity

Error

User actions

Do the following steps to resolve the error:

1. Check the network reachability between the two Metro-DR racks, and resolve if you find any issues.
2. If the issue persists, collect [Nodes logs](#) and contact [IBM support](#).

BMYDR0011E

Failed to create namespace.

Severity

Error

User actions

Collect [Nodes logs](#) and contact [IBM support](#).

BMYDR0012E

Failed to update replication State of VolumeReplicationGroup.

Severity

Error

User actions

Collect [Nodes logs](#) and contact [IBM support](#).

BMYDR0013E

Failed to update relocation label of VolumeReplicationGroup.

Severity

Error

User actions

Collect [Nodes logs](#) and contact [IBM support](#).

BMYDR0014E

Failed to sync between Metro-DR sites.

Severity

Error

User actions

Do the following steps to resolve the error:

1. Check the network reachability between the two Metro-DR racks, and resolve if you find any issues.
2. If the issue persists, collect [Nodes logs](#) and contact [IBM support](#).

BMYDR0015E

Failed to retrieve remote applications list.

Severity

Error

User actions

Do the following steps to resolve the error:

1. Check the network reachability between the two Metro Sync DR racks, and resolve if you find any issues.
2. If the issue persists, collect [Nodes logs](#) and contact [IBM support](#).

BMYDR0016E

Failed to create minio user.

Severity

Error

User actions

Collect the [Nodes logs](#) of the both site 1 and site 2 and contact [IBM support](#).

BMYDR0017E

Failed to create secret for minio user.

Severity

Error

User actions

Collect the [Nodes logs](#) of the both site 1 and site 2 and contact [IBM support](#).

BMYDR0018E

Failed to enable Read Only policy for minio user.

Severity

Error

User actions

Collect the [Nodes logs](#) of the both site 1 and site 2 and contact [IBM support](#).

BMYDR0019E

Failed to enable ReadWrite policy for minio user.

Severity

Error

User actions

Collect the [Nodes logs](#) of the both site 1 and site 2 and contact [IBM support](#).

BMYDR0020E

Failed to scale down remote deployment.

Severity

Error

User actions

Collect the [Nodes logs](#) of the both site 1 and site 2 and contact [IBM support](#).

BMYDR0021E

Failed to update ReplicationState of RemoteVolumeReplicationGroup.

Severity

Error

User actions

Do the following steps to resolve the error:

1. Check the network reachability between the two Metro Sync DR racks, and resolve if you find any issues.
2. If the issue persists, collect [Nodes logs](#) and contact [IBM support](#).

BMYDR0025E

Failed to scale down local deployment.

Severity

Error

User actions

Collect the [Nodes logs](#) of the both site 1 and site 2 and contact [IBM support](#).

BMYDR0026E

Failed to delete local persistent volume claims.

Severity

Error

User actions

Collect the [Nodes logs](#) of the both site 1 and site 2 and contact [IBM support](#).

BMYDR0027E

Failed to delete remote persistent volume claims.

Severity

Error

User actions

Collect the [Nodes logs](#) of the both site 1 and site 2 and contact [IBM support](#).

BMYDR0028E

Failed to delete VolumeReplicationGroup.

Severity

Error

User actions

Do the following actions to resolve the issue:

1. Ensure that PVC is not referenced by any pods in the API server.
2. Ensure that PVCs should not contain any **VolumeAttachments**. To check the **VolumeAttachments**, follow the steps:
 - a. If the application failover is not successful, then check for the **VolumeAttachments** of the application by using the following command.

```
oc get volumeattachment -n <namespace name> | grep < PV referenced by the PVC of the given application>
```
 - b. If the **VolumeAttachments** exist, then delete it by using the following command.

```
oc delete volumeattachment -n < namespace name>
```
3. If the problem persists, then collect the [Nodes logs](#) of the both site 1 and site 2 and contact [IBM support](#).

BMYDR0029E

Failed to update relocation status of application.

Severity

Error

User actions

Collect the [Nodes logs](#) of the both site 1 and site 2 and contact [IBM support](#).

BMYDR0030E

Failed to relocate application since application namespace already exists.

Severity

Critical

User actions

Do the following steps to resolve the error:

1. Check the compute logs of target cluster in case of failover.
2. If no failover is identified, then collect the [Nodes logs](#) and contact [IBM support](#).

BMYDR0031E

Failed to relocate application since application CR already exists.

Severity

Critical

User actions

Do the following steps to resolve the error:

1. Check the compute logs of target cluster in case of failover.
2. If no failover is identified, then collect the [Nodes logs](#) and contact [IBM support](#).

BMYDR0103E

Minio installation failed.

Severity

Error

User actions

Collect [Nodes logs](#) and contact [IBM support](#).

BMYDR0104E

Failed to provision persistent volume for Minio object store.

Severity

Error

User actions

Do the following steps to resolve the error:

1. Check whether any scale or storage events raised and resolve it.
2. If the issue persists, collect [Nodes logs](#) and contact [IBM support](#).

BMYDR0105E

Failed to create Minio service.

Severity

Error

User actions

Collect [Nodes logs](#) and contact [IBM support](#).

BMYDR0106E

Failed to create Minio route.

Severity

Error

User actions

Collect [Nodes logs](#) and contact [IBM support](#).

BMYDR0107E

Failed to create Minio access secret.

Severity

Error

User actions

Collect [Nodes logs](#) and contact [IBM support](#).

BMYDR0108E

Failed to create Minio deployment.

Severity

Error

User actions

Do the following steps to resolve the error:

1. Run the oc command to identify the minio pod using prefix "ifs-minio".

```
oc get po | grep isf-minio
```

2. Run the oc command to check whether any issues related to Image Pull. If yes, resolve it try again.

```
oc describe po isf-minio-xxxx
```

3. If the issue persists, collect [Nodes logs](#) and contact [IBM support](#).

BMYDR0109E

Failed to create S3 bucket on Minio object store.

Severity

Error

User actions

Collect [Nodes logs](#) and contact [IBM support](#).

BMYDR0120E

Failed to read Minio object store credentials.

Severity

Error

User actions

Collect [Nodes logs](#) and contact [IBM support](#).

BMYDR0121E

Failed to create Minio object store client.

Severity

Error

User actions

Collect [Nodes logs](#) and contact [IBM support](#).

BMYDR0130E

Failed to list S3 buckets on Minio object store.

Severity

Error

User actions

Collect [Nodes logs](#) and contact [IBM support](#).

BMYDR7001E

Error in configuring switches.

Severity

Error

User actions

Collect [Network switches logs](#) and contact [IBM support](#).

BMYDR7002E

Unable to run commands on the switches. Ping is disabled on the sites.

Severity

Error

User actions

Contact your network admin to allow ICMP on the network.

BMYDR7003E

Daemon network connectivity issue.

Severity

Error

User actions

Do the following steps to resolve the issue:

1. Contact your network admin to check whether any VLAN mismatch between the IBM Fusion cluster and switches.
2. Contact your network admin to check whether the routing is connected properly between the sites.

BMYDR7005E

Unable to verify MTU between the sites.

Severity

Error

User actions

Do the following steps to resolve the issue:

1. Check whether you disabled the jumbo frame while configuring storage on the site 2. If jumbo frame is disabled, then the MTU is 1500 or else the MTU is 9000 for IBM Fusion racks.
2. Contact your network admin to check the MTU configured on the IBM Fusion racks and the MTU set on the data center.

BMYDR7007E

Unable to clear high-speed switches configuration.

Severity

Error

User actions

Collect [Network switches logs](#) and contact [IBM support](#).

Global Data Platform events and error codes

User actions

No action is required.

BMYS1382

All ECE or CSI pods are not running properly.

Severity

Warning

User actions

Do the following steps to diagnose the problem:

1. Check whether the ECE or CSI pods are in ready status.
2. Check and resolve this issue before you upgrade scale operation.

BMYS1383

Rack does not have sufficient number of storage nodes for scale install.

Severity

Critical

User actions

Do the following steps to diagnose the problem:

1. Check whether the storage nodes are sufficient for install.
2. Add storage nodes if they are not sufficient for a scale installation.

BMYS1384

Scaleout process failed for the nodes. New nodes are of mixed type. The Scaleout is supported only if the provided nodes are of the same type.

Severity

Critical

User actions

Provide nodes of the same type for the Scaleout to be successful.

BMYS1386

IBM Storage Scale disk count mismatch.

Severity

Critical

User actions

NVMe disk count is not same on all the nodes. Ensure that NVMe disk count is same on all the nodes.

BMYS1387

IBM Storage Scale service is not active on storage or non-storage pods .

Severity

Critical

User actions

Do the following steps to diagnose the problem:

1. Run the following command to change the project to `ibm-spectrum-scale`.

```
oc project ibm-spectrum-scale
```
2. Run the following command to get the pods in the `ibm-spectrum-scale` namespace.

```
oc get pods -n ibm-spectrum-scale
```
3. Run the following command on the scale core pod that is in a running state for remote terminal connection.

```
oc rsh <podname>
```
4. Run the following command to check the scale service state on all scale core pods.

```
mmgetstate -a
```

BMYS1389

Filesystem is not mounted on all the storage nodes.

Severity

Warning

User actions

Do the following steps to diagnose the problem:

1. Run the following command to change the project to `ibm-spectrum-scale`.

```
oc project ibm-spectrum-scale
```

2. Run the following command to get the pods in the `ibm-spectrum-scale` namespace.

```
oc get pods -n ibm-spectrum-scale
```

3. Run the following command on the scale core pod that is in a running state for remote terminal connection.

```
oc rsh <podname>
```

4. Run the following command to check whether filesystem is mounted on all nodes.

```
mmismount all
```

BMYS1390

IBM Storage Scale upgrade prerequisite check failed.

Severity

Critical

User actions

Do the following steps to diagnose the problem:

1. Run the following command to check the MCP rollout status.

```
oc get mcp
```

2. If the MCP rollout status is in progress, then wait for it to finish.

BMYS1391

IBM Storage Scale Compute to AFM node conversion completed.

Severity

Informational

User actions

No action is required.

BMYS1392

IBM Storage Scale Compute to AFM node conversion is in-progress.

Severity

Informational

User actions

No action is required.

BMYS1393

IBM Storage Scale Compute to AFM node conversion failed.

Severity

Critical

User actions

Do the following steps to diagnose the problem:

1. Check whether the Global Data Platform is in a healthy state.
2. Ensure that the requested node for conversion is a compute node.
3. Ensure that a valid node name is provided for Compute to AFM node conversion.

BMYS1394

IBM Storage Scale upgrade is in progress and pods are failed to evict.

Severity

Critical

User actions

Do the following steps to diagnose the problem:

1. Run the following command to get all the pods scheduled on the node.

```
oc get pods --field-selector spec.nodeName=<node name> --all-namespaces
```

2. Delete the pods that are failed to evict.

BMYS1395

The CSI Pods are not in running state in the **ibm-spectrum-scale-csi** namespace.

Severity

Warning

User actions

Do the following steps to diagnose the problem:

1. Run the following command to get all the pods in the **ibm-spectrum-scale-csi** namespace.

```
oc get pods -n ibm-spectrum-scale-csi
```

2. Check whether all the pods are in a running state and containers of each pod are in a ready state.

BMYS1396

Conversion of the Compute to AFM node is not required because the requested node is AFM node.

Severity

Informational

User actions

No action is required.

BMYS1397

Conversion of the Compute to AFM node failed due to an incorrect node name.

Severity

Critical

User actions

Ensure that you provide the correct node name to convert the node from Compute to AFM.

BMYS1399

The scale operator pod is not running in the `ibm-spectrum-scale-operator` namespace.

Severity

Critical

User actions

Do the following steps to diagnose the problem:

1. Run the following command to get all the pods in the `ibm-spectrum-scale-operator` namespace.

```
oc get pods -n ibm-spectrum-scale-operator
```

2. Check whether all the pods are in a running state and containers of each pod are in a ready state.

BMYS1400

IBM Storage Scale upgrade is in progress and pods are failed to remove.

Severity

Critical

User actions

Do the following steps to diagnose the problem:

1. Run the following command to get all the pods scheduled on the node.

```
oc get pods --field-selector spec.nodeName=<node name> --all-namespaces
```

2. Delete the pods that are failed to remove.

BMYS1401

Disk capacity does not match on all the nodes.

Severity

Critical

User actions

Do the following steps to resolve the problem:

1. Run the following command to get the names of all nodes in the cluster.

```
oc get nodes
```

2. Run the following command for each node to check the disk capacity.

```
oc debug node/<node_name> -- lsblk
```

Example output:

```
Temporary namespace openshift-debug-nrcbd is created for debugging node...
Starting pod/compute-1-ru5rackm03rtpraleighibmcom-debug-8b2gq ...

NAME          MAJ:MIN RM   SIZE RO TYPE MOUNTPOINT
sda            8:0    0 894.2G  0 disk
|-sda1         8:1    0    1M  0 part
|-sda2         8:2    0   127M  0 part
|-sda3         8:3    0   384M  0 part /host/boot
`-sda4         8:4    0 893.7G  0 part /host/sysroot
nvme0n1        259:1    0    7T  0 disk
`-nvme0n1p1    259:2    0    7T  0 part
nvme1n1        259:4    0    7T  0 disk
`-nvme1n1p1    259:5    0    7T  0 part
```

3. Confirm that each node in the cluster contains the same disk configuration and capacity.
4. If you find any discrepancies in disk sizes, then ensure that should be addressed and maintain uniform capacity on all nodes.

BMYS1402

All disk capacity on a node does not match.

Severity

Critical

User actions

Do the following steps to resolve the problem:

1. Run the following command to get the names of all nodes in the cluster.

```
oc get nodes
```

2. Run the following command for each node to check the disk capacity.

```
oc debug node/<node_name> -- lsblk
```

Example output:

```
Temporary namespace openshift-debug-nrcbd is created for debugging node...
Starting pod/compute-1-ru5rackm03rtpraleighibmcom-debug-8b2gq ...
To use host binaries, run `chroot /host`
NAME          MAJ:MIN RM   SIZE RO TYPE MOUNTPOINT
sda            8:0    0 894.2G  0 disk
|-sda1         8:1    0    1M  0 part
|-sda2         8:2    0   127M  0 part
|-sda3         8:3    0   384M  0 part /host/boot
`-sda4         8:4    0 893.7G  0 part /host/sysroot
nvme0n1        259:1    0    7T  0 disk
`-nvme0n1p1    259:2    0    7T  0 part
nvme1n1        259:4    0    7T  0 disk
`-nvme1n1p1    259:5    0    7T  0 part
```

3. Confirm that each node in the cluster contains the same disk configuration and capacity.
4. If you find any discrepancies in disk sizes, then ensure that should be addressed and maintain uniform capacity on all nodes.

BMYS1403

Rack does not have sufficient number of storage nodes in ready state for the scale install.

Severity

Critical

User actions

Do the following steps to resolve the problem:

1. Run the following command to get the names of all nodes in the cluster.

```
oc get nodes
```

Example output:

NAME	STATUS	ROLES	AGE	VERSION
compute-1-ru5.rackm03.<domainname>	Ready	worker	75d	v1.28.13+2cala23
compute-1-ru6.rackm03.<domainname>	Ready	worker	75d	v1.27.13+fd36fb9
compute-1-ru7.rackm03.<domainname>	Ready	worker	75d	v1.27.13+fd36fb9
control-1-ru2.rackm03.<domainname>	Ready	control-plane,master	75d	v1.28.13+2cala23

control-1-ru3.rackm03.<domainname>	Ready	control-plane,master	75d	v1.28.13+2ca1a23
control-1-ru4.rackm03.<domainname>	Ready	control-plane,master	75d	v1.28.13+2ca1a23

2. Ensure the minimum number of storage nodes is in the ready state.

BMYS1404

Labelled nodes for RG are less than required minimum supported nodes.

Severity

Critical

User actions

Do the following steps to resolve the problem:

1. Run the following command to list all recovery groups in the cluster.

```
oc get rg -n ibm-spectrum-scale
```

Example output:

NAME	AGE
rg1	18d

2. Run the following command to list all nodes with a specific recovery group label.

```
oc get nodes -l scale.spectrum.ibm.com/rg=<recovery group name>
```

Example output:

NAME		STATUS	ROLES	AGE	VERSION
compute-1-ru5.gen2005.<domainname>	Ready	worker		18d	v1.29.8+632b078
compute-1-ru6.gen2005.<domainname>	Ready	worker		18d	v1.29.8+632b078
compute-1-ru7.gen2005.<domainname>	Ready	worker		18d	v1.29.8+632b078
control-1-ru2.gen2005.<domainname>	Ready	control-plane,master		18d	v1.29.8+632b078
control-1-ru3.gen2005.<domainname>	Ready	control-plane,master		18d	v1.29.8+632b078
control-1-ru4.gen2005.<domainname>	Ready	control-plane,master		18d	v1.29.8+632b078

3. Verify the number of nodes for each recovery group and ensure that the minimum required nodes have the recovery group label.

BMYS1405

Recovery group is not created successfully.

Severity

Critical

User actions

Do the following steps to resolve the problem:

1. Run the following command to list all recovery groups in the cluster.

```
oc get rg -n ibm-spectrum-scale
```

Example output:

NAME	AGE
rg1	18d

2. Run the following command to describe the details of a specific recovery group.

```
oc describe rg <rg name> -n ibm-spectrum-scale
```

3. Check the status of the recovery group to find the reason for unsuccessful recovery group creation.

BMYS1406

Filesystem is not created successfully.

Severity

Critical

User actions

Do the following steps to resolve the problem:

1. Run the following command to list filesystem in the cluster.

```
oc get fs -n ibm-spectrum-scale
```

Example output:

NAME	ESTABLISHED	AGE
ibmspectrum-fs	True	18d

2. Run the following command to describe the details of a specific filesystem.

```
oc describe fs <fs name> -n ibm-spectrum-scale
```

3. Check the status of the filesystem to find the reason for unsuccessful filesystem creation.

BMYPE5018

Global Data Platform status is degraded.

Severity

Warning

Problem description

It indicates that the Global Data Platform status is degraded. The Global Data Platform status must be healthy for a successful upgrade.

User actions

Check for the issues that cause the degraded state of the Global Data Platform and take an appropriate action to resolve them. To know more about the reasons for the degraded state, see [Installing Global Data Platform](#).

BMYPE6018

Global Data Platform status is in a critical or down state.

Severity

Warning

Problem description

It indicates that the Global Data Platform status is in a critical or down state. The Global Data Platform status must be healthy for a successful upgrade.

User actions

Check for the issues that cause the critical or down state of the Global Data Platform take an appropriate action to resolve them. To know more about the reasons for the degraded state, see [Installing Global Data Platform](#).

BMYPE6024

A scale up operation on the Red Hat® OpenShift® cluster is in progress.

Severity

Critical

Problem description

It indicates that the scale up operation on the Red Hat OpenShift cluster is in progress. To ensure a successful upgrade, wait for the scale up operation to complete successfully.

User actions

Wait for all nodes to be added to the cluster before you proceed with the upgrade.

BMYPE6025

A scale out operation on the Red Hat® OpenShift® cluster is in progress.

Severity

Critical

Problem description

It indicates that the scale out operation on the Red Hat OpenShift cluster is in progress. To ensure a successful upgrade, wait for the scale out operation to complete successfully.

User actions

Wait for all nodes to be added to the cluster before you proceed with the upgrade.

BMYPE6026

The current version of the Global Data Platform is already up to date.

Severity

Critical

Problem description

It indicates that the version of the Global Data Platform is already up to date. The current scale version is identical to the available IBM Storage Scale version.

User actions

An upgrade is not required because the Global Data Platform version is already up to date.

BMYPE6031

A scale up operation on the Red Hat® OpenShift® cluster is triggered.

Severity

Critical

Problem description

It indicates that the scale up operation on the Red Hat OpenShift cluster is triggered. To ensure a successful upgrade, wait for the scale up operation to complete successfully.

User actions

Wait for all nodes to be added to the cluster before you proceed with the upgrade.

BMYPE6032

A scale out operation on the Red Hat® OpenShift® cluster is triggered.

Severity

Critical

Problem description

It indicates that the scale out operation on the Red Hat OpenShift cluster is triggered. To ensure a successful upgrade, wait for the scale out operation to complete successfully.

User actions

Wait for all nodes to be added to the cluster before you proceed with the upgrade.

BMYP6033

The OpenShift® Container Platform version is not compatible with the Global Data Platform version.

Severity

Critical

Problem description

It indicates that the OpenShift Container Platform version is not compatible with the Global Data Platform version. The IBM Storage Scale 5.2.3 is incompatible with the current OpenShift Container Platform version.

User actions

Upgrade the OpenShift Container Platform version to 4.16 or later for a successful upgrade.

Global Data Platform error codes

List of all the error codes that you might encounter while you work with storage.

- [BMYS0101E](#)
Block size is not set correctly.
- [BMYS0102E](#)
Error in getting and applying the 100G workaround.
- [BMYS01015E](#)
The scale operator pod is not in a running state.
- [BMYS01017E](#)
The CSI pods are not up and in a running state.
- [BMYS01019E](#)
Pods fail to evict the node that is in the drain state.
- [BMYS01024W](#)
Issues in fetching details of the IBM Storage Scale cluster upgrade approval.
- [BMYS01025W](#)
Issues in fetching details of the IBM Storage Scale filesystem upgrade approval.
- [BMYS01026E](#)
The Global Data Platform service is not active on all the scale pods.
- [BMYS01027E](#)
The IBM Storage Scale filesystem is not mounted on all the scale pods.
- [BMYS01028E](#)
Storage service image is not matched in the `cr-version-cm` configmap.
- [BMYS01034E](#)
Failed to scale down the IBM Storage Scale operator.
- [BMYS01035I](#)
Node upgrade is in progress.
- [BMYS01037W](#)
Storage cluster status is degraded since some of the IBM Storage Scale or IBM Storage Scale CSI pods are down.
- [BMYS01038W](#)
The scale pods are not up and running.
- [BMYS01040E](#)
Pods fail to evict on the node.
- [BMYS01041E](#)
Failed to delete IBM Storage Scale security context constraints.
- [BMYS01042E](#)
Failed to delete IBM Storage Scale role binding configuration.
- [BMYS01043E](#)
Failed to delete IBM Storage Scale webhook configuration.
- [BMYS01045I](#)
All scale core pods in `ibm-spectrum-scale ns` is up and running.
- [BMYS01046I](#)
Nodes are successfully upgraded during the Global Data Platform upgrade.

- [BMYSS01047I](#)
All nodes are successfully upgraded during the Global Data Platform upgrade.

BMYSS0101E

Block size is not set correctly.

Severity

Error

User actions

Do the following steps to diagnose the problem:

1. Check whether the block size in scale CR is properly set.
2. If the block size is not set correctly, then specify the correct block size.

BMYSS0102E

Error in getting and applying the 100G workaround.

Severity

Error

User actions

Do the following steps to diagnose the problem:

1. Run the oc command to check for the node that has a problem.

```
oc get nncp
```

2. If the issue persists, then collect the [Global Data Platform](#) and contact [IBM support](#).

BMYSS01015E

The scale operator pod is not in a running state.

Severity

Error

Problem description

It indicates that the scale operator pod is not in a running state. The scale operator pod must be in a running state for a successful upgrade.

User actions

Do the following steps to resolve the issue:

1. Run the following command to get the list of pods in the `ibm-spectrum-scale-operator` namespace.

```
oc get pods -n ibm-spectrum-scale-operator
```
2. If the pod is in a `ImagePullBackOff` state, then resolve the issue.
3. If the pod is in the `CrashLoopBackOff` state, then collect the [Global Data Platform](#) logs and contact [IBM support](#).

BMYSS01017E

The CSI pods are not up and in a running state.

Severity

Error

Problem description

It indicates that the CSI pods are not up and in a running state. All CSI pods must be in running state for a successful upgrade.

User actions

Do the following steps to resolve the issue:

1. Run the following command to get the list of pods in the `ibm-spectrum-scale-csi` namespace.

```
oc get pods -n ibm-spectrum-scale-csi
```

2. Wait until all CSI pods are in the running state.
3. If the issue persists for a long time, then collect the [Global Data Platform](#) logs and contact [IBM support](#).

BMYS01019E

Pods fail to evict the node that is in the drain state.

Severity

Error

Problem description

It indicates that the pods fail to evict the node that is draining. The node restart initiates only after the node is fully drained. All nodes must be rebooted for a successful upgrade.

User actions

Do the following steps to resolve the issue:

1. Check the upgrade details in the IBM Fusion user interface to retrieve the name of the failed pods to evict on the node.
2. Terminate the failing pods to evict.
The upgrade operation resumes automatically after the issue is resolved.

BMYS01024W

Issues in fetching details of the IBM Storage Scale cluster upgrade approval.

Severity

Warning

Problem description

It indicates the issues in fetching details of the IBM Storage Scale cluster upgrade approval. Upgrade approval resources are needed to enable the new functions of the installed release and lock in the new level. You must resolve this issue even though it does not impact the upgrade.

User actions

Do the following steps to resolve the issue:

1. Run the following command to get the cluster `UpgradeApprovals` instances of `TYPE=cluster` in the `ibm-spectrum-scale` namespace.

```
oc get UpgradeApprovals -n ibm-spectrum-scale
```

2. Wait for some time for the status to be updated.
The upgrade operation resumes automatically after the issue is resolved.
3. If the issue persists for a long time, then collect the [Global Data Platform](#) logs and contact [IBM support](#).

BMYS01025W

Issues in fetching details of the IBM Storage Scale filesystem upgrade approval.

Severity

Warning

Problem description

It indicates the issues in fetching details of the IBM Storage Scale cluster upgrade approval. Upgrade approval resources are needed to enable the new function of the installed release and lock in the new level. You must resolve this issue even though it does not impact the upgrade.

User actions

Do the following steps to resolve the issue:

1. Run the following command to get the cluster `UpgradeApprovals` instances of `TYPE=cluster` in the `ibm-spectrum-scale` namespace.

```
oc get UpgradeApprovals -n ibm-spectrum-scale
```

2. Wait for some time for the status to be updated.
The upgrade operation resumes automatically after the issue is resolved.
3. If the issue persists for a long time, then collect the [Global Data Platform](#) logs and contact [IBM support](#).

BMYS01026E

The Global Data Platform service is not active on all the scale pods.

Severity

Error

Problem description

It indicates that the Global Data Platform service is not active on all the scale pods. The Global Data Platform service must be active on all pods with the latest scale configuration for the upgrade to be successful.

User actions

Do the following steps to resolve the issue:

1. Run the following command to get the list of pods in the `ibm-spectrum-scale` namespace.

```
oc get pods -n ibm-spectrum-scale
```

2. Run the following command on the Global Data Platform core pod that is running for remote terminal connection.

```
oc rsh <podname>
```

3. Run the following command to check the Global Data Platform service state on all the nodes.

```
mmgetstate -a
```

4. Wait for the Global Data Platform service to be active on all the nodes.
The upgrade operation resumes automatically after the Global Data Platform service is active on all the pods.
5. If the issue persists for a long time, then collect the [Global Data Platform](#) logs and contact [IBM support](#).

BMYS01027E

The IBM Storage Scale filesystem is not mounted on all the scale pods.

Severity

Error

Problem description

It indicates that the IBM Storage Scale filesystem is not mounted on all the scale pods. The IBM Storage Scale filesystem is mounted on all the scale pods for the upgrade to be successful.

User actions

Do the following steps to resolve the issue:

1. Run the following command to get the list of pods in the `ibm-spectrum-scale` namespace.

```
oc get pods -n ibm-spectrum-scale
```

2. Run the following command on the IBM Storage Scale core pod that is running for remote terminal connection.

```
oc rsh <podname>
```

3. Run the following command to check the IBM Storage Scale filesystem is mounted on all nodes.

```
mmismount all
```

4. Wait for the IBM Storage Scale filesystem is mounted on all nodes.
The upgrade operation resumes automatically after the IBM Storage Scale filesystem is mounted.
5. If the issue persists for a long time, then collect the [Global Data Platform](#) logs and contact [IBM support](#).

BMYS01028E

Storage service image is not matched in the `cr-version-cm` configmap.

Severity

Error

Problem description

It indicates that the storage service image is not matched in the `cr-version-cm` configmap. The `isf-storage-services` image in `cr-version-cm` configmap and `isf-storage-service-dep` pod image must match for the upgrade to be successful.

User actions

Do the following steps to resolve the issue:

1. Run the following command to check the `isf-storage-services` image in the `cr-version-cm` configmap.

```
oc get cm cr-version-cm -n ibm-spectrum-fusion-ns -oyaml
```

2. Run the following command to get the list of pods in the `ibm-spectrum-fusion-ns` namespace.

```
oc get pods -n ibm-spectrum-fusion-ns
```

3. Run the following command to get the image of the `isf-storage-service-dep` pod.

```
oc get pod <pod name> -n ibm-spectrum-fusion-ns -oyaml | grep 'image:'
```

4. Check whether the `isf-storage-service` image is same on configmap and deployment.
5. Wait for the image to be updated. If images are different, then replace `isf-storage-services` deployment image with `isf-storage-services` image in the `cr-version-cm` configmap.
The upgrade operation resumes automatically after the image mismatch is resolved.

BMYS01034E

Failed to scale down the IBM Storage Scale operator.

Severity

Error

Problem description

It indicates that the IBM Storage Scale operator is failed to scale down. The IBM Storage Scale is not scaled down for a successful upgrade.

User actions

Do the following steps to resolve the issue:

1. Check the IBM Storage Scale operator pod logs for errors in scaling down of the operator and take an appropriate action.
The upgrade operation resumes automatically after the issue is resolved.
2. If the issue persists for a long time, then collect the [Global Data Platform](#) logs and contact [IBM support](#).

BMYS01035I

Node upgrade is in progress.

Severity

User actions

No action is required.

BMYS01037W

Storage cluster status is degraded since some of the IBM Storage Scale or IBM Storage Scale CSI pods are down.

Severity

Warning

Problem description

It indicates that the storage cluster status is degraded since some of the IBM Storage Scale or IBM Storage Scale CSI pods are down. The storage cluster status needs to be healthy for a successful upgrade.

