

IBM Fusion HCI

Tables of Contents

What's new	1
Product overview	3
AI-enhanced integration	5
Hardware overview	5
Compute servers	7
GPU servers	9
Network switches	10
Compute storage servers	10
Service node	12
Power Distribution Units (PDUs)	13
Supported PDU power cords	13
Power consumption specification for client-provided PDUs	16
Power consumption by configuration	17
Deployment configurations	18
IBM Storage Expert Care	21
Security in IBM Fusion	21
FIPS 140-3 support	22
Verifying image signatures	23
IBM Fusion HCI deployment overview	24
Planning your installation	25
Identify your deployment architecture	25
Review use case design guidance	25
Identify storage for your use case	26
Identify hardware for your use case	26
General Metro-DR prerequisites	26
Preparing the tiebreaker	27
Identify your resource allocation and management	28
Review recommended resources	28
Installation prerequisites	30
Confirm your data center readiness	31
Confirm data center facility and space readiness	31
Review space requirements	31
Conduct a floor load assessment	32
Identify computer room location	32
Confirm data center environmental readiness	33
Review cooling requirements	33
Review vibration guidance	33
Review noise emission guidance	34
Review electromagnetic guidance	35
Confirm data center safety and protection readiness	36
Review static electricity guidance	36
Review data storage protection guidance	37
Confirm your power and infrastructure readiness	37
Power quality	38
Voltage and frequency limits	40
Power load	40
Power source	41
Dual-power installation configurations	41
Plan your networking and connectivity readiness	42
Review IBM Fusion HCI network architecture	43
General requirements	44
Firewall requirements	52
Network cable requirements	54
Installing LACP spine switches	55
Identify IP address assignment method	60
Configuring sub-domains	60
Setting up DHCP for IBM Fusion HCI	60
Setting up DHCP	62
Setting up DNS	63
Setting up Static IP	65
Review proxy configuration guidance	65
Preventing Scale network IP conflicts	66
Configuring the enterprise registry	67
Identify your registry strategy	67
Enterprise registry for IBM Fusion HCI installation	67
Mirroring prerequisites	67
End-to-end mirroring of IBM Fusion HCI and its services images to the enterprise registry	70
Mirroring OpenShift Container Platform release images to enterprise registry	76
Mirroring Red Hat operator images to enterprise registry	77
Mirroring individual images	80
Mirroring IBM Fusion HCI images	80

Mirroring IBM Storage Scale images	88
Mirroring IBM Storage Scale 6.0.1.0 images	93
Mirroring Fusion Data Foundation images	94
Mirroring Backup & Restore images	98
Mirroring IBM Data Cataloging images	100
Mirroring Content-Aware Storage (CAS) images	104
Mirroring IBM Software Hub, watsonx.ai, and watsonx Orchestrate images	106
Troubleshooting and known issues in offline mirroring	110
Quay on IBM Fusion HCI	112
Converting a rack from internal registry to offline using enterprise registry	112
Converting a rack from online proxy to offline using external Quay	112
Activate your subscriptions and entitlements	113
Activating Red Hat OpenShift Container Platform subscriptions purchased from IBM	113
Red Hat OpenShift distributions	114
Activating IBM Fusion HCI Software to be downloaded	114
How to Activate NVIDIA AI Enterprise Subscriptions	116
Run the installation	117
Installing IBM Fusion HCI	117
Network configuration	121
Installing IBM Fusion HCI in a Metro-DR setup	122
Validate your installation	122
Validating IBM Fusion HCI installation	123
Collecting log files of final installation	123
Install your IBM Fusion HCI services	124
Resolve installation issues	124
Installation issues	124
Troubleshooting installation issues	125
Operator installation or upgrade fails with DeadlineExceeded error	128
Uninstalling services	129
Disabling the connection	129
Uninstalling IBM Data Cataloging	130
Uninstalling Backup & Restore	131
Uninstalling Fusion Data Foundation	131
Removing monitoring stack from Fusion Data Foundation	133
Uninstalling Global Data Platform remote mount	134
Storage	136
Storage deployment combinations from the user interface	137
Deploying your workloads with Persistent volumes	138
Static provisioning of Persistent Volume in filesystem	138
Dynamic provisioning of Persistent Volume in filesystem	139
Fusion services and capabilities	140
Fusion services	140
Fusion Data Foundation	142
Release notes	142
New features	142
Enhancements	143
Known issues	144
Deprecated features	148
Introduction to Fusion Data Foundation	148
Installing Fusion Data Foundation	148
Fusion Data Foundation storage compatibility across rack configurations	150
Installing a Fusion Data Foundation client	151
Configuring the provider cluster for external client access	152
Configuring the client cluster to access provider storage	153
Installing Data Foundation for MCG only	154
Configuring Fusion Data Foundation	154
Configuring Fusion Data Foundation in provider mode	155
Creating a NetworkFenceClass CR	157
Viewing Fusion Data Foundation topology	157
Preparing to connect to an external KMS server in Fusion Data Foundation	158
Enabling encryption with the token authentication using HashiCorp Vault(manual part)	158
Enabling encryption with the Kubernetes authentication using HashiCorp Vault (manual part)	159
Enabling key rotation for Kubernetes authentication	160
Disabling key rotation for Kubernetes authentication	161
Enabling encryption using Thales CipherTrust Manager (manual part)	162
Managing hybrid and multicloud resource	162
Accessing the Multicloud Object Gateway with your applications	163
Accessing the Multicloud Object Gateway from the terminal	164
Accessing the Multicloud Object Gateway from the MCG command-line interface	165
Support of Multicloud Object Gateway data bucket APIs	167
Adding storage resources for hybrid or Multicloud	167
Creating a new backing store	167

Overriding the default backing store	168
Adding storage resources for hybrid or Multicloud using the command line interface	169
Creating an AWS-backed backingstore	169
Creating an AWS-STS-backed backingstore	170
Creating an AWS role using a script	170
Installing Red Hat OpenShift Data Foundation operator in AWS STS OpenShift cluster	172
Creating a new AWS STS backingstore	172
Creating an IBM COS-backed backingstore	172
Creating an Azure-backed backingstore	173
Creating an Azure STS-backed backingstore	174
Creating an Azure managed identity for NooBaa	175
Installing the Fusion Data Foundation operator in an Azure STS OpenShift cluster	176
Creating a new Azure STS backingstore	176
Creating a GCP-backed backingstore	177
Creating a local Persistent Volume-backed backingstore	178
Creating an s3 compatible Multicloud Object Gateway backingstore	179
Creating a new bucket class	180
Editing a bucket class	181
Editing backing stores for bucket class	181
Creating and managing buckets using the object browser	182
Accessing the object browser	182
Signing in to the object browser as a developer user	182
Creating and managing buckets	183
Creating new buckets using the object browser	183
Listing bucket details using the object browser	183
Deleting or emptying bucket using object browser	184
Managing objects	184
Listing objects and object details using MCG object browser	184
Downloading or previewing objects using the object browser	184
Generating the presigned URL to share the object	185
Uploading objects using the object browser	185
Creating folder using the object browser	185
Deleting objects using the object browser	186
Enabling or suspending object versioning in a bucket using the object browser	186
Listing object versions using the object browser	186
Creating and managing lifecycle rules	187
Creating new lifecycle rules by using the object browser	187
Editing lifecycle rules by using the object browser	187
Creating CORS rule	188
Editing CORS rule	188
Applying bucket policy to grant public or restricted access to objects	188
Setting up public access limit to S3 resources	189
Creating and managing IAM user	189
Creating an IAM user using the object browser	190
Generating additional access key for an IAM user	190
Activating or deactivating access key	190
Deleting access key for an IAM user	191
Deleting an IAM user	191
Managing namespace buckets	191
Amazon S3 API endpoints for objects in namespace buckets	192
Adding a namespace bucket using the Multicloud Object Gateway CLI and YAML	192
Adding an AWS S3 namespace bucket using YAML	192
Adding an IBM COS namespace bucket using YAML	194
Adding an AWS S3 namespace bucket using the Multicloud Object Gateway CLI	196
Adding an IBM COS namespace bucket using the Multicloud Object Gateway CLI	197
Adding a namespace bucket using the OpenShift Container Platform user interface	198
Sharing legacy application data with cloud native application using S3 protocol	198
Creating a NamespaceStore to use a file system	199
Creating accounts with NamespaceStore file system configuration	199
Accessing legacy application data from the openshift-storage namespace	200
Changing the default SELinux label on the legacy application project to match the one in the openshift-storage project	205
Modifying the SELinux label only for the deployment config that has the pod which mounts the legacy application PVC	205
Configuring or modifying the PublicAccessBlock configuration for S3 bucket	206
Securing Multicloud Object Gateway	207
Changing the default account credentials to ensure better security in the Multicloud Object Gateway	208
Resetting the noobaa account password	208
Setting Multicloud Object Gateway account credentials using CLI command	209
Regenerating the S3 credentials for the accounts	209
Regenerating the S3 credentials for the OBC	210
Enabling secured mode deployment for Multicloud Object Gateway	211
Disabling routes that enable external access to Multicloud Object Gateway	212
Disabling HTTP access for the NooBaa S3 route	212

Disabling the HTTP route for RADOS Object Gateway	213
Mirroring data for hybrid and Multicloud buckets	213
Creating bucket classes to mirror data using the MCG command-line-interface	213
Creating bucket classes to mirror data using a YAML	214
Bucket policies in the Multicloud Object Gateway	214
Introduction to bucket policies	214
Using bucket policies in Multicloud Object Gateway	214
Creating a user in the Multicloud Object Gateway	215
Bucket notification in Multicloud Object Gateway	216
Configuring bucket notification in Multicloud Object Gateway	216
Multicloud Object Gateway bucket replication	219
Replicating a bucket to another bucket	219
Replicating a bucket to another bucket using the MCG command-line interface	220
Replicating a bucket to another bucket using a YAML	220
Setting a bucket class replication policy	221
Setting a bucket class replication policy using the MCG command-line interface	221
Setting a bucket class replication policy using a YAML	222
Enabling log based bucket replication	223
Enabling log based bucket replication for new namespace buckets using OpenShift Web Console in AWS environment	223
Enabling log based bucket replication for existing namespace buckets using YAML	223
Enabling log based bucket replication in Microsoft Azure	224
Enabling log-based bucket replication deletion	225
Bucket logging for Multicloud Object Gateway	225
Enabling bucket logging by using the Best-Effort option	225
Enabling bucket logging by using the Guaranteed option	226
Synchronizing versions in Multicloud Object Gateway bucket replication	227
Obtaining metrics to reflect bucket replication state	227
Managing S3 Vectors	228
S3 Vectors in Multicloud Object Gateway	228
Creating a vector BucketClass	229
Creating vector buckets using ObjectBucketClaim	229
Creating vector buckets using the S3 API	230
Managing vector indexes	230
Listing vector indexes	231
Creating a vector index	231
Viewing vector index details	231
Deleting a vector index	232
Deleting vector buckets	232
Object Bucket Claim	232
Dynamic Object Bucket Claim	233
Creating an Object Bucket Claim using the command line interface	234
Creating an Object Bucket Claim using the OpenShift Container Platform	236
Attaching an Object Bucket Claim to a deployment	236
Viewing object buckets using the OpenShift Web Console	236
Deleting Object Bucket Claims	237
Object Bucket Claims on hosted clusters	237
Enabling Object Bucket Claim support on a client cluster	238
Distributing the NooBaa storage class to a client cluster	238
Creating an Object Bucket Claim on a client cluster	239
Deleting an Object Bucket Claim on a client cluster	240
Regenerating OBC credentials for a client cluster OBC	241
Object browser on client clusters	241
Enabling data operations in the object browser on a client cluster	242
Managing bucket quota	243
Bucket quota in Multicloud Object Gateway	243
Setting quota on a BucketClass	244
Creating a BucketClass with quota using YAML	244
Creating a BucketClass with quota using the CLI	245
Setting quota on an Object Bucket Claim using YAML	245
Updating quota on an existing Object Bucket Claim	246
Setting quota on an Object Bucket Claim using the CLI	246
Setting quota on buckets	247
Creating a bucket with quota	247
Updating quota on an existing bucket	248
Caching policy for object buckets	248
Creating an AWS cache bucket	248
Creating an IBM COS cache bucket	250
Lifecycle bucket configuration in Multicloud Object Gateway	251
Scaling Multicloud Object Gateway performance	251
Automatic scaling of MultiCloud Object Gateway endpoints	252
Autoscaling RGW in Fusion Data Foundation using HPA and KEDA	252
Scaling the Multicloud Object Gateway with storage nodes	253