User actions

Do the following steps to resolve the issue:

1. After all the nodes are updated, wait for storage cluster status to turn healthy.
2. If storage cluster status is unhealthy even after waiting, then check the logs of the `isf-storage-operator` pod in the `isf-spectrum-fusion-ns` namespace for any errors and take an appropriate action to resolve them.
3. Check the logs of the `ibm-spectrum-scale-controller-manager` pod in the `ibm-spectrum-scale-operator` namespace for any errors and take an appropriate action to resolve them.
The upgrade operation resumes automatically after the issue is resolved.
4. If the issue persists for a long time, then collect the [Global Data Platform](#) logs and contact [IBM support](#).

BMYS01038W

The scale pods are not up and running.

Severity

Warning

Problem description

It indicates that the scale pods are not up and running. The scale core pods must be up and running for the scale upgrade to be successful.

User actions

Do the following steps to resolve the issue:

1. Check the logs of the `ibm-spectrum-scale-controller-manager` pod in the `ibm-spectrum-scale-operator` for any errors and take an appropriate action to resolve them.
2. Check the logs of the `isf-storage-operator` pod in the `isf-spectrum-fusion-ns` namespace for any errors and take an appropriate action to resolve them.
The upgrade operation resumes automatically after the issue is resolved.
3. If the issue persists for a long time, then collect the [Global Data Platform](#) logs and contact [IBM support](#).

BMYS01040E

Pods fail to evict on the node.

Severity

Error

Problem description

It indicates that the pods fail to evict on the node. The node restart initiates only after the node is fully drained. All nodes must be rebooted for the upgrade to finish.

User actions

Do the following steps to resolve the issue:

1. Check the upgrade details in the IBM Fusion user interface to retrieve the name of the failed pods to evict on the node.
2. Terminate the failing pods to evict.
The upgrade operation resumes automatically after the issue is resolved.

BMYS01041E

Failed to delete IBM Storage Scale security context constraints.

Severity

Error

Problem description

It indicates that the IBM Storage Scale security context constraints are failed to delete. Delete the existing security context constraints **ibm-spectrum-scale-privileged** so that it creates a new security context constraint when a new manifest is applied.

User actions

Do the following steps to resolve the issue:

1. Check the logs of the **isf-storage-operator** pod within the **isf-spectrum-fusion-ns** namespace to identify the issues and take an appropriate action to resolve them.
2. Check the logs of the **ibm-spectrum-scale-controller-manager** pod within the **ibm-spectrum-scale-operator** namespace to identify the issues and take an appropriate action to resolve them.
3. Check the logs of the **isf-storage-operator** pod in the **isf-spectrum-fusion-ns** namespace for any errors and take an appropriate action to resolve them.
The upgrade operation resumes automatically after the issue is resolved.
4. If the issue persists for a long time, then collect the [Global Data Platform](#) logs and contact [IBM support](#).

BMYS01042E

Failed to delete IBM Storage Scale role binding configuration.

Severity

Error

Problem description

It indicates that the IBM Storage Scale role binding configuration is failed to delete. Delete the existing role binding configuration **ibm-spectrum-scale-privileged** so that it creates a new role binding configuration when a new manifest is applied.

User actions

Do the following steps to resolve the issue:

1. Check the logs of the **isf-storage-operator** pod within the **isf-spectrum-fusion-ns** namespace to identify the issues and take an appropriate action to resolve them.
2. Check the logs of the **ibm-spectrum-scale-controller-manager** pod within the **ibm-spectrum-scale-operator** namespace to identify the issues and take an appropriate action to resolve them.
3. Check the logs of the **isf-storage-operator** pod in the **isf-spectrum-fusion-ns** namespace for any errors and take an appropriate action to resolve them.
The upgrade operation resumes automatically after the issue is resolved.
4. If the issue persists for a long time, then collect the [Global Data Platform](#) logs and contact [IBM support](#).

BMYS01043E

Failed to delete IBM Storage Scale webhook configuration.

Severity

Error

Problem description

It indicates that the IBM Storage Scale webhook configuration is failed to delete. Delete the existing webhook configuration `ibm-spectrum-scale-mutating-webhook-configuration` or `ibm-spectrum-scale-validating-webhook-configuration` so that it creates a webhook configuration when a new manifest is applied.

User actions

Do the following steps to resolve the issue:

1. Check the logs of the `isf-storage-operator` pod within the `isf-spectrum-fusion-ns` namespace to identify the issues and take an appropriate action to resolve them.
2. Check the logs of the `ibm-spectrum-scale-controller-manager` pod within the `ibm-spectrum-scale-operator` namespace to identify the issues and take an appropriate action to resolve them.
3. Check the logs of the `isf-storage-operator` pod in the `isf-spectrum-fusion-ns` namespace for any errors and take an appropriate action to resolve them. The upgrade operation resumes automatically after the issue is resolved.
4. If the issue persists for a long time, then collect the [Global Data Platform](#) logs and contact [IBM support](#).

Data foundation events and error codes

List of all the events and error codes that you might encounter while you work with Data Foundation storage.

- [BMYS0100](#)
Data Foundation installation is in progress.
- [BMYS0101](#)
Data Foundation installation succeeded.
- [BMYS0102](#)
Data Foundation installation failed.

- [BMYS0103](#)
Data Foundation status is degraded.
- [BMYS0104](#)
Data Foundation status is healthy.
- [BMYS0105](#)
Data Foundation upgrade is in progress.
- [BMYS0106](#)
Data Foundation upgrade succeeded.
- [BMYS0107](#)
Data Foundation upgrade failed.
- [BMYS0108](#)
Data Foundation storage cluster installation is in progress.
- [BMYS0109](#)
Data Foundation storage cluster installation succeeded.
- [BMYS0110](#)
Data Foundation storage cluster status is degraded.
- [BMYS0111](#)
Data Foundation storage cluster status is healthy.
- [BMYS0112](#)
Data Foundation is scaling up automatically.
- [BMYS0121](#)
Failed to validate Data Foundation encryption configuration.
- [BMYS0122](#)
Data Foundation capacity is adding.
- [BMYS0125](#)
Data Foundation capacity is added.
- [BMYS0126](#)
Nodes are added to Data Foundation storage cluster successfully.
- [BMYS0127](#)
Data Foundation is auto-scaled up successfully.
- [BMYS0128](#)
Storage Class `ibm-spectrum-fusion-mgmt-sc` is not provisioned in accordance with Fusion Data Foundation guidelines.
- [BMYS0131](#)
The LVM disk is present either on a control or GPU node.
- [BMYS0132](#)
Nodes contain the LVM disks in the specified disk slot, but the total number of disks are less than three.
- [BMYS0133](#)
Existing LVM drives cannot be used for LVM cluster configuration due to not meet the prerequisites.
- [BMYS0134](#)
Selected worker nodes with LVM drives for LVM cluster configuration with respective disk slots.
- [BMYS0135](#)
A node from each zone must contribute an LVM disk for LVM cluster configuration. The current node selection does not satisfy the criteria.
- [BMYS0136](#)
The LVM cluster is successfully configured.
- [BMYS0137](#)
The LVM cluster is in a degraded or failed state.
- [BMYS0138](#)
The LVM configmap in the specified namespace contains fewer than three nodes in the `data.computeNodes` field.
- [BMYS0139](#)
The LVM configmap in the specified namespace contains an empty `data.drives` field without disk path.
- [BMYS0140](#)
No LVM drives are available for configuring the LVM cluster.

BMYS0102

Data Foundation installation failed.

Error conditions

The error message can be for the following conditions:

- Unable to install Data Foundation operators.
- Unable to install local storage operator.

Severity

Warning

User actions

Collect [Data Foundation logs](#) and contact [IBM support](#).

BMYS0103

Data Foundation status is degraded.

Error conditions

The error message can be for the following conditions:

- Some Data Foundation operators are not running.
- The CSV phase state of Data Foundation is not succeeded.

Severity

Warning

User actions

Collect [Data Foundation logs](#) and contact [IBM support](#).

BMYS0104

Data Foundation status is healthy.

Severity

Informational

User actions

No action is required.

BMYS0105

Data Foundation upgrade is in progress.

Severity

Informational

User actions

No action is required.

BMYS0106

Data Foundation upgrade succeeded.

Severity

Informational

User actions

No action is required.

BMYS0107

Data Foundation upgrade failed.

Error conditions

The error message can be for the following condition:

- Unable to upgrade Data Foundation operators.

Severity

Warning

User actions

Collect [Data Foundation logs](#) and contact [IBM support](#).

BMYS0108

Data Foundation storage cluster installation is in progress.

Severity

Informational

User actions

No action is required.

BMYS0109

Data Foundation storage cluster installation succeeded.

Severity

Informational

User actions

No action is required.

BMYS0110

Data Foundation storage cluster status is degraded.

Error conditions

The error message can be for the following condition:

- The phase of the Data Foundation storage cluster is not ready

Severity

Warning

User actions

Collect [Data Foundation logs](#) and contact [IBM support](#).

BMYS0111

Data Foundation storage cluster status is healthy.

Severity

Informational

User actions

No action is required.

BMYS0112

Data Foundation is scaling up automatically.

Severity

Informational

User actions

No action is required.

BMYS0121

Failed to validate Data Foundation encryption configuration.

Error conditions

The error message can be for the following conditions:

- Encryption configuration provided is not correct.
- Error occurs when validating encryption configuration.

Severity

Warning

User actions

Do the following steps to diagnose the problem:

1. Check the event description for detailed reason and ensure that the encryption configuration provided is valid.
2. If the issue persists, collect [Data Foundation logs](#) and contact [IBM support](#).

BMYS0122

Data Foundation capacity is adding.

Informational

User actions

No action is required.

BMYS0125

Data Foundation capacity is added.

Severity

Informational

User actions

No action is required.

BMYS0126

Nodes are added to Data Foundation storage cluster successfully.

Severity

Informational

User actions

No action is required.

BMYS0127

Data Foundation is auto-scaled up successfully.

Severity

Informational

User actions

No action is required.

BMYS0128

Storage Class **ibm-spectrum-fusion-mgmt-sc** is not provisioned in accordance with Fusion Data Foundation guidelines.

Severity

Critical

User actions

To resolve this critical event, manually delete the storage claim **ibm-spectrum-fusion-mgmt-sc**.

1. Check for PVCs that are using the storage class **ibm-spectrum-fusion-mgmt-sc**.

```
oc get pvc --all-namespaces -o json | jq '.items[] | select(.spec.storageClassName == "ibm-spectrum-fusion-mgmt-sc") | {namespace: .metadata.namespace, name: .metadata.name, storageClass: .spec.storageClassName}'
```

2. Migrate PVCs (if any) from **ibm-spectrum-fusion-mgmt-sc** storage class to **ocs-storagecluster-cephfs** storage class.

If there are any application PVCs using this storage class, plan to migrate them to the `ocs-storagecluster-cephfs` storage class. Go through the Red Hat® documentation for guidance on migrating PVCs.

Note: If any service (Backup & Restore, IBM Data Cataloging, or CAS) is installed on the cluster and is using the `ibm-spectrum-fusion-mgmt-sc` storage class, contact [IBM support](#).

3. Delete the storage claim.

After all PVCs are successfully migrated and none are using the `ibm-spectrum-fusion-mgmt-sc` storage class, run the following command to manually delete the storage claim:

```
oc delete storageclaim ibm-spectrum-fusion-mgmt-sc
```

4. Verify deletion of the storage class.

After you delete the storage claim, run the following command to ensure that the storage class does not exist:

```
oc get storageclass | grep ibm-spectrum-fusion-mgmt-sc
```

BMYS0131

The LVM disk is present either on a control or GPU node.

Severity

Critical

Problem description

It indicates that a 1.6 TB drive is placed either on a control or GPU node. For that reason, the drive cannot be used for LVM cluster configuration.

User actions

Ensure that you placed a drive on a worker node for a successful LVM configuration.

BMYS0132

Nodes contain the LVM disks in the specified disk slot, but the total number of disks are less than three.

Severity

Warning

Problem description

It indicates that the set of nodes that are listed contain the LVM disks in the disk slot that is mentioned in the event, but the total number of disks are less than three.

User actions

Ensure that a minimum of three worker nodes must have LVM disks in the same disk slots to configure the LVM cluster.

BMYS0133

Existing LVM drives cannot be used for LVM cluster configuration due to not meet the prerequisites.

Severity

Critical

Problem description

It indicates that the existing LVM drives cannot be used for LVM cluster configuration because they do not meet the prerequisites.

User actions

Ensure that you must meet the following conditions for a successful LVM cluster configuration:

1. The LVM disks (1.6 TB) must be available on worker nodes (excluding GPU nodes).
2. Disks must be installed in the same slot across all nodes.
3. Global Data Platform service must not be installed.
4. The Data Foundation service must be installed with `BackingStorageType` set to provider mode.

BMYSS0134

Selected worker nodes with LVM drives for LVM cluster configuration with respective disk slots.

Severity

Informational

User actions

No action is required.

BMYSS0135

A node from each zone must contribute an LVM disk for LVM cluster configuration. The current node selection does not satisfy the criteria.

Severity

Critical

Problem description

It indicates that a node from each zone must contribute an LVM disk for LVM cluster configuration. The current selection does not satisfy the criteria.

User actions

Ensure that each zone has a worker node with an LVM drive in the same disk slot.

BMYSS0136

The LVM cluster is successfully configured.

Severity

Informational

User actions

No action is required.

BMYSS0137

The LVM cluster is in a degraded or failed state.

Severity

Critical

User actions

Contact IBM support to resolve the issue.

BMYSS0138

The LVM configmap in the specified namespace contains fewer than three nodes in the `data.computeNodes` field.

Severity

Critical

Problem description

It indicates that the `lvm-config` configmap in the `ibm-spectrum-fusion-ns` namespace is custom created and contains fewer than three nodes in the `data.computeNodes` field.

User actions

Ensure that the minimum three worker nodes are listed under `data.computeNodes` field.

BMYS0139

The LVM configmap in the specified namespace contains an empty `data.drives` field without disk path.

Severity

Critical

Problem description

It indicates that the `lvm-config` configmap in the `ibm-spectrum-fusion-ns` namespace is custom created without a disk path.

User actions

Ensure that a minimum one drive path is specified.

BMYS0140

No LVM drives are available for configuring the LVM cluster.

Severity

Critical

Problem description

It indicates that the `lvm-config` configmap in the `ibm-spectrum-fusion-ns` namespace is custom created without LVM drivers.

User actions

Ensure that minimum one LVM drive is present for configuring the LVM cluster.

High availability cluster events and error codes

List of all the events that you might encounter during High availability cluster setup.

For Informational, Warning, and Critical events, see the following:

- [BMYC00004](#)
Hardware monitoring data, including BIOS configuration data, could not be retrieved from the node BMC (Baseboard Management Controller).
- [BMYC00031](#)
Auxiliary details validation failed.
- [BMYC00032](#)
Add Rack succeeded.
- [BMYC00033](#)
Add Rack discovery failed.

BMYC00004

Hardware monitoring data, including BIOS configuration data, could not be retrieved from the node BMC (Baseboard Management Controller).

Severity

Warning

Error conditions

This warning event is raised when the compute operator cannot retrieve hardware monitoring data, including BIOS configuration data, from the node BMC during a monitoring cycle.

User actions

Do the following steps to diagnose the error:

1. This is a temporary error and it gets resolved on its own.
2. If the issue persists for a longer period, collect the compute-monitoring CR status and [Nodes logs](#), and contact [IBM support](#).

BMYC00031

Auxiliary details validation failed.

Error conditions

The number of NVMe disks on the auxiliary rack is less than that of the base rack storage nodes.

The number of storage nodes are insufficient to build storage cluster.

Severity

Warning

User actions

Ensure you check the sufficient number of storage nodes on the auxiliary rack to meet the raid parity of the base rack storage cluster.

BMYC00032

Add Rack succeeded.

Severity

Informational

User actions

No action is required.

BMYC00033

Add Rack discovery failed.

Error conditions

The error message can be for the following conditions:

1. Provisioner is not accessible.
2. Provisioner is invalid.
3. Invalid OCP Role in the auxiliary kickstart.
4. Insufficient number of storage nodes on the auxiliary rack.
5. Insufficient number of NVMe disks per node on the auxiliary rack.
6. SCP failed for stage-1 generated JSON files.
7. Malformed stage-1 generated files.
8. Duplicate entries in the appliance-info configmap.
9. Failed to detect the provisioner node.
10. Insufficient nodes; current status of the nodes that were successfully added to compute cluster.
11. Internal error caused by K8S resource creation.

Severity

Critical

User actions

Do the following steps to diagnose the error:

1. For error condition one and two, check the DNS configuration and retry. If the issue persists, then collect the [Nodes and Network switches logs](#) and contact [IBM support](#).
2. For error condition three, check the stage 1 installation generated kickstart JSON and ensure that the stage 1 installation is done successfully with expansion rack as the selected option.
3. For error condition four, the number of nodes available on the auxiliary rack and ensure that all the nodes are connected.
4. For error condition five, check that all the storage node should have disks for storage.
5. For error condition six, copying stage 1 generated files from the auxiliary rack provisioner node failed. Check access and connectivity to the provisioner host.
6. For error condition seven, the files that are generated in Stage 1 installation on the provisioner node of the auxiliary rack are malformed. Retry stage 1 installation and choose an expansion rack for the additional rack to succeed.
7. For error condition eight, the auxiliary details are already available on the base rack, and this issue is caused by incorrect inputs during stage1 install of the auxiliary rack installation. Retry stage 1 installation with valid inputs.
8. For error condition nine, check the network and DNS configuration and retry.
9. For error condition 10, all the discovered auxiliary nodes cannot be configured within the stipulated timeout. This issue resolves itself. If the issue persists for more than 30 minutes, then check the network connectivity to the failed auxiliary nodes.
10. For error condition 11, this issue resolves itself. If the issue persists for a long time, then you can collect [Nodes and Network switches logs](#) and contact [IBM support](#).

BMYPD1143

Backup policy unassigned.

Severity

Informational

User actions

No action is required.

BMYPD1146

Policy assignment is created initial backup for an application.

Severity

Informational

User actions

No action is required.

BMYPD1161

Created backup for application from backup policy.

Severity

Informational

User actions

No action is required.

BMYPDP1163

Completed backup for application from backup policy.

Severity

Informational

User actions

No action is required.

BMYPDP1181

Starting restore from backup.

Severity

Informational

User actions

No action is required.

BMYPDP1182

Completed restore from backup.

Severity

Informational

User actions

No action is required.

BMYPDP1364

Failed for application from backup policy.

Severity

Critical

User actions

Do the following steps to diagnose the error:

1. Verify that the backup storage location is available and has sufficient capacity.
2. Correct the issue that caused the backup to fail, and then re-attempt the backup.
3. If the issue persists, then collect [Backup and Restore logs](#) and contact [IBM support](#).

BMYPDP2103

Deleted backup storage location.

Severity

Informational

User actions

No action is required.

BMYP2123

Backup policy deleted.

Severity

Informational

User actions

No action is required.

BMYP2162

Deleted backup for application from the backup policy.

Severity

Informational

User actions

No action is required.

BMYP3104

Failed to register backup storage location.

Severity

Critical

User actions

Do the following steps to diagnose the error:

1. Verify the Information in the backup storage location CR is valid.
2. Verify both connectivity and credentials for the backup storage location.
3. If you do not find any issue related to backup storage location, then collect [Backup and Restore logs](#) and contact [IBM support](#).

BMYP3106

Backup storage location is unavailable.

Severity

Critical

User actions

Do the following steps to diagnose the error:

1. Verify whether the backup storage location is operational and that the backup storage location has sufficient capacity.
2. If you do not find any issue related to backup storage location, then collect [Backup and Restore logs](#) and contact [IBM support](#).

BMYP3124

Failed to create the backup policy.

Severity

Warning

User actions

Do the following steps to diagnose the error:

1. Verify the backup storage location is correctly specified and available.
2. If you do not find any issue related to backup storage location, then collect [Backup and Restore logs](#) and contact [IBM support](#).

BMYP3144

Creation of **PolicyAssignment** failed, referenced custom resource could not be found or is in a error state.

Severity

Critical

User actions

Do the following steps to diagnose the error:

1. Verify that the application and policy are correctly specified.
2. Correct the custom resource and re-attempt the policy assignment.
3. If the issue persists, then collect [Backup and Restore logs](#) and contact [IBM support](#).

BMYP3145

Application validation failed.

Severity

Critical

User actions

Do the following steps to diagnose the error:

1. Verify that the application and policy are correctly specified.
2. Ensure the application is valid, then retry the policy assignment.
3. If the issue persists, then collect [Backup and Restore logs](#) and contact [IBM support](#).

BMYP3165

Canceled for application from backup policy.

Severity

Critical

User actions

Collect [Backup and Restore logs](#) and contact [IBM support](#).

BMYP3166

Failed to start a job for backup for application from backup policy.

Severity

Critical

User actions

Do the following steps to diagnose the error:

1. Verify that the backup storage location is available and has sufficient capacity.
2. Check and correct the issue that caused the backup to fail, and then re-attempt the backup.
3. If the issue persists, then collect [Backup and Restore logs](#) and contact [IBM support](#).

BMYPDP3183

Failed restore from backup.

Severity

Critical

User actions

Collect [Backup and Restore logs](#) and contact [IBM support](#).

BMYPDP3184

Canceled restore from backup.

Severity

Critical

User actions

Collect [Backup and Restore logs](#) and contact [IBM support](#).

BMYPDP3185

Failed to start a job for restore from backup.

Severity

Critical

User actions

Collect [Backup and Restore logs](#) and contact [IBM support](#).

Connection services events and error codes

List of all the events that you might encounter during connection service for the IBM Fusion HCI .

Connection service is a common service for the Backup & Restore.

For Informational, Warning and Critical events, see the following:

- **BMYPDP0001**
Failed to send heartbeat to remote cluster `<remote-apiendpoint>`: `<Error>`.
- **BMYPDP0002**
No heartbeat received from the remote cluster `<remote-apiendpoint>`.
- **BMYPDP0003**
Connection to remote cluster is healthy.
- **BMYPDP0004**
Connection from remote cluster is healthy.

- [BMYCS0005](#)
Init secret has the same API endpoint with the local cluster.
- [BMYCS0006](#)
Bootstrap token in init secret is not correct or expired: `<Error>`.
- [BMYCS0007](#)
Failed to get CA certificate from remote cluster: `<Error>`.
- [BMYCS0008](#)
CA certificate of peer cluster is not correct: `<Error>`.
- [BMYCS0009](#)
Failed to get infrastructure provider of the remote cluster: `<Error>`.
- [BMYCS0010](#)
Failed to get cluster name of remote cluster: `<Error>`.
- [BMYCS0011](#)
Bootstrap secret created.
- [BMYCS0012](#)
Failed to wait for the client config to be ready: `<Error>`.
- [BMYCS0013](#)
Kubeconfig secret created.
- [BMYCS100](#)
Create a bootstrap secret in progress.
- [BMYCS101](#)
Create bootstrap secret completed.
- [BMYCS102](#)
Create a kubeconfig secret in progress.
- [BMYCS103](#)
Create kubeconfig secret completed.
- [BMYCS104](#)
Connection to remote API endpoint `<remote-apiendpoint>` is disabled.
- [BMYCS105](#)
Connection to remote API endpoint `<remote-apiendpoint>` is healthy.
- [BMYCS106](#)
Connection from remote API endpoint `<remote-apiendpoint>` is healthy.
- [BMYCS300](#)
Init secret has the same API endpoint as the local cluster.
- [BMYCS301](#)
The Bootstrap token in the init secret is not correct or expired.
- [BMYCS302](#)
Failed to get infrastructure provider of the remote cluster.
- [BMYCS303](#)
Failed to get CA certificate from the remote cluster.
- [BMYCS304](#)
The CA certificate of the remote cluster is not correct.
- [BMYCS305](#)
Failed to get the cluster name of the remote cluster.
- [BMYCS306](#)
Failed to wait for the client configuration of the remote cluster to be ready.
- [BMYCS307](#)
Connection to remote API endpoint is unhealthy.
- [BMYCS308](#)
Connection from remote API endpoint is unhealthy.

BMYCS0001

Failed to send heartbeat to remote cluster `<remote-apiendpoint>`:
`<Error>`.

Severity

Critical

User actions

Collect [Storage logs](#) and contact [IBM support](#).

BMYCS0002

No heartbeat received from the remote cluster `<remote-apiendpoint>`.

Severity

Critical

User actions

Collect [Storage logs](#) and contact [IBM support](#).

BMYCS0003

Connection to remote cluster is healthy.

Severity

Informational

User actions

No action is required.

BMYCS0004

Connection from remote cluster is healthy.

Severity

Informational

User actions

No action is required.

BMYCS0005

Init secret has the same API endpoint with the local cluster.

Severity

Critical

User actions

Do the following steps to resolve the error:

1. Copy the code snippet from the remote cluster instead of local cluster to set up connection.
2. If the issue persists, then collect [Storage logs](#) and contact [IBM support](#).

BMYCS0006

Bootstrap token in init secret is not correct or expired: **<Error>**.

Severity

Critical

User actions

Do the following steps to resolve the error:

1. Re-generate the bootstrap token and replace it in the init secret.
2. If the issue persists, then collect [Storage logs](#) and contact [IBM support](#).

BMYCS0007

Failed to get CA certificate from remote cluster: **<Error>**.

Severity

Critical

User actions

Do the following steps to resolve the error:

1. Check whether the `kube-root-ca.crt` configmap in the `kube-public` namespace contains CA certs in the remote cluster.
2. If the issue persists, then collect [Storage logs](#) and contact [IBM support](#).

BMYCS0008

CA certificate of peer cluster is not correct: `<Error>`.

Severity

Critical

User actions

Do the following steps to resolve the error:

1. Check whether the `kube-root-ca.crt` configmap in the `kube-public` namespace contains the correct CA certificate.
2. If it does not contain the correct CA certificate, then put the correct CA certificate in the configmap.
3. If the issue persists, then collect [Storage logs](#) and contact [IBM support](#).

BMYCS0009

Failed to get infrastructure provider of the remote cluster: `<Error>`.

Severity

Informational

User actions

No action is required.

BMYCS0010

Failed to get cluster name of remote cluster: `<Error>`.

Severity

Critical

User actions

Collect [Storage logs](#) and contact [IBM support](#).

BMYCS0011

Bootstrap secret created.

Severity

Informational

User actions

No action is required.

BMYCS0012

Failed to wait for the client config to be ready: <Error>.

Severity

Critical

User actions

Collect [Storage logs](#) and contact [IBM support](#).

BMYCS0013

Kubeconfig secret created.

Severity

Informational

User actions

No action is required.

BMYCS100

Create a bootstrap secret in progress.

Severity

Informational

User actions

No action is required.

BMYCS101

Create bootstrap secret completed.

Severity

Informational

User actions

No action is required.

BMYCS102

Create a kubeconfig secret in progress.

Severity

Informational

User actions

No action is required.

BMYCS103

Create kubeconfig secret completed.

Severity

Informational

User actions

No action is required.

BMYCS104

Connection to remote API endpoint <remote-apiendpoint> is disabled.

Severity

Informational

User actions

No action is required.

BMYCS105

Connection to remote API endpoint <remote-apiendpoint> is healthy.

Severity

Informational

User actions

No action is required.

BMYCS106

Connection from remote API endpoint <remote-apiendpoint> is healthy.

Severity

Informational

User actions

No action is required.

BMYCS300

Init secret has the same API endpoint as the local cluster.

Severity

Critical

User actions

Do the following steps to resolve the error:

1. Edit the init secret with the right remote cluster API endpoint.

2. If the issue persists, then collect [Storage logs](#) and contact [IBM support](#).

BMYES301

The Bootstrap token in the init secret is not correct or expired.

Severity

Critical

User actions

Do the following steps to resolve the error:

1. Re-generate the bootstrap token and replace it in the init secret.
2. If the issue persists, then collect [Storage logs](#) and contact [IBM support](#).

BMYES302

Failed to get infrastructure provider of the remote cluster.

Severity

Critical

User actions

Collect [Storage logs](#) and contact [IBM support](#).

BMYES303

Failed to get CA certificate from the remote cluster.

Severity

Critical

User actions

Do the following steps to resolve the error:

1. Check if the configmap `kube-root-ca.crt` in namespace kube-public has CA certs in the remote cluster.
2. If the issue persists, then collect [Storage logs](#) and contact [IBM support](#).

BMYES304

The CA certificate of the remote cluster is not correct.

Severity

Critical

User actions

Do the following steps to resolve the error:

1. Check if the configmap `kube-root-ca.crt` in namespace kube-public has the right CA. If not, put the right CA in this configmap.
2. If the issue persists, then collect [Storage logs](#) and contact [IBM support](#).

BMYES305

Failed to get the cluster name of the remote cluster.

Severity

Critical

User actions

Collect [Storage logs](#) and contact [IBM support](#).

BMYCS306

Failed to wait for the client configuration of the remote cluster to be ready.

Severity

Critical

User actions

Collect [Storage logs](#) and contact [IBM support](#).

BMYCS307

Connection to remote API endpoint is unhealthy.

Severity

Critical

User actions

Collect [Storage logs](#) and contact [IBM support](#).

BMYCS308

Connection from remote API endpoint is unhealthy.

Severity

Critical

User actions

Collect [Storage logs](#) and contact [IBM support](#).

Content-Aware Storage events and error codes

List of all the events that you might encounter while you work with CAS for the .

ClusterWatchDisableFail

BMYCA0201

KAFKAInstallFail

Severity

Critical

Problem description

It indicates that Kafka has failed to deploy.

User actions

Follow the steps to resolve the issue:

1. Review the `cas-operator` logs to identify the cause of the Kafka installation failure.
2. Collect [CAS](#) logs and check whether you find any errors that are related to CAS operator.
3. Take appropriate action based on the error or contact [IBM support](#) to resolve the issue.

BMYCA0204

QueryServiceInstallFail

Severity

Critical

Problem description

It indicates that the query service failed to install correctly.

User actions

Follow the steps to resolve the issue:

1. Check whether `query-service` pods are running in the `ibm-cas` namespace.
2. Check whether image is being correctly pulled. If not, check the `icr.io` pull-secret.
3. Check logs in `ibm-cas-operator-controller` pod for query service errors.
4. Take appropriate action based on the error or contact [IBM support](#) to resolve the issue.

BMYCA0216

`DProcCRAbsent`

Severity

Critical

Problem description

The `DocumentProcessor` CR is missing.

User actions

Review the `cas-operator` logs to identify the cause of the CR creation failure.

BMYCA0217

`PipelineInstanceRetrievalFailed`

Severity

Critical

Problem description

The pipeline instance retrieval has failed.

User actions

Review the `cas-operator` logs to identify the cause of the pipeline instance retrieval failure.

BMYCA0225

`KAFKAApplyYamlFailed`

Severity

Critical

Problem description

It indicates that the Kafka installation has failed.

User actions

Follow the steps to resolve the issue:

1. Check whether the Kafka operator is installed successfully.
2. Check whether any errors or warning messages in CAS installation.
3. Collect [CAS](#) logs and check whether you find any errors that are related to CAS operator.
4. Take appropriate action based on the error or contact [IBM support](#) to resolve the issue.

BMYCA0227

KAFKAClusterDeploymentFailed

Severity

Critical

Problem description

It indicates that the Kafka installation has failed.

User actions

Follow the steps to resolve the issue:

1. Check whether the Kafka operator is installed successfully.
2. Check whether any errors or warning messages in CAS installation.
3. Collect [CAS](#) logs and check whether you find any errors that are related to CAS operator.
4. Take appropriate action based on the error or contact [IBM support](#) to resolve the issue.

BMYCA0228

KAFKAClusterNotHealthy

Severity

Low

Problem description

It indicates that the Kafka cluster is not in a healthy state.

User actions

Follow the steps to resolve the issue:

1. Wait until the Kafka instance is present to let the log info fix by itself.
2. Check whether the Kafka operator is installed successfully.
3. Check whether any errors or warning messages in CAS installation.
4. Collect [CAS](#) logs and check whether you find any errors that are related to CAS operator.
5. Take appropriate action based on the error or contact [IBM support](#) to resolve the issue.

BMYCA0229

KAFKAInstanceRetrivalFailed

Severity

Low

Problem description

It indicates that the Kafka instance is not present or is being installed.

User actions

Follow the steps to resolve the issue:

1. Wait until the Kafka instance is present to let the log info fix by itself.
2. Check whether the streams for Apache Kafka operator are installed successfully.
3. Collect [CAS](#) logs and check whether you find any errors that are related to CAS operator.
4. Take appropriate action based on the error or contact [IBM support](#) to resolve the issue.

BMYCA0230

KAFKAClusterStatusRetrievalFailed

Severity

Low

Problem description

It indicates that the Kafka cluster status has failed to retrieve.

User actions

Follow the steps to resolve the issue:

1. Wait until the Kafka instance is present to let the log info fix by itself.
2. Check whether the streams for Apache Kafka operator are installed successfully.
3. Collect [CAS](#) logs and check whether you find any errors that are related to CAS operator.
4. Take appropriate action based on the error or contact [IBM support](#) to resolve the issue.

BMYCA0231

KAFKAInstanceNotReady

Severity

Low

Problem description

It indicates that the Kafka instance is not in the ready state.

User actions

Follow the steps to resolve the issue:

1. Wait until the Kafka instance is present to let the log info fix by itself.
2. Check whether the streams for Apache Kafka operator are installed successfully.
3. Collect [CAS](#) logs and check whether you find any errors that are related to CAS operator.
4. Take appropriate action based on the error or contact [IBM support](#) to resolve the issue.

BMYCA0232

ParadeDBClusterRetrivalFailed

Severity

Critical

Problem description

It indicates that the **ParadeDB** cluster has failed to retrieve.

User actions

Follow the steps to resolve the issue:

1. Check whether the CNPG operator is installed successfully.
2. Check whether the **RemoteFilesystem** status is connected.
3. Check whether all PVCs in the **ibm-cas** namespace in a bound state.
4. Collect [CAS](#) logs and check whether you find any errors that are related to CAS operator.
5. Take appropriate action based on the error or contact [IBM support](#) to resolve the issue.

BMYCA0233

ParadeDBClusterDeploymentFailed

Severity

Critical

Problem description

It indicates that the Parade DB Cluster has failed to deploy.

User actions

Follow the steps to resolve the issue:

1. Check whether the CloudNativePG operator is installed successfully.
2. Check whether the Parade DB pods are running in the **ibm-cas** namespace.
3. Collect [CAS](#) logs and check whether you find any errors that are related to CAS operator and CloudNativePG operator.
4. Check the logs whether there is any other related error code.
5. Take appropriate action based on the error or contact [IBM support](#) to resolve the issue.

BMYCA0234

ParadeDBClusterNotHealthy

Severity

Critical

Problem description

It indicates that the **ParadeDB** cluster is not in a healthy state.

User actions

Follow the steps to resolve the issue:

1. Check whether the CNPG operator is installed successfully.
2. Check whether the **RemoteFilesystem** status is connected.
3. Check whether all PVCs in the **ibm-cas** namespace in a bound state.
4. Collect [CAS](#) logs and check whether you find any errors that are related to CAS operator.
5. Take appropriate action based on the error or contact [IBM support](#) to resolve the issue.

BMYCA0235

ParadeDBPoolerInstanceRetrivalFailed

Severity

Critical

Problem description

It indicates that the **ParadeDB** pooler instance has failed to retrieve.

User actions

Follow the steps to resolve the issue:

1. Check whether the CNPG operator is installed successfully.
2. Check whether the **RemoteFilesystem** status is connected.
3. Check whether all PVCs in the **ibm-cas** namespace in a bound state.
4. Collect [CAS](#) logs and check whether you find any errors that are related to CAS operator.
5. Take appropriate action based on the error or contact [IBM support](#) to resolve the issue.

BMYCA0243

ParadeDBConnectionFail

Severity

Critical

Problem description

It indicates that the **ParadeDB** connection has failed.

User actions

Follow the steps to resolve the issue:

1. Check whether the CNPG operator is installed successfully.
2. Check whether the **RemoteFilesystem** status is connected.
3. Check whether all PVCs in the **ibm-cas** namespace in a bound state.
4. Collect [CAS](#) logs and check whether you find any errors that are related to CAS operator.
5. Take appropriate action based on the error or contact [IBM support](#) to resolve the issue.

BMYCA0244

QueryServicePodFailed

Severity

Critical

Problem description

It indicates that the query service pod fails to maintain a running state.

User actions

Follow the steps to resolve the issue:

1. Check whether **query-service** pods are running in the **ibm-cas** namespace.
2. Check whether image is being correctly pulled. If not, check the **icr.io** pull-secret.
3. Check logs in **ibm-cas-operator-controller** pod in the **ibm-cas** namespace for query service errors.
4. Check logs in **query-service** pod in the **ibm-cas** namespace for query service errors.
5. Check for errors in the **query-service** deployment in the **ibm-cas** namespace.
6. Take appropriate action based on the error or contact [IBM support](#) to resolve the issue.

BMYCA0245

QueryServiceNotHealthy

Severity

Critical

Problem description

It indicates that the query service is missing one or more expected resources.

User actions

Follow the steps to resolve the issue:

1. Check whether **query-service** pods are running in the **ibm-cas** namespace.
2. Check whether image is being correctly pulled. If not, check the **icr.io** pull-secret.
3. Check logs in **ibm-cas-operator-controller** pod in the **ibm-cas** namespace for query service errors.
4. Check logs in **query-service** pod in the **ibm-cas** namespace for query service errors.
5. Check for errors in the **query-service** deployment in the **ibm-cas** namespace.
6. Check for the presence of the **ibm-cas** route in the **ibm-cas** namespace.
7. Take appropriate action based on the error or contact [IBM support](#) to resolve the issue.

BMYCA0258

GetUsersFail

Severity

Critical

Problem description

It indicates that the CAS service failed to retrieve users from the identity provider (Red Hat® OpenShift® or external identity provider depending on configuration).

User actions

Follow the steps to resolve the issue:

1. Collect CAS logs and check CAS operator pod logs to identify the cause of the failure while retrieving users from the identity provider.
2. If external identity provider is configured, validate identity provider configuration including **issuerURL**, and **client_id** and **client_secret** parameters defined in the secret.
3. Ensure that the identity provider is up and accessible to the cluster.
4. Take appropriate action based on the error or contact [IBM support](#) to resolve the issue.

BMYCA0259

ValidateUsersFail

Severity

Critical

Problem description

It indicates that one or more users who are specified in the **CasResourceAccessControl** (CRAC) custom resource (CR) are not present in Red Hat® OpenShift® or the configured external identity providers depending on identity provider configuration.

User actions

Follow the steps to resolve the issue:

1. Check the **status.conditions** field of the CRAC CR for the **ValidatedUsers** condition, which lists the users that failed validation.
2. Ensure that the users are correctly defined in the CRAC CR.
3. Verify that the specified users exist either in the Red Hat OpenShift cluster or the external identity provider.
4. If the issue persists, collect relevant logs and contact [IBM support](#) for assistance.

BMYCA0260

GetGroupsFail

Severity

Critical

Problem description

It indicates that the CAS service failed to retrieve groups from the identity provider (Red Hat® OpenShift® or external identity provider depending on configuration).

User actions

Follow the steps to resolve the issue:

1. Collect CAS logs and check CAS operator pod logs to identify the cause of the failure while retrieving groups from the identity provider.
2. If the external identity provider is configured, validate identity provider configuration including **issuerURL**, and **client_id** and **client_secret** parameters defined in the secret.
3. Ensure that the identity provider is up and accessible to the cluster.
4. Take appropriate action based on the error or contact [IBM support](#) to resolve the issue.

BMYCA0261

ValidateGroupsFail

Severity

Critical

Problem description

It indicates that one or more groups that are specified in the `CasResourceAccessControl` (CRAC) custom resource (CR) are not present in Red Hat® OpenShift® or the configured external identity providers depending on identity provider configuration.

User actions

Follow the steps to resolve the issue:

1. Check the `status.conditions` field of the CRAC CR for the `ValidatedGroups` condition, which lists the groups that failed validation.
2. Ensure that the groups are correctly defined in the CRAC CR.
3. Verify that the specified groups exist either in the Red Hat OpenShift cluster or the external identity provider.
4. If the issue persists, collect relevant logs and contact [IBM support](#) for assistance.

BMYCA0263

`DBConnectionFail`

Severity

Critical

Problem description

It indicates that the database (DB) connection has failed.

User actions

Follow the steps to resolve the issue:

1. Check whether the CNPG operator is installed successfully.
2. Check whether the `RemoteFilesystem` status is connected.
3. Check whether all PVCs in the `ibm-cas` namespace in a bound state.
4. Collect CNPG operator logs.
5. Collect [CAS](#) logs and check whether you find any errors that are related to CAS operator.
6. Take appropriate action based on the error or contact [IBM support](#) to resolve the issue.

BMYCA0264

`DBPopulationFail`

Severity

Critical

Problem description

It indicates that the database (DB) population has failed.

User actions

Follow the steps to resolve the issue:

1. Check whether the CNPG operator is installed successfully.
2. Check whether the `RemoteFilesystem` status is connected.
3. Check whether all PVCs in the `ibm-cas` namespace in a bound state.
4. Collect CNPG operator logs.
5. Collect [CAS](#) logs and check whether you find any errors that are related to CAS operator.
6. Take appropriate action based on the error or contact [IBM support](#) to resolve the issue.

BMYCA0266

`DeleteEntriesOfUsersAndGroupFromACLTableFail`

Severity

Critical

Problem description

It indicates that the deletion of user and group entries from the Access Control List (ACL) database table failed.

User actions

Follow the steps to resolve the issue:

1. Review the `cas-operator` logs to identify the cause of the failure when deleting user and group entries from the Access Control List (ACL) table.
2. Collect [CAS](#) logs and check whether you find any errors that are related to CAS operator.
3. Take appropriate action based on the error or contact [IBM support](#) to resolve the issue.

BMYCA0267

`DeleteEntriesOfDomainsFromACLTableFail`

Severity

Critical

Problem description

It indicates that the deletion of domain entries from the Access Control List (ACL) database table failed.

User actions

Follow the steps to resolve the issue:

1. Review the `cas-operator` logs to identify the cause of the failure when deleting domain entries from the Access Control List (ACL) table.
2. Collect [CAS](#) logs and check whether you find any errors that are related to CAS operator.
3. Take appropriate action based on the error or contact [IBM support](#) to resolve the issue.

BMYCA0268

`ClusterWatchDisableFail`

Severity

Critical

Problem description

It indicates that the Watch Folder Deletion of associated data source has failed.

User actions

Follow the steps to resolve the issue:

1. Check whether the CAS operator is installed successfully.
2. Check whether the Remote Scale Cluster is connected.
3. Collect [CAS](#) logs and check whether you find any errors that are related to CAS operator.
4. Take appropriate action based on the error or contact [IBM support](#) to resolve the issue.

Serviceability events and error codes

List of all the events that you might encounter that related to serviceability.

For Informational, Warning, and Critical events, see the following:

BMFYA1005

Successfully removed storage from the cluster.

Severity

Informational

User actions

No action is required.

BMFYA1301

The ACM operator installation is preventing the addition of labels.

Severity

Warning

User actions

Install advanced cluster management operator on the IBM Fusion HCI or provided cluster.

BMFYA1302

Unable to uninstall the service.

Severity

Warning

User actions

Do the following steps to resolve the issue:

1. To uninstall the IBM Fusion service, uninstall the backup and restore agent and Fusion Data Foundation service from Hosted Control Plane cluster by removing their respective labels.
2. To uninstall the Fusion Data Foundation, ensure that you have to uninstall backup and restore agent from the Hosted Control Plane cluster by removing their respective labels.

BMFYFA1303

Failed to remove storage from the cluster.

Severity

Warning

User actions

Do the following steps to resolve the issue:

1. Check whether any **openshift-storage** namespace is stuck in a terminating state.
2. In the status, check for the resource which the namespace is waiting for.
3. Remove the finalizer for the resource from the **openshift-storage** namespace status list.
4. Check whether namespace is deleted successfully.

BMFYFA1304

Unable to remove the storage from the clusters.

Severity

Warning

User actions

Do the following steps to resolve the issue:

1. Check whether any **openshift-storage** namespace is stuck in a terminating state.
2. In the status, check for the resource which the namespace is waiting for.
3. Remove the finalizer for the resource from the **openshift-storage** namespace status list.
4. Check whether namespace is deleted successfully.

BMFYFA1305

The service client is waiting for the service installation to complete on the cluster.

Severity

Warning

User actions

Wait for the installation of the service to be completed.

BMFYFA1306

Failed to delete the **NetworkPolicy** for clusters.

Severity

Warning

User actions

Run the following command to delete the **NetworkPolicy** from the **openshift-storage-egress** clusters namespace.

```
oc delete networkpolicy openshift-storage-egress -n <clusters-<cluster_name>>
```

BMFYFA1307

The fusion-base label is missing for clusters.

Severity

Warning

User actions

Add `isf.ibm.com/fusion-base` label to the cluster

BMFYFA1601

The `fusion-addon-config` configmap does not exist in the namespace.

Severity

Critical

User actions

Add `isf.ibm.com/fusion-base` label to the cluster.

BMFYFA1604

The add-on is missing resources.

Severity

Critical

User actions

Collect the [Storage logs](#) and contact IBM support.

BMFYFA1605

Failed to create install agent on cluster.

Severity

Critical

User actions

Collect the [Storage logs](#) and contact support team.

BMFYFA1606

Failed to create install agent on the cluster where Global Data Platform is the storage provider.

Severity

Critical

User actions

Remove the label from the cluster because the Fusion Data Foundation cannot be installed if the primary storage is Global Data Platform.

BMFYA1607

Failed to install Backup & Restore agent.

Severity

Critical

User actions

Do the following steps to resolve the issue:

1. Create the storage class for the Backup & Restore agent.
2. If you use Fusion Data Foundation storage class, then ensure that the Fusion Data Foundation client is installed.

BMFYA1608

Failed to delete the Backup & Restore connection for the clusters.

Severity

Critical

User actions

Delete the connection from IBM Fusion user interface manually.

BMFYA1610

Failed to retrieve the storage provider.

Severity

Critical

User actions

Collect the [Storage logs](#) and contact IBM support.

BMYHC9001

Nodes are not ready.

Severity

Critical

User actions

It indicates that a Node in Hosted Control Plane cluster is not ready. To trigger firmware upgrade, all nodes of the cluster must be healthy state.

BMYHC9002

Updating config for `nodepool`

Severity

Critical

Description

It indicates that the `nodepool1` config update is in progress for the Hosted Control Plane cluster.

User actions

Ensure that the `nodepool1` config update is complete before you start the firmware upgrade for the cluster.

If you want to override the prechecks that are blocking the upgrade, do the following steps:

Note: It converts the Error prechecks to Warning prechecks and triggers the upgrade. Before using the `precheck-acks configmap` to override the pre-checks, ensure that these not ready nodes do not affect the upgrade.

1. Run the following command and export IBM Fusion namespace as an environmental variable.

```
export FUSION_NS="namespace-where-fusion-is-installed"
```

2. Run the following command to create a `precheck-acks` configmap in the namespace where the IBM Fusion is installed.

```
oc create configmap precheck-acks -n $FUSION_NS
```

3. In the `precheck-acks` config map, add the key `HCPNodePoolUpdateConfigInProgress` and set the value of Hosted Control Plane cluster name.

```
oc edit configmap precheck-acks -n $FUSION_NS
```

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: precheck-acks
  namespace: ibm-spectrum-fusion-ns
data:
  HCPNodeNotReady: <HCP-cluster1>,<HCP-cluster2>
```

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: precheck-acks
  namespace: ibm-spectrum-fusion-ns
data:
  HCPNodePoolUpdateConfigInProgress: <HCP-cluster1>,<HCP-cluster2>
```

BMYHC9003

This is single node cluster, updating config might not work

Severity

Warning

Description

It indicates that this is a single node cluster, so node upgrade or reboot may make the cluster unreachable.

Virtualization events and error codes

List of all the events that you might encounter that are related to Red Hat OpenShift Virtualization on ROKS clusters.

For Informational, Warning, and Critical events, see the following:

- [BMYFA1617](#)
Failed to retrieve `cp.icr.io` credentials from the Hub for cluster.
- [BMYFA1618](#)
Invalid credentials configuration detected in the global pull secret of host cluster.

BMYFA1617

Failed to retrieve `cp.icr.io` credentials from the Hub for cluster.

Severity

Critical

User actions

Complete the following steps to resolve the issue:

1. Verify the Hub connectivity and ensure that the `cp.icr.io` credentials exist in the Hub.
2. Resolve any authentication or configuration issues.
3. Retry the credential retrieval.

BMYFA1618

Invalid credentials configuration detected in the global pull secret of host cluster.

Severity

Critical

User actions

Complete the following steps to resolve the issue:

1. Validate the `Docker config JSON` in the global pull secret and correct any errors.
2. Ensure that the registry authentication format is correct.
3. Update and reapply the global pull secret in the host cluster.
4. Retry the validation.

BMYOA0102

OpenShift® AI installation is completed.

Severity

Informational

User actions

No action is required.

BMYOA0103

OpenShift® AI installation failed.

Severity

Critical

User actions

Do the following steps to diagnose the error:

1. Run the following commands to check whether all pods running or completed with the **READY** state.

```
oc get pods -n redhat-ods-operator -o wide
oc get pods -n redhat-ods-applications -o wide
```

2. Run the following command to check whether the pods in states like **ImagePullBackOff**, **CrashLoopBackOff**, or **Error**.

```
oc describe pod/ <pod> -n <ns>
```

3. Run the following command to check CR health (DSCI/DSC) and verify that **Ready condition** is set to **True**.

```
oc get dsci,dsc -A
```

If the issue persists, identify the failing component (for example, KServe, ModelMesh, or Pipelines) and check its deployment status and events in the **redhat-ods-applications** namespace.

4. Run the following command to verify that exactly one **OperatorGroup** is configured to target the correct namespace.

```
oc get og -n redhat-ods-operator
```

5. Run the following command to check whether the **InstallPlan** is completed.

```
oc get csv,installplan -n redhat-ods-operator
```

If the **InstallPlan** status is **Pending** or **Failed** for version 2.19.1, either approve or correct the source. If the CSV status is **Failed**, delete the failed CSV file to retry the process.

6. Run the following command to verify whether the subscription is installed.

```
oc describe subscriptions.operators.coreos.com/rhods-operator -n redhat-ods-operator
```

7. Run the following commands to verify that the catalog source status is **Ready**.

```
oc get catalogsource -n openshift-marketplace
oc describe catalogsource redhat-operators -n openshift-marketplace
```

If the source is not ready, restart the **Marketplace** pods.

8. If the issue persists, then contact [IBM support](#).

Learn how to troubleshoot virtualization issues, including virtual machines that enter a **CrashLoopBackOff** state after a GPU node power cycle.

Connection setup after OpenShift Container Platform cluster recovery

The OpenShift® Container Platform cluster can have problems and become unusable. After you recover the cluster, rejoin the connections.

Disaster recovery

- Two clusters must be connected to failover and failback applications
- Reconnect to another cluster

Backup & Restore

- One hub cluster and more than one spoke clusters can be connected to manage application backups in multi clusters.
- Reconnect to the hub or spoke

If the cluster recovers before the expiration time, then no action is needed as the cluster rejoins the connection automatically. If the cluster recovers after the client cert expires, then clean the connection and setup again to rejoin the recovered cluster. You can get the client cert effective time from the connection CR status, for example:

```
oc get connection <connection_name> -n ibm-spectrum-fusion-ns

- lastTransitionTime: '2024-01-03T10:23:20Z'
  message: >-
    client certificate rotated starting from 2024-01-03 10:18:31 +0000 UTC
    to 2024-01-19 13:12:00 +0000 UTC
    reason: ClientCertificateUpdated
    status: 'True'
    type: ClusterCertificateRotated
```

Clean the connection and setup the connection between cluster-a and cluster-b again.

1. Clean the connection:

Delete the connection CR in both cluster-a and cluster-b clusters:

- In cluster-a

```
oc delete connection <connection_cr_with_cluster-b_endpoint_in_spec> -n ibm-spectrum-fusion-ns
```
- In cluster-b

```
oc delete connection <connection_cr_with_cluster-a_endpoint_in_spec> -n ibm-spectrum-fusion-ns
```

2. Set up the connection between clusters again.

a. Get the bootstrap token in cluster-a:

```
kubectl create token isf-application-operator-cluster-bootstrap -n <namespace of isf-application-operator>
```

b. Create connection CR and **init** secret in cluster-b with the bootstrap token and API endpoint of cluster-a.

For example, create **init** secret in cluster-b:

```
apiVersion: v1
kind: Secret
metadata:
  name: init-<cluster-a>
  namespace: ibm-spectrum-fusion-ns
```

```
stringData:
  apiserver: <cluster-a api endpoint>
  bootstrapToken: <token generated in step 2.1>
```

3. Create connection CR with this `init` secret in `spec` in cluster-b:

```
apiVersion: application.isf.ibm.com/v1
kind: Connection
metadata:
  name: <connection-name>
  namespace: ibm-spectrum-fusion-ns
spec:
  remoteCluster:
    apiEndpoint: <cluster-a api endpoint>
    initSecretName: init-<cluster-a>
```

Global Data Platform service issues

This section lists the troubleshooting tips and tricks when you use IBM Fusion storage.

Warning: Do NOT delete IBM Storage Scale pods. Deletion of Scale pods in many circumstances has implications on availability and data integrity.

Filesystem status from Remote file systems is stuck in Connecting state

Cause

The secure boot is not supported by Scale and CNSA.

Resolution

1. Check whether the nodes are running with secure boot:

```
mokutil --sb-state

SecureBoot enabled
```

2. As a root password, you can disable the secure boot with the following command:

```
mokutil --disable-validation

password length: 8~16
input password:
input password again:
```

Increased CPU usage on Scale pods after upgrading to Cloud Pak for Integration (CP4I)

Problem statement

Scale pod CPU usage has increased due to changes in MQ streams application. It is because of IBM MQ's liveness and readiness probes.

Resolution

The file handle reservation can be turned off by setting the environment variable `AMQ_NO_RESERVE_FD=1`. It fixes the high CPU usage.

Scale operator failed to add quorum label

Problem statement

During Storage configuration, the recovery group status can be "Waiting on some daemons in the recovery group to be restarted".

Resolution

1. Run the following command to check the count of the quorum node:

```
oc get nodes -l scale.spectrum.ibm.com/designation=quorum
```

2. Check the number of quorum nodes. Whenever the node count is less than 10, there must 3 quorum nodes. If not, apply the following quorum label for the missing nodes:

```
scale.spectrum.ibm.com/designation=quorum
```

Remote filesystem connection goes to a Disconnected state

Problem statement

If even one scale core pod is not ready due to node restart or other issues, then a problem occurs on the filesystem mount of that node and the filesystem CR reports errors. As a result, the filesystem goes to a Disconnected and the same is displayed on the IBM Fusion user interface.

Resolution

Wait for the scale core pod to go to Ready state, and the filesystem automatically changes to Connected state.

PVCs stuck in pending state

Resolution

If PVCs are stuck in a pending state for a long time, restart Scale GUI pods.

Nodes with pods scheduled for storage results in a `crashloopbackoff` or container creating errors

Problem statement

When install, upgrade, or upsize operations are in progress and the storage configuration is not yet done, the nodes with pods scheduled for storage results in a `crashloopbackoff` or container creating errors.

Resolution

To resolve this issue, disable schedule on these nodes before you begin these operations, and schedule the pods on nodes that are configured for storage.

File system is not mounted on some nodes

Problem statement

After IBM Storage Scale upgrade, the file system is not mounted on some nodes.

Resolution

Do the following workaround steps:

1. Delete the problematic pod where the file system is not mounted. Delete one pod at a time.
2. Refresh the pod overview page until the pod appears. Run `watch oc get pods`.
3. When the problematic pod comes up, set the replicas to 0 in the `Spec` section in the `ibm-spectrum-scale-operator` namespace. You must stop the operator deployment immediately. Ensure that no operator pod is running in `ibm-spectrum-scale-operator` namespace. Command for setting the operator replica to 0:

```
oc patch deploy ibm-spectrum-scale-controller-manager \
--type='json' -n ibm-spectrum-scale-operator \
-p='[{"op": "replace", "path": "/spec/replicas", "value": 0}]'
```

```
oc get deployment -n ibm-spectrum-scale-operator
```

Sample output:

```
I0420 16:56:23.579340 4184 request.go:645] Throttling request took 1.192496025s, request: GET:https://api.
<domainname>:6443/apis/nmstate.io/v1beta1?timeout=32s
NAME                                READY  UP-TO-DATE  AVAILABLE  AGE
ibm-spectrum-scale-controller-manager 0/0    0           0          28h
```

4. Wait till the problematic pod is in `init` container state and run the following command:

```
oc exec podname -- mmsdrrestore -p <any working core ip/name[Specify pod IP where FS is mounted]>
```

5. After the previous step is successful, set the replicas to 1 again in the `ibm-spectrum-scale-operator` deployment. Ensure that the operator pod is running in `ibm-spectrum-scale-operator` namespace.

Run the following command for setting the operator replica to 0:

```
oc patch deploy ibm-spectrum-scale-controller-manager \
--type='json' -n ibm-spectrum-scale-operator \
-p='[{"op": "replace", "path": "/spec/replicas", "value": 1}]'
```

```
oc get deployment -n ibm-spectrum-scale-operator
```

Sample output:

```
I0420 16:56:23.579340 4184 request.go:645] Throttling request took 1.192496025s, request: GET:https://api.
<domainname>:6443/apis/nmstate.io/v1beta1?timeout=32s
NAME                                READY  UP-TO-DATE  AVAILABLE  AGE
ibm-spectrum-scale-controller-manager 1/1    0           0          28h
```

6. Wait for some time for the problematic pod to come in running state and file system gets mounted on this problematic node.

IBM Storage Scale user interface does not load properly or IBM Storage Scale CSI pods are in `CrashLoopBack` state

Problem statement

Sometimes, IBM Storage Scale user interface might not load properly or IBM Storage Scale CSI pods are in `CrashLoopBack` state.

Resolution

As a workaround, do the following steps:

1. Restart the GUI pods and check whether it is working properly.
2. If GUI pod restart does not open the IBM Storage Scale console, then restart the `ibm-spectrum-scale-controller-manager` pod and then restart GUI pod.

Not able to log in to IBM Storage Scale user interface

Cause

The secret that is mounted in GUI pods `/etc/gui-oauth/oauth.properties` file and secret present in the `ibm-spectrum-scale-gui-oauthclient` are different.

```
gui-1
sh-4.4$ cd /etc/gui-oauth/
sh-4.4$ cat oauth.properties
```

```

secret=tjCK6kE0pmCe2d8b7azw
oauthServer=https://oauth-openshift.apps.<domainname>

```

Resolution

As a resolution, do the following steps:

1. As a resolution, restart the GUI pods.
2. If the previous step (step 1) does not resolve the issue, then restart IBM Storage Scale Operator pod and then restart the GUI pods.

Download log files of all deployments

If you cannot download log files of all deployments, individually download the log files.

Issues in node drain and node restart

Resolution

To resolve such node related issues, see [Issues related to IBM Fusion HCI node drains](#).

IBM Storage Scale cluster failed to recover after powering off and on the compute nodes

Diagnosis

Identify if the nodes joining the cluster are in an out-of-tolerance situation.

1. mmhealth reported UNKNOWN RG status on some nodes.
2. mmrepquota commands have been generated repeatedly, likely by the GUI, which has caused many long waits.
3. Due to the large number of long waits, the cluster manager node was not responding to any **ts** cmd other than **tsctl nqStatus**.
As a resolution, follow the steps defined in the [Recover storage cluster from an unplanned multi-node restart or failure](#).