Increasing CPU and memory for PV pool resources	253
Accessing the RADOS Object Gateway S3 endpoint	254
Using TLS certificates for applications accessing RGW	254
Accessing external RGW server	254
Using the security token service of Multicloud Object Gateway to assume the role of another user	255
Replacing nodes and devices	255
Fusion Data Foundation storage node failure	255
Disk replacement and OpenShift dedicated OSD failure recovery	259
Troubleshooting Fusion Data Foundation service issues	264
Global Data Platform	267
Installing Global Data Platform	267
Global Data Platform storage support for multi rack	269
Configuring Global Data Platform local storage	269
Setting up encryption for storage	271
Configuring encryption for Global Data Platform storage	271
Configuring storage	272
Sharing data	272
Retrieving credentials	272
Active file management (AFM) fileset creation	273
Create Persistent Volume and Persistent Volume Claim	275
Global Data Platform service install and upgrade issues	275
Global Data Platform service issues	278
Recover storage cluster from an unplanned multi-node restart or failure	281
IBM Storage Scale file system not showing newly added file system size	282
Remote IBM Storage Scale storage cluster in IBM Fusion	282
Connecting to remote IBM Storage Scale file systems	283
Backup & Restore	285
Backup & Restore overview	285
Backup and restore planning	286
How Backup & Restore service backups up application data	286
Backup & Restore service architecture	287
Hub and spoke model overview	288
Install Backup & Restore	289
Prerequisites	289
Backup & Restore hub	289
Backup & Restore spoke	292
Establishing connection between hub and spoke	296
Reduce and restore operator cluster-admin privileges	296
Uninstalling Backup & Restore	131
Getting started	297
Quick start Backup & Restore service	297
Service protection	298
Backup & Restore of your workloads	298
Backup & Restore of your applications and virtual machines	299
Backup storage locations	299
Creating a secret	299
Adding a backup storage location	300
Using MCG or Noobaa as a backup storage location	301
Using IBM Storage Protect as a backup storage location	302
Managing backup storage location details	303
Backup policies	303
Creating backup policy	303
Managing backup policy	304
Setting up backup policies	305
Managing your application workloads	306
Managing the application details	306
Running on demand backups	308
Jobs	309
Restoring an application	310
Backup and restore as code	311
Reducing elevated privileges for Fusion Backup and Restore service	315
Backup & restore service from OpenShift Container Platform	316
Service protection	319
Configuring service backups	320
Recovering service backups	320
Self-service Backup & Restore	321
Managing backup for multi-cluster environment	323
Connecting and managing cluster connections	324
Reconnecting OpenShift Container Platform cluster	325
Disabling the connection	129
Backup consistencies	326
Achieving data consistency for containers	326

Achieving data consistency for virtual machine workloads	327
Orchestrate a backup or restore	328
Custom backup and restore workflows	328
Creating a Recipe	329
Additional hooks	332
Dynamic recipe	334
Assigning a Recipe	337
Resource Transformation	339
Backup and restore of IBM Software Hub to the same or different cluster	343
IBM Fusion repository for recipes	343
Performance and scaling	343
Backup & restore resource self-monitoring	343
Backup & restore hub performance and scaling	344
Backup & restore configuration parameters	347
FIPS-140-2	355
Backup & Restore service installation and upgrade issues	355
Troubleshooting Backup & Restore service issues	357
Backup issues	359
Restore issues	362
IBM Software Hub backup and restore issues	367
Hub and spoke connection issues	368
Backup & restore service from OpenShift Container Platform console	369
Data Cataloging	369
IBM Data Cataloging architecture	370
Role-based access control	372
Data source connections	372
Cataloging metadata	373
Enriching metadata	373
Policy engine	373
Applications	374
Graphical user interface	374
Reports for IBM Data Cataloging	376
Installing IBM Data Cataloging	376
Uninstalling IBM Data Cataloging	130
Configuring IBM Data Cataloging	380
Setting up IBM Data Cataloging custom user and password	380
Configure data source connections	381
IBM Storage Scale data source connections	381
IBM Storage Scale scanning considerations	381
Security considerations	382
Performance considerations	382
Prerequisites for automated scanning	382
Identify the IBM Storage Scale cluster and node list	383
Creating or identifying a user ID and password for scanning	383
Validate scan user permissions and configuration	383
Check the dependencies for optimized scanning	384
Creating an IBM Storage Scale data source connection	384
Automated scanning of an IBM Storage Scale data source	385
Automated scanning of an IBM Storage Scale fileset	386
Manual scanning of an IBM Storage Scale data source	387
Performing file system scan to collect metadata from IBM Storage Scale	387
Copying the output of the IBM Storage Scale file system scan to the IBM Data Cataloging master node	389
Ingesting metadata from IBM Storage Scale file system scan in IBM Data Cataloging	389
Ingesting quota information from the file system	389
IBM Storage Archive data source connections	389
IBM Cloud Object Storage data source connection	390
Prerequisites	390
Creating an IBM Cloud Object Storage data source connection	391
Scanning an IBM Cloud Object Storage data connection	392
Best practices for scanning IBM Cloud Object Storage systems	394
Enabling bucket notifications for Ceph Object Storage	394
Enabling bucket notifications for Ceph Object Storage on Red Hat OpenShift	396
Replaying IBM Cloud Object Storage notifications	397
Overview of architecture	397
Configuration file	398
Replay performance	402
Replay tasks and vault settings	403
Including and excluding vaults	404
Stats files	405
Replay	405
Initialization for Replay	405
Error conditions	405

Output	405
Renaming a vault for Replay	406
Starting the Replay	406
Debug mode for Replay	406
Notifier	407
Limitations	407
Starting the Notifier	407
Notifier operation	407
Stopping the Notifier	408
Restarting the Notifier	408
Progress report	408
Logging	410
IBM Cloud Object Storage Scanner output data	411
Appendix	413
Configure IBM Cloud Object Storage notifications for IBM Data Cataloging	418
Enabling IBM Cloud Object Storage notification services	419
Authenticating, encrypting, and enabling	419
Authenticating, encrypting, and enabling services on Red Hat OpenShift	420
Testing the IBM Cloud Object Storage notification service	421
Monitoring the IBM Cloud Object Storage accesser logs	422
Monitoring the IBM Data Cataloging producer IBM Cloud Object Storage logs	422
Monitoring the IBM Data Cataloging dashboard for IBM Cloud Object Storage ingestion	422
IBM Data Cataloging and S3 object storage data source connections	423
Creating an S3 object storage data connection	423
Scanning an S3 object storage data connection	425
Best practices for scanning an S3 object storage system	427
Scanning an Elastic Storage Server data source connection	427
Creating a Network File System data source connection	428
Creating an SMB data source connection	428
Creating an IBM Storage Protect data source connection	429
Configuring data source connections offline	430
Editing and using the TimeSinceAccess and Size Range buckets	430
IBM Spectrum Storage software requirements	432
IBM Data Cataloging installation with alternative VLAN	433
Multiple connection managers	435
Enabling feature for skipping the snapshot directories	436
Enabling skip snapshot directories feature on Red Hat OpenShift	436
Managing IBM Data Cataloging rules when integrated with CAS	437
Administering IBM Data Cataloging	437
AI-enabled capabilities	438
IBM Data Cataloging MCP server	438
AI-powered content-based tagging	443
Managing user access	448
Initial login	449
Resetting the sdadmin password	452
Password policies	452
Changing password	453
Managing user accounts	453
Creating user accounts	454
Managing groups	455
Creating groups	455
Managing collections	456
Creating collections	457
Managing LDAP and IBM Cloud Object Storage System connections	457
Creating an LDAP connection	458
Configuring self-signed certificates to secure LDAPS connection	459
Creating an IBM Cloud Object Storage connection	459
Managing metadata policies	460
Adding policies	461
Adding auto-tagging policy parameters	462
Adding deep-inspection policy parameters	462
Adding content search policy parameters	462
Running policies	463
Viewing policies	463
Viewing policy history details and logs	464
Modifying policies	465
Deleting policies	465
Using content search policies	466
Identifying the required regex expressions	466
Creating a content search policy	467
Viewing content search application logs	467
Hints and tips for using content search	467

Tiering data by using ScaleILM application	468
Viewing ScaleILM application logs	470
Copying data by using ScaleAFM application	471
Viewing ScaleAFM application logs	472
Exporting metadata to IBM Watson Knowledge Catalog	472
Configuring Watson Knowledge Catalog connector	473
Configuring Watson Knowledge Catalog using the utility script	473
Configuring Watson Knowledge Catalog manually	473
Exporting metadata	474
Mapping similar source connections in Watson Knowledge Catalog	474
Troubleshooting export issues	475
Authentication failure with Watson Knowledge Catalog - both on-Premise and IBM Cloud	476
Incorrect WKC URL configuration	476
Invalid connection type in catalog	476
No linked connection type	476
WKC connector pod in CrashLoopBackoff state	477
S3 connection issues	477
Importing externally curated tags for COS/S3 using import tags application	478
Initiating Policy Using REST API	479
Registering import tags application	479
Defining the import tag policy type	479
Viewing the policy status	480
Viewing the import tags application log	481
Performing retention analytics on IBM Storage Protect archive data	481
Enabling the retention analytics feature	481
Adding IBM Storage Protect data source and initiating scan	482
Searching expiry time	483
Managing tags	484
Creating tags	485
Viewing and searching tags	487
Editing tags	488
Deleting tags	490
Discover data	492
Searching	492
Grouping data by file type	493
Searching system and custom metadata fields	493
System metadata fields to search on	494
Access control list metadata to search on	495
How to use ACL data in policies	496
Search on custom metadata fields	498
Examples of search filters	499
Search results table	499
Refine search results	499
Sort search results	499
Tag search results manually	499
Managing applications	500
Reports	500
Creating a IBM Data Cataloging application for metadata-based policies	501
Graceful shutdown	502
Flushing Kafka topics	503
Returning IBM Data Cataloging to a running state	504
REST API for IBM Data Cataloging	506
IBM Data Cataloging REST APIs	506
API endpoints	507
Asynchronous endpoints	507
Status codes	508
Authentication process	508
Endpoints for working with a Db2 Warehouse	509
/db2whrest/v1/search: POST	509
/db2whrest/v1/report: POST	513
/db2whrest/v1/report: GET	519
/db2whrest/v1/report/<report_id>: GET	519
/db2whrest/v1/report/<report_id>/download: GET	520
/db2whrest/v1/bucket: GET	521
/db2whrest/v1/buckets/<bucket>: GET	521
/db2whrest/v1/report/<report_id>: PUT	522
/db2whrest/v1/buckets/<bucket>: PUT	522
/db2whrest/v1/report/<report_id>: DELETE	524
/db2whrest/v1/sql_query?<sql>: GET	524
/db2whrest/v1/sql_query: POST	525
/db2whrest/v1/sql_query_async?<sql>: GET	526
/db2whrest/v1/sql_query_async: POST	527

/db2whrest/v1/task_status/<task_id>: GET and <task_id>/peek	528
/db2whrest/v1/summary_tables -X GET	529
/db2whrest/v1/summary_tables/<table> -X GET	530
/db2whrest/v1/summary_tables/<table> -X PUT	530
/db2whrest/v1/summary_tables/<table>/<action> -X PUT	531
/db2whrest/v1/bulk_add_tags/docs: POST	532
Endpoints for working with policy management	532
/policyengine/v1/policies: GET and /policyengine/v1/policies/<policy_name>: GET	533
/policyengine/v1/policies/<policy_name>/preview: GET	534
/policyengine/v1/policies/<policy_name>/status: GET	535
/policyengine/v1/policyhistory: GET	536

/policyengine/v1/policies/<policy_name>/<action>: POST	539
/policyengine/v1/policies -d '<data>': POST	539
/policyengine/v1/policies/<policy_name> -d '<data>': PUT	540
/policyengine/v1/policies/<policy_name>: DELETE	541
/policyengine/v1/policyhistory: DELETE	541
/policyengine/v1/tags: GET	542
/policyengine/v1/tags/: POST	543
/policyengine/v1/tags/: PUT	543
/policyengine/v1/tags/: DELETE	544
/policyengine/v1/regex: POST	544
/policyengine/v1/regex: GET	545
/policyengine/v1/regex/<regex_name>: GET	546
/policyengine/v1/regex: PUT	547
/policyengine/v1/regex: DELETE	548
Adding fields with the AUTOTAG action	548
Adding fields that contain initial values	548
Adding fields that are extracted by rule from existing fields	549
Endpoints for working with connection management	549
/connmgr/v1/connections: GET and /connmgr/v1/connections/<connection_name>: GET	550
/connmgr/v1/scan/<connection>/partitions: GET	551
/connmgr/v1/connections -d '<data>': POST	552
/connmanager/v1/scan/<connection>/partial: POST	554
/connmgr/v1/connections/<connection_name> -d '<data>': PUT	554
/connmgr/v1/connections/<connection_name>: DELETE	555
/connmgr/v1/scan/<connection_name>: POST	556
/connmgr/v1/scan/<connection_name>: GET	557
/connmgr/v1/scan: GET	557
/connmgr/v1/scan/<connection_name>: PUT	558
Application management by using APIs	559
/policyengine/v1/applications: POST	559
Example: Create a DeepInspect policy using the application	560
/policyengine/v1/applications/<application name>: GET	562
/policyengine/v1/tlscert: GET	562
/policyengine/v1/action_ids: GET	564
/policyengine/v1/applications/<deployment_name>/schema?action_id=<action_id>: GET	564
/policyengine/v1/application_names?action_id=<action_id>: GET	565
/policyengine/v1/applications: DELETE	566
RBAC management by using APIs	566
Managing tokens	567
/auth/v1/token: GET	567
Managing users	568
/auth/v1/users: GET	568
/auth/v1/users: POST	569

What's new

Each release offers new functions and improvements. IBM is constantly updating the infrastructure, security, and stability of IBM Fusion HCI to improve your experience. Review this information for a high-level summary of the new features and changes in each release.