MCO rollout is not progressing for more than 5 hours during the scale upgrade

Cause

Whenever the nodes are over committed and no pod limit is available, you might see delays in the policy rollout, ICSP, pull secret, and MCO rollout changes.

Resolution

As a resolution, do the following step:

- IBM Fusion HCI nodes allow the maximum number of pods on a node as defined by OpenShift® Container Platform default and ensure to keep that count within the limit. Otherwise, you might see this issue.

IBM Storage Scale cluster status is in a critical state after power on/off the rack

Cause

IBM Storage Scale cluster status is in critical state due to **unmounted_fs_check** is present on the **filesystem** CR.

Resolution

As a resolution, wait until this **filesystem** CR status gets cleared; after that, the IBM Storage Scale cluster status automatically returns to a healthy state. If the issue persists for a long time, then contact [IBM support](#).

Disk upsize issues

- Manual steps to test the **/dev** mount:

After you add a new NVMe disk to the server, the new disk cannot be discovered in the IBM Storage Scale pod. The disks do not show up with **/dev/nvme*** device names in the POD, IBM Storage Scale need the device name **/dev/nvme*** to access the disks. Without the **/dev/nvme*** device name, the new disks cannot be added into recovery group.

Resolution

Do the following manual steps to mount disks to **/dev** in the pod.

1. Log in to each IBM Storage Scale storage pods.

```
oc exec -it <pod name> -c <container> /bin/sh
```

2. Stop the GPFS daemons on one or more nodes:

```
mmshutdown
```

3. Mount **/dev** from the host running the following command:

```
mount -t devtmpfs none /dev
```

4. Validate that the content of **/dev** is from host and you can see sub directories like block, bus, char.

```
mmstartup
```

- [Recover storage cluster from an unplanned multi-node restart or failure](#)

The service of IBM Storage Scale file system might hang if the storage nodes are restarted.

- [IBM Storage Scale file system not showing newly added file system size](#)

The IBM Storage Scale file system is not showing the newly added file system size after adding six nodes as upsize.

Recover storage cluster from an unplanned multi-node restart or failure

The service of IBM Storage Scale file system might hang if the storage nodes are restarted.

The storage nodes might get restarted unexpectedly and might cause the disk to miss in the storage cluster. If the missing disks exceed the fault tolerance RAID code used that is used in the storage cluster, the file system might stop to provide service. It cannot finish the log recovery process for the lost nodes. It might also block the restarting nodes to join the cluster again.

Follow these steps to recover IBM Spectrum® Storage Scale Erasure Code Edition (ECE) from the out of fault tolerance.

Note: Out of fault tolerance in the IBM Storage Scale Erasure Code Edition (ECE) environment can be caused due to different reasons.

1. Identify the problem.

- a. Run the **mmfsadm dump waiters** command on the running node of the application. It displays the long waiters of I/O threads.
- b. Run the **mmgetstate** command. It displays the restart nodes in arbitrating state and others in active state.
- c. Run the **tslsrecgroup rg_1 --server --v2** command several times. It displays that Log Groups jumps between nodes.
- d. Check the **mmfs.log** file on all storage nodes. The log message shows up in loop on different nodes. See the message as follows:

```
[E] Beginning to resign log group LG002 in recovery group rg1 ....
```

It means that the user log group continues to resign.

2. Start the recovery process.

- a. Run the **mmlscluster** command to find all the quorum nodes.
- b. Run the **mmshutdown** command on all quorum nodes. This action causes all nodes to unmount from the file system.
- c. Run the **mmstartup** command on all quorum nodes.
- d. Run the **mmlsrecoverygroup rg1 -L --pdisk** to check whether the recovery group is active again and that no missing **pdisk** exists.
- e. Mount the file system again on all the client nodes and restart the application.

IBM Storage Scale file system not showing newly added file system size

The IBM Storage Scale file system is not showing the newly added file system size after adding six nodes as upsize.

About this task

A system with a single recovery group (setup with 4+2p erasure code) needs to do node upsizing with six nodes all together.

Procedure

- Follow the steps to upsize nodes:
 - Follow the standard node upsize process. For more information, see [Configuring nodes for management](#).
 - IBM Fusion HCI user interface shows the Running state for the newly added nodes.
 - In the IBM Fusion HCI user interface, use the app switcher to go to the IBM Storage Scale user interface.
 - Click Recovery groups on the IBM Storage Scale RAID tile.

The entry for the recovery group server nodes column shows up empty. If true, perform the following steps. Otherwise, contact the [IBM support](#).
 - Edit the labels of newly added nodes, change the label `scale.spectrum.ibm.com/rg: rg1` to `scale.spectrum.ibm.com/rg: rg2`.
 - Repeat the following process for each newly added node.
 - Open the OpenShift Container Platform user interface.
 - Go to Compute > Nodes > Details > Actions > Edit labels.
 - Remove the label `scale.spectrum.ibm.com/rg: rg1` and add the label `scale.spectrum.ibm.com/rg: rg2`.
 - Click Save.
- Follow the steps to validate the upsized nodes:
 - In the IBM Fusion HCI user interface, use the app switcher to go to the IBM Storage Scale user interface.
 - Click Recovery groups on the IBM Storage Scale RAID tile.
 - Click the entry of the recovery group server nodes column for rg2.
 - Check all the newly added nodes are listed and in healthy state.
 - Create a sample PVC to check that storage can be provisioned.

Lenovo node issues

This topic provides a comprehensive list of common troubleshooting steps and known issues that may arise while working with the nodes.

Known issues

The following known issues exist while you work with the compute nodes. The workarounds are included wherever possible. If you come across an issue that cannot be solved by using these instructions, contact [IBM Support](#).

- [Incorrect port speed display for up Ports on configured and discovered nodes](#)
- [Management switch high availability is lost](#)
- [Upgrade progress display error](#)

Troubleshooting issues

The following troubleshooting issues exist while you work with the compute nodes with workarounds included wherever possible. If you come across an issue that cannot be solved by using these instructions, contact [IBM support](#).

- [Node halts at UEFI blue screen during deployment or expansion](#)
- [Unable to add node to OpenShift Container Platform](#)
- [mmaddnode command fails during node upsize on storage cluster](#)
- [NVMe drives missing on XCC but seen on CoreOS](#)
- [Issues in node restart](#)
- [GPU node capacity value shows 0](#)
- [Compute nodes in a hung state](#)
- [Pod migration gets stuck in the Terminating or ContainerCreating state](#)
- [Compute node can abruptly become unreachable](#)
- [Add rack workflow from base rack fails in node validation](#)
- [OpenShift Container Platform node status shows NotReady but IBM Fusion HCI user interface node status shows as Running](#)
- [Node goes missing from the IBM Fusion HCI rack graphical view](#)
- [Node in NotReady state due to certificate errors in OpenShift pods](#)

Node halts at UEFI blue screen during deployment or expansion

Problem statement

During Stage 2 cluster deployment or node addition to the OpenShift® Container Platform cluster, a Lenovo compute or control node might halt at a UEFI blue screen. The node waits indefinitely for user input in the pre-OS stage, which prevents Red Hat Enterprise Linux CoreOS (RHCOS) from booting and joining the cluster. This issue is specific to Lenovo ThinkSystem nodes during bare-metal deployment and expansion.

Confirm that the node is stuck at the UEFI blue screen prompt by checking the following symptoms:

- Stage 2 deployment:** The installation fails at the **OpenShift Installation** stage.
- Node addition:** The operation fails at the **Configuring node** stage with the error: Unable to add a new node. OpenShift node not found after Bare metal host provisioning. Please Contact IBM Support.

Run the following command and confirm that the **STATE** for the target node is **provisioned**:

```
oc get bmh -n openshift-machine-api
```

Run the following command. If the BareMetalHost (BMH) shows **provisioned** but the node does not appear in the output after 15–20 minutes, the node has likely halted at the UEFI prompt:

```
oc get nodes
```

Resolution

Before you begin, retrieve the following information:

- **BMC IP address:** Replace `<rackname>` with the rack name. During Stage 2 deployment, open `~/isfconfig/kickstart-<rackname>.json` on the provisioner node and locate the `ipv4` address under the BMC configuration. During node addition or expansion, retrieve the BMC IP of the node from the `ipv4` field in the kickstart ConfigMap:

```
oc get configmap kickstart-<rackname> -n ibm-spectrum-fusion-ns -o yaml
```

- **BMC credentials:** Run the following commands to extract the decoded username and password:

```
export BMC_SECRET="<node-name>-bmc-secret"
export NAMESPACE="openshift-machine-api"

# Extract BMC Username
echo "BMC Username: $(oc get secret ${BMC_SECRET} -n ${NAMESPACE} -o jsonpath='{.data.username}' | base64 -d)"

# Extract BMC Password
echo "BMC Password: $(oc get secret ${BMC_SECRET} -n ${NAMESPACE} -o jsonpath='{.data.password}' | base64 -d)"
```

Use one of the following options to clear the UEFI blue screen prompt:

Option A: BMC web console (recommended)

1. Establish SSH local port forwarding to forward both the Lenovo XClarity Controller (XCC) web dashboard port and the remote console viewer port:

```
sudo ssh -L 443:<BMC-IP>:443 -L 3900:<BMC-IP>:3900 kni@<provisioner-ip>
```

Enter your local machine password for `sudo`, followed by the provisioner credentials.

2. Open a browser and go to `https://localhost`.
3. Log in using the BMC credentials that you retrieved.
4. In the navigation menu, go to Remote Console.
5. In the Remote Console Preview section, click the pop-out launch icon.
6. In the remote viewer window, locate the blue UEFI dialog that displays **Boot Option Restored** or **Reset System**.
Note: If the prompt displays "Press any key to stop system reset", press any key or use the virtual keyboard immediately.
7. Use the arrow keys to select Always continue boot and press Enter. The server resumes booting into RHCOS.

Note: Exit the SSH port forwarding session after the node is added to the cluster.

Option B: Redfish API (no console access)

If you cannot reach the graphical remote console, clear the persistent boot override programmatically.

1. From a host with network access to the Baseboard Management Controller (BMC) (for example, the provisioner node), run the following command and confirm that the output returns **"Continuous"**:

```
curl -k -u <BMC_USER>:<BMC_PASSWORD> \
https://<BMC_IP>/redfish/v1/Systems/1 | jq '.Boot.BootSourceOverrideEnabled'
```

2. Reset the boot source override to allow normal local disk boot:

```
curl -k -X PATCH \
-u <BMC_USER>:<BMC_PASSWORD> \
-H "Content-Type: application/json" \
-d '{"Boot": {"BootSourceOverrideEnabled": "Disabled", "BootSourceOverrideTarget": "None"}}' \
https://<BMC_IP>/redfish/v1/Systems/1
```

Wait 10 minutes after the server resumes booting. If the node is not added to the cluster, approve any pending certificate signing requests (CSRs):

```
oc get csr -o name | xargs -r oc adm certificate approve
```

Result

Verify that the node joins the cluster within 5–10 minutes:

```
oc get nodes -w
```

If the node does not join the OpenShift Container Platform cluster after completing all the steps, contact [IBM Support](#).

Unable to add node to OpenShift Container Platform

Problem statement

The node cannot be added to the OpenShift Container Platform cluster.

Cause

The issue might be caused by a hung power operation (powerop) for the node. This can be identified by checking the logs on the system.

Symptoms

- The power operation is not progressing.
- The live powerop CR logs for the node are blank or do not show any activity.
- The powerop CR is not getting updated.

Resolution

To resolve this issue, follow these steps:

1. Check the live logs on the system for the powerop operation.
2. If the logs are blank or not updating, delete the powerop CR by running the following commands in the `ibm-spectrum-fusion-ns` namespace:

```
oc get cpr
```

```
oc delete cpr <node-powerop-cr-name>
```

- Important: Wait for the command to delete the powerop CR. Avoid forceful deletion as it may cause further issues.
3. After deleting the powerop CR, verify if the node can be added to the OpenShift Container Platform cluster.
 4. If the issue persists, contact [IBM support](#).

mmaddnode command fails during node upsize on storage cluster

Resolution

After the initial failure of the **mmaddnode** command during node addition, run the following command to remove the files that do not get cleaned up properly:

```
oc exec -it compute-1-ru13 -c config -- /bin/sh
sh-5.1# rm /var/mmfs/gen/mmsdrfs
```

NVMe drives missing on XCC but seen on CoreOS

Resolution

1. Run **resetsp** to restart the BMC.
2. If the step 1 does not resolve the issue, run **OS reboot** command to reboot the node.
3. If both step 1 and step 2 do not resolve the issue, then contact [IBM support](#) to replace the faulty drive or faulty NVMe backplane.

Issues in node restart

Problem statement

Sometimes, after you restart a node, it may not change its state to ready and the **ovs-configuration.service** may fail.

Resolution

As a resolution, restart the node. For more information about Scale behavior during node restarts, see [Scale behavior during node restarts](#).

GPU operator error

Certain Linux kernels that have KASLR enabled might experience a known issue with **High Memory Mode** initialization. This issue can cause CUDA initialization to fail. As a workaround, disable the **High Memory Mode**. For more information, see [Disable High Memory Mode](#).

Management switch high availability is lost

When the management switch high availability is lost due to the management switch at RU18 being down, the cluster continues to function, but autodiscovery of nodes is not supported.

Incorrect port speed display for up Ports on configured and discovered nodes

Sometimes, the port speed for all up ports on configured and discovered nodes may be displayed as 0 Gbps instead of the actual speed.

Upgrade progress display error

After initiating an upgrade, the IBM Fusion HCI user interface upgrade page may briefly display Upgrade available instead of showing the upgrade in progress. This is a display issue only and the upgrade is running in the background. Wait for a while for the upgrade progress status to be reported.

GPU node capacity value shows 0

Problem statement

It is observed that sometimes users might see GPU node capacity as 0 and also that the NFD discovery instance has the **nfd-worker-xxx** in a constant crashloopback.

Resolution

This issue was observed in OpenShift Container Platform release 4.10.21. Upgrade the OpenShift Container Platform to 4.10.61, reinstall the NFD operator with the NFD Discovery CR, and install the NVIDIA operator and create the cluster policy that detects the GPUs.

Compute nodes in a hung state

Resolution

Steps to restart when the compute nodes get into a hung state:

As a prerequisite, you must have administrator access to Red Hat® OpenShift and OC (Red Hat OpenShift CLI) command access to the cluster.

1. Log in to OpenShift UI.
2. Go to Compute > Bare Metal Hosts.
3. Ensure to select **openshift-machine-api** project on the Bare Metal Hosts page.
4. From the ellipsis menu, click Power Off for the node.
5. Power it on again and check whether the issue is resolved.

Pod migration gets stuck in the Terminating or ContainerCreating state

Problem statement

A controller node goes down and the migration of the pod gets stuck in Terminating or ContainerCreating state.

Resolution

As a workaround, delete the container creating pod so that it can get scheduled in another available controller node.

Compute node can abruptly become unreachable

Problem statement

A compute node can abruptly become unreachable either due to a power outage or network disruption.

Cause

The pods that run on that specific compute node might have not got evacuated cleanly and they remain stuck in **Terminating** or **Unknown** state.

Resolution

To ensure a complete evacuation and migration of the pod that is stuck on the failed node, force delete the pod manually by using the following command:

```
oc delete pod <pod name> --grace-period=0 --force --namespace <namespace>
```

Add rack workflow from base rack fails in node validation

Problem statement

Add rack workflow from base rack fails in node validation for the nodes of auxiliary rack in case of high availability cluster.

Cause

The issue might occur because monitoring failed for the nodes of the auxiliary rack.

Resolution

1. Before performing the add rack operation, ensure that all the nodes on the auxiliary rack are healthy and that there are no warnings, critical events or any component failures on any of the nodes.
2. Restart the BMC on the failing nodes to clear the events on the compute node.

OpenShift Container Platform node status shows NotReady but IBM Fusion HCI user interface node status shows as Running

Problem statement

The Running state of the node on the IBM Fusion HCI user interface indicates that the Baremetal node is healthy and running. Whenever you see IBM Fusion HCI node status is Running and OpenShift Container Platform node status is Not ready, then follow the steps in the resolution.

Resolution

1. Log in to OpenShift user interface.
2. Go to Compute > Bare Metal.
3. From the ellipsis menu, click Power Off for the node.
4. Power it on again and check if the issue is resolved.

Node goes missing from the IBM Fusion HCI rack graphical view

Problem statement

OpenShift Container Platform node status shows **Ready** even though the IBM Fusion HCI user interface node status shows the node state as **Error connecting to node**

For more information about node status, see [Monitoring hardware from IBM Fusion HCI user interface](#).

This issue might occur due to the power or network issues.

Resolution

The node can be viewed graphically in the user interface of the IBM Fusion HCI rack after it gets into a healthy state. For more information, see [Monitoring hardware from IBM Fusion HCI user interface](#).

1. Get the name of the compute-operator pod name:

```
oc get po -n ibm-spectrum-fusion-ns | grep isf-compute-operator
```

2. Copy the OneCli folder from the operator pod:

```
oc rsync -c manager isf-compute-operator-controller-manager-<pod name>:/fw/onecli
```

Note: For the subsequent commands, create a separate session.

3. Start a debug pod on the target node (BMC has error connecting to the node) that is in Ready state.

```
oc debug node/<nodename>
```

4. Get the debug pod name:

```
oc get po -A -o wide | grep <nodename> | grep debug
```

5. Copy the local copy of the OneCli folder to debug pod.

```
oc rsync onecli pod/<debug pod>:/tmp
```

6. From the other session, run the following command to restart the node:

```
cd /tmp/onecli
./onecli misc rebootbmc
```

7. Go to the Infrastructure > Nodes and wait for the following error message to go away:

```
Error connecting to node
```

It takes around three minutes for the error to disappear from the page.

Node in NotReady state due to certificate errors in OpenShift pods

Problem statement

Issues can occur when a node is in the **NotReady** state. One common reason is that the OpenShift network related pods go into a **crashloopbackoff** state due to an expired certificate file.

Diagnose

Follow the steps to diagnose the issue:

1. Check the output using the following command.

```
oc get co
```

2. If you see any error message related to network, then check if any of the pods in namespace **openshift-ovn-kubernetes** are in crashing state.
3. If a pod is crashing state, then check the logs for it using following command.

```
oc logs <pod-name> -c ovnkube-controller -n openshift-ovn-kubernetes
```

Check for error related to wrong certificate.

```
I1210 14:50:40.305586 78501 certificate_store.go:130] Loading cert/key pair from "/etc/ovn/ovnkube-node-certs/ovnkube-c
I1210 14:50:40.305640 78501 certificate_store.go:130] Loading cert/key pair from "/etc/ovn/ovnkube-node-certs/ovnkube-c
F1210 14:50:40.305690 78501 ovnkube.go:136] failed to start the node certificate manager: failed to initialize the cert
```

4. In a similar way, check if any pod contains issue in namespace **openshift-multus**.

Resolution

Follow the steps to resolve the issue:

1. Use the following steps to resolve the crashing pod issue in **openshift-ovn-kubernetes** namespace:
 - a. Run the following command to change the project.

```
oc project openshift-ovn-kubernetes
```

- b. Run the following command to log in to the failing pod.

```
oc rsh <pod-name>
```

- c. Run **rm -rf /etc/ovn/ovnkube-node-certs/ovnkube-client-current.pem**

- d. Run the following command to restart the crashing pod.

```
oc delete <pod-name>
```

2. Use the following steps to resolve the crashing pod issue in **openshift-multus** namespace:
 - a. Run the following command to check the node of the failing pod.

```
oc get pods -n openshift-multus -owide
```

- b. Run the following command to log in to the respective node .

```
oc debug node/<node-name>
```

- c. Run the following command to delete the **symlink**.

```
rm -rf etc/cni/multus/certs/multus-client-current.pem
```

After fixing the pods in both the namespaces, check if the error message is gone in the output of **oc get co**. The node should come into **Ready** state in sometime.

- [Add node failure](#)

Node addition failures and their resolutions.

- [Issues related to IBM Fusion HCI node drains](#)

Use these common troubleshooting tips and tricks when you work with IBM Fusion HCI.

Multi-rack issues

This topic covers issues related to multi-rack HA, 3-zone HA, and expansion racks.

Rack shutdown issues

Problem statement

A rack shutdown in a multi-rack HA setup can cause the Backup & Restore service to go to an unknown state.

Resolution

In the case of a rack shutdown, if a graceful shutdown is not working or the node is in a non-recoverable state, you can manually add an **out-of-service** taint on the node. For more information about how it works, see [Kubernetes Blogs](#).

Remove the taint on the affected node after the node is recovered.

Using Vault with IBM Fusion HCI

This section describes about the diagnostic utility for IBM Fusion HCI.

IBM Fusion HCI uses Vault to securely store and manage sensitive credentials, secrets, and cryptographic keys. Vault provides centralized secrets management with strong access controls, audit logging, and encryption.

Key features

The Vault provides the following key features:

- Centralized secret storage: All sensitive credentials are stored in one secure location.
- Audit logging: Complete audit trail of all access and operations.
- Access control: Fine-grained policies for secret access.
- TLS encryption: HTTPS communication with self-signed certificates.

Initialization parameters

- Unseal keys: The system generates five unseal keys.
- Threshold: Three unseal keys are required to unseal the Vault.

Note: After stage 2 installation completes, Vault files are deleted from the `/var/vault` directory if the user selects the option to delete sensitive data. The Vault files (`vaultLogin` and `vault.config`) are included in the `keysAndPassword` archive.

Security features

Vault provides the following security features.

Seal and unseal mechanism

Sealed state: The Vault starts in a sealed state, where it encrypts all data and prevents access.

Unsealing: The unseal process requires three of the five generated unseal keys to reconstruct and decrypt the master key.

Encryption

Data encryption: Vault protects data by using the following encryption mechanisms.

- Encrypts all data at rest by using AES-256-GCM
- Encrypts the master key by using Shamir's Secret Sharing with unseal keys
- Secures all network communication with TLS by using self-signed certificates

File encryption: Vault stores sensitive files in the `/var/vault/` directory in Base64-encoded format.

Vault self-healing synchronization

IBM Fusion HCI 2.14 automatically keeps Vault synchronized with OpenShift® secrets during every operator reconcile cycle. After a Vault replacement or restore, manual credential re-synchronization is no longer required. The system automatically restores synchronization within the next reconcile cycle, typically within 5 minutes.

Troubleshooting Vault

Prerequisites

- Access to the OpenShift cluster.
- Vault-related secrets available, either from `/var/vault` (if present) or the `vault-secrets` resource in OpenShift.
- Access to the service node to execute Vault-related commands.
- The Vault is installed and checked using the `vault version` command.

Vault version

To check the installed Vault version, run the following command:

```
vault --version
```

Vault status

1. Before you begin troubleshooting, run the following command on the service node to check the Vault service status:

```
systemctl status vault
```
2. Review the output to determine the current state of Vault, and then run the appropriate troubleshooting commands on the service node.

The following sections describe common Vault issues and their resolutions:

Vault is sealed

Note: IBM Fusion HCI 2.14 automatically detects and unseals Vault within a single operator reconcile cycle (typically within 5 minutes). Manual unsealing is required only as a fallback if the Fusion operator is unavailable or unable to complete the unseal operation.

Symptoms

- The Vault API returns a *Vault is sealed* error.
- The `vault status` command shows `Sealed: true`.

Resolution

- Unsealing Vault using IBM Fusion-managed `vault-secret`:

You can unseal Vault by using the `vault-secret` stored in the `ibm-spectrum-fusion-ns` namespace. This secret contains the required unseal keys and credentials.

Procedure

- Verify that the Vault is sealed:

```
vault status
```

When Vault is sealed, the output includes entries similar to the following:

```
Sealed: true
Seal Type: shamir
Initialized: true
Total Shares: 5
Threshold: 3
Unseal Progress: 0/3
```

- Extract unseal keys from the `vault-secret`.

The `vault-secret` in the `ibm-spectrum-fusion-ns` namespace stores all unseal keys. Extract the required keys and store them in environment variables:

```
# Extract unseal keys from the secret
oc get secret vault-secret -n ibm-spectrum-fusion-ns -o jsonpath='{.data.unsealKey1}' | base64 -d
oc get secret vault-secret -n ibm-spectrum-fusion-ns -o jsonpath='{.data.unsealKey2}' | base64 -d
oc get secret vault-secret -n ibm-spectrum-fusion-ns -o jsonpath='{.data.unsealKey3}' | base64 -d
oc get secret vault-secret -n ibm-spectrum-fusion-ns -o jsonpath='{.data.unsealKey4}' | base64 -d
oc get secret vault-secret -n ibm-spectrum-fusion-ns -o jsonpath='{.data.unsealKey5}' | base64 -d
```

```
# Store the extracted keys in environmental variables for easy use
UNSEAL_KEY_1=$(oc get secret vault-secret -n ibm-spectrum-fusion-ns -o jsonpath='{.data.unsealKey1}' |
base64 -d)
UNSEAL_KEY_2=$(oc get secret vault-secret -n ibm-spectrum-fusion-ns -o jsonpath='{.data.unsealKey2}' |
base64 -d)
UNSEAL_KEY_3=$(oc get secret vault-secret -n ibm-spectrum-fusion-ns -o jsonpath='{.data.unsealKey3}' |
base64 -d)
```

- Unseal Vault.

The Vault requires three of the five unseal keys. Apply the keys sequentially:

```
# Set Vault address
export VAULT_ADDR='https://127.0.0.1:8200'
export VAULT_SKIP_VERIFY=true

# Unseal with first key
vault operator unseal $UNSEAL_KEY_1

# Expected output:
# Key              Value
# ---             -
# Seal Type        shamir
# Initialized       true
# Sealed           true
# Total Shares      5
# Threshold         3
# Unseal Progress  1/3    <-- Progress indicator
# Unseal Nonce      <nonce-value>
# Version           1.21.1
# Storage Type      raft
# HA Enabled        true

# Unseal with second key
vault operator unseal $UNSEAL_KEY_2

# Expected output:
# Unseal Progress  2/3    <-- Progress indicator

# Unseal with third key (final)
vault operator unseal $UNSEAL_KEY_3

# Expected output when successfully unsealed:
# Sealed           false    <-- Vault is now unsealed
# Unseal Progress  0/3
```

- Verify that the Vault is unsealed:

```
# Check vault status
vault status

# Expected output:
## Sealed: false
## Initialized: true
## HA Enabled: true
```

Alternative: Unseal in a single command

You can also unseal Vault by running a single command that applies three unseal keys sequentially:

```
export VAULT_ADDR='https://127.0.0.1:8200'
export VAULT_SKIP_VERIFY=true

vault operator unseal $(oc get secret vault-secret -n ibm-spectrum-fusion-ns -o
jsonpath='{.data.unsealKey1}' | base64 -d) && \
```

```

vault operator unseal $(oc get secret vault-secret -n ibm-spectrum-fusion-ns -o
jsonpath='{.data.unsealKey2}' | base64 -d) && \
vault operator unseal $(oc get secret vault-secret -n ibm-spectrum-fusion-ns -o
jsonpath='{.data.unsealKey3}' | base64 -d)

```

Troubleshooting the unseal process

This section describes common issues that can occur during the Vault unseal process and the corresponding resolutions.

vault-secret not found in the **ibm-spectrum-fusion-ns** namespace

Symptom

- The **vault-secret** does not appear in the **ibm-spectrum-fusion-ns** namespace.

Resolution

1. Review the **vault.config** file (Base64-encoded) located in the **/var/vault** directory.
2. Run the following command to decode the file and get the unseal keys:

```
cat /var/vault/vault.config | base64 -d
```

Invalid unseal key

Symptom

- The unseal command fails with an *invalid unseal key* error.

Resolution

Verify that the unseal key is correctly decoded and that the secret stores the keys in Base64-encoded format:

```

# Verify that the key is correctly decoded
echo $UNSEAL_KEY_1 | wc -c # Must be 44 characters (Base64-encoded key)

# Check if keys are Base64-encoded in the secret
oc get secret vault-secret -n ibm-spectrum-fusion-ns -o yaml | grep unsealKey

```

Connection refused

Symptoms

- Vault commands fail with *connection refused* errors.
- You cannot connect to the Vault API.

Resolution

Verify that the Vault service runs and listens on the expected port:

```

# Check if the Vault service is running
systemctl status vault

# Check if the Vault is listening on port 8200
ss -tlnp | grep 8200

# Verify the Vault address
echo $VAULT_ADDR

```

- Unsealing Vault using **/var/vault** artifacts on the service node:

Note: During a service node upgrade or when the service node is added as part of Day 2 operations, the required Vault artifacts are available in the **/var/vault** directory in the encoded format. These files contain sensitive information and are automatically deleted after the operation completes.

1. Decode the unseal keys:

```

base64 -d /var/vault/unsealKey1
base64 -d /var/vault/unsealKey2
base64 -d /var/vault/unsealKey3

```

2. Check seal status:

```
vault status
```

3. Run the following command three times with different keys to unseal Vault:

```

vault operator unseal <decoded-unseal-key-1>
vault operator unseal <decoded-unseal-key-2>
vault operator unseal <decoded-unseal-key-3>

```

4. Verify that the Vault is unsealed:

```
vault status
```

Vault service not running

Note: IBM Fusion HCI 2.14 automatically remediates these conditions through the IBM Fusion Install operator. Manual intervention is required only if the operator pod is unavailable or if the operator cannot establish SSH connectivity to the service node.

Symptoms

- You cannot connect to the Vault.
- Connection attempts return *connection refused* errors.

Resolution

```
# Check the Vault service status
systemctl status vault
```

```
# Start the Vault service
systemctl start vault
```

```
# Check the Vault logs
journalctl -u vault -n 100 --no-pager
```

```
# Verify that Vault listens on the expected port
ss -tlnp | grep 8200
```

Vault service is masked

Symptoms

- You cannot connect to the Vault.