IBM Fusion HCI 2.14.0 advances three strategic directions: AI and data infrastructure readiness, expanded resilience and disaster recovery coverage, and a major generational update to the Fusion Data Foundation storage platform. The release also adds FIPS 140-3 compliance support, a new high-core-count compute server option, and significant improvements to operational observability and automated support.

The most significant delivery is Fusion Data Foundation 4.22, which introduces new capabilities, including native vector storage for AI workloads, expanded erasure coding support, and substantially wider disaster recovery coverage. On the resilience side, Regional-DR now applies to erasure-coded storage classes and to Hosted Control Plane workloads on 2AZ+arbitrator topology, closing gaps that previously constrained how customers could combine storage efficiency with DR protection. For regulated industries, 2.14.0 adds FIPS 140-3 compliant cryptographic modules. Operationally, the release improves automated support (alert-driven Call Home), backup observability (Prometheus metrics and Grafana dashboards), and log collection for OpenShift® virtualization.

AI and data infrastructure

IBM Fusion watsonx.data service

Bring your enterprise data closer to AI and analytics with watsonx.data (WXD), a flexible lakehouse service designed for modern data-driven workloads. Built for on-premises environments, WXD helps organizations store, govern, and analyze data across multiple formats and engines from a single platform, while maintaining control over data location, security, and compliance. For more information, see [watsonx.data \(WXD\)](#).

S3 Vectors support for AI workloads

Fusion Data Foundation 4.22 introduces S3 Vectors support in the Multicloud Object Gateway (MCG). S3 Vectors provides native vector database storage within the IBM Fusion object store, enabling AI pipelines, including Retrieval-Augmented Generation (RAG) workflows to store and query vector embeddings without an external vector database. This is a foundational capability for on-premises AI workloads that require vector search over enterprise data. For more information, see [S3 Vectors in Multicloud Object Gateway](#).

Content-Aware Storage, IBM Data Cataloging, and Software Hub updates

The data services that directly support AI workloads are updated in this release:

- IBM Data Cataloging 2.5.6 - metadata indexing and AI-powered content tagging.
- Software Hub 5.4.0 - the deployment platform for watsonx.ai and watsonx Orchestrate.

For supported IBM Cloud Paks versions, see [IBM Cloud Paks support for IBM Fusion](#).

Security and compliance

FIPS 140-3 support

IBM Fusion HCI now supports FIPS 140-3 compliant cryptographic modules, covering data at rest and data in transit. This support is designed for organizations with stringent regulatory and industry requirements for cryptographic security, including US federal agencies, defense contractors, and financial institutions subject to compliance mandates. For more information, see [FIPS 140-3 support](#).

New hardware

Lenovo SR650a V4 128-core compute server (model 9155-C25)

IBM Fusion HCI now supports the Lenovo SR650a V4 server (model 9155-C25). The server is built on two 64-core Intel Xeon 6 P-series ("Granite Rapids") processors, delivering 128 cores per node. Key specifications:

- 2048 GB RAM
- Up to 8× 7.68 TB PCIe Gen 5 NVMe drives
- Dual-port 100 GbE connectivity

The high core count makes this server well suited to workloads that require dense compute per node, including running virtual machines on OpenShift Virtualization, where core count maps directly to Red Hat® subscription licensing, and high-throughput containerized applications. For more information, see [Hardware configuration](#).

Operations and serviceability

Alert-based Call Home

IBM Fusion HCI now automatically opens IBM Support tickets when critical Prometheus alerts fire in OpenShift AlertManager. When an alert triggers, IBM Fusion HCI creates the support case, attaches a collected log bundle, and applies deduplication logic to avoid duplicate tickets for the same underlying condition. Resolved alerts gate ticket creation, so transient conditions that self-heal do not generate unnecessary cases. The result: when a critical condition occurs, IBM Support is engaged and has diagnostic data before you make a support call. For more information, see [Alert-based Call Home](#).

Red Hat OpenShift Virtualization log collection

IBM Fusion HCI now supports log collection for Red Hat OpenShift Virtualization. You can collect virtualization namespace resources and must-gather data for troubleshooting virtualization workloads. For more information, see [Log package](#).

Backup & Restore observability - Prometheus metrics and Grafana dashboards

The Backup & Restore service now publishes Prometheus metrics covering backup jobs, policy execution status, and backup storage location health. You can consume these metrics through your existing OpenShift monitoring stack. Example Grafana dashboards are available in the [IBM Storage Fusion GitHub repository](#). For the full list of metrics, see [IBM Fusion metrics](#).

Backup & Restore agent configuration (OADP 1.6, OpenShift Container Platform 4.22 and later)

For deployments running OpenShift Container Platform 4.22 or later with OADP 1.6, several new configuration fields are available for the Backup & Restore agent. These fields support more granular control over storage class selection for data movement, backup PVC annotations, data mover pod scheduling, and maintenance job retention. For more information, see [Backup and restore configuration parameters](#).

Resilience and disaster recovery

This release significantly expands disaster recovery coverage across both storage back ends and cluster topologies.

Regional-DR for erasure-coded storage classes

Regional-DR asynchronous replication now extends support for erasure-coded Ceph File System (CephFS) file storage and RADOS Gateway (RGW) object storage classes, in addition to RADOS Block Device (RBD) block storage classes. If you chose erasure coding to reduce raw storage overhead, you can now protect those workloads with Regional-DR while retaining your existing storage class.

For configuration instructions, see [Configuring Regional-DR](#).

Regional-DR for Hosted Control Plane on 2AZ+arbiter topology

Workloads hosted on a 2AZ+arbiter topology can now be protected in regional DR relationships.

For configuration instructions, see [Configuring Regional-DR](#).

Storage-agnostic disaster recovery

Fusion Data Foundation 4.22 transitions DR orchestration to a vendor-agnostic DR operator. DR configurations are no longer tied to a specific vendor's tooling, improving portability and reducing dependency on vendor-specific integrations. Third-party storage vendors are also now supported for storage-agnostic DR.

Disaster recovery relationship monitoring using topology view

You can now monitor disaster recovery relationships using the topology view in the Fusion Data Foundation console. This provides a visual representation of replication relationships and their health status, making it easier to verify DR posture without querying the CLI.

For more information, see [Monitoring regional disaster recovery relationships and actions by using Topology view](#).

Fusion Data Foundation

Fusion Data Foundation 4.22 is a major generational update to the storage platform, delivering new capabilities across object storage, file storage, erasure coding, and operational improvements. The highlights are described below and for the complete list, see the [New features](#) and [Enhancements](#) sections in the *Fusion Data Foundation 4.22 release notes*.

Erasure coding advances

Erasure coding support is extended to additional storage types and topologies:

- **CephFS file storage** - erasure coding is now supported for CephFS, in addition to the existing RBD block storage support.
- **RADOS Object Gateway (RGW) object storage** - erasure coding is now supported for RGW.
- **Expansion rack topology** - erasure coding is now supported when adding expansion racks to a cluster.

Together these changes mean that erasure coding, which reduces raw storage overhead compared to replica-3 is now available across all three major storage types in Fusion Data Foundation.

Object storage improvements

- **Object Bucket Claim support on hosted clusters** - workloads running on hosted clusters can now provision object storage buckets directly through the Object Bucket Claim API.
- **Object browser support on client clusters** - the object browser UI is now available on client clusters in provider or consumer mode.
- **Object bucket quota support** - you can now set storage quotas on individual Object Bucket Claims.
- **Disabling HTTP route for RADOS Object Gateway** - you can disable the insecure HTTP route for RGW, enforcing HTTPS-only access.
- **STS authentication for RGW enabled by default** - Security Token Service (STS) authentication is now the default for RADOS Object Gateway, improving security posture without additional configuration.
- **Standardized Azure Identity configuration** - Azure Identity configuration for Fusion Data Foundation is now standardized, simplifying multi-cloud object storage setup.

Operational improvements

- **Clone count alert for client clusters** - an alert fires when the clone count on client clusters in provider or consumer mode approaches configured limits, enabling proactive capacity management
- **Configurable NooBaa operator log levels** - you can now adjust the log verbosity of the NooBaa operator (which powers MCG object storage), reducing log noise in stable environments
- **Hosted Control Plane support on 2AZ+arbiter topology** - Fusion Data Foundation now supports Hosted Control Plane on two-availability-zone plus arbiter node topology.

For known issues and limitations in Fusion Data Foundation 4.22, see [Known issues](#).

Hosted Control Plane enhancements

Isolated VLAN for virtualized Hosted Control Plane

IBM Fusion HCI now supports configuring an isolated VLAN for virtualized Hosted Control Plane clusters. An isolated VLAN provides dedicated network isolation for Hosted Control Plane cluster networking, separating workload traffic from the management network. For more information, see [Configuring network for Hosted Control Plane](#).

Hosted Control Plane support on 2AZ and arbiter node topology

With Fusion Data Foundation 4.22, IBM Fusion HCI extends Hosted Control Plane support to the 2AZ and arbiter node topology. You can now deploy [virtualized](#) and [bare metal](#) hosted clusters on a 2AZ and arbiter node configuration. The control plane and `etcd` are distributed across all three control nodes, one per availability zone, so the cluster remains operational during a single AZ failure. LVM persistent storage for `etcd` is provisioned on control nodes using the LVM storage operator.

Component version updates

This release updates or certifies the following component versions. Upgrading to IBM Fusion HCI 2.14.0 brings these versions as part of the standard upgrade.

- OpenShift Container Platform 4.22
- Fusion Data Foundation 4.22
- IBM Storage Scale Erasure Code Edition (ECE) or Global Data Platform 5.2.3.9
- IBM Storage Scale Data Management Edition or Global Data Platform 6.0.0.3, 6.0.1.0, and 6.0.1.1
- Backup & Restore 2.14.0
- IBM Data Cataloging 2.5.6
- Content-Aware Storage 1.1.8
- Software Hub 5.4.0

For supported IBM Cloud Paks versions, see the [IBM Cloud Paks support for IBM Fusion](#). For supported IBM Maximo versions, see [IBM Maximo® Applications support for IBM Fusion](#).

For a complete list of currency support, see [Support matrix for IBM Fusion versions](#).

Product overview

IBM Fusion is a container-native hybrid cloud data platform that offers simplified deployment and data management for Kubernetes applications on Red Hat® OpenShift® Container Platform. IBM Fusion is designed to meet the storage requirements of modern, stateful Kubernetes applications and to make it easy to deploy and manage container-native applications and their data on Red Hat OpenShift Container Platform.

IBM Fusion is an advanced storage and backup solution that is designed to simplify data accessibility and availability across hybrid clouds. Companies can expand data availability across complex hybrid clouds for greater business performance and resilience. With the IBM Fusion solutions, organizations manage only a single copy of data. They need not create duplicate data when moving application workloads across the enterprise, easing management functions when you streamline analytics and AI.

IBM Fusion provides a streamlined way for organizations to discover, secure, protect, and manage data from the edge, to the core data center, to the public cloud.

IBM Fusion is available as two deployments, namely IBM Fusion HCI and IBM Fusion.

IBM Fusion HCI

IBM Fusion HCI is a purpose-built, hyper-converged architecture that is designed to deploy bare metal Red Hat OpenShift container management and deployment software alongside IBM Fusion software. For consistent and rapid deployment and management, it features an appliance form-factor, hyper-converged infrastructure along with integrated software-defined storage to meet the storage requirements of modern, stateful Kubernetes applications. Built with a storage platform that includes the essential elements necessary for mission-critical containers and hybrid cloud, the IBM Fusion provides a comprehensive infrastructure with compute, networking, and storage resources, including a data platform and global data services for Red Hat OpenShift.

The following *Figure 1. High-level conceptual overview of IBM Fusion HCI* provides a high-level conceptual overview of IBM Fusion HCI architecture:

- The IBM Fusion HCI provides a fully integrated infrastructure, which combines compute, networking, and storage resources optimized for containerized workloads.
- Designed to run on Bare Metal Red Hat OpenShift Container Platform, it supports the building and running of cloud-native applications.
- The Fusion Base offers essential services such as serviceability for issue diagnosis and resolution, a user interface for interaction with IBM Fusion HCI, and observability for monitoring system performance and health.
- The Fusion infrastructure management layer, built on top of OpenShift, simplifies lifecycle management of compute nodes, networking, and storage, ensuring operational efficiency.
- The Fusion services layer delivers a suite of solutions to secure and manage data across hybrid cloud environments.

Figure 1. High-level conceptual overview of IBM Fusion HCI

IBM Fusion

IBM Fusion is software-defined storage with protection, backup, and caching elements and can be run on existing hardware resources. The following *Figure 2. High-level conceptual overview of IBM Fusion* provides a high-level conceptual architecture overview:

- IBM Fusion is designed to run on OpenShift Container Platform across your infrastructure and various supported platforms, enabling the building and running of cloud-native applications.
- Built atop OpenShift, Fusion Base provides foundational services such as serviceability for efficient issue diagnosis and resolution, a user interface for seamless interaction with IBM Fusion, and observability for system performance insights.
- Layered above Fusion Base, Fusion services deliver a suite of solutions to secure and manage data across hybrid cloud environments.

Figure 2. High-level conceptual overview of IBM Fusion

For more information about IBM Fusion, see [IBM Fusion documentation](#).

- [AI-enhanced integration](#)
IBM Fusion HCI provides AI-driven data management capabilities through Model Context Protocol (MCP) integrations and content-based automation features.
- [Hardware overview](#)
Review the system layout and hardware summary of the IBM Fusion HCI. The IBM Fusion HCI mainly contains the Lenovo and Dell hardware components.
- [Deployment configurations](#)
The stand-alone rack, multiple rack, and disaster recovery deployment configurations are available in IBM Fusion HCI. The multi rack topology offers these variants: high-availability multi-rack, 3 zone high-availability multi-rack, two availability zones with an arbiter node in a third zone, and expansion rack.
- [IBM Storage Expert Care](#)
IBM Storage Expert Care is a simplified method of selecting services and support for systems at the time of the purchase. IBM Storage Expert Care is designed to simplify and standardize the support approach for IBM Fusion HCI with transparent pricing and selection of services.
- [Security in IBM Fusion](#)
IBM Fusion is a secure platform to deploy your applications.
- [FIPS 140-3 support](#)
IBM Fusion HCI supports Federal Information Processing Standards (FIPS) 140-3, enabling organizations to deploy infrastructure that complies with the latest cryptographic security standards for protecting sensitive data.
- [Verifying image signatures](#)
Digital signatures provide a way for consumers of content to ensure that what they download is both authentic (it originated from the expected source) and has integrity (it is what we expect it to be). All images for IBM Fusion are signed. This page describes how to verify the signatures on those images.

AI-enhanced integration

IBM Fusion HCI provides AI-driven data management capabilities through Model Context Protocol (MCP) integrations and content-based automation features.

AI-driven capabilities

- Automatically gather observability data, system events, and inventory information for your clusters with smart agents. For more information, see [AI-enabled observability with Red Hat OpenShift Lightspeed](#).
- Search and interact with vector stores by using natural language queries through AI chat applications. For more information, see [Integrating Model Context Protocol \(MCP\) with CAS](#).
- Simplify tool discovery, execution, and lifecycle management of a unified set of cataloging and data management tools without requiring direct LLM-to-tool integrations. For more information, see [IBM Data Cataloging MCP server](#).
- Analyze document content to automatically generate metadata tags through content-based autotagging. For more information, see [AI-powered content-based tagging](#).

Hardware overview

Review the system layout and hardware summary of the IBM Fusion HCI. The IBM Fusion HCI mainly contains the Lenovo and Dell hardware components.

The IBM Fusion HCI is a hyper-converged infrastructure solution that integrates compute, storage, and networking resources into a single, scalable platform. The IBM Fusion HCI is built using with two reliable hardware options for your business needs.

- Dell hardware
- Lenovo hardware

You can choose from either "Lenovo" or "Dell" hardware option to build a robust IBM Fusion HCI management software. Here is an overview of the key hardware components:

Compute servers

The compute servers that are used in IBM Fusion HCI compute servers are based on industry-standard x86 architecture, offering high-performance, reliability, and flexibility. They are available on Lenovo (9155-C10 and 9155-C14) and Dell (9155-D10 and 9155-D14) hardware. For more information, see [Compute servers](#).

GPU servers

The IBM Fusion is a comprehensive management software that uses GPU servers to accelerate various workloads, including artificial intelligence, high-performance computing, and data analytics. They are available on Lenovo (9155-G03) and Dell (9155-DG1, DG2, DG3, and DG4) hardware. For more information, see [GPU servers](#).

Network switches

The IBM Fusion HCI management software uses management and high-speed switches to facilitate communication between nodes, manage traffic, and ensure high availability. They are available on Lenovo (9155-S01, S02, S04, S05) and Dell (9155-S04 and 9155-S05) hardware. For more information, see [Network switches](#).

Storage servers

IBM Fusion HCI management software uses a range of storage servers to provide a scalable and efficient storage solution. They are available on Lenovo (9155-C10 and 9155-C14), Dell (9155-D10 and 9155-D14). For more information, see [Storage servers](#).

Power Distribution Units (PDUs)

The PDUs are designed to provide reliable and efficient power distribution to the appliances components. It enables remote power on/off, restart, and power cycle control of connected devices, reducing the need for physical intervention. For more information, see [Power Distribution Units \(PDUs\)](#).

Service node

The service node is a critical component of a distributed network, responsible for providing a specific set of capabilities to the network. For more information, see [Service node](#).

Hardware configuration

The IBM Fusion HCI management software offers you with two options for obtaining a rack: either you can buy a rack directly from the IBM, or you can arrange for a rack yourself. For more information about rack options, see [Identify hardware for your use case](#).

Rack configuration

The rack configuration includes the physical arrangement of servers, storage systems, and network devices.

Rack configuration	Description
Rack size	42U
Networking	2x Ethernet high-speed switches 2x Ethernet management switches
Compute only or compute-storage servers	3x servers with 2-10 NVMe drives per server - KVM connected to the service node - Servers in RU2, RU3, and RU4 become the OpenShift® control plane servers - You can choose any one of the following server configuration options: 3x 32 core servers 3x 64 core server
Storage	2x 7.68 TB NVMe PCIe drives or 3.84 TB NVMe drives Important: No mixing of 7.68 TB and 3.84 TB drives is allowed within a rack.

Scalable options

To customize your rack configuration, the following options are available:

Rack configuration	Description
Additional compute-storage servers	Add up to 10 additional compute-storage servers, for a maximum total of 16 servers
Additional storage	Add more storage to compute-storage servers using: 7.68 TB NVMe PCIe drives (up to 10 drives per server) 3.84 TB NVMe PCIe drives (up to 10 drives per server) Important: No mixing of 7.68 TB and 3.84 TB drives is allowed within a rack.
Additional compute power	Add compute-only servers to increase compute power

Drives and usable storage capacities

To determine the usable storage capacities for drives, use the [IBM Sales Configurator tool](#). This tool provides an accurate calculation of the available storage space, taking into account various factors that affect storage capacity for the IBM Fusion HCI solution.

Weight of miscellaneous rack parts

The following table lists the weight of the rack configurations that include miscellaneous parts beyond individual components like cables, Constellation rack and so on:

• Dell hardware:

Table 1. Weight of the Dell hardware miscellaneous rack parts

Component	Weight (lbs)	Weight (kg)	Model
SN3700 200GbE switch	30.8	14.0	S05
SN2201 1GbE switch	16.3	7.4	S04
SN3700C switch	27.5	12.5	S01
7316-TF5 console	12.0	5.5	TF5
R660XL 32-core 256GB server, 0 drives	47.8	21.7	D10
R660XL 32-core 256GB server, 2 drives	52.2	23.7	D10
R660XL 32-core 256GB server, 10 drives	69.8	31.7	D10
R660XL 64-core 1024GB server, 0 drives	47.8	21.7	D14
R660XL 64-core 1024GB server, 2 drives	52.2	23.7	D14
R660XL 64-core 1024GB server, 10 drives	69.8	31.7	D14
R660 8-core service node	44.8	44.8	DB1
Constellation rack	398.2	181.0	R42
Intelligent switched PDU+	9.5	4.3	NA
All cables, rails, and so on.	395.5	179.8	NA

• Lenovo hardware:

Table 2. Weight of the Lenovo hardware miscellaneous rack parts

Component	Weight (lbs)	Weight (kg)	Model
SN3700 200GbE switch	30.8	14.0	S05
SN2201 1GbE switch	16.3	7.4	S04
SN3700C switch	27.5	12.5	S01
7316-TF5 console	12.0	5.5	TF5
AS4610 switch	11.8	5.4	S02
SR665 GPU server	85.5	38.9	G01
SR645-0 32-core 256GB server	39.1	17.8	C00
SR645-2 32-core 256GB server	40.2	18.3	C01 with 2 drives
SR645-10 32-core 256GB server	44.6	20.3	C01 with 10 drives
SR645-0 64-core 1024GB server	39.1	17.8	C04

SR645-2 64-core 1024GB server	40.2	18.3	C05 with 2 drives
SR645-10 64-core 1024GB server	40.2	18.3	C05 with 10 drives
SR630 V3 32-core	45.9	20.8	C10
SR630 V3 64-core	45.9	20.8	C14
SR630 V3 8-core	40.6	18.5	B01
Constellation rack The 9155-R42 is also known as the 7965-S42 used by Power. For hardware specifications, see Model 7965-S42 rack specifications .	398.2	181.0	R42
Intelligent switched PDU+	9.5	4.3	NA
All cables, rails, and so on.	395.5	179.8	NA
SR675 V3 GPU server	72.1 lbs	32.8 kg	G03 with 1 GPUs
SR675 V3 GPU server	87.5 lbs	39.8 kg	G03 with 8 GPUs

Before you up size the nodes, consider the power consumption data that is depicted in the following *Power consumption* tables.

Compute servers

Use this section to get a detailed understanding and configuration details of compute servers that are used in the IBM Fusion HCI appliance.

Compute-only nodes are designed for applications that require high processing power and can use external storage solutions. These nodes are ideal for workloads that depend on shared storage or have low storage requirements and provide the necessary resources for workloads to run efficiently. Also, the compute servers are used as control nodes and worker nodes in the OpenShift® cluster.

The available compute servers are:

- Dell hardware - 9155-D10 and 9155-D14. For configuration details, see [Dell hardware](#).
- Lenovo hardware - 9155-C10 and 9155-C14. For configuration details, see [Lenovo hardware](#).

You can have either three 9155-C10/D10 and 9155-C14/D14 servers with storage as a minimum configuration, and also you can expand your IBM Fusion HCI beyond the minimum three servers by adding combinations of models C10/D10 and D10/D14. Each rack can support up to 16 servers. Each compute server can have a minimum of two storage drives that can be increased up to a maximum of ten storage drives.

Important: You cannot mix and match different drive capacities within the same rack. Choose one capacity and use it consistently throughout.

Key capabilities

The following are the key capabilities of the compute server:

- Compute servers offer customizable CPU and memory allocation, allowing you to tailor resources to meet specific workload requirements.
- You can adjust the amount of CPU and memory in each server to optimize performance and cost.
- Compute servers can be configured as storage-rich servers, providing additional storage capacity for workloads that require it.

Advantages

The following are the key benefits of the compute servers:

Improved resource utilization

By customizing CPU and memory allocation, you can ensure that workloads have the necessary resources to run efficiently, reducing waste and optimizing utilization.

Enhanced flexibility

Compute servers can be scaled up or down to accommodate changing workload demands, making it easier to adapt to evolving business needs.

Cost effective

With the ability to customize resources, you can optimize costs by allocating only the necessary resources for each workload, reducing unnecessary expenses.

Hardware configuration

Lenovo

9155-C10 (32 core)

- Lenovo SR630 V3
- 2x 16-core Intel Gold 6426Y 2.5GHz 185W processors ("Sapphire Rapids")
- 256GB RAM (16x 16GB DDR5 DIMMs), expandable to 512GB RAM
- 0-10x 7.68TB or 3.84TB PCIe generation 5 NVMe drives
- 1x NVIDIA ConnectX-6 DX dual-port 100GbE PCIe NIC
- 1x NVIDIA ConnectX-6 LX dual-port 25GbE PCIe NIC
- 1x Intel I350 1GbE RJ45 4-port OCP Ethernet Adapter
- 2x 960GB M.2 NVMe OS drives (RAID 1)

9155-C14 (64 core)

- Lenovo SR630 V3
- 2x 32-core Intel Gold 6438 2.0GHz 205W processors ("Sapphire Rapids")
- 1024GB RAM (16x 64GB DDR5 DIMMs), expandable to 2048GB RAM
- 0-10x 7.68TB or 3.84TB PCIe generation 5 NVMe drives
- 1x NVIDIA ConnectX-6 DX dual-port 100GbE PCIe NIC
- 1x NVIDIA ConnectX-6 LX dual-port 25GbE PCIe NIC
- 1x Intel I350 1GbE RJ45 4-port OCP Ethernet Adapter
- 2x 960GB M.2 NVMe OS drives (RAID 1)

9155-C20 (32 core)

- Lenovo SR630 V4
- 2x 16-core Intel Xeon 6515P 2.3GHz 150W processors ("Granite Rapids")
- 256GB RAM (16x 16GB DDR5 DIMMs), expandable to 512GB RAM
- 0-10x 7.68TB PCIe generation 5 NVMe drives
- 1x Broadcom 57508 dual-port 100GbE PCIe NIC
- 1x Broadcom 57508 dual-port 100GbE OCP Ethernet Adapter
- 1x Broadcom 5719 1GbE RJ45 4-port OCP Ethernet Adapter
- 2x 960GB M.2 NVMe OS drives (RAID 1)

9155-C24 (64 core)

- Lenovo SR630 V4
- 2x 32-core Intel Xeon 6 P-series 205W processors ("Granite Rapids")
- 512GB RAM (16x 32GB DDR5 DIMMs), expandable to 1024GB RAM
- 0-10x 7.68TB PCIe generation 5 NVMe drives
- 1x Broadcom 57508 dual-port 100GbE PCIe NIC
- 1x Broadcom 57508 dual-port 100GbE OCP Ethernet Adapter
- 1x Broadcom 5719 1GbE RJ45 4-port OCP Ethernet Adapter
- 2x 960GB M.2 NVMe OS drives (RAID 1)