Resolution

1. Check whether the vault status is masked on the service node:

```
[kni@servicenode-1 ~]$ systemctl status vault
○ vault.service
   Loaded: masked (Reason: Unit vault.service is masked.)
   Active: inactive (dead)
[kni@servicenode-1 ~]$ vault status
WARNING! VAULT_ADDR and -address unset. Defaulting to https://127.0.0.1:8200.
Error checking seal status: Get "https://127.0.0.1:8200/v1/sys/seal-status": dial tcp 127.0.0.1:8200: connect:
connection refused
```

2. Run the following commands to unmask the vault:

```
# Unmask the service
sudo systemctl unmask vault

# Reload systemd units
sudo systemctl daemon-reload

# Enable Vault at boot
sudo systemctl enable vault

# Start Vault
sudo systemctl start vault
```

3. Verify the vault status. The Vault must be in a running state.

```
[kni@servicenode-1 ~]$ vault status
WARNING! VAULT_ADDR and -address unset. Defaulting to https://127.0.0.1:8200.
Key          Value
---          -
Seal Type     shamir
Initialized   true
Sealed        true
Total Shares  5
Threshold     3
Unseal Progress 0/3
Unseal Nonce  n/a
Version       1.21.1
Build Date    2025-11-18T13:04:32Z
Storage Type  raft
Removed From Cluster false
HA Enabled    true
[kni@servicenode-1 ~]$ systemctl status vault
● vault.service - "HashiCorp Vault - A tool for managing secrets"
   Loaded: loaded (/usr/lib/systemd/system/vault.service; enabled; preset: disabled)
   Active: active (running) since Mon 2026-05-25 13:33:40 UTC; 14s ago
     Docs: https://developer.hashicorp.com/vault/docs
  Main PID: 215850 (vault)
    Tasks: 12 (limit: 818971)
   Memory: 25.6M
      CPU: 138ms
   CGroup: /system.slice/vault.service
           └─215850 /usr/bin/vault server -config=/etc/vault.d/vault.hcl

[kni@servicenode-1 ~]$ ss -lntp | grep 8200
LISTEN 0      4096      0.0.0.0:8200      0.0.0.0:*

[kni@servicenode-1 ~]$ curl -k https://127.0.0.1:8200/v1/sys/health
{"initialized":true,"sealed":true,"standby":true,"performance_standby":false,"replication_performance_mode":"unknown",
"replication_dr_mode":"unknown","server_time_utc":1779716110,"version":"1.21.1","enterprise":false,"echo_duration_ms":0,
"clock_skew_ms":0,"replication_primary_canary_age_ms":0,"removed_from_cluster":false}
```

Service node is down

Symptoms

- Unable to access the service node.
- As the service node is down, unable to access the vault.

Resolution

Wait until the service node is fully operational. The Vault service restarts automatically and remains in a sealed state. After the service node is up and the Vault service is active, unseal Vault by following the standard [unseal procedure](#).

Vault readiness check fails during service node upgrade

Symptoms

- Vault is configured and in an unsealed state.
- AppRole ID is configured and present in isf-ui/conf/app.conf.
- Vault-related API calls fail and the service node upgrade does not proceed.
- The isfLogs/isf-install-api.log file contains the following error:

```
AppRole not configured for credential lookup at path "servicenode/users/servicenode-internal": vaultRoleID
configuration is missing or empty
```

Cause

The `isf-ui.service` reads `app.conf` at startup. If the Vault installer writes the AppRole ID to `app.conf` after `isf-ui.service` starts, the service continues to reference the earlier configuration that does not contain the role ID. As a result, all Vault-related API calls fail.

Resolution

1. Verify that the vault is configured and unsealed:

```
vault status
```

2. Verify that the Vault AppRole ID is present in `app.conf`:

```
cat isf-ui/conf/app.conf | grep -i vault
```

The output must include an entry similar to the following:

```
vaultRoleID=3f102f6d-2af9-2cd8-9a12-cfeb077blaca
```

3. Confirm that the `isf-ui.service` log contains the missing role ID error:

```
sudo grep -E "AppRole|failed to get credential|vault" ~/isfLogs/isf-install-api.log | tail -n 25
```

If the output contains the following error, the service is referencing a stale configuration:

```
vaultRoleID configuration is missing or empty in app.conf
```

4. Restart the `isf-ui.service` on the service node to reload the configuration:

```
sudo systemctl restart isf-ui.service
```

5. Verify that the vault information API is accessible:

```
curl -k "https://<servicenode-hostname>:3000/api/v1/vault/information" \
-H "X-Username: servicenode-internal" \
-H "X-Password: <password>"
```

6. Trigger the service node upgrade again.

Token expired

Symptoms

- Requests fail with *permission denied* errors after previously succeeding.
- Commands return *token expired* errors.

Resolution

Check token time-to-live (TTL) and renew the token if it supports renewal:

```
# Check token TTL
vault token lookup
```

```
# Renew the token if it is renewable
vault token renew
```

Support

If you encounter Vault-related issues, collect the service node logs from the service node and attach it to the [IBM Support](#) ticket. For more information, see [Service node logs](#).

Virtualization issues

Learn how to troubleshoot virtualization issues, including virtual machines that enter a `CrashLoopBackOff` state after a GPU node power cycle.

GPU node power cycle issues

Symptom

After a planned or unplanned power cycle of a GPU node, virtual machines (VMs) that use a virtual GPU (vGPU) enter a `CrashLoopBackOff` state.

Resolving the problem

1. Restart the `vgpu-device-config` pod in the `nvidia-gpu-operator` namespace.
2. Verify the available vGPU profiles by running the following command:

```
oc get node <gpu_node_name> -o json | jq '.status.allocatable | with_entries(select(.key | startswith("nvidia.com/")) | with_entries(select(.value != "0")))'
```

Example output:

```
{
  "nvidia.com/NVIDIA_RTX_Pro_6000_Blackwell_DC-48Q": "4"
}
```

3. Start the VM.

Collecting logs for virtualization issues

For diagnostic and state information, see the Red Hat OpenShift Virtualization section in [Log package](#) to collect `openshift-cnv` namespace resources and must-gather artifacts.

Frequently asked questions

General

Common question and answers related to IBM Fusion HCI.

1. What is the official name of the hardware offering?
IBM Fusion HCI is the name of the hardware. Three additional software parts get installed to complete a solution:
 - Red Hat® OpenShift® Container Platform
 - IBM Fusion HCI Management Software
 - IBM Fusion HCI Storage Software
2. Does IBM Fusion HCI support both Red Hat OpenShift and VMware?
Red Hat OpenShift Virtualization supports both native VMWare images and converted OpenShift VM images. IBM Fusion HCI is a perfect platform to run both Virtual Machines and Containers. Acquire guidance on what virtual workloads work best on OpenShift with IBM Fusion HCI. For more information about Red Hat OpenShift Virtualization, see [About Red Hat OpenShift Virtualization](#) in *Red Hat OpenShift Container Platform* documentation.
3. Can IBM Fusion HCI with OpenShift Virtualization be used to migrate clients off VMware?
Yes, IBM Fusion HCI with OpenShift Virtualization can be used to migrate you off VMware. For more information about migration, see <https://access.redhat.com/products/migration-toolkit-virtualization>.
4. Differences between the IBM Fusion HCI and IBM Fusion versions?
IBM Fusion can be deployed two different ways:
 - IBM Fusion is an operator that is installed on Red Hat OpenShift Container Platform.
 - IBM Fusion HCI is an entire rack of devices (servers, switches, and so on) which will have Red Hat OpenShift Container Platform and IBM Fusion software installed on it.

User experience varies because of those different deployment models:

- IBM Fusion HCI has hardware-centric experience and features (monitoring, troubleshooting, adding drives/nodes), whereas for IBM Fusion, those actions take place in Red Hat OpenShift Container Platform.
- The storage management experience between IBM Fusion HCI and IBM Fusion will vary. IBM Fusion HCI lets you define multiple storage classes but you can only have one file system.

5. What is the difference between IBM Fusion HCI and Cloud Pak System? Is IBM Fusion HCI a replacement for Cloud Pak System?

IBM Fusion HCI provides a cost-effective computing platform, comprised of storage rich servers and network hardware, for OpenShift container-based workloads. It is easy to deploy, simple to maintain, and easy to scale-out capacity as workload demand grows. IBM Fusion HCI is purpose-built for modern container-based workloads and makes it easy for Infrastructure and Operations (I&O) teams to achieve cloud operating models in their private datacenters. As IBM Fusion HCI is purpose-built for modern container-based workloads, it eliminates unnecessary baggage and operational complexity of systems that were designed for last-generation VM based workloads. The Cloud Pak System is designed to run VM based applications on VMware.

6. Where can I learn more about IBM Fusion HCI and IBM Fusion?

You can see IBM Documentation at [IBM Fusion documentation](#).

7. Can we use Fusion Advanced with Red Hat OpenShift Virtualization Engine VE and OpenShift Kubernetes Engine (OKE)?

Yes

8. What is supported to run IBM Fusion HCI in a customer supplied rack?

There is a recommended option of purchasing IBM Fusion HCI without a rack. You can bring your own rack but must ensure that the rack meets the necessary specifications and requirements for the IBM Fusion HCI. If you are interested in using the own racks, contact your IBM Sales representatives for this offering.

9. What is the reasoning behind having 6 PDUs for all config? Why do you have to configure 6 PDUs in econfig?

IBM Fusion HCI no longer ships 6 PDUs instead only the number of PDUs that are needed are shipped. The number of PDUs that need to be energized depends on the specific rack configuration.

For more information, see [Hardware overview](#).

10. IBM Fusion HCI has which OS (Red Hat core OS or RHEL)?

IBM Fusion HCI uses CoreOS as the base platform to deploy Red Hat OpenShift Clusters.

11. IBM Fusion HCI comes with preinstalled Red Hat OpenShift or do we have to deploy it?

It has a automated installer to deploy Red Hat OpenShift at customer site.

12. What would happen if a customer deletes the IBM Fusion HCI or IBM Fusion operators from Red Hat OpenShift Container Platform console > Installed operator page?

It is not recommended to delete the operator. If you delete, then it leaves the appliance in an inconsistent mode. Contact [IBM support](#) for further assistance.

13. Is KEDA (Kubernetes-based Event Driven Autoscaling) supported with IBM Fusion HCI?

Yes, you should be able to use KEDA on IBM Fusion HCI. In general, see the following document on using KEDA with Red Hat OpenShift, and IBM Fusion HCI is based on an Red Hat OpenShift on Bare Metal cluster - <https://developer.ibm.com/patterns/scaling-an-event-driven-architecture-with-kafka-on-openshift/>

14. How to configure or order IBM Fusion services (IBM Data Cataloging, Global Data Platform, Backup & Restore, Fusion Data Foundation)?

Yes, you can install IBM Fusion services from the IBM Fusion HCI user interface. For the procedure to install, see [Install your IBM Fusion HCI services](#).

15. Do the AFM nodes for IBM Fusion HCI run as containers or bare metal AFM servers?

The AFM nodes are compute nodes in the Red Hat OpenShift cluster that host the containers running the code that implements AFM. For more information about how IBM Storage Scale handles AFM, see [Sharing data](#).

16. Does IBM Fusion HCI support the usage of NFS protocol RWM protection in 3-site configuration?

IBM Storage Scale AFM DR does not support 3-site configuration. You can configure IBM Storage Scale stretch cluster with three copies if you have low latency networks available between three sites. Alternatively, you can configure two sites by using IBM Storage Scale Stretch cluster configuration over low latency network and configure AFM-DR over NFS RWX for the 3rd site.

17. If the GPU enhanced nodes are not sufficient, then is there another option apart from acquiring another IBM Fusion HCI appliance? (Like adding GPU worker nodes outside the IBM Fusion HCI rack?)

IBM Fusion HCI can be ordered with up to four GPU nodes. Each of these GPU nodes can hold from 1 to 8 GPU cards. These cards can be either NVIDIA L40S or NVIDIA H100 NVL GPU cards.

18. IBM Visual Insights will run on Maximo Red Hat OpenShift Container Platform instead of IBM Power but it requires GPU. Will IBM Fusion HCI include GPUs?

IBM Fusion HCI can be ordered with 6 NVIDIA A100 GPUs. If required, you can order another 2 GPU units.

19. What to do if we see a red icon for some of the widgets in the IBM Fusion HCI infrastructure overview user interface page?

The red icon indicates a problem with that component and it needs attention. Refer to the widget page or to the events page for further details. For more information about infrastructure overview and events, see [Monitoring hardware from IBM Fusion HCI user interface](#) and [Analyzing events in IBM Fusion HCI](#). If the problem persists, then contact [IBM support](#) for assistance.

20. On top of the embedded Prometheus monitoring, can the user go further with monitoring integration of their systems. Can they use Alert manager to extract data and send it to an external monitoring tools? Which other options are available to centralize the IBM Fusion HCI appliance on a standard customer monitoring platform?

For every metric that is seen in Prometheus, you can configure the OpenShift alert manager to create alerts and send them to destinations supported by alert manager. As IBM Fusion feeds events into OpenShift event manager, they show up in any integration that you use to monitor OpenShift events. For more information, see [Monitoring and logging by using any monitoring tool](#).

21. What configurations are available for IBM Fusion HCI? Can the hardware be ordered in different configurations? Can the hardware be upgraded in the field?

Yes, the hardware can be upgraded in the field. For more information about upgrade, see [Upgrading node firmware](#) and [Upgrading switch firmware](#).

The base and minimal configuration consists of a 42U rack, dual TORs, dual management switches, and 6 dual-socket servers each populated with two 7.68 TB NVMe drives or 3.84TB drives.

64 core servers with 1024GB of RAM are also available for the base.

22. What are the minimum and maximum number of nodes?

This procedure installs and configures all the default nodes (Three controllers and three compute nodes). If you ordered additional nodes, then they get installed as well. The maximum number of nodes in a rack is 16 and the minimum is 6 nodes.

23. Can two IBM Fusion HCI racks be clustered in an active-active configuration?

We are calling this configuration 'Metro sync DR'. To achieve synchronous replication between the racks, the racks must reside within a metropolitan area (for low latency) and must be connected by a high-bandwidth, high-quality network link. For the exact specification, see [Upgrade and upsize considerations in Metro-DR](#).

24. Can three IBM Fusion HCI racks be clustered in a multi-zone configuration? What are the RPO characteristics?

We are calling this configuration as 'High-availability cluster', also known as AFM DR in the IBM Storage Scale community. The Recovery Point Objective (RPO) depends on several factors: the latency and bandwidth of the link connecting racks across zones and the size and quantity of the transactions that need to be replicated.

25. Is IBM Spectrum® Storage Scale Erasure Code Edition (ECE) deployed as a container?

Yes. IBM Storage Scale Erasure Code Edition (ECE) is deployed container native and managed through an operator.

26. Can IBM Fusion HCI support traditional VMs and containers on the same system?

Yes, IBM Fusion HCI can support running containers and VMs side-by-side on the same system with Red Hat OpenShift Virtualization. OpenShift Virtualization comes with Red Hat OpenShift Container Platform.

Note: The OpenShift Virtualization is a technology based on KubeVirt.

27. Can user run content from Red Hat Marketplace on IBM Fusion HCI?

Yes, user can run content from Red Hat Marketplace on IBM Fusion HCI.

28. What Cloud Paks will run on IBM Fusion HCI?

For existing Cloud Pak support, see [IBM Cloud Paks support for IBM Fusion](#).

29. Can IBM Fusion HCI support Windows?

Yes, IBM Fusion HCI can support both Windows and Linux virtual machines with Red Hat OpenShift Virtualization.

30. Is support available for "protocol"?

Protocol is the ability to access data in IBM Storage Scale via a mechanism other than native Scale. The IBM Storage Scale supports NFS and SMB.

31. If a IBM Fusion HCI deployed spans 3 racks, then can the control nodes be deployment across the 3 OpenShift Container Platform clusters?

When the 3 racks are initially setup, all control nodes are in the first rack (basically, you set up and configure the first rack, and then add the other two). After the initial installation is complete, control nodes can be dispersed over 3 racks.

In expansion, the control nodes remain in one rack. The reason because the cluster is already created and you cannot change the control nodes. In expansion rack, the control nodes remain in one rack because the cluster is already created and you cannot change the control nodes.

32. Can IBM Fusion HCI be used to expand an existing cluster?

If you use an existing HCI rack, then the new rack can be extended with an existing OpenShift Container Platform cluster. It is called the expansion rack.

33. Do we support single OpenShift Container Platform cluster across multiple IBM Fusion HCI racks?

Although there are restrictions, you can cluster 3 racks together in one big OpenShift Container Platform cluster.

34. What is the minimum size of the Client environment? (3/4 x86 bare servers dedicated to containers)?

The minimum size of a IBM Fusion HCI is currently 6 nodes in a rack. The rack can scale up to 16 nodes, and 3 racks can be interconnected.

35. What is the max power draw and cooling figures for IBM Fusion HCI especially with the newly announced hardware?

Use the StorM tool to calculate the power consumption of a particular configuration.

36. Is mixing of 9155-C10 / 9155-C14 compute nodes supported (for example: 3 x 32 core servers + 3 x 64 cores servers)? Also, in StorM is there a possibility to choose only one GPU server?

Yes, mixing of 9155-C10 / 9155-C14 servers is allowed. The only server requirement is a minimum of 6x 9155-C10 or 9155-C14 servers with storage to form the base storage cluster. All servers, including GPU servers, can be purchased in increments of one after the base minimum server requirement (mentioned in this topic) is met.

37. Can I add an expansion rack to an existing IBM Fusion HCI rack?

Yes, you can add a new rack to an existing rack using multi-rack capability.

38. Can I deploy more than one rack in single IBM Fusion HCI cluster?

Yes, you can deploy two or three racks as a single cluster IBM Fusion HCI using a multi-rack set up.

Workloads

Common question and answers related to IBM Fusion HCI.

1. Can we customize IBM Fusion HCI to deploy OpenShift® Virtualization for general Linux VM workloads?

You can directly use Red Hat OpenShift Virtualization to deploy virtual machines on the IBM Fusion HCI.

2. In IBM Fusion HCI, how much storage capacity is available for customer workloads after system has been fully installed?

Usable Storage Capacity in TB Using 4+2P Coding.

The 8+2P and 4+3P encodings are also supported.

The units of the drive size are 7.68 TB:

- Depends on how many flash modules you deploy and how many storage nodes you deploy
- Base configuration - 6 nodes with 2 drives each

For more information storage capacity, see [Installing IBM Fusion HCI](#).

3. Is MyInvenio Processing Mining (within CP4BA) a tested service for IBM Fusion HCI?

For Cloud Paks support with IBM Fusion HCI and IBM Fusion, see [IBM Cloud Paks support for IBM Fusion](#).

Install

Answers to questions that are related to installation of IBM Fusion HCI.

1. Is it possible to configure custom ingress certificate?
Yes, it can be done at installation time by using the IBM Fusion HCI installer or manually as Day 2 following [Red Hat® OpenShift® Container Platform documentation](#).
2. Is it possible to setup cluster-wide proxy?
Yes, you can setup cluster-wide proxy.
3. Is offline installation supported for air-gapped data centers?
Yes, offline installation is supported for air-gapped data centers.
It is common in production to have a cluster that does not have internet access (air gap, offline, disconnected). In such cases, you can still install the IBM Fusion HCI solution in your air gap environment. The experience is the same as an online installation where you use the IBM and Red Hat entitled registries. However, you must do additional steps to mirror images to your enterprise registry. For more information about mirroring images, see [End-to-end mirroring of IBM Fusion HCI and its services images to the enterprise registry](#).
4. Is Quay registry supported for air gap installation?
Yes, from 2.8 release onwards, support is available for Quay registry.
5. Is self-signed certificate registry support available for air gap installation?
Yes, from 2.8 release onwards, support is available for registries with self-signed certificate.
6. What are the stages of the IBM Fusion HCI installation and approximately how long does each stage take?

Installation stage	Approximate time duration
Stage 1: Network configuration	12 minutes
Stage 2: IBM Fusion HCI software installation	90 minutes

Total: 1 hour 42 minutes
7. Is it possible to change the network configuration of the customer after the initiation of an installation?
For example, if the customer wants to make changes to their DNS configuration (including changing the cluster name and/or domain name), or make changes to their DHCP configuration?
It is possible to make network-related changes and restart the installation. To make network changes and restart installation from stage 1. For more information, see [Installing IBM Fusion HCI](#).
8. Can the customer customize the following during IBM Fusion HCI installation - (a) Subnet (b) Red Hat has one of the default pod networks?
Yes, user interface support exists in stage 2 to customize the pages for OpenShift Container Platform network customization.
9. Is there a limit on the number of Red Hat OpenShift Container Platform clusters that can be deployed on a single IBM Fusion HCI?
A single IBM Fusion HCI appliance is limited to one Red Hat OpenShift Container Platform cluster.
10. Is Deployment Guide available for IBM Fusion HCI?
The deployment guide is available in the following customer-facing IBM Documentation location: [Planning your installation](#).
11. Who is responsible for running the rack initialization script?
IBM installs the IBM Fusion HCI. Customers must provide information about the network where IBM Fusion HCI is installed. The client will also need to bring entitlement for Red Hat OpenShift Container Platform.
12. Where can IBM Fusion HCI be deployed?
IBM Fusion HCI can be deployed in datacenters and in edge locations that can accommodate 42 u racks that meet all the [Planning your installation](#) of the IBM Fusion HCI.

Multi cluster IBM Fusion HCI using Hosted Control Plane

This section answers questions that are related to the Hosted Control Plane in the IBM Fusion HCI.

1. Can I use Multi Cluster Engine (MCE) for creating hosted control planes?
Yes
2. Is Red Hat® Advanced Cluster Management for Kubernetes (ACM) required for creating hosted control planes?
ACM is not necessary for creating hosted control planes, as MCE alone is sufficient.
3. Do I need OPP license to create hosted control planes?
No, hosted control planes can be created with OpenShift® Container Platform license by using MCE operator.
4. How do I size my cluster for hosted control planes?
For sizing information, see [Red Hat OpenShift Container Platform documentation](#).
5. What must be the values of cluster and service network for hosted control plane cluster?
For more information about the values, see [Red Hat OpenShift Container Platform documentation](#).
6. Can I create VMs in Virtualized hosted control plane cluster?
No, Red Hat does not support nested virtualization.
7. Can I create VMs in Bare Metal Hosted Control Plane cluster?
Yes
8. Can I create Bare Metal hosted cluster with GPUs nodes?

Yes

9. Can I create Hosted Control Plane clusters on IBM Fusion HCI with Dell hardware?

Yes

10. I have hosted control plane clusters running on IBM Fusion HCI with ACM. Can I configure IBM Fusion HCI in a Regional-DR relation?

Yes. You must migrate ACM to an external OpenShift Container Platform cluster leaving MCE and hosted clusters in IBM Fusion HCI.

11. Can I provide storage through remote mount scale to Hosted Control Plane?

Yes, only in Bare Metal hosted clusters with minimum three compute nodes.

12. Can I restrict how much storage a hosted cluster can consume from Fusion Data Foundation provider?

Yes, using storage quota option of Fusion Data Foundation starting version 4.17.

13. How do I pin a specific IP for a Hosted Control Plane cluster?

Define MetalLB ipaddresspool. For the procedure, see [MetalLB documentation](#).

14. How many clusters can I create?

With the base rack, 5 Hosted Control Plane clusters are supported. Extended racks are 3 additional clusters per node.

15. Is Global Data Platform supported as a storage for Hosted Control Plane clusters?

No, this is still a Technical Preview.

16. What are the network requirements?

All Hosted Control Plane clusters must have a private or external IP assigned to them to communicate with the control pods on the hub cluster. A load balancer, such as MetalLB, must be installed for this purpose.

17. Can hosted clusters use the Fusion Data Foundation storage?

Yes, by installing the Fusion Data Foundation client on each hosted cluster, the cluster receives the Data Foundation storage from the Fusion Data Foundation provider on IBM Fusion HCI.

Red Hat Advanced Cluster Management (RHACM)

This section answers questions related to RHACM in IBM Fusion HCI.

1. Is RHACM license available with IBM Fusion HCI?

No, RHACM license is not included in IBM Fusion HCI. Contact Red Hat® for RHACM license queries.

2. What is the deployment model for application onboarding load balancing etc? How to ensure that an application is HA across at least 2 “sites” and not all installing on a single rack within a site.

Each IBM Fusion HCI today is in its own cluster. You can use Red Hat Advanced Cluster Management (RHACM) to manage multiple clusters and deploy applications to and across clusters. RHACM also has a policy engine that can lay down policies on OpenShift® and enforce how users configure the cluster and deploy applications. For more information on RHACM, see <https://www.redhat.com/en/technologies/management/advanced-cluster-management>.

3. Are there any major limitations for customization after this stack is deployed?

For disk drives, all nodes that are a part of the storage cluster must have the same number of drives (this is just the way 4+2p ECE works). Otherwise, this is a fully functional OpenShift on bare metal cluster, and it's yours to customize and install apps.

Expansion rack

Frequently asked questions about expansion rack support in IBM Fusion HCI.

1. Is rack Expansion support on Fusion Data Foundation cluster?

Yes, it supports on Fusion Data Foundation cluster.

2. If storage nodes on the initial rack have 4 NVMe drives per node. Can I add nodes with 2 NVMe drives per node to the expansion racks of the cluster?

No. The storage node upsize must be uniform. The number of NVMe drives in the new storage nodes must match the number of NVMe drives in the existing storage nodes.

3. Can I expand the rack only to increase the compute capacity by using IBM Fusion HCI expansion multi-rack?

Yes, it is possible to add compute capacity without adding the minimum of six storage nodes.

4. Is erasure coding supported on an expansion rack topology?

Yes. Erasure coding is supported on Red Hat® OpenShift® Container Platform 4.22 or later with Fusion Data Foundation 4.22 or later. For more information, see [Fusion Data Foundation storage compatibility across rack configurations](#).

Rack reset

Answers to questions that are related to rack reset in IBM Fusion HCI.

Troubleshooting questions

1. What if rack reset fails?

Follow these steps:

- a. Review error logs in UI.

- b. Fix the underlying issue.
 - c. Re-launch rack reset.
 - d. Workflow resumes from the last checkpoint.
 - e. If the issue persists, contact [IBM Support](#).
2. Can I restart a failed rack reset?
- Yes, re-launch from the UI:
- Workflow automatically resumes from the last checkpoint.
 - No need to start from the beginning.
 - Skips already completed phases.

Post-reset questions

1. Where are the output files located?
- Output files are in /home/kni/isfconfig:
- kickstart.json - Node configurations
 - rackInfo.json - Rack metadata
2. How do I verify rack reset was successful?
- Confirm that the Workflow status shows **Completed**.

Upgrade

This section answers questions that are related to upgrade in IBM Fusion HCI.

1. Is firmware upgrade available in IBM Fusion HCI?
- Yes, firmware upgrade available in IBM Fusion HCI. For firmware upgrade, see [Firmware upgrade](#).
2. Is OpenShift Container Platform upgrade automated?
- No, OpenShift Container Platform upgrade is not automated.
3. **Are IBM Fusion HCI upgrades disruptive?**
- No, upgrades are not disruptive. Rack firmware can be updated non-disruptively. The IBM Fusion HCI management software makes it easy to evacuate compute nodes and switches so that they can be updated without disrupting workloads.
4. Can I upgrade the version of IBM Fusion HCI services independently?
- No, components of IBM Fusion HCI must not be upgraded. You should upgrade on the IBM Fusion software, which would then orchestrate and upgrade other components as needed.
5. If I run the service node upgrade script and it exited with an error, what is the issue?
- The script output prints the exact error that indicates what action needs to be taken. The output also specifies a log file name (in the `tmp/log` directory) where all the script output logs are present. It can help further troubleshoot the issue.
6. How can I get the help options for the service node upgrade script?
- Run the following command:
- ```
./upgrade_servicenode_to_2_12.sh --help
```

---

## Global Data Platform

This section answers questions that are related to Global Data Platform storage in IBM Fusion HCI.

1. Does IBM Fusion HCI (with IBM Storage Scale) support block and object storage?
- Support is available for object storage and RWO & RWX storage. IBM Fusion HCI does not support block. Most container workloads use RWO and do not actually need block. Many people conflate block and RWO.
2. In IBM Fusion HCI, the IBM Storage Scale ECE filesystem is considered as container-native or container-ready?
- IBM Storage Scale Fusion deploys containerized ECE filesystem, which works together with IBM Storage Scale Container Storage Interface (CSI) plug-in to provide persistent storage service for applications. From technical perspective, applications can use ECE filesystem almost the same way as ODF/NFS to define PVC and get storage service from ECE with CSI. You need to use different storage class and other properties for configuration.
3. FlashSystems can provide persistent storage for containers on block storage. Why is block storage not mentioned within the context of IBM Fusion HCI?
- IBM Fusion HCI is hyperconverged infrastructure that includes compute, storage, and network. It currently does not support accessing external block storage.
- For the IBM Fusion variant (SDS), OpenShift® can use any storage supported via CSI drivers, including IBM FlashSystems and other 3<sup>rd</sup> party systems. Also, note that when a container uses "block Storage", it is internally formatted with a filesystem.
4. Is it supported to setup Advanced File Management (AFM) DR manually between two IBM Fusion HCI without integration with Fusion Data Foundation and the operators?
- No. The proposed disaster recovery solutions are as follows:
- Metro DR
  - AFM cache to external storage array and do DR on external storage.
5. Does IBM Fusion HCI support OpenShift?
- Yes, the IBM Fusion HCI supports OpenShift.
6. Is Fusion Data Foundation available as a service?

Yes, Fusion Data Foundation is available as a service in IBM Fusion HCI.

7. Can and how does IBM Fusion HCI connect to external storage?

Yes. The IBM Fusion HCI supports AFM cache capabilities, which means that you can configure IBM Fusion HCI to connect to popular NFS filers and S3 compliant object stores. Data residing in these external storage can be cached locally on the IBM Fusion HCI for performance.

8. Can IBM Fusion HCI connect to external object storage?

Yes, IBM Fusion HCI can connect to external S3 object stores. This requires the AFM compute nodes 9155-F01.

9. Does IBM Fusion HCI support S3 compliant object storage?

Yes

10. Can IBM Fusion HCI connect to external Scale/ESS storage?

For this requirement, the IBM Fusion HCI must have AFM nodes. The AFM nodes can be either 9155-F01 servers or 32-core compute-only servers (9155-C00 or 9155-C10) that have been configured to provide AFM features.