9155-C25 (128 core)

- Lenovo SR650a V4
- 2x 64-core Intel Xeon 6 P-series processors ("Granite Rapids")
- 2048GB RAM (32x 64GB DDR5 DIMMs)
- 0-8x 7.68TB PCIe generation 5 NVMe drives
- 1x NVIDIA ConnectX-6 LX dual-port 25GbE PCIe NIC
- 1x Broadcom 57508 dual-port 100GbE OCP Ethernet Adapter
- 1x Broadcom 5719 1GbE RJ45 4-port OCP Ethernet Adapter
- 2x 960GB M.2 NVMe OS drives (RAID 1)

Dell

9155-D10 (32 core)

- Dell R660XL
- 2x 16-core Intel Xeon 4th Gen Gold 6426Y 2.5GHz 185W processors
- 256GB RAM (16x 16GB DDR5 DIMMs)
- Optional memory upgrade to 512GB (32x 16GB DIMMs)
- 0-10x 7.68TB or 3.84TB PCIe NVMe drives
- 1x NVIDIA ConnectX-6 DX dual-port 100GbE PCIe NIC
- 1x Intel I350 1GbE RJ45 4-port OCP Ethernet Adapter
- 2x 960GB M.2 NVMe OS drives (RAID 1)

9155-D14 (64 core)

- Dell R660XL
- 2x 32-core Intel Xeon 4th Gen Gold 6438N 2.0GHz 205W processors
- 1024GB RAM (16x 64GB DDR5 DIMMs)
- Optional memory upgrade to 2048 GB (32x 64GB DIMMs)
- 0-10x 7.68TB or 3.84TB PCIe Gen 5 NVMe drives
- 1x NVIDIA ConnectX-6 DX dual-port 100GbE PCIe NIC
- 1x Intel I350 1GbE RJ45 4-port OCP Ethernet Adapter
- 2x 960GB M.2 NVMe OS drives (RAID 1)

GPU servers

Use this section to get a detailed understanding and configuration details of GPU servers that are used in the IBM Fusion HCI appliance.

The GPU is a specialized server node in the IBM Fusion HCI appliance that is equipped with one or more graphics processing units. These nodes are designed to handle compute-intensive workloads that require massive parallel processing, such as AI and high-performance computing applications. The available GPU servers are:

- Dell hardware - 9155-DG1, DG2, DG3, and DG4. For configuration details, see [Dell hardware](#).
- Lenovo hardware - 9155-G03 and 9155-G04. For configuration details, see [Lenovo hardware](#).

Note: GPU card migration between nodes is not supported in IBM Fusion HCI, regardless of whether the nodes belong to the same cluster or different clusters.

Key capabilities

The following are the key capabilities of the GPU servers:

- Provides massive parallel processing capabilities, making them ideal for workloads that require high-performance computing, such as scientific simulations, data analytics, and AI model training.
- Improves the performance of compute-intensive workloads, reducing processing times and increasing overall system efficiency.
- GPU nodes can be virtualized, allowing multiple virtual machines to share the same GPU resources, improving resource utilization and reducing costs.

Advantages

The following are the key benefits of the GPU servers:

Improved performance and efficiency

GPU servers can significantly improve the performance and efficiency of compute-intensive workloads.

Increased agility

GPU servers can be quickly provisioned and deployed, allowing organizations to rapidly respond to changing business needs.

Reduced costs

GPU servers can help reduce costs by improving resource utilization and reducing the need for specialized hardware.

Simplified management

GPU servers are fully integrated with the IBM Fusion HCI platform, providing a single, a unified management interface for administrators.

Hardware configuration

Dell

Hardware configuration of 9155-DG1 GPU server:

- Dell XE7745 4U 2-socket server
- 2x 64-core AMD EPYC 5 9575 3.3 GHz 400 W processors
- 2304 GB DDR5 6400 MT/s RAM (24x 64 GB DIMMs)
- 4x NVIDIA L40S 48 GB GPU PCIe Gen 4
- 2x 960 GB M.2 SED NVMe hot-swappable OS drives (RAID 1)
- 4x NVIDIA ConnectX-6 DX dual-port 100 GbE PCIe NICs
- Broadcom Quad Port 1 GbE PCIe Ethernet Adapter
- 8x 3200 W Titanium power supplies

Important:

The 9155-DG2, DG3, and DG4 GPU servers contain the same configuration similar to 9155-DG1, but they come up with different GPU cards configuration:

- 9155-DG2 - 8x NVIDIA PCIe Gen 4 L40S instead of 4x NVIDIA PCIe Gen 4 L40S.
- 9155-DG3 - 4x NVIDIA H200 NVL 141 GB GPU PCIe Gen 5 instead of 4x NVIDIA PCIe Gen 4 L40S.
- 9155-DG4 - 8x NVIDIA H200 NVL 141 GB GPU PCIe Gen 5 instead of 4x NVIDIA PCIe Gen 4 L40S.

Lenovo

Hardware configuration of 9155-G03 GPU server:

- SR675 V3 8DW PCIe GPU Base
- 2x AMD EPYC 9254 24C 200W 2.9GHz
- (1-8)x NVIDIA L40S 48GB GPU Gen4 PCIe adapter cards
- NVIDIA H100 NVL 94GB PCIe Gen5 Passive GPU
 - Two H100 NVL can be inter-connected with NVLink to efficiently support models up to 188 GB.
- AMD MI210 PCIe GPU Adapter Card
- 768GB RAM (24x 32GB TruDDR5 4800MHz (2Rx8) RDIMM-A)
- Intel I350 1GbE RJ45 4-port OCP Ethernet Adapter
- ConnectX-6 Dx dual port 100GbE network interface card
- ConnectX-6 Lx dual port 25GbE network interface card
- 2x M.2 960GB NVMe drives for the operating system and the drives are in a RAID 1 configuration
- 3U height

Important: Each G03 server supports between 1 and 8 GPU PCIe cards, with options including NVIDIA L40S, NVIDIA H100 NVL, and AMD MI210. However, you cannot mix different GPU models within the same server.

Hardware configuration of 9155-G04 GPU server:

- SR675 V3 PCIe GPU Base

- 2x AMD EPYC 9555 64-Core CPU
- (1-8)x NVIDIA H200 NVL 141GB GPU
- (1-8)x NVIDIA RTX PRO 6000 Blackwell Server Edition 96GB GPU
- 1536GB RAM (24x 64GB)
- Intel I350 1GbE RJ45 4-port OCP Ethernet Adapter
- ConnectX-7 Dx dual port 200GbE network interface card
- ConnectX-6 Lx dual port 25GbE network interface card
- 2x M.2 960GB NVMe drives for the operating system and the drives are in a RAID 1 configuration
- 3U height

Important: Each G04 server supports between 1 and 8 GPU PCIe cards, with options including NVIDIA H200 NVL, and NVIDIA RTXPRO6000. However, you cannot mix different GPU models within the same server.

Network switches

The IBM Fusion HCI is configured with a dual-network architecture, designed to optimize performance, management, resiliency, and redundancy.

The IBM Fusion HCI appliance features a robust networking infrastructure, designed to provide high-speed connectivity and redundancy for optimal performance and reliability. To ensure high availability, each rack is equipped with two high-speed and management switches.

The IBM Fusion HCI appliance comes with two types of networks:

High-speed network

Used for the OpenShift® cluster, this network can be connected to the data center network. This network is dedicated to handling high-speed data transfer between the storage cluster and applications, ensuring optimal performance and low latency.

Management network

Used by IBM Fusion HCI to manage the compute, storage, and switches in the appliance. This network is used for managing the servers, monitoring their health, and performing administrative tasks, ensuring the overall system's stability and security.

Key capabilities

The following are the key capabilities of the network switches:

- High-speed connectivity enables fast data transfer and communication between nodes in the OpenShift cluster.
- Ensures that the appliance remains operational even in the event of a switch failure.
- Allows Fusion to coordinate capabilities like firmware upgrades and power operations.

Advantages

The following are the key benefits of the network switches:

Improved performance

High-speed connectivity and redundancy ensure optimal performance and minimize downtime.

Simplified management

Centralized management of the appliance's compute, storage, and switches streamlines operations.

Scalability

Supports multi-rack deployments with spine switches, enabling scalable expansion of the appliance.

Connectivity

200GbE high-speed network switches (Model S05)

The high-speed network is built around a pair of 32-port, 200Gb Ethernet switches. The switches are configured together using MLAG to create a redundant pair. All compute-storage servers have a 2-port, 100Gb Ethernet adapter. One port on the adapter is connected to the first high-speed switch and the second port is connected to the second high-speed switch. The Lenovo G04 GPU server has a 2-port, 200Gb Ethernet adapter. One port on the adapter is connected to the first high-speed switch and the second port is connected to the second high-speed switch. The Dell GPU servers have four 2-port, 100Gb Ethernet adapters. Four ports from these adapters are connected to the first high-speed switch and the other four ports are connected to the second high-speed switch. All Lenovo compute-storage servers and the Lenovo GPU server also have a 2-port, 25Gb Ethernet adapter. Using breakout cables that split the 100GbE ports on the switch into four 25GbE ports, one port on the server's 25GbE network adapter is connected to the first high-speed switch and the second port is connected to the second high-speed switch.

1GbE management network switches (Model S04)

The management network is built around a pair of 48-port Ethernet management switches. The BMC interface of each server is connected to the 1GbE ports on the management switches, providing out-of-band management connectivity.

Compute storage servers

Use this section to get a detailed understanding and configuration details of compute storage servers that are used in the IBM Fusion HCI appliance.

Compute-storage servers combine processing power with integrated storage, providing a self-contained solution for applications that require both compute and storage resources. This configuration is suitable for workloads that require low-latency access to data or have high storage demands.

The available compute servers are:

- Dell hardware - 9155-D10 and 9155-D14. For configuration details, see [Dell hardware](#).
- Lenovo hardware - 9155-C10 and 9155-C14. For configuration details, see [Lenovo hardware](#).

You can have either three 9155-C10/D10 and 9155-C14/D14 servers with storage as a minimum configuration, and also you can expand your IBM Fusion HCI beyond the minimum three servers by adding combinations of models C10/D10 and D10/D14. Each rack can support up to 16 servers. Each compute server can have a minimum of two storage drives that can be increased up to a maximum of ten storage drives.

Important: You cannot mix and match different drive capacities within the same rack. Choose one capacity and use it consistently throughout.

Key capabilities

The following are the key capabilities of the compute storage server:

- You can scale up or down to meet changing workload demands. This scalability is achieved through the addition or removal of nodes, allowing organizations to quickly adapt to changing business needs.
- Compute storage server provides a single, unified storage pool for all workloads. This integrated storage is optimized for virtualized workloads and provides features such as deduplication, compression, and thin provisioning.
- Provides robust data protection and security features, including encryption, replication, and snapshots.
- Provides high-performance computing capabilities, with support for multiple CPU cores, high-speed memory, and low-latency storage.

Advantages

The following are the key benefits of the compute storage servers:

Reduced complexity

Compute storage servers can simplify infrastructure management by integrating compute, storage, and networking resources into a single platform.

Improved scalability

Scales to meet changing workload demands, reducing the need for costly hardware upgrades.

Increased efficiency

The integrated storage and high-performance computing capabilities improve overall system efficiency, reducing power consumption and cooling costs.

Cost efficiency

The simplified management and scalability of compute storage servers reduce the total cost of ownership, making it an attractive solution for organizations of all sizes.

Hardware configuration

Lenovo

9155-C10 (32 core)

- Lenovo SR630 V3
- 2x 16-core Intel Gold 6426Y 2.5GHz 185W processors ("Sapphire Rapids")
- 256GB RAM (16x 16GB DDR5 DIMMs), expandable to 512GB RAM
- 0-10x 7.68TB or 3.84TB PCIe generation 5 NVMe drives
- 1x NVIDIA ConnectX-6 DX dual-port 100GbE PCIe NIC
- 1x NVIDIA ConnectX-6 LX dual-port 25GbE PCIe NIC
- 1x Intel I350 1GbE RJ45 4-port OCP Ethernet Adapter
- 2x 960GB M.2 NVMe OS drives (RAID 1)

9155-C14 (64 core)

- Lenovo SR630 V3
- 2x 32-core Intel Gold 6438 2.0GHz 205W processors ("Sapphire Rapids")
- 1024GB RAM (16x 64GB DDR5 DIMMs), expandable to 2048GB RAM
- 0-10x 7.68TB or 3.84TB PCIe generation 5 NVMe drives
- 1x NVIDIA ConnectX-6 DX dual-port 100GbE PCIe NIC
- 1x NVIDIA ConnectX-6 LX dual-port 25GbE PCIe NIC
- 1x Intel I350 1GbE RJ45 4-port OCP Ethernet Adapter
- 2x 960GB M.2 NVMe OS drives (RAID 1)

9155-C20 (32 core)

- Lenovo SR630 V4
- 2x 16-core Intel Xeon 6515P 2.3GHz 150W processors ("Granite Rapids")
- 256GB RAM (16x 16GB DDR5 DIMMs), expandable to 512GB RAM
- 0-10x 7.68TB PCIe generation 5 NVMe drives
- 1x Broadcom 57508 dual-port 100GbE PCIe NIC
- 1x Broadcom 57508 dual-port 100GbE OCP Ethernet Adapter
- 1x Broadcom 5719 1GbE RJ45 4-port OCP Ethernet Adapter
- 2x 960GB M.2 NVMe OS drives (RAID 1)

9155-C24 (64 core)

- Lenovo SR630 V4
- 2x 32-core Intel Xeon 6 P-series 205W processors ("Granite Rapids")
- 512GB RAM (16x 32GB DDR5 DIMMs), expandable to 1024GB RAM
- 0-10x 7.68TB PCIe generation 5 NVMe drives
- 1x Broadcom 57508 dual-port 100GbE PCIe NIC
- 1x Broadcom 57508 dual-port 100GbE OCP Ethernet Adapter
- 1x Broadcom 5719 1GbE RJ45 4-port OCP Ethernet Adapter

- 2× 960GB M.2 NVMe OS drives (RAID 1)

9155-C25 (128 core)

- Lenovo SR650a V4
- 2× 64-core Intel Xeon 6 P-series processors ("Granite Rapids")
- 2048GB RAM (32× 64GB DDR5 DIMMs)
- 0-8× 7.68TB PCIe generation 5 NVMe drives
- 1× NVIDIA ConnectX-6 LX dual-port 25GbE PCIe NIC
- 1× Broadcom 57508 dual-port 100GbE OCP Ethernet Adapter
- 1× Broadcom 5719 1GbE RJ45 4-port OCP Ethernet Adapter
- 2× 960GB M.2 NVMe OS drives (RAID 1)

Dell

9155-D10 (32 core)

- Dell R660XL
- 2x 16-core Intel Xeon 4th Gen Gold 6426Y 2.5GHz 185W processors
- 256GB RAM (16x 16GB DDR5 DIMMs)
- Optional memory upgrade to 512GB (32x 16GB DIMMs)
- 0-10x 7.68TB or 3.84TB PCIe NVMe drives
- 1x NVIDIA ConnectX-6 DX dual-port 100GbE PCIe NIC
- 1x Intel I350 1GbE RJ45 4-port OCP Ethernet Adapter
- 2x 960GB M.2 NVMe OS drives (RAID 1)

9155-D14 (64 core)

- Dell R660XL
- 2x 32-core Intel Xeon 4th Gen Gold 6438N 2.0GHz 205W processors
- 1024GB RAM (16x 64GB DDR5 DIMMs)
- Optional memory upgrade to 2048 GB (32x 64GB DIMMs)
- 0-10x 7.68TB or 3.84TB PCIe Gen 5 NVMe drives
- 1x NVIDIA ConnectX-6 DX dual-port 100GbE PCIe NIC
- 1x Intel I350 1GbE RJ45 4-port OCP Ethernet Adapter
- 2x 960GB M.2 NVMe OS drives (RAID 1)

Service node

Use this section to get a detailed understanding and configuration details of service nodes that are used in the IBM Fusion HCI appliance.

A service node is a critical component of a distributed network, responsible for providing a specific set of capabilities to the network. It acts as a bastion node for IBM Fusion HCI. The service node is pre-wired and integrated as a part of the IBM Fusion HCI with default configuration and it acts as a jump server, provides serviceability functions, and enhances overall infrastructure management. The available compute servers are:

- Dell hardware - 9155-DB1. For configuration details, see [Dell hardware](#).
- Lenovo hardware - 9155-B01. For configuration details, see [Lenovo hardware](#).

Key capabilities

The following are the key capabilities of the service node:

- Act as a jump server for secure remote access.
- Acts as the central control point for managing clusters, virtual machines, storage, and networking within the IBM Fusion HCI.
- Provides a secure entry point for administrators and support teams.
- Ensures system health monitoring, logging, and alerting for smooth operations.

Advantages

The following are the key benefits of the service node:

Centralized administration

Administer nodes and switches from the service node, even when the OpenShift® Container Platform cluster or the IBM Fusion user interface is down.

Simplified troubleshooting

- Enable remote support sessions to eliminate the need for live debugging with the service node.
- Initiate remote debugging of IBM Fusion HCI problems by accessing nodes and switches through the service node, even when the IBM Fusion HCI user interface is inaccessible.

Easy log collection

Collect logs from switches and nodes using the service node, even when the IBM Fusion user interface is down.

Simplified recovery

If you need to reset IBM Fusion HCI to its original configuration, you can redeploy the OpenShift cluster from the service node.

Hardware configuration

Dell

9155-DB1

- Dell R660
- 1x 8-core Intel Xeon 4th Gen processor
- 128GB RAM (8x16GB DDR5 DIMMs)
- 2x 960GB M.2 NVMe OS drives (RAID 1)
- 1x NVIDIA ConnectX-6 LX dual-port 25GbE PCIe NIC
- 1x Intel I350 1GbE RJ45 4-port OCP Ethernet Adapter

Lenovo

9155-B01

- Lenovo SR630 V3
- Intel Xeon Bronze 3408U 8C 125W 1.8 GHz processor
- 128GB RAM (8x ThinkSystem 16GB TruDDR5 4800MHz (1Rx8) RDIMM)
- ThinkSystem Intel I350 1 GbE RJ45 4-port OCP Ethernet Adapter
- ThinkSystem Mellanox ConnectX-6 Lx 10/25 GbE SFP28 2-Port PCIe Ethernet Adapter
- M.2 7450 PRO 960 GB Read Intensive NVMe PCIe 0.4 x 4 NHS SSD
- M.2 NVMe 2-Bay Raid enable kit
- 750 W 230V/115V Platinum hot-swap Gen2 power supply v3
- V3 1U x16/x16 BF PCIe Gen5 Riser 1

Power Distribution Units (PDUs)

Use this section as a guidance for PDU positions in the IBM Fusion HCI.

Additional PDUs may be added depending upon the configuration of the system. These additional PDUs get horizontally mounted in the space above PDU 6.

Figure 1. IBM Fusion HCI PDU positions

Important: There may be more than 6 PDUs for racks that have one or more GPU servers. Those servers are added in pairs, horizontally mounted, and placed on top of PDUs 5 and 6.

All the PDUs that are installed in the rack are needed and all of them must be connected to power.

Note: For independent or redundant power feeds, the two power sources must be split between the left and lower (odd numbered) PDUs and the right and upper (even numbered) PDUs.

There are two possible models of the PDU and the one you get depends on your power connection:

- For all single-phase power and for wye-wired three-phase power, there is one PDU feature code. See *Supported PDU power cords are ECJN with Souriau inlet* table in [Supported PDU power cords](#).
- For delta-wired three-phase power (typically used only in N America), there is a different PDU feature code. See *Supported PDU power cords for PDU feature codes ECJQ with Amphenol inlet* table in [Supported PDU power cords](#).

For more information about the line cords for power connections, see [Supported PDU power cords](#). For more information about power prerequisites for IBM Fusion, see [Confirm your power and infrastructure readiness](#).

To know more about power distribution in IBM Fusion HCI MTM (Gen 1), see [Hardware overview of a stand-alone IBM Fusion HCI](#).

Supported PDU power cords

Find out which power distribution unit (PDU) power cords are supported for your system.

Use the following table to determine the appropriate PDU power cord to use with your system in your country.

Table 1. Supported PDU power cords for PDU feature code ECJN with Souriau inlet and ECJJ PDUs

Feature code (FC)	Description - Voltage - Amperage - Phase - Length - Wall plug	IBM® shipped plug	View of plug	Matched female connector (on cord)	Matched female wall receptacle (on wall)	IBM part number	Countries
6489	Power cord, PDU to wall 230 V ac output 32 A - Three-phase wye 4.3 m (14 ft) - IEC 309, 3P+N+G	Plug type 532P6W 		Connector type 532C6W	Receptacle type 532R6W 	39M5413	Europe, Middle East, Africa (EMEA), China, Asia Pacific
6491	Power cord, PDU to wall 230 V ac 63 A - Single phase¹ 4.3 m (14 ft) - IEC 309, P+N+G	Plug type 363P6W 		Connector type 363C6W	Receptacle type 363P6W	39M5415	Europe, Middle East, Africa (EMEA), China, Asia Pacific
6492	Power cord, PDU to wall 200 - 208 V ac or 240 V ac 60 A plug (48 A derated) - Single phase¹ 4.3 m (14 ft) - IEC 309, 2P+G	Plug type 360P6W 		Connector type 360C6W	Receptacle type 360P6W 	39M5417	United States, Canada, Latin America, Japan, and Taiwan
6653	Power cord, PDU to wall 230 V ac output 16 A 3-phase wye 4.3 m (14 ft) - IEC 309, 3P+N+G	Plug type 516P6W 		Connector type 516C6W	Receptacle type 516R6W 	39M5412	Switzerland

Power consumption by configuration

Before you up size the nodes, consider the power consumption data that is depicted in the following *Power consumption* tables.

Table 1. 32 Core Servers with 256GB RAM, 10 NVMe Drives per Gen 2 Compute/Storage Node

Number of Compute or Storage nodes	6	8	10	12	14	16
Power consumption (kW)	5.25	6.76	8.27	9.77	11.28	12.78
Power Consumption with 1xG03 H100 NVL GPU (kW)	8.86	10.37	11.88	13.38	14.89	n/a
Power Consumption with 2xG03 H100 NVL GPU (kW)	12.47	13.98	15.49	16.99	18.50	n/a
Power Consumption with 3xG03 H100 NVL GPU (kW)	16.08	17.59	19.10	20.60	n/a	n/a
Power Consumption with 4xG03 H100 NVL GPU (kW)	19.69	21.20	22.71	24.21	n/a	n/a
Power Consumption with 1xG04 H200 NVL GPU (kW)	11.14	12.64	14.15	15.65	17.16	NA
Power Consumption with 2xG04 H200 NVL GPU (kW)	17.02	18.52	20.03	21.54	23.04	n/a
Power Consumption with 3xG04 H200 NVL GPU (kW)	22.90	24.41	25.91	27.42	n/a	n/a
Power Consumption with 4xG04 H200 NVL GPU (kW)	28.78	30.29	31.79	33.30	n/a	n/a
Power Consumption with 1xG04 RTX Pro 6000 GPU (kW)	10.54	12.05	13.55	15.06	16.57	n/a
Power Consumption with 2xG04 RTX Pro 6000 GPU (kW)	15.83	17.33	18.84	20.35	21.85	n/a
Power Consumption with 3xG04 RTX Pro 6000 GPU (kW)	21.12	22.62	24.13	25.63	n/a	n/a
Power Consumption with 4xG04 RTX Pro 6000 GPU (kW)	26.40	27.91	29.41	30.92	n/a	n/a

Note: These values assume 8x L40S GPUs in each G03 server. Reduce by 0.28 kW for each L40S that is less than the maximum.

Table 2. 64 Core Servers with 1024 GB RAM, 10 NVMe Drives per Gen 2 Compute/Storage Node and 32 core control plane servers

Number of Compute or Storage nodes	6	8	10	12	14	16
Power consumption (kW)	5.46	7.10	8.74	10.38	12.02	13.66
Power Consumption with 1xG03 GPU (kW)	9.07	10.71	12.35	13.99	15.63	n/a
Power Consumption with 2xG03 GPU (kW)	12.68	14.32	15.96	21.21	19.24	n/a
Power Consumption with 3xG03 GPU (kW)	16.29	17.93	19.57	20.21	n/a	n/a
Power Consumption with 4xG03 GPU (kW)	19.90	21.54	23.18	24.82	n/a	n/a
Power Consumption with 1xG04 H200 NVL GPU (kW)	11.34	12.98	14.62	16.26	17.90	n/a
Power Consumption with 2xG04 H200 NVL GPU (kW)	17.22	18.86	20.50	22.14	23.78	n/a
Power Consumption with 3xG04 H200 NVL GPU (kW)	23.10	24.74	26.38	28.02	NA	n/a
Power Consumption with 4xG04 H200 NVL GPU (kW)	28.98	30.62	32.26	33.90	n/a	n/a
Power Consumption with 1xG04 RTX Pro 6000 GPU (kW)	10.74	12.38	14.02	15.66	17.30	n/a
Power Consumption with 2xG04 RTX Pro 6000 GPU (kW)	16.03	17.67	19.31	20.95	22.59	n/a
Power Consumption with 3xG04 RTX Pro 6000 GPU (kW)	21.32	22.96	24.60	26.24	n/a	n/a
Power Consumption with 4xG04 RTX Pro 6000 GPU (kW)	26.60	28.24	29.88	31.52	n/a	n/a

Note: These values assume 8x L40S GPUs in each G03 server. Reduce by 0.28 kW for each L40S that is less than the maximum.

Deployment configurations

The stand-alone rack, multiple rack, and disaster recovery deployment configurations are available in IBM Fusion HCI. The multi rack topology offers these variants: high-availability multi-rack, 3 zone high-availability multi-rack, two availability zones with an arbiter node in a third zone, and expansion rack.