11. Can IBM Fusion HCI connect to external NFS storage?

Yes. Leverage the AFM cache capabilities provided by IBM Storage Scale ECE. This requires the AFM compute nodes 9155-F01.

12. Is it possible to integrate with third-party storage?

Yes, IBM Fusion HCI uses IBM Storage Scale AFM capabilities to access data from any vendor's NAS.

13. Is the IBM Fusion HCI storage presented as NFS? Can it be accessed via NFS?

No.

14. Does IBM Fusion HCI deliver a curated Kubernetes and container native storage solution?

IBM Fusion HCI provides OpenShift cluster, and best practices-based compute, storage and network infrastructure stack. It is a highly available enterprise-ready OpenShift platform.

15. Does IBM Fusion HCI support the access of object storage from applications that run on OpenShift?

To access object storage from applications that run on OpenShift, use standard S3 interfaces. IBM Fusion HCI itself provides a S3-compatible object store.

16. Does IBM Fusion HCI support encrypted S3?

Fusion does not provide S3 protocol support such as providing S3 protocol access to data for container native applications or applications outside IBM Fusion HCI.

17. Does the third-party file system manage the data and write to IBM Fusion HCI as if it is a storage resource?

IBM Fusion HCI does not provide storage to 3rd party file systems. IBM Fusion HCI itself includes a file system (via IBM Storage Scale). It can also consume storage from external third-party file systems using the AFM technology of IBM Storage Scale.

18. Is IBM Fusion Data Foundation support included with Cloud Pak for Data (CP4D)?

Depending on the CP4D version, you might have limitations on what OpenShift Container Platform and Fusion Data Foundation version you can use. From an Red Hat® OpenShift Data Foundation perspective, the version is linked to the OpenShift Container Platform version you have deployed IBM Software Hub on. For example, OpenShift Container Platform 4.16.x, you can run Red Hat OpenShift Data Foundation 4.16 only (except when doing an upgrade of OpenShift Container Platform where you can have a mismatch between the 2 versions). Red Hat OpenShift Data Foundation scalability will depend on the amount of CPU and RAM you have on each node where Red Hat OpenShift Data Foundation is deployed but Red Hat lifted limits on the number of Red Hat OpenShift Dedicated per node (although 9 is still the recommended number to limit the failure domain size). The last limit published is 2000 nodes for Red Hat OpenShift Data Foundation. Check here <https://access.redhat.com/articles/5001441>

Based on this it gives you 2000x9x4TB = 24PB theoretical limit. One thing to consider for Red Hat OpenShift Data Foundation vs IBM Fusion HCI is the data services you need as IBM Fusion HCI offers more features than Red Hat OpenShift Data Foundation.

19. What is the version of IBM Storage Scale ECE that will be deployed in IBM Fusion HCI?

For the supported version of IBM Storage Scale ECE, see <https://supportcontent.ibm.com/support/pages/node/6824743>.

20. With IBM Fusion HCI and encryption, what policy is defined or is there a scope to define the policy? Is the encryption/policy user defined or is it fixed?

It is for the whole filesystem.

21. Does it allow for different key per worker nodes? Can workload on the node "A" decrypt data from worker "B" or it is per HCI cluster?

No. It is per IBM Fusion HCI cluster (two racks are using same key for Metro sync DR scenarios)

22. Is IBM Fusion HCI license required for persistence storage on Infrastructure nodes?

You do not need to license Fusion on infra nodes when you only host the persistent storage offered by Fusion. The deployment of Fusion services other than storage on the infra nodes (for example, catalog or backup) are called application-level services. It means the infra nodes require OCP and Fusion licensing like a worker node. When infra nodes need to be licensed, they use the same model as normal worker nodes; you can use Bare Metal licensing for x86 Bare Metal nodes, or else you can use VPC licensing.

23. Does IBM Fusion HCI support Ceph now?

Yes, IBM Fusion HCI supports IBM Ceph Storage.

24. Does Fusion Data Foundation support encryption?

No, encryption is not supported for Fusion Data Foundation storage type in IBM Fusion HCI.

25. Does applications using remote Global Data Platform storage applicable for Backup & Restore?

No

26. Does applications using remote Global Data Platform storage applicable for disaster recovery?

No

27. Where to check node drain or MCP rollout logs?

Run the following command to get the node drain or MCP rollout logs.

```
oc logs -n openshift-machine-config-operator machine-config-controller-xxxxxx -c machine-config-controller
```

for details

---

## Global Data Platform Metro-DR

This section answers questions that are related to Metro-DR in IBM Fusion HCI.

1. What is the admin network?  
The default OpenShift® container network is referred to as the admin network.
2. What is a daemon or storage network?  
The network that is used by scale on the 100GbE ports is called the storage/daemon network. All scale pods require an extra IP address on this interface.
3. What is a submariner?  
Submariner is an open source software that is used to bring connectivity across the admin network of both sites.
4. What are the site 1 and site 2 network requirements?  
Following are the site 1 and site 2 network requirements:
  - a. The default pod IPs on the scale pods must be routable across both the sites.
  - b. The storage IPs configured on the scale pods both sites must be routable.
  - c. The tie breaker must be routable to both the sites and daemon network.
5. What is a Tie Breaker?  
In a disaster recovery setup, tiebreaker is a mechanism that is used to resolve conflicts between replicated data or services. It determines which site must be considered the primary site during disasters like hardware failure, or other issues.
6. How does Metro-DR ensures data consistency?  
Metro-DR ensures integrity and data consistency through synchronous data replication, that is, data is replicated on both sites always .
7. How does Metro-DR perform failover and failback operations?  
Metro-DR performs failover and failback operations automatically, ensuring minimum disturbance to active services or data. In a disaster situation, failover occurs to the secondary site. After the primary site is healthy, failback is triggered to return services to the primary site.

---

## Data Foundation Storage

This section answers questions that are related to storage in IBM Fusion.

1. Does the Data Foundation support Object Storage?  
Yes, the Data Foundation support Object Storage.
2. What is the supported Data Foundation version?  
The Data Foundation version is the same as the OpenShift® Container Platform version, for example, on OpenShift Container Platform 4.16, install Data Foundation 4.16.  
For a complete list of supported versions, see [Support matrix for IBM Fusion HCI versions](#).
3. What is the difference between Fusion Data Foundation and Red Hat® OpenShift Data Foundation?  
Fusion Data Foundation and Red Hat OpenShift Data Foundation provide similar functionality for provisioning container-native storage in an OpenShift cluster. IBM allows Red Hat to resell support for ODF through a subscription model, with some minor differences in capability. For example, Provider mode is not available in ODF. Red Hat offers ODF in two editions: ODF Essentials and ODF Advanced, with ODF Advanced including Disaster Recovery (DR) capabilities. Currently, neither IBM Fusion nor IBM Cloud Paks include a subscription to Red Hat ODF. The FDF image is sourced from the IBM image repository, while the ODF image is sourced from the Red Hat image repository.
4. What levels of encryption are supported?  
Both cluster-wide encryption and storageclass encryption are supported.
5. How to handle and support key management?  
Support is available for external Key Management System, either HashiCorp Vault or Thales CipherTrust Manager.
6. Does Fusion Data Foundation support encryption of data in flight?  
Yes, it uses Transport Layer Security (TLS).

---

## Network

This section answers questions related to networking in IBM Fusion HCI.

1. Each node has both a dual-port 25GbE network interface card and a dual-port 100GbE network interface card. Are there two cards of each?  
There is one card of each.
2. Is any of this information in stage 1 network setup screen auto-populated? Must the Service Support Representative (SSR) get this information from the TDA or other planning worksheets?  
Some of the fields are auto-populated, and most of the information should come from the TDA worksheets.
3. Are the connectors to the customer switches DAC or AOC or QSFP?  
Both DAC and AOC cables are supported, and QSA adapter is also supported for using SFP.
4. Are there options to physically isolate data network traffic between applications running inside the POD by using dedicated physical network ports?  
It is not possible to create physically separate data traffic like that.
5. Does the switch firmware upgrade process supports failover/failback?

When upgrading switch firmware, only one switch can be upgraded at a time. While this is happening, the other switch in the pair carries the traffic so that applications remain connected.

6. Does IBM Fusion HCI include all power and network cables (intra-rack)?  
Yes, all network cables needed within the rack are included. Only the cables needed for the servers ordered are included. However, you need to supply the network cables that connect the IBM Fusion HCI high-speed switches to your networks switches. For multi-rack appliance, you must purchase cables. For more information about cables and transceivers, see [Network cable requirements](#).
7. Which Network topology does IBM Fusion HCI support?  
Currently, the configuration is OpenShift® Container Platform CNI networkType Governesses. IPVLAN is used for the multi-NIC. The two NICs on baremetal are bonded and used for CNI POD network. The NICS are SRIOV compatible, but it is not configured, tuned, or enabled. For more information about network topology, see [General requirements](#).
8. What does connecting these switches upstream look like? Is there a prerequisite document?  
Network planning is here: configurable 4 x 100GB uplinks to your datacenter switch (see Network topologies and Network cable requirements) [Planning your installation](#).
9. How many switches are there in IBM Fusion HCI?  
There are 2 management switches and 2 high-speed switches. These switches are paired via MLAG to form a single logical switches.
10. What is the switch model for high-speed switch?  
The switch is NVIDIA switch. The switch model is SN3700V.
11. What is the switch model for management switch?  
The switch is NVIDIA switch. The switch model is SN2201.
12. Which ports are used for storage network?  
The 100 Gb ports are used for storage network.
13. Which ports are used for application network?  
The 25 Gb ports in Lenovo are used for application network.
14. Should the CIDR be unique across sites in Metro sync DR setup?  
Yes, it must be unique. For more information on CIDR, see [General Metro-DR prerequisites](#).

---

## Compute

This section answers questions related to compute/storage node management and upsizing.

1. If I add four compute nodes, is each node added one at a time or would all four pull in at the same time?  
Nodes can be purchased in any number of units, and you can add them in groups from the user interface.  
Node addition is a 3-step procedure:
  - a. Compute configuration that readies the hardware and configures XCC.
  - b. Add node to OpenShift® Container Platform.
  - c. Add node to IBM Storage Scale.All three steps can be done with multiple nodes at a time. However, in Step a, it is recommended to fill the nodes from lower RU to higher RU to maintain the center of gravity of the rack.
2. How long does each node take to add?  
It takes approximately 30 minutes to add one node into IBM Fusion HCI ecosystem. Contact IBM support to help with node addition. For more information about node upsize, see [Adding nodes to the cluster](#).  
Compute configuration steps take 20 minutes to configure. If in case the node needs firmware updates, it will take another 90 minutes to update the firmware and complete the configuration.
3. Where does the Service Support Representative (SSR) configure the XCC from?  
The SSR does not configure the XCC. Based on the Link-Local Address (LLA), the IBM Fusion HCI management software connects to the XCC using the default credentials. It also performs the remaining configurations.
4. After the SSR does the rack-and-stack all at once, can I add the nodes later? Does the SSR verify the correctness of the installation or connectivity?  
SSR assists you with *Step 1: Configure node* wherein new nodes are added to cluster for configuration. The configuration completion includes verification. After the completion, you can do the remaining two phases of adding to OpenShift Container Platform and IBM Storage Scale.
5. Would it be possible to add on drives to the nodes after they join the IBM Fusion HCI cluster? For example, there is a need for more storage over time.  
Yes, if you started with less than the full disk count, you can add more drives to the storage nodes. Drives need to be added across all the storage nodes. You can also add more storage nodes but they also have to match the number of existing disks.
6. Do the 64-core compute nodes provide double the number of cores and quadruple the amount of RAM compared to the original compute nodes that were released a year ago?  
IBM Fusion HCI supports 64-core servers (9155-C04, 9155-C05, and 9155-C14) that come with a base memory of 1024 GB RAM, upgradeable to 2048 GB RAM. It is an alternative to 32-core servers (9155-C00, 9155-C01, and 9155-C10), so you can get the most out of demanding applications that are ideal for businesses with high data processing needs.
7. Are there any interop concerns if compute nodes are not on the same firmware release?  
It is always recommended to have all the compute nodes at the same firmware level.
8. Is it possible to remove the expansion rack from the cluster or IBM Fusion HCI after adding an expansion rack to a base rack?  
There is no provision to remove the expansion after the nodes are added to the OpenShift Cluster. If such a need arises, then contact [IBM support](#).

---

## IBM Data Cataloging

This section answers questions that are related to IBM Data Cataloging in IBM Fusion HCI.

1. What is IBM Data Cataloging?  
IBM Data Cataloging is an IBM Fusion service that provides the capability to analyze the metadata of your data sources. It provides rapid automated data discovery and robust metadata capture, curation and enrichment.
2. How can I perform that data analysis and metadata capture?  
In first place, you need to create connections to the wanted data source. After that, you need to select the connection and run a scan over it. You see different statuses when running your scan (as scanning or indexing, for example). After it is terminated, you can see your data that is indexed in the IBM Data Cataloging database.
3. What other actions can you do with your data?  
You can do more complex management with your data by adding tag management or running specific policies.
4. What kind of data sources are supported?  
IBM Data Cataloging supports connection to several kinds of data sources, such as IBM Storage Scale, NFSv4, S3, Cloud Object Storage, IBM Storage Protect, and Server Message Block.
5. Can I use IBM Storage Scale as storage provider for IBM Data Cataloging?  
Yes, IBM Storage Scale can be used as storage provider to install IBM Data Cataloging. You need to have a Scale cluster to be set as remote storage provider, and use the Global Data Platform service available in IBM Fusion to connect your Fusion cluster with the remote Scale.
6. Can I use Red Hat® OpenShift® Data Foundation as a storage provider for IBM Data Cataloging?  
Yes, Red Hat OpenShift Data Foundation can be used as a storage provider for IBM Data Cataloging. You just need to install the IBM Data Cataloging service available in IBM Fusion. After it is installed, you can install IBM Data Cataloging. When installing IBM Data Cataloging as a storage class, be sure that you select the `ocs-storagecluster-cephfs` as storage class.
7. Can I use any storage class to install IBM Data Cataloging?  
IBM Data Cataloging is designed to be storage-agnostic, which means that you can use any storage provider. Only ensure that the storage class selected meets with the requirements that are specified in the [prerequisites](#) section.

---

## Content-Aware Storage (CAS)

This section answers questions that are related to Content-Aware Storage in IBM Fusion HCI.

1. What is Content-Aware Storage (CAS) in IBM Fusion Systems?  
CAS is a storage service that helps unlock the value of unstructured data through AI technologies. It enables the access to this value in new data-driven solutions, without the complexities of implementing and managing large AI solutions.
2. What is the primary objective of the CAS architecture?  
The CAS architecture is designed to enable seamless interaction between large language models (LLMs) and vast volumes of unstructured data, enhancing insight generation and suggestion capabilities.
3. How does CAS process unstructured data?  
CAS automatically processes files that are stored on a remote IBM Storage Scale cluster. It extracts parsed content and normalizes metadata, which is then stored along with vector embeddings in a managed vector database.
4. What type of storage platforms does CAS support?  
CAS supports IBM Storage Scale software-based clusters, and Storage Scale Server 3500 and 6000 platforms. It uses remote mounting by using the IBM Fusion Global Data Platform service.
5. How does CAS detect and ingest modified data?  
CAS uses IBM Storage Scale watch folders to detect changes (additions, deletions, or updates) in the file system. Only the modified content is ingested, optimizing performance and resource usage.
6. Can CAS ingest data from external S3 sources?  
Yes, CAS supports ingest processing of files that are stored in external S3 sources by using Active File Management (AFM). It automatically scans AFM-S3 filesets to identify data for ingestion.
7. What type of document processing services does CAS support?  
CAS integrates with IBM's Docling Multimodal services and NVIDIA NeMo Retriever Extraction microservices for document parsing and content extraction.
8. How does CAS perform search operations?  
CAS provides a search API that supports semantic, keyword, and hybrid search methods. It aggregates results and optionally uses NVIDIA's reranking for enhanced accuracy.
9. How do customer applications interact with CAS?  
Applications such as chatbots can send natural language queries to the CAS search API. CAS converts the query into a vector representation and performs a search against its vector database, returning optimized results.
10. What is the role of NVIDIA reranking service in CAS search?  
In the NVIDIA multimodal pipeline, CAS uses an aggregator component to refine the top 100 search results. These results are further optimized by using keyword-based and optional reranking before they are returned to the API.
11. Does CAS support Retrieval-Augmented Generation (RAG) workflows?  
Yes, CAS search results can be combined with user prompts and sent to an LLM to generate responses, enabling RAG-based client applications.
12. What types of data does CAS support for semantic extraction?  
CAS focuses on unstructured text data. It uses natural language processing (NLP) and AI technologies to extract semantic meaning from documents.
13. Which IBM Fusion version is required to install CAS?

CAS requires the newest IBM Fusion version. Installation must be performed by using the default **ibm-spectrum-fusion-ns** namespace. Custom namespaces are not supported for CAS installation.

14. What are the hardware requirements for CAS?

To run CAS on three OpenShift® compute nodes, the following resources are required:

- 3 × NVIDIA GPUs
- One other GPU for optional reranker service
- 166 vCPUs (83 physical cores)
- 1024 GB memory
- 1 TB IBM Storage Scale

15. What is the recommended IBM Storage Scale configuration?

The most common configuration includes:

- 48 NVMe drives
- 30 TB capacity (Enterprise Storage Server 6000)
- 4 CX-7 network adapters
- 1.5 TB memory

16. What software versions are required for IBM Storage Scale?

Ensure that IBM Storage Scale version 5.2.3.1 or later is installed. Remote file systems must be configured and available for CAS.

17. How do you verify the availability of a storage class for CAS?

In the OpenShift console, go to Storage > Storage Class and confirm that the storage class (for example, **ibm-spectrum-fusion**) created from the IBM Storage Scale remote file system is available and marked as default.

18. What are the prerequisites for enabling GPU workloads in OpenShift?

Install the following components:

- Red Hat® Node Feature Discovery Operator
- NVIDIA GPU Operator (compatible version)

19. What is NVIDIA NIM and why is it required?

NVIDIA NIM is a set of optimized microservices for deploying generative AI models. CAS uses NVIDIA NeMo Retriever for document processing. Provide NVIDIA NGC license keys to pull components from the NVIDIA NGC registry.

20. Is the NVIDIA text reranker mandatory?

No, the NVIDIA text reranker is optional and requires an additional supported GPU. It enhances search result accuracy by using advanced scoring.

21. What type of proxy URLs must be allowlisted for CAS installation?

Add the following URLs to your proxy allowlist:

- **apigee.googleapis.com**
- **apigeeconnect.googleapis.com**
- **binaryauthorization.googleapis.com** (optional)
- **gcr.io**
- **raw.githubusercontent.com**

22. How do you configure CAS to use the NVIDIA reranker service?

Add the following flags to the **cas-config** ConfigMap:

- **NVMM\_NEMO\_RANKER**
- **NVMM\_NEMO\_RANKER\_SERVICE**

23. What user permissions are required for remote file system setup?

The Global Data Platform user must be part of the **StorageAdmin** group to enable watch creation. Membership in **CsiAdmin** or **ContainerOperator** alone is insufficient.

24. How do you initiate the installation of CAS?

You can start the installation from the IBM Fusion user interface by navigating to the Services page and selecting the Content-Aware Storage tile.

25. What components are installed with CAS?

The CAS installation includes Kafka, the CAS operator, and CNPG (Cloud Native PostgreSQL).

26. What prerequisites must be met before installing CAS?

Ensure the following items:

- All prerequisites that are listed in the [Planning and prerequisites](#) section are fulfilled.
- A default storage class (for example, **ibm-spectrum-fusion**) is available and marked as default.
- All IBM Storage Scale projects and pods are running.

27. What can you do if the installation pre-check raises a warning?

Resolve the warning at the OpenShift level before proceeding. The pre-check ensures that the environment is ready for CAS deployment.

28. How can you monitor the CAS installation progress?

After initiating installation, a notification appears on the Services page. You can track progress under Services > Installed. After completed, the CAS service status shows as Healthy.

29. How do you verify that CAS is installed successfully?

You can verify installation from:

- **IBM Fusion UI:** Check service version and health status. Use the ellipsis menu to download logs and view documentation.
- **OpenShift Console:** Go to Home > Projects and search for a namespace that contains **ibm-cas**. Then check Operators > Installed Operators for CAS availability and service version.

30. How do you configure CAS after installation?  
Set up a Scale user to enable watch creation, configure domains and data sources, and map domains to data sources. For more information, see [Configuring Content-Aware Storage \(CAS\)](#).
31. Can you download installation logs?  
Yes. From the ellipsis menu in the CAS service window, you can download logs and view related documentation. A success notification confirms log collection.
32. What happens if the CAS service status is not healthy after installation?  
Check the logs for errors, verify that all prerequisites are met, and ensure that all required services (Kafka, CNPG, CAS operator) are running. Revalidate the environment and retry installation if needed.

---

## Remote support

This section answers questions that are related to remote support in IBM Fusion HCI.

- When would be a service node available for remote connection?  
The IBM support engineer able to connect to the service node only when the remote support connection is enabled by IBM Fusion administrator.
- Is IBM support engineer authorized to view and connect to a customer environment?  
Yes, access control is managed by the w3 Blue groups. So, the IBM support engineers who are part of the IBM Fusion remote support Blue group can view the available systems and connect to it.
- Is remote support connection process secured?  
Yes, after the remote support connection is enabled, it creates a secure channel between the service node and remote support connection servers. IBM support engineers can connect to servers using remote support controller application. In such a way, all the actions performed by the IBM Support engineer will be routed through the secured channel.
- Is there any second layer of authentication for remote support connection?  
Yes, second layer authentication exists. After SSR is connected to the customer network using remote connection, they need to log in to the service node via CLI and complete the challenge response authentication. The service node generates a challenge and that needs to obtain corresponding response from the another server which is managed using Blue groups. The challenge response validation is a combination of IBM support engineers ID and serial number of the service node.
- Can i terminate ongoing remote support session?  
Yes, as soon as the remote support connection is turned off from the customers end, then all active connections will be terminated.
- What customer data is used by the remote support session?  
The remote support session is used to support customer storage devices reporting active support issues. It collects personal information such as name, customer organization name and email address which is then be stored in the application database and log files. This information is used to allow IBM support personnel to identify the devices require support and the contact information of the user. Is responsible for the system should remote attempts at resolution should fail.  
The contact information is stored in the database and log files and is only accessible to IBM support personnel with a legitimate business need.
- Which ports are used for remote support session connectivity  
All remote support session communication happens through a secured **https** port 443.
- How are switch and node accessed by IBM support representative?  
After logging in to the service node, customer need to provide the credentials of the switch or node that the IBM support representative wants to log in
- How to log in to the OpenShift® Container Platform?  
Similar to nodes and switches, IBM support engineer needs to get the OpenShift Container Platform log in credentials from the customer.
- what level of access does a remote support engineer have on a service node?  
On service node, support engineer gets non **sudo** Linux user. The level of access for the OpenShift is in hands of the customer.
- what happens if a service engineer credentials get compromised?  
Only clients who have enabled a remote support session gets impacted. At maximum intruder will be able to login to the service node. Further accesses requires customer to explicitly share more credentials.
- How can I request audit logs for the previous IBM support remote sessions?  
Yet to get inputs.

---

## Backup and Restore

This section answers questions related to backup and restore feature of IBM Fusion.

- Can I install the Backup & restore as a day 2 operation?  
Yes, from the Services user interface page of IBM Fusion.
- How to verify whether Velero was installed and what gets backed up behind the scenes?  
Velero runs as a pod in the **ibm-backup-restore ns** namespace. If you are in the OpenShift® Container Platform console, look at the pods in the **ibm-backup-restore ns** namespace or run the following **oc** command:  

```
oc get pods -n ibm-backup-restore ns
```
- What are the supported backup storage locations?  
You can use IBM Fusion to create both local backups and copy data to an external, even offsite, S3 compliant object store.

4. Does IBM Fusion backs up application data consistently across all the Persistent Volumes (PV)? Which applications are supported in an application consistent backup mode within IBM Fusion?

Yes, it backs up application data consistently across all the PVs. There are two ways to achieve consistency. One is to quiesce the application. That can be done for virtually any application, but it does imply the willingness to accept some downtime. Another way is crash consistent backup. Not all applications may be able to restore themselves using a crash consistent backup. It depends on the application and how it is designed. For more information about data consistency support in IBM Fusion, see [Achieving data consistency for containers](#).

5. Will IBM Fusion data protection support ODF remote mount?

Yes, ODF supports a remote mount. For more information, see [Deploying Red Hat® OpenShift Data Foundation in external mode](#) in *Red Hat OpenShift Data Foundation* documentation.

---

## Support and serviceability

This section answers questions related to serviceability.

1. How can I display events from the command line?

The following OC command lists a summary of each IBM Fusion HCI event currently in the event queue:

```
oc get events --field-selector reason=ISFEventManager
```

The following OC command lists the contents of each IBM Fusion HCI event currently in the event queue:

```
oc get events --field-selector reason=ISFEventManager -o yaml
```

2. How long do events stay in the event queue?

- INFO events stay in the queue 3 hours just like regular OCP events
- WARNING events stay in the event queue 7 days
- CRITICAL events stay in the event queue 14 days

3. How can I delete events?

The events are deleted as per default rules specified in question 2 of this section.

4. Which events will open Call Home tickets?

The list of events that open Call Home tickets is in the configmap allow-tickets. This configmap also contains the list of logs that will be collected automatically when the ticket is opened.

```
lenovoxcc:
 allowed: true
 defaultlogs:
 loglevel01: isf-collection-sets:compute
```

This section indicates that when a ticket is opened for the lenovoxcc component, it will automatically generate the compute collection set in the isf-collection-sets configmap.

For more information about Call Home tickets, see *Providing service for server hardware* chapter of the [Service guide](#).

5. How can I mark a Call Home ticket as closed?

There is no automatic update of the ISF events from the Call Home server. After a ticket gets closed, you must go to the ISF Events UI, select the event that opened the ticket, and then in the events context menu, choose "Mark as fixed".

6. Is the IBM Call Home feature mandatory?

Call Home is an optional feature. Customers can disable the feature if they have concerns that prevent them from giving IBM Fusion HCI access to the internet.

7. What collection sets are defined?

There are 2 main config maps that define what logs will be collected. isf-logs is a list of individual requests

```
logcollector-dep:
 type: k8s-resource
 group: apps
 version: v1
 kind: deployments
 namespace: ibm-spectrum-fusion-ns
 name: logcollector
 description: Log Collector log
```

This entry in **isf-logs** indicates that when the **logcollector-dep** request is made, Log Collector will gather all information about the **logcollector** deployment in the **ibm-spectrum-fusion-ns** namespace (including its pods and pod logs). The second config map is **isf-collection-sets**, which can group requests from **isf-logs**, other entries in **isf-collection-sets**, and individual requests.

```
compute:
 type: collection-set
 collections:
 must-gather:
 type: list-entry
 source-list: isf-collection-sets
 list-entry: must-gather
 ibm-spectrum-fusion-namespace:
 type: list-entry
 source-list: isf-logs
 list-entry: ibm-spectrum-fusion-namespace
```

This entry in **isf-collection-sets** indicates that when the compute collection set is requested, Log Collector will gather the must-gather collection set (defined in **isf-collection-sets**) and **ibm-spectrum-fusion-namespace** (defined in **isf-logs**).

8. What files are included in each collection set shown on the Log Collector UI?

The specific contents will change as more functions are added to the product, but for now a good summary is in the "Collection Contents" section of this blog post: <https://community.ibm.com/community/user/storage/blogs/byron-williams/2021/10/28/viewing-and-examining-logs-in-ibm-spectrum-fusion?CommunityKey=e596ba82-cd57-4fae-8042-163e59279ff3>

9. How long should it take for logs to be collected from the UI?  
All collection sets must finish within 10 minutes, except for the "System health check", which takes 2 to 3 hours. Sometimes, it can take up to a maximum of 6 hours to run.
10. How long will log collections remain on the server?  
Logs will be automatically deleted after 24 hours. Logs can be intentionally deleted from the UI page.
11. If my log collection status is partial, does it indicate a log collection failure?  
Partial state of log collection does not mean that the process failed during log collection. It indicates the failure of at least one item in the collection, but no impact to other logs in the collection.
12. What filter options are available for the IBM Fusion HCI Events page?  
See the "Event UI" section of this blog post: <https://community.ibm.com/community/user/storage/blogs/byron-williams/2021/10/26/viewing-and-interpreting-events-in-ibm-spectrum-fu?CommunityKey=e596ba82-cd57-4fae-8042-163e59279ff3&tab=recentcommunityblogsdashboard>
13. What services are sold with IBM Fusion HCI?  
Today, support will be provided via IBM Expert Care contracts. Add on services will be developed later.
14. What is IBM Storage Expert Care?  
Storage Expert Care is a simplified method of selecting services and support for storage systems at the time of purchase. Storage Expert Care is designed to simplify and standardize the support approach on IBM Fusion HCI, FlashSystem 5200, 7200 & 9200 with pricing calculated as a percentage of the net system (HW & SW). Clients may choose the support level and duration, to align with their business needs.
15. Must clients purchase Storage Expert Care?  
A client has the option of 1) buying the hardware with the Warranty alone, or 2) choosing from Storage Expert Care Basic or Premium on IBM Fusion HCI. The standard Warranty is: 1 Year of Warranty services, 9x5xNBD, Parts-only, IOL Limited and 90-day SWMA. IBM does not offer separate HW or SW maintenance for these products except for Storage Expert Care.
16. Which Storage Expert Care tiers are available?  
Basic and Premium for IBM Fusion HCI was announced on 8/10/21. Support terms are available for 1, 2, 3, 4, and 5 years.
17. What are the components of the Premium tier?  
Premium tier includes IBM Software Maintenance (SWMA), Technical Account Manager (TAM), 30 Min. Enhanced Response (Sev1 and Sev2), and Predictive Support.
18. Is remote support available for upgrade?  
IBM offers twice a year updates and they can be applied remotely. However, the client must enable remote access to IBM Fusion HCI. Support is not yet available for IBMers to remotely access client systems on-demand and without client interaction.
19. Where to find more information about Remote support?  
For more information about remote support, see Chapter 16 of our internal service guide- [http://worklodepid1.fyre.ibm.com:8081/spectrum\\_fusion/9155\\_spectrum\\_fusion\\_24\\_service\\_book.pdf](http://worklodepid1.fyre.ibm.com:8081/spectrum_fusion/9155_spectrum_fusion_24_service_book.pdf).
20. Will clients be able to purchase Storage Expert Care only if they selected Warranty at initial purchase?  
Storage Expert Care will be available for separate purchase in TSS Systems (CONGA) in 1Q22. IBM highly recommends selling Storage Expert Care together with the system at time of purchase to ensure the client's systems are protected beyond the standard Warranty. Standard warranty provides 90-day SWMA and 9x5xNBD, Parts-only, IOL Limited.
21. What services are sold with IBM Fusion HCI?  
Today, support will be provided via IBM Expert Care contracts. Add on services will be developed later.
22. When will Renewals become available in TSS Systems (ISAT/CONGA)?  
Renewals will be available in TSS Systems (CONGA) in 1Q22. Prices will be based on the original services price and discount.
23. Will TSS be able to quote additional years than what is available in the configurator (years 1-5)?  
Yes, clients can request special bid pricing for years 6 and 7 of Storage Expert Care.
24. Which date will IBM consider as a start date for Expert Care after the order?  
Storage Expert Care starts at the same time as Warranty start. IBM has published rules for Warranty start for Customer Setup machines (CSU) and IBM Installed (IBI) machines.
25. What is Predictive Support?  
IBM provides predictive alerts for performance, space capacity, and other system problems. If there is a significant need for immediate action to be taken to avoid or prevent an incident, an action plan will be discussed with Client.
26. How will customers get support for IBM Fusion HCI? Will they need to manage multiple support contacts or will there be a single point of contact to receive support?  
There will be a single point of contact for support. The customer will open support tickets against IBM Fusion HCI to receive support for both hardware and software. In some instances, the customer may be required to open support tickets with Red Hat® to obtain support for OpenShift® Container Platform. IBM and Red Hat will collaborate to make the support experience as unified as possible.
27. Is Lab service team involved to help the client? If so, is it charged service or included in Expert Care premium?  
After IBM Fusion HCI is installed and ready for customer usage, customers can then begin creation and deployment of containers. Customers will also be able to monitor the system containers/workloads, system resource utilization and alerts. IBM Fusion HCI will support Premium Expert Care and will include the installation services.
28. Is Lab Services required to implement IBM Fusion HCI in the Customer location?  
IBM Fusion HCI does not require lab services. IBM Fusion HCI is physically installed into the customer datacenter by an IBM SSR. The SSR will inspect the hardware and connect power and network cables. The SSR will additionally perform necessary configuration steps to integrate the appliance in the customer's network.

---

## Security

This section answers questions related to security in IBM Fusion HCI.

- Does IBM Fusion HCI support Multi-factor authentication(MFA)?  
Yes, IBM Fusion HCI supports MFA with IBM Security Verify. For more information, see <https://www.redbooks.ibm.com/Redbooks.nsf/RedpieceAbstracts/redp5662.html?Open>.
- Does IBM Fusion HCI integrate with Identity providers?  
IBM Fusion HCI uses the authentication & authorization mechanisms provided by Red Hat® OpenShift® Container Platform. For more information, see [Red Hat OpenShift Container Platform documentation](#).
- How IBM Fusion HCI is a secure platform to deploy customer applications?  
IBM Fusion HCI is a secure platform to deploy your applications. For more information, see [Security in IBM Fusion](#).
- Can security patching be done against Red Hat repositories or must wait IBM validated patches?  
Red Hat OpenShift Container Platform patching will come directly from Red Hat image repositories. The patching or updates are applied in the usual OpenShift way. IBM Fusion HCI does not introduce or add any impediments on top of OpenShift. OpenShift admins can work with IIBM Fusion HCI.

---

## Role-based access control (RBAC)

RBAC related questions and answers for IBM Fusion HCI.

1. Users of which identity providers can be authenticated with IBM Fusion HCI?  
Any identity provider that can be configured with OpenShift® can be used to authenticate to IIBM Fusion HCI. Labs has tested only with `htpasswd` and LDAP.
2. Which OpenShift roles are authorized to access IBM Fusion HCI user interface?  
Any user with clusteradmin or view roles can access IBM Fusion HCI.
3. What happens when a user with an invalid role tries to login the user interface?  
The user will not get authenticated to IBM Fusion HCI.
4. Does the IBM Fusion HCI GUI have multi-factor authentication (MFA) for sign in?  
IBM Fusion HCI uses SSO through Red Hat® OpenShift Data Foundation authentication. Red Hat OpenShift Data Foundation can also be configured to enforce MFA. IBM Fusion HCI supports all of the OAuth authenticators that OpenShift supports.
5. How does SSO work between IBM Fusion HCI and other integrated applications?
  - Red Hat OpenShift:  
Yes, SSO is configured for IBM Fusion HCI and Red HatOpenShift. It works for Kubeadmin. For identity providers, there is a RFE raised against OpenShift team for enabling SSO login for identity providers.
  - IBM Storage Scale:  
Yes, SSO is configured for IBM Fusion HCI and IBM Storage Scale.
6. How does authorization and authentication work in OpenShift?  
For more information about authorization and authentication, see [https://docs.redhat.com/en/documentation/openshift\\_container\\_platform/4.21/html/authentication\\_and\\_authorization/understanding-authentication](https://docs.redhat.com/en/documentation/openshift_container_platform/4.21/html/authentication_and_authorization/understanding-authentication).
7. Who are the primary personas/roles to whom Fusion is targeted?  
There are two primary personas:
  - a. The team that is setting up and managing the OpenShift infrastructure.
  - b. The application team that works on developing and deploying applications to OpenShift.

---

## Accessibility features for IBM Fusion

Accessibility features assist users who have a disability, such as restricted mobility or limited vision, to use information technology content or products successfully.

---

### Accessibility features

IBM Fusion includes the following major accessibility features:

- Keyboard-only operation
- Operations that use a screen reader
- Interfaces that are commonly used by screen readers
- Keys that are discernible by touch but do not activate just by touching them
- Industry-standard devices for ports and connectors
- The attachment of alternative input and output devices

IBM® Documentation, and its related publications, are accessibility-enabled. The IBM Fusion online product documentation in IBM Documentation (IBM Docs) is enabled for accessibility. The accessibility features are described in [IBM Documentation](#) at [Accessibility](#).

IBM Fusion uses the recent W3C Standard, [WAI-ARIA 1.0](#) ([www.w3.org/TR/wai-aria/](http://www.w3.org/TR/wai-aria/)), to ensure compliance with [US Section 508](#) ([www.access-board.gov/guidelines-and-standards/communications-and-it/about-the-section-508-standards/section-508-standards](http://www.access-board.gov/guidelines-and-standards/communications-and-it/about-the-section-508-standards/section-508-standards)) and [Web Content Accessibility Guidelines \(WCAG\) 2.0](#) ([www.w3.org/TR/WCAG20/](http://www.w3.org/TR/WCAG20/)). To take advantage of accessibility features, use the recent release of your screen reader and the recent web browser that is supported by IBM Fusion.

## Keyboard navigation

---

This product uses standard Microsoft Windows navigation keys and the following keyboard shortcuts.

Table 1. Keyboard shortcuts in IBM Fusion

| Action                                       | Shortcut for Internet Explorer | Shortcut for Firefox       |
|----------------------------------------------|--------------------------------|----------------------------|
| Move to and around the navigation menu       | Tab and up/down/left/right     | Tab and up/down/left/right |
| Exit the navigation menu or close the dialog | Esc                            | Esc                        |

## Interface information

---

The IBM Fusion user interfaces do not have content that flashes 2 - 55 times per second.

The IBM Fusion web user interfaces rely on cascading stylesheets to render content properly and to provide a usable experience. The application provides an equivalent way for low-vision users to use a user's system display settings, including high-contrast mode. You can control font size by using the device or web browser settings.

The IBM Fusion web user interface includes WAI-ARIA navigational landmarks that you can use to quickly go to functional areas in the application.

## Exception and work-around

---

The following pages do not provide keyboard-only operation and a screen reader:

- Deploy Distribute UI
- Monitoring UI of deployment manage inlet
- Pattern builder UI

## Related accessibility information

---

In addition to standard IBM help desk and support websites, IBM established a TTY telephone service for use by deaf or hard of hearing customers to access sales and support services:

TTY service 800-IBM-3383 (800-426-3383) (within North America)

## IBM and accessibility

---

For more information about the commitment that IBM has to accessibility, see the [IBM Human Ability and Accessibility Center](#).

## IBM Fusion considerations for GDPR readiness

---

IBM Fusion considerations for GDPR readiness cover data classification, lifecycle management, and user account controls for protecting personal data.

## Notice

---

This document is intended to help you in your preparations for GDPR readiness. It provides information about features of IBM Fusion that you can configure, and aspects of the product's use, that you must consider to help your organization with GDPR readiness. This information is not an exhaustive list, due to the many ways that clients can choose and configure features, and the large variety of ways that the product can be used in itself and with third-party applications and systems.

**Clients are responsible for ensuring their own compliance with various laws and regulations, including the European Union General Data Protection Regulation. Clients are solely responsible for obtaining advice of competent legal counsel as to the identification and interpretation of any relevant laws and regulations that might affect the clients' business and any actions the clients might need to take to comply with such laws and regulations.**

**The products, services, and other capabilities that are described here are not suitable for all client situations and might have restricted availability. IBM does not provide legal, accounting, or auditing advice or represent or warrant that its services or products ensure that clients are in compliance with any law or regulation.**

## GDPR

---

General Data Protection Regulation (GDPR) is adopted by the European Union ("EU") and applies from 25 May 2018.

**Why is GDPR important?**

GDPR establishes a stronger data protection regulatory framework for processing of personal data of individuals. GDPR brings:

- New and enhanced rights for individuals
- Widened definition of personal data
- New obligations for processors
- Potential for significant financial penalties for non-compliance
- Compulsory data breach notification

**Read more about GDPR**

- [EU GDPR Information Portal](#)
- [ibm.com/GDPR website](http://ibm.com/GDPR)

## Product configuration – considerations for GDPR readiness

---

The following sections provide considerations for configuring IBM Fusion to help your organization with GDPR readiness.

### Data life cycle

---

**User accounts**

The IBM Fusion system administrator or security administrator creates a user by providing a user ID, email address, full name, and password to grant the user access to the system. This personal data is stored in the database on the client's hardware and can be fully managed by the system administrator or security administrator and edited by the user.

Information on managing users is documented in IBM Documentation (IBM Docs) for IBM Fusion.

**System logs**

Personal data, including IP addresses, session IDs, user IDs, web-page URLs, and cookie names, might exist within operating system and application logs. The data within these logs is captured automatically as part of the offering and is beyond the control of the client. The logs are retained on disk when sufficient space is available. As more space is needed, older log files are removed. The log files might not be modified or deleted by the client.

The purpose of the system log files is for use during troubleshooting situations. As needed, the log files might be collected and downloaded from the offering for transfer to IBM Support. The log files are not included in the system backups and are therefore constrained to the node unless involved while logs are collected for troubleshooting activity.

Information on system logs is documented in IBM Documentation for IBM Fusion.

**Personal data used for online contact with IBM**

IBM Fusion clients can submit online comments/feedback/requests to contact IBM about IBM Fusion subjects in various ways, primarily:

- Public comments area on pages in the IBM Fusion community.
- Public comments area on pages of IBM Fusion documentation in IBM Documentation.
- Public comments in the IBM Fusion space of dWAnswers
- Feedback forms in the IBM Fusion community

Typically, only the client name and email address are used, to enable personal replies for the subject of the contact, and the use of personal data conforms to the [IBM Online Privacy Statement](#).

### Data collection

---

For more information, see [Data life cycle](#).

### Data storage

---

Personal data is contained within backups of the offerings. Such personal data includes the personal data that is associated with user accounts that are stored within the database. The IBM Documentation provides information pertaining to creating the backups within the IBM Fusion offering.

The backup feature enables the client to transfer the backup archives to an external location. However, management of any external backup archives is beyond the scope of the offering. The client must implement a set of established 'best practices' for managing and securing such backup files. Information on managing backups is documented in IBM Documentation for IBM Fusion.

### Data access

---

General security measures (for example, disk encryption, physical and remote access) either directly implemented by the offering or suggested actions for the client's preparedness to deploy the offering are documented in IBM Documentation.

For user account data, read or write access can be given to specific users.

### Data processing

---

General security measures are directly implemented by the offering.

### Data deletion

---

Personal data associated with user accounts (as described in [Data life cycle](#)) can be fully managed by the system administrator or security administrator, including deletion. Users are not authorized to delete the personal data associated with the accounts. Information on managing users is documented in IBM Documentation for IBM Fusion.

Personal data, including IP addresses, session IDs, and user IDs, might exist within operating system and application logs. The log files might not be modified or deleted by the client. The logs are retained on disk when sufficient space is available. As more space is needed, older log files are removed. The log files might not be modified or deleted by the client. Information on system logs is documented in [IBM Documentation for IBM Fusion](#).

## Data monitoring

---

IBM Fusion does not monitor operating system or application logs, which are collected by the system and remain on the node as space permits. When needed for troubleshooting, logs might be downloaded from the console. Typically, such files remain local to the offering and cannot be managed or altered by users or administrators. Administrators might be able to review some log files (for troubleshooting purposes and without context of any personal data that is contained within) from the offering console. For more complex troubleshooting situations, such logs might be collected and downloaded from the offering for transmission to IBM Support.

## Responding to data subject rights

---

IBM Fusion meets the following data subject rights: right to access, modify, forgotten, and portability.

## Glossary

---

Glossary terms and definitions cover key storage, networking, Kubernetes, and AI concepts used across storage and data management products.

This glossary provides terms and definitions for the IBM Fusion software and products.

The following cross-references are used in this glossary:

- *See* refers you from a nonpreferred term to the preferred term or from an abbreviation to the spelled-out form.
- *See also* refers you to a related or contrasting term.

[A](#) [B](#) [C](#) [D](#) [E](#) [F](#) [G](#) [H](#) [I](#) [J](#) [K](#) [L](#) [M](#) [N](#) [O](#) [P](#) [Q](#) [R](#) [S](#) [T](#) [U](#) [V](#) [W](#) [X](#) [Y](#) [Z](#)

### A

---

ACL\_Checker container

A specialized CAS container responsible for performing access control list (ACL) checks during query execution to enforce file-level security.

AI platform

Infrastructure that is optimized for deploying and scaling AI workloads like watsonx.

air gap

A security measure that consists of a physical and wireless separation between an isolated computer or network and any computer or network that is directly or indirectly connected to the internet or other insecure network.

air-gapped environment

A network environment that does not have internet access.

appliance

A hardware device with integrated software that is dedicated to a specific task or set of business requirements.

application consistency

A backup state where all application data, including data in memory buffers, is written to disk before a snapshot. This ensures the application is in a fully consistent state for recovery.

application-consistent backup

A backup that ensures all parts of an application are saved in a usable state.

activation key

See [license key](#).

advisory lock

A type of lock that a process holds on a region of a file that signals any other process to not use or lock the region or an overlapping region. Other processes are not forced to comply.

AFM-S3 fileset

A logical grouping of files in an Active File Management (AFM) enabled IBM Storage Scale system that connects to an external S3 bucket for data ingestion.

allocatable extent limit

A maximum total capacity for the system. The allocatable extent limit is calculated from pool extent sizes.

allowlist

A list of items, such as usernames, email addresses, or IP addresses, that are granted access to a certain system or function. When an allowlist is used for access control, all entities are denied access, except for those that are included in the allowlist.

application key

See [license key](#).

array

An ordered collection, or group, of physical devices (disk drive modules) that are used to define logical volumes or devices. An array is a group of drives designated to be managed with a Redundant Array of Independent Disks (RAID).

asynchronous replication

A type of replication in which control is given back to the application as soon as the write operation is made to the source volume. Some time later, the write operation is made to the target volume. See also [synchronous replication](#).

audit log

An unalterable record of all commands or user interactions that are issued to the system.

authenticated user

A user who has logged in to the system with a valid account (user ID and password).

authentication

The mechanism by which a system determines what permissions a particular authenticated user has to access specific resources or actions. See also [authorization](#).

authorization

The mechanism by which a system determines what permissions a particular authenticated user has to access specific resources or actions. See also [authentication](#).

authorization code

An alphanumeric code generated for administrative functions, such as password resets or two-factor authentication bypass.

available capacity  
The amount of usable capacity that is not yet used in a system, pool, array, or MDisk.

## B

---

bare metal  
Pertaining to a computer or network independent of its operating system or hypervisor.

bare-metal Red Hat OpenShift  
Red Hat OpenShift installed directly on physical servers, without a hypervisor.

bearer token  
A security token used in the HTTP Authorization header to authenticate API requests. In Content-Aware Storage, it can be obtained from OpenShift® or an external identity provider (IDP).

block storage  
A unit of data storage on a device.

bucket  
A container for storing unstructured data.

business continuity  
The capability of a business to withstand outages and to operate mission-critical services normally and without interruption in accordance with predefined service-level agreements.

## C

---

cache  
Storage or memory that is used to improve access times to instructions, data, or both. For example, data that resides in cache memory is normally a copy of data that resides elsewhere in slower, less expensive storage, such as on a disk or on another network node.

cache eviction  
A process by which data associated with a file is removed from the cache system. The data is removed either by using a Least Recently Used (LRU) algorithm when configured General Parallel File System (GPFS) hard or soft quota limits are exceeded or by issuing a command. When referenced again in the cache system, the data that is associated with the file is retrieved from the home system.

caching file system  
A storage mechanism that temporarily stores frequently accessed data to improve performance and reduce latency in data retrieval.

caching I/O group  
The I/O group in the system that performs the cache function for a volume.

call home  
A communication link established between a product and a service provider. The product can use this link to place a call to a service provider when it requires service. With access to the machine, service personnel can perform service tasks, such as viewing error and problem logs or initiating trace and dump retrievals.

capacity  
The amount of data that can be contained on a storage system, or a measure of computing power that is delivered by a cluster.

capacity recycling  
The amount of provisioned capacity that can be recovered without causing stress or performance degradation. This capacity identifies the amount of resources that can be reclaimed and provisioned to other objects in an environment.

capacity threshold  
The percent of total usable physical capacity that used capacity must exceed before a notification is sent. See also [total usable physical capacity](#).

CasInstall custom resource  
A Kubernetes custom resource used to configure the installation parameters of the Content-Aware Storage (CAS) service, including enabling optional features like NVIDIA reranking.

CAS namespace  
A dedicated Kubernetes namespace where CAS components (such as pods, services, and configurations) are deployed. Deleting this namespace removes all CAS-related resources.

CAS operator  
A Kubernetes operator that automates the deployment, configuration, and lifecycle management of the CAS service within the OpenShift environment.

CAS query user  
A user that is authorized to perform search queries against CAS domains. This includes users from Red Hat® OpenShift or external identity providers, depending on the access control configuration.

certificate  
A digital document that binds a public key to the identity of the certificate owner, thereby enabling the certificate owner to be authenticated. A certificate is issued by a certificate authority and is digitally signed by that authority.

change volume  
A volume that is used in Global Mirror that holds earlier consistent revisions of data when changes are made.

child pool  
A user-defined capacity that is formed from capacity that is defined either in another pool or a system. See also [parent pool](#).

CIFS  
See [Common Internet File System](#).

CIM  
See [Common Information Model](#).

CIM object manager (CIMOM)  
The common conceptual framework for data management that receives, validates, and authenticates the CIM requests from the client application. It then directs the requests to the appropriate component or service provider.

CIMOM  
See [CIM object manager](#).

CKD  
See [count key data](#).

cold standby  
A recovery method in which backup servers with installed applications are in place and in a stopped state.

CLI  
See [command-line interface](#).

client

A software program or computer that requests services from a server. See also [host](#), [server](#).

cloud account  
An agreement with a cloud service provider to use storage or other services at that service provider. Access to the cloud account is granted by presenting valid credentials.

cluster  
A group of computers and other resources that operate together as a single system.

command-line interface (CLI)  
A computer interface in which the input and output are text based.

Common Information Model (CIM)  
An implementation-neutral, object-oriented schema for describing network management or systems management information. The Distributed Management Task Force (DMTF) develops and maintains CIM specifications.

Common Internet File System (CIFS)  
A protocol that manages shared, remote file access for applications to files, printers, serial ports, and so on over a TCP/IP network.

compression  
A function that removes repetitive characters, spaces, strings of characters, or binary data from the data being processed and replaces characters with control characters. Compression reduces the amount of storage space that is required for data.

compute  
Infrastructure or resources that serve as the basis for building apps in the cloud.

compute node  
An independent machine that contains one or more microprocessors, memory, storage, and network controllers and runs its own operating system and applications.

container  
A standard unit of software that packages code and dependencies so that applications runs quickly and reliably from one computer environment to another.

content-aware storage (CAS)  
An event driven storage service that uses natural language processing (NLP) and AI technologies to extract semantic meaning from unstructured data, such as text, charts, graphs, and images. It allows for more efficient data retrieval and integration with AI workflows, particularly in retrieval-augmented generation (RAG) processes.

control plane  
In Kubernetes, the part of a cluster that manages workloads and orchestrates containers.

control tower  
A centralized management configuration for multiple Fusion clusters.

concurrent copy  
A function of the DFSMSDss component that is used to back up any collection of data at a point in time with minimum down time for the database or application that uses the collection of data.

ConfigMap  
An API object that holds key-value pairs of configuration data that can be consumed in pods or used to store configuration data. Pods can consume ConfigMaps as environment variables, command-line arguments, or as configuration files in a volume.

copyback  
A process that moves data back to its expected or preferred location to maintain an array in a more efficient configuration after a failed drive is replaced.

crash consistency  
A backup state where only data that is already written to disk is captured. It is equivalent to the virtual machine experiencing a sudden crash before a backup.

crash-consistent backup  
A backup that captures data at a single point in time without stopping applications.

count-key-data record  
See [data record](#).

count key data (CKD)  

1. An architecture for a direct access storage device (DASD) device or logical device that specifies the access mechanisms for the logical data units on the device through a specific set of supported channel commands. Extensions to the CKD command set form the basis of Extended CKD.
2. A data recording format that uses self-defining record formats in which each record on a volume is represented by up to three fields: a count field identifying the record and specifying its format, an optional key field that can be used to identify the data area contents, and an optional data field that typically contains the user data. See also [data record](#), [storage architecture type](#).

CRU  
See [customer-replaceable unit](#).

customer-replaceable unit (CRU)  
An assembly or part that can be replaced in its entirety by a user when any one of its components fails.

custom resource  
A Kubernetes extension that is used to define and manage custom configurations for applications and services.

cylinder  
A unit of storage on a count-key-data (CKD) device with a fixed number of tracks.

## D

data cataloging  
A service that provides the capability to analyze the metadata of customer's data sources. It provides rapid automated data discovery and robust metadata capture, curation and enrichment.

data center  
In a virtualized environment, a container that holds hosts, clusters, networks, and data stores.

Data Foundation  
A service that provides a foundational data layer for applications to function and interact with data in a simplified, consistent, and scalable manner.

data mobility  
The ability to move data to and from locations such as cloud storage, data centers, remote sites, and mobile devices.

data resiliency  
An organization's ability to recover from data breaches and other types of data loss.

data consistency  
A characteristic of the data at the target site where dependent write order is maintained to guarantee the recoverability of applications.

data lakehouse

A unified data storage and processing architecture that combines the flexibility of a data lake with the structured querying and performance optimizations of a data warehouse, enabling scalable and efficient data analysis for AI and analytics applications.

data record

A basic unit of data recording format. See also [count key data](#), [fixed-block architecture](#).

data reduction

A set of techniques that can be used to reduce the amount of usable capacity that is required to store data. Examples of data reduction include data deduplication and compression. See also [data reduction savings](#), [stored capacity](#).

data reduction savings

The total amount of usable capacity that is saved in a system, pool, or volume through the application of an algorithm such as compression or deduplication on the written data. This saved capacity is the difference between the written capacity and the used capacity. See also [data reduction](#).

data source

A storage location that hosts documents for use in AI workflows. Also see [Creating a data source](#).

disaster recovery (DR)

The process of restoring a database, system, policies after a partial or complete site failure that was caused by a catastrophic event such as an earthquake or fire. Typically, disaster recovery requires a full backup at another location.

destage

To move data from cache to a nonvolatile storage medium.

directory server

A server that can add, delete, change, or search directory information on behalf of a client.

distributed RAID

An alternative RAID scheme where the number of drives that are used to store the array can be greater than the equivalent, typical RAID scheme. The same data stripes are distributed across a greater number of drives, which increases the opportunity for parallel I/O and hence improves overall array performance. See also [rebuild area](#).

DNS

See [Domain Name System](#).

domain

A configuration that collects, transforms, and transfers data from multiple sources to a destination, enabling efficient data flow for analysis and AI models. Also see [Creating a vector store and connecting with data source](#).

Domain Name System (DNS)

The distributed database system that maps domain names to IP addresses.

drive

A data storage device. A drive can be either a magnetic disk drive or a solid-state drive (SSD).

drive class

A combination of drive technology and speed, which uniquely defines a class of drives that have approximately the same performance characteristics.

drive technology

A category of a drive that pertains to the method and reliability of the data storage techniques being used on the drive. Possible values include enterprise (ENT) drive, nearline (NL) drive, or solid-state drive (SSD).

---

## E

edge cluster

A small, remote Red Hat OpenShift cluster usually managed from a central hub.

encryption

The protection of data by using mathematical models to convert the original data into an unintelligible form.

ECKD

See [extended count key data](#).

effective capacity

The amount of provisioned capacity that can be created in a system or pool without running out of usable capacity given the current data reduction savings being achieved. This capacity equals the usable capacity divided by the data reduction savings percentage.

enclosure

The metal structure in which various electronic components are mounted.

encryption deadlock

The inability to access encryption keys to decrypt data. See also [encryption recovery key](#).

encryption key label

The list of encryption key labels used by the storage system to identify keys that will be used on the key server.

encryption key manager

See [encryption key server](#).

encryption key server

An internal or external system that runs a key manager that receives and then serves existing encryption keys or certificates to a storage system.

encryption recovery key

An encryption key that allows a method to recover from an encryption deadlock situation where the normal encryption key servers are not available. See also [encryption deadlock](#).

enterprise

Pertaining to a type of data storage device that has higher error recovery limits, vibration tolerance, and end-to-end error detection than standard desktop hard drives.

extended count key data (ECKD)

An extension of the count-key-data (CKD) architecture. It includes additional commands that can be used to improve performance.

extent type

See [storage architecture type](#).

---

## F

failback

The restoration of an appliance to its initial configuration after detection and repair of a failed network or component.

failover

An automatic operation that switches to a redundant or standby system or node in the event of a software, hardware, or network interruption.

FAST API

A high-performance Python web framework used to build RESTful APIs. In Content-Aware Storage, it powers the query service pod that handles search requests from client applications.

FBA  
See [fixed-block architecture](#).

FC  
See [Fibre Channel](#).

FC-AL  
See [Fibre Channel Arbitrated Loop](#).

FCIP  
See [Fibre Channel over IP](#).

FCP  
See [Fibre Channel Protocol](#).

feature activation code  
See [license key](#).

Fibre Channel (FC)  
A technology for transmitting data between computer devices. It is especially suited for attaching computer servers to shared storage devices and for interconnecting storage controllers and drives. See also [zoning](#).

Fibre Channel Arbitrated Loop (FC-AL)  
An implementation of the Fibre Channel standards that uses a ring topology for the communication fabric; refer to American National Standards Institute (ANSI) INCITS 272-1996, (R2001). In this topology, two or more Fibre Channel end points are interconnected through a looped interface.

Fibre Channel connection (FICON)  
A Fibre Channel communication protocol designed for IBM mainframe computers and peripherals.

Fibre Channel extender  
A device used to extend a Fibre Channel link over a greater distance than is supported by the standard, usually a number of miles or kilometers. Devices must be deployed in pairs at each end of a link.

Fibre Channel over IP (FCIP)  
A network storage technology that combines the features of the Fibre Channel Protocol and the Internet Protocol (IP) to connect distributed SANs over large distances.

Fibre Channel Protocol (FCP)  
The serial SCSI command protocol used on Fibre Channel networks. See also [open system](#).

FICON  
See [Fibre Channel connection](#).

field-replaceable unit (FRU)  
An assembly that is replaced in its entirety when any one of its components fails.

file module  
A component that provides file systems to network users. A file module must be provided with storage for the file systems.

fileset  
A logical subdivision of a file system used to organize and manage data independently within a larger storage environment.

file system consistency  
A backup state where the file system is frozen, and all pending writes are flushed to disk before the snapshot. This ensures that the file system structure is intact, but any data still in application buffers is not included.

file system (FS)  
A collection of files and certain attributes associated with those files.

file system storage  
Data storage that is organized into files and directories.

fixed-block architecture (FBA)  
An architecture for a virtual device that specifies the format of and access mechanisms for the virtual data units on the device. The virtual data unit is a block. All blocks on the device are the same size (fixed size). The system can access them independently. See also [data record](#), [storage architecture type](#).

fixed block  
See [fixed-block architecture](#).

FlashCopy  
Pertaining to a point-in-time copy where a virtual copy of a volume is created. The target volume maintains the contents of the volume at the point in time when the copy was established. Any subsequent write operations to the source volume are not reflected on the target volume.

flash drive  
A data storage device, which is typically removable and rewritable, that uses solid-state memory to store persistent data. See also [flash module](#).

flash module  
A modular hardware unit containing flash memory, one or more flash controllers, and associated electronics. See also [flash drive](#).

flush-through mode  
See [write-through mode](#).

form factor  
The industry-standard physical dimensions of a storage system drive enclosure. Possible values include “3.5 inch”, “2.5 inch”, and “1.8 inch.”

frame  
The hardware support structure, covers, and all electrical parts mounted therein that are packaged as one entity for shipping.