Stand-alone rack topology

The stand-alone rack of IBM Fusion HCI consists of management switches, high speed switches, PDUs, storage nodes, compute nodes, and GPU nodes to form a single OpenShift® cluster. For a single rack setup, you can simplify the deployment and begin with three nodes.

You can upsize the node to scale up the capacity of a stand-alone rack. It does not have fault tolerance for a complete rack failure.

To know more about each of the components of a Stand-alone rack, see [Hardware overview](#).

High-availability multi-rack and 3 zone HA rack topology

IBM Fusion HCI comes with the bootstrapping software that is installed from the factory for installing Fusion HCI in data centre. For high available multi rack, the IBM support representative completes the initial verification and physically connects a minimum of three racks to network and power. Then, they conduct the network setup of the first two racks which are called auxiliary racks. Network setup of 3rd, also known as last rack, is done after first two racks. This network setup validates hardware and wiring of rack and connects the rack to the data centre network. This procedure configures all the default nodes. During network setup of last rack, software collects network configuration details from first two racks automatically and shows consolidated appliance view. After the network setup is complete for all three racks, the control plane is created across the three racks. In this setup, the cluster remains operational even when a rack fails, which ensures resilience and continuity. The IBM SSR provides stage 2 URL to customer to continue next phase of the installation.

In high-availability multi-rack, at installation time, you can connect three IBM Fusion HCI racks to create a single large OpenShift Container Platform cluster. The control nodes are distributed across multiple racks for fault tolerance. This topology also spreads Fusion Data Foundation replicas across the racks to withstand the loss an entire rack of infrastructure without impacting the availability of the platform.

Note: Order three similar racks from IBM factory with a minimum of six storage nodes per rack.

IBM Fusion HCI provides flexible rack configuration within availability zones, allowing precise control over failure domains. You have the option of setting up high-availability multi-rack in two different ways. When you select an availability zone, you can choose to deploy all the racks within a single physical zone (three virtual zones) or distribute them across three physical availability zones. Spreading deployments across different physical locations enhances resilience by ensuring physical isolation, with separate power and networking infrastructure. This guarantees that Fusion remains operational even if one zone experiences an outage.

Single Zone HA

The OpenShift control plane is distributed across three racks. The Fusion Data Foundation replicas are distributed across three racks containing storage nodes.

The following diagram shows a single physical availability zone. In this setup, IBM Fusion HCI provides failure domain as a rack.

Figure 1. Three failure domains within a single physical availability zone

3-Zone HA

IBM Fusion HCI supports 3 zone HA where the racks are distributed across distinct locations within a region that are designed to be isolated from failures occurring in other zones. For 3 zone HA, each rack must be connected to the customer switches in such a way that they are in the same broadcast domain.

In a high-availability multi-rack or three Availability Zone (AZ) deployment, each node is automatically assigned a distinct zone label. This ensures that all nodes within a single rack share the same zone label, effectively creating three distinct zones for load distribution.

Deploy racks in each of the two or three availability zones to achieve a three AZ deployment of IBM Fusion HCI. The OpenShift control plane is distributed across racks in each of the three AZs. Fusion Data Foundation replicas are distributed across storage nodes in each AZ. Storage nodes are placed in the same rack as the control nodes. Additional racks of compute or GPU only servers provide additional worker nodes, and are placed in each AZ.

The following diagram shows how the OpenShift control plane and storage replicas are stretched across racks in separate availability zones.

Figure 2. OpenShift control plane and storage replicas are stretched across racks in separate availability zones

For both high-availability multi-rack and 3-Zone HA, Fusion Data Foundation is the only supported storage type. The Fusion Data Foundation storage spreads its resources in these three racks so that you do not lose data when a rack goes down either because of maintenance or power failure. The three side-by-side (adjacent) appliances act as a single unit and hosts a single Fusion Data Foundation storage and OpenShift Container Platform cluster. To achieve high availability, 1 control node (Rack Unit 2) is available in each of these three racks so even when one rack goes down, the cluster stays available. The components in each of the three racks are the same as a single rack.

The service node can be made available in any one of the racks. The rack to which the service node is connected is designated and used as the base rack.

For more information about component details and hardware configuration, see [Hardware overview](#). For more information about the storage configuration for multi-rack, see [Fusion Data Foundation storage compatibility across rack configurations](#). For more information about the known issues and limitations in multi-rack, see [Multi-rack issues](#).

Important: The high-availability multi-rack is only supported with Fusion Data Foundation storage 4.16 and higher.

Two availability zones and arbiter node topology

IBM Fusion HCI supports a two-availability-zone and arbiter node (2AZ and arbiter node) configuration, in which two racks are deployed across separate availability zones within a region, while an arbiter node (or control node) is deployed in a third zone. This configuration ensures that one zone or rack can remain isolated if a failure occurs in another zone. The OpenShift Container Platform control plane is formed using the control node of each rack and the arbiter node, ensuring high availability for the OpenShift Container Platform cluster.

Figure 3. Two availability zones and arbiter node topology

Fusion Data Foundation is the only supported storage type for the 2AZ and arbiter node configuration. Fusion Data Foundation distributes its resources across the two racks to ensure that no data is lost if a rack goes down due to maintenance or a power failure. For more information, see [Two availability zones and arbiter node configuration with Fusion Data Foundation](#).

The 2AZ and arbiter node topology can be deployed in a metropolitan-spanned data centers where latency between servers stays within specific limits. For more information on network requirements and planning, see [Network for two-availability-zone and arbiter node \(2AZ and arbiter node\) configuration](#).

Expansion rack topology

The expansion rack extends the capacity of an existing running cluster, which can be stand-alone system, high-availability multi-rack setup, or a previously expanded configuration. Expansion allows you to start with just one node. For Fusion Data Foundation based topology, all the networks are connected to the customer switch.

Disaster recovery topology

IBM Fusion HCI supports disaster recovery (DR) through two primary configurations: Metro-DR and Regional-DR.

The Metro-DR topology provides synchronous data replication between two IBM Fusion HCI clusters located within metropolitan distances (with latency under 40 milliseconds). Global Data Platform is the only supported storage type for the Metro-DR topology. For information on Metro-DR topology configuration, see [Metro-DR configuration for Global Data Platform](#).

The Regional-DR topology uses asynchronous data replication between clusters located at long distances or two geographically separated clusters. While it introduces a slight delay in data synchronization, it is ideal for scenarios where geographical separation is necessary for disaster recovery. Fusion Data Foundation is the only supported storage type for the Regional-DR topology. For information on Regional-DR topology configuration, see [Regional-DR configuration for Fusion Data Foundation](#).

IBM Storage Expert Care

IBM Storage Expert Care is a simplified method of selecting services and support for systems at the time of the purchase. IBM Storage Expert Care is designed to simplify and standardize the support approach for IBM Fusion HCI with transparent pricing and selection of services.

For more information about IBM Storage Expert Care for IBM Fusion, see [Support reference guide](#).

Security in IBM Fusion

IBM Fusion is a secure platform to deploy your applications.

The following security measures are followed for IBM Fusion product:

- Penetration testing to check for exploitable vulnerabilities
- Threat modelling and threat assessment to ensure that threats are assessed and resolved
- Static scan to maintain high code quality and to ensure that no security vulnerabilities are left in the code
- Dynamic scan to detect and remove runtime vulnerabilities

- Open Source Scan to detect and remove open source vulnerabilities in open source libraries that are used by IBM Fusion
- Security and Privacy by Design (SPbD) compliance certified by IBM BISO to ensure security and privacy compliance
- Container Software certifications (IBM Certification and Red Hat® Certifications) to ensure adherence to container security standards.
- Automated password rotation in IBM Fusion HCI ensures hardware (nodes) credentials are regularly updated to maintain security compliance, reduce unauthorized access risk, and eliminate manual intervention. For more information about enabling password rotation, see [Enabling password rotation for IBM Fusion HCI system](#).
- Least-privilege operator mode: Customers can reduce cluster-admin-level authority from IBM Fusion operators post-install by using a provided utility script. The authority change must be reversed before every upgrade or patch and can be re-applied after the operation completes. For more information, see [Reduce and restore operator cluster-admin privileges](#).

FIPS 140-3 support

IBM Fusion HCI supports Federal Information Processing Standards (FIPS) 140-3, enabling organizations to deploy infrastructure that complies with the latest cryptographic security standards for protecting sensitive data.

Overview

By using FIPS 140-3 validated cryptographic modules, IBM Fusion HCI strengthens the protection of data both at rest and in transit while helping organizations meet stringent regulatory and industry compliance requirements.

This capability enhances the platform's security posture through validated encryption mechanisms, modern cryptographic controls, and improved key management practices, making IBM Fusion HCI ideal for security-sensitive enterprise and public sector environments.

Supported hardware

FIPS 140-3 support is available on the following hardware platforms:

- IBM Fusion HCI Gen 2 and Gen 3 Lenovo racks
- Dell Gen 1 racks
- NVIDIA networking switches

To enable FIPS compliance on systems that are deployed in the field, you must complete the appropriate IBM Fusion HCI manufacturing process.

Installation

During cluster deployment, administrators can enable FIPS mode as part of the installation workflow. In the IBM Fusion HCI Install UI > Deployment type section, FIPS 140-3 ready installation option is available only on FIPS-compliant hardware. If the underlying hardware does not meet FIPS compliance requirements, this option is not available.

After IBM Fusion HCI software installation is complete, you can verify the cluster's FIPS status from the Details section of the IBM Fusion HCI dashboard.

Cluster lifecycle

Cluster expansion

When expanding an existing cluster, all newly added hardware must meet the same FIPS compliance requirements as the existing environment. Review all applicable manufacturing and deployment requirements before you perform cluster expansion activities.

Upgrade and rack reset

Converting an existing non-FIPS cluster to FIPS mode is not supported. Clusters that require FIPS compliance must be deployed with FIPS mode enabled during the initial IBM Fusion HCI manufacturing process.

A rack reset reverts a FIPS-compliant cluster to a non-FIPS compliant state. To restore or maintain FIPS compliance, you must run the IBM Fusion HCI manufacturing process.

Supported topologies

All IBM Fusion HCI topologies are supported in FIPS mode.

For multi-rack deployments, all participating clusters must be deployed and configured in FIPS mode to maintain a consistent compliance posture across the environment.

Storage considerations

The following storage limitation applies when you operate in FIPS mode:

- Global Data Platform Remote Mount is not supported.
- FIPS mode does not support IBM Storage Scale Erasure Code Edition (ECE) deployments on Global Data Platform. FIPS support is available only for deployments that use Data Foundation storage.

Hosted clusters

Each hosted cluster that is deployed within a FIPS-compliant environment must be explicitly configured and created in FIPS mode. Hosted clusters do not automatically inherit FIPS compliance from the management or hosting environment.

Warning: Ensure that the etcd data for each hosted cluster is encrypted. Unlike operating system disks, Logical Volume Manager (LVM) disks used for Hosted Control Plane are not automatically encrypted before the LVM cluster is created and must be manually configured for encryption.

Encryption and security controls

When FIPS mode is enabled, the following security controls are applied:

- IPsec secures node-to-node communication.
- OpenShift® nodes operate in FIPS mode.
- Service nodes operate in FIPS mode.
- Network switches and Baseboard Management Controllers (BMCs) operate in FIPS mode.
- Data Foundation encrypts data on local NVMe storage devices using LUKS2-based encryption when configured in encryption mode.

Limitations

Network-isolated components

The following components are not FIPS validated. Risk is mitigated because all communication is restricted to isolated private networks.

SNMPv3 monitoring

SNMPv3 monitors switches and node Baseboard Management Controllers (BMCs). SNMPv3 relies on cryptographic algorithms that are not FIPS-compliant, including Data Encryption Standard (DES) and SHA-1.

PXE boot

PXE boot is used for node provisioning and cluster expansion operations and does not provide encrypted data transfer during the boot process.

AWX server

AWX server manages automation and operational workflows and does not currently have formal FIPS validation. SSH and TLS connections that are used by the platform remain FIPS compliant.

Assist On Site (AOS)

The Assist On Site (AOS) remote support capability is not FIPS compliant. When FIPS mode is enabled:

- AOS is disabled by default.
- Users receive a warning before enabling AOS.
- If AOS is enabled, an additional compliance warning is displayed indicating that the cluster no longer maintains full FIPS compliance.

IBM Fusion data services

The following services are excluded from the FIPS support:

- Content-Aware Storage (CAS) and Data Lakehouse do not support FIPS mode because both IBM Storage Scale Remote Mount and the IBM Storage Scale CNSA driver do not support FIPS mode.

Verifying image signatures

Digital signatures provide a way for consumers of content to ensure that what they download is both authentic (it originated from the expected source) and has integrity (it is what we expect it to be). All images for IBM Fusion are signed. This page describes how to verify the signatures on those images.