FRU  
See [field-replaceable unit](#).

FS  
See [file system](#).

full restore operation  
A copy operation where a local volume is created by reading an entire a volume snapshot from cloud storage.

full snapshot  
A type of volume snapshot that contains all the volume data. When a full snapshot is created, an entire copy of the volume data is transmitted to the cloud.

## G

gitOps  
An operational framework that automates the process of provisioning infrastructure, especially modern cloud infrastructure, by using configuration files stored as code.

Global Data Platform  
A clustered file system that provides concurrent access to a single file system or set of file systems from multiple nodes.

graphics processing unit (GPU)

A specialized processor designed to rapidly manipulate and alter memory to accelerate the creation of images in a frame buffer intended for output to a display. GPUs are heavily utilized in machine learning due to their parallel processing capabilities.

General Parallel File System (GPFS)

A high-performance shared-disk file system that can provide data access from nodes in a clustered system environment.

Global Mirror

A method of an asynchronous replication that maintains data consistency across multiple volumes within or across multiple systems. Global Mirror is generally used where distances between the source site and target site cause increased latency beyond what the application can accept.

GPFS

See [General Parallel File System](#).

GPU resource indicator

A Kubernetes resource identifier (for example, `nvidia.com/gpu`, `nvidia.com/mig-7g.80gb`) used to specify the type and configuration of GPU resources allocated to a container or service.

Granite Embedding model

One of a collection of embedding models that generate high-quality text embeddings and a reranker model to improve the relevance and quality of search results or recommendations.

group id (GID)

In the UNIX or Linux operating system, an integer that uniquely identifies each group of users to the operating system.

## H

---

high availability (HA)

The ability of a service or workload to withstand failures and continue providing processing capability according to some predefined service level.

hub cluster

The central controller running in a cluster. The hub cluster aggregates information from multiple clusters using an asynchronous work request model.

hybrid cloud

A cloud computing environment that consists of multiple public and private resources.

hyperconverged infrastructure (HCI)

A software-defined approach to data center infrastructure that uses virtualization to combine compute, networking and storage components into a single system managed by a hypervisor software layer.

hypervisor

A service that creates and runs virtual machines (VMs), providing them compute and storage resources. The hypervisor treats on-prem resources such as CPU, memory, and storage as a pool that can be easily reallocated between existing guests or to new virtual machines.

Hardware Management Console (HMC)

A system that controls managed systems, including the management of logical partitions and use of Capacity Upgrade on Demand. Using service applications, the HMC communicates with managed systems to detect and consolidate information, which can then be sent for analysis.

HMC

See [Hardware Management Console](#).

host

A physical or virtual computer system that hosts computer applications, with the host and the applications using storage. See also [client](#), [host](#), [server](#).

host cluster

A configured set of physical or virtual hosts that share one or more storage volumes to increase scalability or availability of computer applications.

host interface card

See [interface card](#).

host object

A logical representation of a host within a storage system that is used to represent the host for configuration tasks.

hot-spare

Pertaining to redundant hardware (such as an adapter, a disk, a drive, or a server) that is installed and available in the event of a hardware failure.

hybrid search

A search approach that combines semantic and keyword search methods to improve accuracy and relevance.

HyperSwap

Pertaining to a function that provides continuous, transparent availability against storage errors and site failures, and is based on synchronous replication.

## I

---

identity provider (IDP)

A service that creates, maintains, and manages identity information and is the source of identities that are communicated to service providers in federated relationships.

IDP token

A secure token issued by an external identity provider (IDP) used to authenticate users when accessing CAS services, including semantic search APIs.

I/O

See [input/output](#).

I/O enclosure

A hardware unit in a storage system where data is transferred into and out of the system.

incremental restore operation

A copy operation where a local volume is modified to match a volume snapshot by reading from cloud storage only the parts of the volume snapshot that differ from the local volume.

incremental snapshot

A type of volume snapshot where the changes to a local volume relative to the volume's previous snapshot are stored on cloud storage.

input/output (I/O)

Pertaining to a device, process, channel, or communication path involved in data input, data output, or both.

infrastructure as code (IaC)

Managing and provisioning of infrastructure through code instead of through manual processes.

interface card

An optional part of a node canister that provides the system with additional host and storage connectivity options.

interface node

A node that connects a system to an Internet Protocol (IP) network for file-serving capabilities by using service protocols.

Internet Small Computer System Interface (iSCSI)

An IP-based standard for linking data storage devices over a network and transferring data by carrying SCSI commands over IP networks. See also [Small Computer System Interface](#).

iSCSI

See [Internet Small Computer System Interface](#).

## J

---

junction path

A mount point in IBM Storage Scale that connects a fileset to the file system hierarchy, allowing access to stored data.

## K

---

Kubernetes

An open-source orchestration tool for containers.

Kafka

An open-source distributed event streaming platform used for building real-time data pipelines and streaming applications. In Content-Aware Storage, Kafka is used to manage messaging and data flow between components.

Kafka broker

A server within a Kafka cluster that stores and distributes messages to consumers. It handles incoming data streams and ensures reliable delivery.

Kafka topic

A category or feed name used in Apache Kafka to which records are sent and from which consumers read.

key server

A server that negotiates the values that determine the characteristics of a dynamic virtual private network (VPN) connection that is established between two endpoints.

keyword search

A traditional search method that retrieves results based on exact word or phrase matches.

## L

---

large language model (LLM)

A language model with many parameters, trained on a large quantity of text.

licensed capacity

The amount of capacity on a storage system that a user is entitled to configure.

license key

An alphanumeric code that activates a licensed function on a product.

license key file

A file that contains one or more licensed keys.

load balancer

Software or hardware that distributes workload across a set of servers to ensure that servers are not overloaded.

## M

---

machine signature

A string of characters that identifies a system. A machine signature might be required to obtain a license key.

management node

A node that is used for configuring, administering, and monitoring a system.

maximum replication delay

The number of seconds that Metro Mirror or Global Mirror replication can delay a write operation to a volume.

Metro Global Mirror

A cascaded solution where Metro Mirror synchronously copies data to the target site. This Metro Mirror target is the source volume for Global Mirror that asynchronously copies data to a third site. This solution has the potential to provide a disaster recovery with no data loss at Global Mirror distances when the intermediate site does not participate in the disaster that occurs at the production site.

Metro Mirror

A method of synchronous replication that maintains data consistency across multiple volumes within the system. Metro Mirror is generally used when the write latency caused by the distance between the source site and target site is acceptable to application performance.

## N

---

natural language processing (NLP)

A field of artificial intelligence and linguistics that studies the problems inherent in the processing and manipulation of natural language, with an aim to increase the ability of computers to understand human languages.

nearline

Pertaining to a type of storage in which data is available in a short amount of time, but not instantly.

nearline SAS drive

A drive that combines the high capacity data storage technology of a Serial Advanced Technology Attachment (SATA) drive with the benefits of a serial-attached SCSI (SAS) interface for improved connectivity.

node

A single processing unit within a system. For redundancy, multiple nodes are typically deployed to make up a system.

NVIDIA NIM pipeline

A pipeline configuration that uses NVIDIA's NeMo Inference Microservices (NIM) to process and extract insights from data, typically integrated with IBM Storage Scale for AI workloads.

## O

---

object storage

A method of storing data, typically used in the cloud, in which data is stored as discrete units, or objects, in a storage pool or repository that does not use a file hierarchy but that stores all objects at the same level.

on-premises

Pertaining to software that is installed and run on the local computers of a user or organization.

open system

A system that complies with industry-defined interoperability standards. An open system can be connected to other systems complying with the same standards.

See also [Small Computer System Interface](#), [Fibre Channel Protocol](#).

order confirmation code

See [authorization code](#).

overhead capacity

An amount of usable capacity that is occupied by metadata in a system or pool and other data that is used for system operations.

overprovisioned ratio

The ratio of provisioned capacity to usable capacity in a system or pool.

overprovisioning

The result of creating more provisioned capacity in a storage system or pool than there is usable capacity. Overprovisioning occurs when thin provisioning or data reduction techniques ensure that the used capacity of the provisioned volumes is less than their provisioned capacity.

## P

---

platform engineering

Creating and managing platforms with standardized tools, automated workflows and consistent environments to boost developer productivity.

policy engine

A tool that enforces rules for backup, storage, and compliance.

Portable Operating System Interface (POSIX)

An IEEE family of standards designed to provide portability between operating systems that are based on UNIX. POSIX describes a wide spectrum of operating-system components ranging from C language and shell interfaces to system administration.

parent pool

A storage pool that receives its capacity from MDisk and has, or will have, some of its capacity allocated to child pools. See also [child pool](#).

performance group

A collection of volumes that is assigned the same performance characteristics. See also [performance policy](#).

performance policy

A policy that specifies performance characteristics, for example quality of service (QoS). See also [performance group](#).

PFC

See [priority flow control](#).

pod

A group of containers that are running on a Kubernetes cluster. A pod is a runnable unit of work, which can be either a stand-alone application or a microservice.

pool

See [storage pool](#).

pool pair

Two storage pools that are required to balance workload. Each storage pool is controlled by a separate node.

port

The physical entity within a host, system, or storage system that performs the data communication (transmitting and receiving) over the Fibre Channel.

priority flow control (PFC)

A link-level flow control mechanism, IEEE standard 802.1Qbb. PFC operates on individual priorities. Instead of pausing all traffic on a link, PFC is used to selectively pause traffic according to its class.

projected capacity

The estimated volume capacity that is available for volume creation, given the current average performance of any data compression, excluding thin-provisioning savings. See also [thin-provisioning savings](#).

protocol

A set of rules controlling the communication and transfer of data between two or more devices or systems in a communication network.

provisioned capacity

The total capacity of all volumes and volume copies in a system or pool.

persistent volume (PV)

Networked storage in a cluster that is provisioned by an administrator.

persistent volume claim (PVC)

A request for cluster storage. It allows a pod to use a persistent volume (PV) by claiming a portion of it.

## Q

---

query service pod

A Kubernetes pod within the CAS namespace that exposes the [search API](#) through [FAST API](#), enabling client applications to query the vector database.

## R

---

recipe

A set of specifications for creating a custom workflow for the backup and restore process.

redundancy

The use of backup components to ensure system availability during failures.

replication

The process of maintaining a defined set of data in more than one location. Replication involves copying designated changes for one location (a source) to another (a target) and synchronizing the data in both locations.

restore

To return to an original value or image, for example, to restore data to main storage from auxiliary storage.

rack

A free-standing structure that can hold multiple servers, storage systems, chassis, switches, and other devices.

RAID

See [Redundant Array of Independent Disks](#).

**RAID 0**  
A data striping technique, which is commonly called RAID Level 0 or RAID 0 because of its similarity to common, RAID, data-mapping techniques. It includes no data protection, however, so, strictly speaking, the appellation RAID is a misnomer. RAID 0 is also known as data striping.

**RAID 1**  
A form of storage array in which two or more identical copies of data are maintained on separate media.

**RAID 10**  
A collection of two or more physical drives that present to the host an image of one or more drives. In the event of a physical device failure, the data can be read or regenerated from the other drives in the RAID due to data redundancy.

**RAID 5**  
A form of parity RAID in which the disks operate independently, the data stripe size is no smaller than the exported block size, and parity check data is distributed across the array's disks.

**RAID 6**  
A form of RAID that can continue to process read and write requests to all of an array's virtual disks in the presence of two concurrent disk failures.

**RAID level**  
The level of protection provided by the specific techniques of striping, mirroring, or parity used by a Redundant Array of Independent Disks (RAID).

**RAID type**  
See [RAID level](#).

**raw capacity**  
The reported capacity of the drives in the system before formatting or RAID (Redundant Array of Independent Disks) is applied.

**rebuild area**  
Reserved capacity that is distributed across all drives in a redundant array of drives. If a drive in the array fails, the lost array data is systematically restored into the reserved capacity, returning redundancy to the array. The duration of the restoration process is minimized because all drive members simultaneously participate in restoring the data. See also [distributed RAID](#).

**reclaimable capacity**  
The amount of provisioned capacity that can be recovered without causing stress or performance degradation. This capacity identifies the amount of resources that can be reclaimed and provisioned to other objects in an environment.

**reclaimed capacity**  
See [reclaimable capacity](#).

**recovery key**  
See [encryption recovery key](#).

**Redundant Array of Independent Disks (RAID)**  
A collection of two or more physical disk drives that present to the host an image of one or more logical disk drives. In the event of a physical device failure, the data can be read or regenerated from the other disk drives in the array due to data redundancy.

**repo**  
See [repository](#).

**repository (repo)**  
A persistent storage area for data and other application resources.

**reranker**  
A specialized AI model that is designed to improve the relevance and accuracy of search and retrieval results, especially in retrieval-augmented generation (RAG) pipelines.

**reranking**  
A post-processing step in search workflows that reorders retrieved results based on additional criteria or AI models to improve relevance.

**reserved capacity**  
The amount of used capacity that is made up of capacity reserved for system use. See also [total usable physical capacity](#).

**retrieval augmented generation (RAG)**  
A technique in which a large language model is augmented with knowledge from external sources to generate text. In the retrieval step, relevant documents from an external source are identified from the user's query. In the generation step, portions of those documents are included in the LLM prompt to generate a response grounded in the retrieved documents.

## S

**self-service infrastructure**  
A platform that enables developers to provision and deprovision resources without IT intervention.

**snapshot**  
An image backup type that consists of a point-in-time view of a volume.

**spoke cluster**  
A managed Red Hat OpenShift cluster connected to a central hub.

**storage area network (SAN)**  
A dedicated storage network tailored to a specific environment, combining servers, systems, storage products, networking products, software, and services.

**stretch cluster**  
A cluster that has servers in geographically separated data centers to provide storage infrastructure with disaster recovery capabilities.

**SCIM client**  
A configuration block in the **IdentityProvider** custom resource that enables CAS to retrieve user and group information from the IDP using the SCIM (System for Cross-domain Identity Management) protocol.

**SCSI**  
See [Small Computer System Interface](#).

**SCSI-FCP**  
See [SCSI Fibre Channel Protocol](#).

**SCSI device**  
A product, such as a drive or adapter, connected to a host through an I/O interface using the Small Computer System Interface (SCSI) protocol. A SCSI device is either an initiator, target, or both. See also [Small Computer System Interface](#).

**SCSI Fibre Channel Protocol (SCSI-FCP)**  
A standard that defines the protocol used to transfer Small Computer System Interface (SCSI) commands over the transport physical layer of the Fibre-Channel interface. This standard is published by ANSI as X3.269-1996.

**SCSI initiator**  
The system component that initiates communications with attached targets.

**SCSI target**  
A device that acts as a subordinate to a SCSI initiator and consists of a set of one or more logical units (LUs), each with an assigned logical unit number (LUN). The LUs on the SCSI target are typically I/O devices.

search API

An application programming interface that enables external applications to perform semantic, keyword, or hybrid searches on ingested content.

security context constraint (SCC)

A Kubernetes policy object used to define permissions and capabilities for pods, such as allowing containers to run with elevated privileges like SETUID and SETGID.

semantic search

A search technique that uses the meaning of words and phrases rather than exact keyword matches to retrieve relevant results.

server

A computer program or a device that provides functions for other programs or devices, called clients. See also [client](#), [host](#).

Server Message Block (SMB)

A protocol that manages requests and responses in a client/server environment so that clients on a network can share files, directories, and devices.

Small Computer System Interface (SCSI)

An ANSI-standard electronic interface that allows personal computers to communicate with peripheral hardware, such as disk drives, tape drives, CD-ROM drives, printers, and scanners faster and more flexibly than previous interfaces. See also [open system](#), [Internet Small Computer System Interface](#), [SCSI device](#).

SMB

See [Server Message Block](#).

solid-state drive (SSD)

1. A storage device that contains nonvolatile flash memory. A solid-state drive (SSD) has no moving mechanical components.

space

See [capacity](#).

space efficient

See [thin provisioning](#).

spare drive

A drive reserved in an array for rebuilding a failed drive in a RAID. Should a drive fail in a RAID, a spare drive from within that device adapter (DA) pair will be selected to rebuild it.

SSD

See [solid-state drive](#).

standard-provisioned volume

A volume that completely uses storage at creation.

standard provisioning

The ability to completely use a volume's capacity for that specific volume.

storage architecture type (storage type)

The type of storage architecture, either count key data (CKD) or fixed block (FB), for which an array, pool, or volume is provisioned. See also [count key data](#), [fixed-block architecture](#).

storage class

In Kubernetes, a definition of a type of storage.

storage enclosure

A specialized chassis that is designed to hold and power drives while providing a mechanism to allow them to communicate to one or more separate computers.

storage node

A component of a storage system that provides internal storage or a connection to one or more external storage systems.

storage pod

A subcomponent of a network-attached storage (NAS) system that consists of two or more storage nodes and one or more supported storage systems.

storage pool (pool)

A collection of storage that identifies an underlying set of resources. These resources provide the capacity and management requirements for a volume or set of volumes.

storage system

A system that provides persistent storage within a network. A storage system can include facilities for host attachment, user role authentication, a command-line interface (CLI), a graphical user interface (GUI), and storage devices that most often include Redundant Array of Independent Disks (RAID) controllers. It might also include agents for enabling third-party management software to monitor or manage the storage devices.

storage type

See [storage architecture type](#).

stored capacity

The amount of capacity that is used to store data that is written by a host after data reduction. See also [data reduction](#), [total usable physical capacity](#).

support assistance

A function that is used to provide support personnel access to the system to complete troubleshooting and maintenance tasks.

synchronous replication

A type of replication in which the application write operation is made to both the source volume and target volume before control is given back to the application.

See also [asynchronous replication](#).

syslog

A standard for transmitting and storing log messages from many sources to a centralized location to enhance system management.

## T

---

tenant

An entity that accesses services through a subscription that is associated with an account or namespace.

turnkey appliance

A fully integrated, ready-to-run hardware-and-software system delivered as a single, factory-configured package.

thin-provisioned volume

A volume that allocates storage when data is written to it.

thin-provisioning savings

The total amount of usable capacity that is saved in a system, pool, or volume by consuming usable capacity only when needed as a result of write operations. The capacity that is saved is the difference between the provisioned capacity minus the written capacity. See also [volume capacity](#), [projected capacity](#), [written capacity](#).

thin provisioning

The ability to defer capacity allocation on a storage resource until data is actually written to it.

time slicing

A GPU resource management technique that allows multiple workloads to share a GPU by allocating time slots for execution, improving utilization.

TLS secret

A Kubernetes secret that stores TLS certificates and keys used to secure communication with external services, such as S3 buckets.

tokenizer  
A text segmentation program that scans text and determines if and when a series of characters can be recognized as a token.

total capacity savings  
The total amount of usable capacity that is saved in a system, pool, or volume through thin provisioning and data reduction techniques. This saved capacity is the difference between the used usable capacity and the provisioned capacity.

total usable physical capacity  
The amount of physical configured storage space that is available for stored capacity or reserved capacity. This capacity can consist of both internal storage through arrays and external storage through MDisks. See also [reserved capacity](#), [capacity threshold](#), [stored capacity](#).

transparent cloud tiering  
The functions that use cloud storage as an extension of on-premises storage.

trial license  
A temporary entitlement to use a licensed function.

TSE for FlashCopy  
A thin-provisioning method in which storage space is allocated from a TSE repository on an as needed basis. See also [TSE repository](#).

TSE repository  
The amount of capacity in a storage pool reserved for volumes that use a thin-provisioning method of TSE for FlashCopy. See also [TSE for FlashCopy](#).

## U

---

unified storage  
A single platform that supports block, file, and object storage.

unmapped volume capacity  
The amount of volume capacity that is not mapped to a host. See also [volume capacity](#).

update

1. Software maintenance such as a manufacturing refresh, refresh pack, or fix pack that changes the modification level of a product.
2. To modify a file or data set with current information.
3. To apply fixes to a system.

upgrade

1. Any hardware or software change to a later release, or any hardware addition or software addition.
2. To install a new version or release of a product to replace an earlier version or release of the same product.

usable capacity  
The amount of capacity that is provided for storing data on a system, pool, array, or MDisk after formatting and RAID techniques are applied.

used capacity  
The amount of usable capacity that is taken up by data or overhead capacity in a system, pool, array, or MDisk after data reduction techniques have been applied.

user role  
An identifier that is assigned to a user that defines the set of permissions that are granted to that user.

## V

---

virtual appliance  
A virtual machine image with a specific application purpose that is deployed to virtualization platforms.

virtual local area network (VLAN)  
A logical association of switch ports based upon a set of rules or criteria, such as Medium Access Control (MAC) addresses, protocols, network address, or multicast address. This concept permits the LAN to be segmented again without requiring physical rearrangement.

virtualization  
In the storage industry, a concept in which a pool of storage is created that contains several storage systems. Storage systems from various vendors can be used. The pool can be split into volumes that are visible to the host systems that use them.

vector database  
A specialized database within the CAS namespace that stores vector embeddings generated from ingested documents, enabling semantic search and retrieval.

vector embedding  
A numerical representation of text data that is used to capture semantic meaning, enabling similarity-based search and retrieval in vector databases.

virtual capacity  
See [provisioned capacity](#).

virtualized capacity  
The amount of capacity that is contributed to a storage pool by a given provisioning group.

virtual machine (VM)  
An emulation of a particular computer system. Virtual machines operate based on the computer architecture and functions of a real or hypothetical computer. Their implementations might involve specialized hardware, software, or a combination of both.

VM  
See [virtual machine](#).

volume  
A fixed amount of physical or virtual storage on a data storage medium.

volume access set  
The set of I/O groups that allows host access to a volume. This set can optionally include the caching I/O group.

volume capacity  
The total capacity for all volumes in a system or storage pool. Volume capacity is defined by the client when a volume is created and surfaced to the host. See also [thin-provisioning savings](#), [unmapped volume capacity](#).

volume snapshot  
A collection of objects on a cloud storage account that represents the data of a volume at a particular time.

## W

---

watch folder

A designated directory in a file system that is monitored for changes, triggering automated processing workflows when new or modified files are detected.

worldwide ID (WWID)  
A name identifier that is unique worldwide and that is represented by a 64-bit value that includes the IEEE-assigned organizationally unique identifier (OUI).

worldwide name (WWN)  
A 64-bit, unsigned name identifier that is unique.

worldwide node name (WWNN)  
A unique 64-bit identifier for a host containing a Fibre Channel port. See also [worldwide port name](#).

worldwide port name (WWPN)  
A unique 64-bit identifier associated with a Fibre Channel adapter port. The WWPN is assigned in an implementation-independent and protocol-independent manner. See also [worldwide node name](#).

write-through mode  
A process in which data is written to a storage device at the same time as the data is cached.

written capacity  
The amount of usable capacity that would have been used to store written data in a system or pool if data reduction was not applied. See also [thin-provisioning savings](#).

written capacity limit  
The largest amount of capacity that can be written to a drive, array, or MDisk. The limit can be reached even when usable capacity is still available.

WWID  
See [worldwide ID](#).

WWN  
See [worldwide name](#).

WWNN  
See [worldwide node name](#).

WWPN  
See [worldwide port name](#).

## X

---

X.509 certificate  
A certificate that contains information that is defined by the X.509 standard.

## Y

---

YAML  
A human-readable data-serialization language. It is commonly used for configuration files and in applications where data is being stored or transmitted.

## Z

---

z Global Mirror  
A method of an asynchronous replication function that maintains data consistency across multiple volumes that are attached to a z/OS system. Time-based data consistency is maintained through the Data Facility Storage Management Subsystem (DFSMS) system data mover (SDM) component.

zoning  
The grouping of multiple ports to form a virtual, private, storage network. Ports that are members of a zone can communicate with each other, but are isolated from ports in other zones. See also [Fibre Channel](#).

## Terms and conditions for product documentation

---

Permissions for the use of these publications are granted subject to the following terms and conditions.

### Applicability

These terms and conditions are in addition to any terms of use for the IBM website.

### Personal use

You may reproduce these publications for your personal, noncommercial use provided that all proprietary notices are preserved. You may not distribute, display or make derivative work of these publications, or any portion thereof, without the express consent of IBM.

### Commercial use

You may reproduce, distribute and display these publications solely within your enterprise provided that all proprietary notices are preserved. You may not make derivative works of these publications, or reproduce, distribute or display these publications or any portion thereof outside your enterprise, without the express consent of IBM.

## Rights

Except as expressly granted in this permission, no other permissions, licenses or rights are granted, either express or implied, to the publications or any information, data, software or other intellectual property contained therein.

IBM reserves the right to withdraw the permissions granted herein whenever, in its discretion, the use of the publications is detrimental to its interest or as determined by IBM, the above instructions are not being properly followed.

You may not download, export or re-export this information except in full compliance with all applicable laws and regulations, including all United States export laws and regulations.

IBM MAKES NO GUARANTEE ABOUT THE CONTENT OF THESE PUBLICATIONS. THE PUBLICATIONS ARE PROVIDED "AS-IS" AND WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING BUT NOT LIMITED TO IMPLIED WARRANTIES OF MERCHANTABILITY, NON-INFRINGEMENT, AND FITNESS FOR A PARTICULAR PURPOSE.

## IBM Online Privacy Statement

---

IBM Software products, including software as a service solutions, ("Software Offerings") may use cookies or other technologies to collect product usage information, to help improve the end user experience, to tailor interactions with the end user, or for other purposes. In many cases no personally identifiable information is collected by the Software Offerings. Some of our Software Offerings can help enable you to collect personally identifiable information. If this Software Offering uses cookies to collect personally identifiable information, specific information about this offering's use of cookies is set forth below.

Depending upon the configurations deployed, this Software Offering may use session and persistent cookies that collect each user's user name and position for purposes of session management, authentication, enhanced user usability, and single sign-on configuration. These cookies cannot be disabled.

If the configurations deployed for this Software Offering provide you as customer the ability to collect personally identifiable information from end users through cookies and other technologies, you should seek your own legal advice about any laws applicable to such data collection, including any requirements for notice and consent.

For more information about the use of various technologies, including cookies, for these purposes, see IBM's Privacy Policy at <http://www.ibm.com/privacy> and IBM's Online Privacy Statement at <http://www.ibm.com/privacy/details> in the section entitled "Cookies, Web Beacons and Other Technologies," and the "IBM Software Products and Software-as-a-Service Privacy Statement" at <http://www.ibm.com/software/info/product-privacy>.

## Safety and environmental notices

---

For more information, see [Safety and environmental notices](#).

## EU Data Act (Regulation 2023/2854)

---

EU Data Act (Regulation 2023/2854) compliance information describes the types of product data generated by storage products, including vital product data, configuration data, and logging data, along with their retention, access, and control characteristics.

### Overview

---

This Data Information Page provides information regarding data generated by this product. To the extent that access to and use of this data is governed by Regulation (EU) 2023/2854 ("Data Act") the EU Data Act Terms available at [this link](#) apply.

## Vital Product Data (VPD) / Machine Readable Product Data (MRPD)

---

### Description

Human readable information on product data including Serial Number, Machine Type and Model, Date of manufacture, and similar identifying information.

### Data characteristics

- Format: Text files, CSV files, HTTP/HTTPS, JSON or XML files, and other human readable file types
- Volume: Varies by product, but VPD/MRPD size does not typically change; as of 2025, this data could be up to 4 GB
- Generation: Real-time when the product is powered on; most VPD/MRPD data remains static

### Storage and retention

- Storage products can send product data to IBM, sometimes through a service or management console
- Products and consoles can store product data sent to IBM temporarily, deleting data based on space management requirements and/or time
- IBM servers can store product data for at least 180 days

### User access and control

- Product data can be obtained by customers through GUIs, CLIs, SNMP, REST interfaces, host commands, and other mechanisms
- Users cannot erase VPD/MRPD data
- Access available through:
  - Service console GUI, CLI and/or REST interface
  - Product-specific interfaces (GUIs, CLIs, REST interface, SNMP, host commands)

## Configuration Data

---

### Description

Human readable information describing the configuration of the product, identifying parts such as FRUs (Field Replaceable Units) and Feature Codes.

Data characteristics

- Format: Text files, CSV files, HTTP/HTTPS, JSON or XML files, and other human readable file types
- Volume: Varies by product and is expected to change with future code product updates and as new features are added; as of 2025, this data could be up to 4 GB
- Generation: Real-time when the product is powered on; most configuration/inventory data is stable until the customer upgrades the product

Storage and retention

- Storage products can send product data to IBM, sometimes through a service or management console
- Products and consoles can store product data sent to IBM temporarily, deleting data based on space management requirements and/or time
- IBM servers can store product data for at least 180 days

User access and control

- Product data can be obtained by customers through GUIs, CLIs, SNMP, REST interfaces, host commands, and other mechanisms
- Access available through:
  - Service console GUI, CLI and/or REST interface
  - Product-specific interfaces (GUIs, CLIs, REST interface, SNMP, host commands)

## Logging Data

---

Description

Files containing data generated by system use and available to customers, including:

- High level error logs tracking error information
- Command logs showing information such as read or write commands sent to the storage device
- Access logs tracking users logging into the system and running admin commands

Data characteristics

- Format: Text files, CSV files, HTTP/HTTPS, JSON or XML files, and other human readable file types
- Volume: Varies by product and is expected to change with future code product updates and as new features are added; as of 2025, this data could be up to 4GB
- Generation: Real-time when the product is powered on; logging runs continuously and is finite in length, with older data removed as newer data is generated

Storage and retention

- Storage products can send product data to IBM, sometimes through a service or management console
- Products and consoles can store product data sent to IBM temporarily, deleting data based on space management requirements and/or time
- IBM servers can store product data for at least 180 days

User access and control

- Product data can be obtained by customers through GUIs, CLIs, SNMP, REST interfaces, host commands, and other mechanisms
- Access available through:
  - Service console GUI, CLI and/or REST interface
  - Product-specific interfaces (GUIs, CLIs, REST interface, SNMP, host commands)