Before you begin

Your machine must have these command line tools installed (they can usually be installed on Linux using the package manager):

- [GNU Privacy Guard v2](#)
- [OpenSSL](#)
- [skopeo](#)

The IBM Fusion public key must exist on the same machine. Copy the following into a text editor, and save it in a file named **storage-fusion.pub.asc**:

```
-----BEGIN PGP PUBLIC KEY BLOCK-----
```

```

```
=YUDL
-----END PGP PUBLIC KEY BLOCK-----
```

You must have a list of images to verify. To get a list of container images used, see the procedure in [Downloading container images](#).

In this procedure, the following example image is used: `icr.io/cpopen/isf-operator-catalog:2.13.0-linux.amd64`.

Procedure

1. Run the following command to delete all previous IBM Fusion public keys:

```
sudo gpg2 --delete-key "Fusion"
```

To confirm the key deletion, enter 'Y'. If you have previous IBM Fusion public keys, repeat this step until gpg2 reports:

```
gpg: key "Fusion" not found: Not found
gpg: Fusion: delete key failed: Not found
```

2. Import the IBM Fusion public key on the machine that you prepared according to the *Before you begin* section:

```
sudo gpg2 --import storage-fusion.pub.asc
```

Note: This step must be done only once on each machine you use for signature verification.

3. Calculate the fingerprint:

```
fingerprint=$(sudo gpg2 --fingerprint --with-colons "Fusion" | grep fpr | tr -d 'fpr:')
```

This command stores the key's fingerprint in an environment variable that is called `fingerprint`, which is needed for the command to verify the signature. When you exit your shell session, the variable gets deleted. The next time that you log in to your machine, you can set it again by rerunning the command.

4. Create a directory for the image and use `skopeo` to pull it into local storage:

```
mkdir images
FUSION_VERSION=<version of Fusion being installed/verified>
skopeo copy docker://icr.io/cpopen/isf-operator-catalog:${FUSION_VERSION}-linux.amd64 dir:./images
```

For example, to check the signatures on 2.13.0:

```
mkdir images
FUSION_VERSION=2.13.0
skopeo copy docker://icr.io/cpopen/isf-operator-catalog:${FUSION_VERSION}-linux.amd64 dir:./images
```

This command downloads the image as a set of files and places them in the `images` directory (or another directory that you choose).

Note: There is a manifest file that is named `images/manifest.json`, and a signature file named `images/signature-1`. You reference both these files in the next step (in the command to verify the signature).

Log in to the `icr.io` entitlement registry to pull the image. Alternatively, you can pass your credentials directly to `skopeo` with `--src-creds iamapikey:<YOUR ENTITLEMENT KEY>`.

5. Verify the signature:

```
FUSION_VERSION=<version of Fusion being installed/verified>
sudo skopeo standalone-verify ./images/manifest.json icr.io/cpopen/isf-operator-catalog:${FUSION_VERSION}-linux.amd64
${fingerprint} ./images/signature-1
```

For example, to check the signatures on 2.13.0:

```
# FUSION_VERSION=2.13.0
sudo skopeo standalone-verify ./images/manifest.json icr.io/cpopen/isf-operator-catalog:${FUSION_VERSION}-linux.amd64
${fingerprint} ./images/signature-1
```

IBM Fusion HCI deployment overview

IBM Fusion HCI installation covers planning, prerequisites, and the configuration steps required for a successful setup.

The IBM Fusion HCI comes with bootstrapping software from the factory. The IBM Service Support Representatives (SSR) complete the initial verification and physically connect the system to network and power. Then, they set up the network of the appliance, which connects the appliance to the data center network. This procedure configures the network for all appliance switches and nodes (three controllers). If you ordered more nodes, they are installed as well. After the network setup is complete, you receive a link to install IBM Fusion HCI. The installation process includes setting up a three-node Red Hat® OpenShift® cluster, followed by installing IBM Fusion software.

The IBM Fusion HCI installation wizard provides a seamless and accelerated experience to get the system up and running with a few clicks. It progressively gathers the information in the following stages of IBM Fusion HCI installation:

1. In the **Network Setup** wizard stage (stage 1), the SSR, in collaboration with your network administrator, configures switches, VLANs, aggregating links, and validates DHCP and DNS configuration. Your NTP server is also configured on each node as a hardware clock.
2. In the **Software installation** wizard stage (stage 2), you can continue with the installation from a remote host by using the details that are provided at the end of the previous stage (Network setup). In this stage, you accept the license agreement contracts, provide the image registry details, optionally customize the Red Hat OpenShift and storage network details, and optionally configure a custom certificate for OpenShift Ingress. At the end of this stage, IBM Fusion HCI completes the installation of three nodes OpenShift cluster and management software.

After you complete the installation stages, you can complete the following tasks:

1. Proceed to add more nodes to the cluster.
2. Configure Fusion Data Foundation or Global Data Platform storage on the cluster.
3. Install IBM Fusion services of your choice.

If you want to bring your own rack, contact IBM Support.

- **[Planning your installation](#)**
Thorough planning ensures that you have everything in place to meet all prerequisites for a successful setup and installation of the system.
- **[Confirm your data center readiness](#)**
Selecting the correct site is the first step in planning your installation.
- **[Plan your networking and connectivity readiness](#)**
Before you install IBM Fusion HCI, review the network architecture, IP address assignment options, firewall rules, cable requirements, proxy settings, and Scale network configuration to ensure your environment is ready.
- **[Configuring the enterprise registry](#)**
Before you install IBM Storage Fusion HCI, confirm that you have the required access to the image registry and software entitlements for your deployment.
- **[Run the installation](#)**
Before you begin the installation of IBM Storage Fusion HCI, confirm that your environment meets all prerequisites and that your site, network, registry, and software access are ready.

Planning your installation

Thorough planning ensures that you have everything in place to meet all prerequisites for a successful setup and installation of the system.

Planning minimizes errors during installation and enables a quicker upgrade or installation. This planning information helps you integrate the system into your data center, plan power and environmental needs, and prepare for any unique configurations you need to handle.

To ensure that the planning is completed successfully, assign a planning project manager to provide a documented plan that includes the following items:

- A timeline for the activities
- Each major activity phase and the intended outcome
- A list of responsibilities and the person assigned
- A current system diagram and configuration listing. Include all hardware content, software content, cabling, and other pertinent configuration items, particularly if this is a modification to an existing system
- A key contacts list, including off-hours contact information for all key task or activities participants
- A plan for communicating appropriate elements of your plan with key personnel.
- **[Identify your deployment architecture](#)**
Identify the deployment architecture that best fits your environment by reviewing available blueprints, storage options, rack ordering choices, and disaster recovery prerequisites before you begin installing.
- **[Identify your resource allocation and management](#)**
Review system requirements and networking prerequisites to ensure your environment meets the resource allocation and management needs of IBM Fusion HCI before you install.
- **[Installation prerequisites](#)**
Go through these general prerequisites and ensure that they are all met before you go ahead with your installation.

Identify your deployment architecture

Identify the deployment architecture that best fits your environment by reviewing available blueprints, storage options, rack ordering choices, and disaster recovery prerequisites before you begin installing.

Use the following resources to determine your deployment architecture before you proceed with site readiness, networking, and installation tasks:

- **Review use case design guidance.** Review reference architectures and workload deployment patterns for IBM Fusion HCI.
- **Identify storage for your use case.** Decide between Fusion Data Foundation and IBM Storage Scale storage based on your workload requirements.
- **Identify hardware for your use case.** Review the rack-based and client-provided rack configuration options available when you order.
- **General Metro-DR prerequisites.** If you plan a metropolitan disaster recovery deployment, review the network and tiebreaker requirements before you install.
- **[Review use case design guidance](#)**
IBM Fusion is an application platform designed for running containers, virtual machines, and AI workloads. It has a set of blueprints that provide guidance on how to deploy different types of workloads. The blueprints provide guidance on topics such as resiliency, performance, and data services. They provide t-shirt sizes and guidance on how to scale out.
- **[Identify storage for your use case](#)**
Guidance to choose between Fusion Data Foundation and IBM Storage Scale storage.
- **[Identify hardware for your use case](#)**
The IBM Fusion HCI offers two hardware configuration options that you can order based on your requirements: a rack-based system and a client provided rack.
- **[General Metro-DR prerequisites](#)**
Prerequisites for Metro-DR between two OpenShift® Container Platform clusters.

Review use case design guidance

IBM Fusion is an application platform designed for running containers, virtual machines, and AI workloads. It has a set of blueprints that provide guidance on how to deploy different types of workloads. The blueprints provide guidance on topics such as resiliency, performance, and data services. They provide t-shirt sizes and guidance on how to scale out.

To view the blueprints documents, see the following links:

- **[AI Applications with IBM Fusion](#)**
- **[Red Hat OpenShift Virtualization with IBM Fusion Blueprints](#)**

- [Containerized workloads with IBM Fusion](#)

Identify storage for your use case

Guidance to choose between Fusion Data Foundation and IBM Storage Scale storage.

Fusion Data Foundation is designed to provide persistent storage and cluster data management. It supports containerized environments and integrates seamlessly with Red Hat® OpenShift®. It supports file, block, and object storage, and provides a consistent storage experience across hybrid cloud environments.

The IBM Storage Scale storage is designed for building a global data platform for AI, high-performance computing (HPC), advanced analytics, and other demanding workloads. It supports file and object storage for unstructured data.

Fusion Data Foundation is tailored for containerized environments, multi cluster, virtualization, and OpenShift deployments, while IBM Storage Scale is more towards AI, HPC, and analytics workloads.

After installing the IBM Fusion HCI, you have the flexibility to install either of these storage types (IBM Storage Scale or Fusion Data Foundation) as a service through the user interface.

Identify hardware for your use case

The IBM Fusion HCI offers two hardware configuration options that you can order based on your requirements: a rack-based system and a client provided rack.

Rack-Based System

The rack based IBM Fusion HCI includes an R42 unit rack, with nodes, switches, and Power Distribution Units (PDUs) pre-stacked and pre-wired at the factory. To begin the installation, you only need to connect your data center network to the high-speed switch. This configuration ensures minimal setup effort at your premises and streamlines deployment.

Client provided rack

In this client provided rack option, you must provide the rack and PDUs. However, you can also order the PDUs from IBM. A technical assessment is essential to ensure compatibility of your rack and PDUs for seamless integration. IBM provides the nodes, switches, and network cables to connect the nodes and switches. The IBM Service Support Representatives (SSR) does the assembly at your premises.

General Metro-DR prerequisites

Prerequisites for Metro-DR between two OpenShift® Container Platform clusters.

Meet the following requirements:

Note: Metro-DR solution is only supported on Global Data Platform storage.

Setting up the tiebreaker

- Install IBM Fusion HCI in two separate data centers within a metropolitan distance from each other. It is recommended to have the third site to host the tiebreaker, and a VM is needed to host the tie breaker. For the actual procedure to setup, see [Preparing the tiebreaker](#).

Setting up a network

- Network connectivity must be available between all three sites for both the Red Hat® OpenShift network and the IBM Fusion HCI storage network. The IBM Fusion HCI storage network is responsible for the synchronous data replication between both sites, and a high-bandwidth L3 connection must be used that has less than 40 milliseconds of latency and within 150 km. It is recommended that all switches used to connect the two clusters support jumbo frames as it improves performance.
- The IBM Storage Scale core pod that runs on every IBM Fusion HCI node at both sites is assigned an IP address on the storage network. As the number of nodes in a cluster can grow over time, a default IP address range is automatically generated for each cluster. This default IP address range is displayed during the installation GUI for each cluster. If needed, you can provide a different range of IP addresses for the storage network. The IP address range must be different for each site and must be reachable across sites.
- By default, IBM Fusion HCI reserves the 3201 VLAN ID for the storage network. If you need to customize the VLAN ID, record the customization in the [planning worksheet](#). IBM SSR needs the completed worksheet to do the initial configuration of the appliance.
- For more information about how to connect both the sites, see [Metro-DR configuration for Global Data Platform](#).
- **Jumbo frames**
 - Configure all the network devices through which the traffic flows from one site to another with Maximum Transmission Unit (MTU) size 9216 or higher. If your network does not support jumbo frames all the way from site 1 to site 2, then do the following steps:
 - Do not enable Jumbo frames during the installation of site 2 and apply the same preference to site 1.
 - For steps to enable or disable, see [Configure GDP storage](#) topic.
 - If you enable jumbo frames on the site 1, then you must enable it on the site 2 and on all network devices in between.
 - Both the client and IBM Fusion HCI switches must have matching packet sizes.
 - For optimal performance, IBM recommends that you enable the jumbo frames.

Setting up communication between the clusters

The Metro-DR solution involves network traffic between two IBM Fusion HCI clusters and the tie breaker. Update the firewall for the three sites to allow traffic between each of the three endpoints in the solution.

- Site one and site two must allow communication between the IP addresses of the two IBM Fusion HCI clusters on both Red Hat OpenShift network and the IBM Fusion HCI storage network. On the Red Hat OpenShift, the network communications across sites take place over UDP port 4500. On the storage network, communication across sites takes place over TCP ports 1191 and 12345.
- Site one and the tie breaker site must allow communication between the IP address on the storage network of site one cluster and the IP address of the tie breaker virtual machine. This communication takes place over 1191 and 12345.
- Site two and the tie breaker site must allow communication between the IP address on the storage network of the site two clusters and the IP address of the tie breaker virtual machine. This communication takes place over 1191 and 12345.
- For Metro-DR allowed ports, see [Firewall requirements](#).

Storage network

- A default IP range is provided out of the box for the storage network.
- If needed, you can provide a different range of IP addresses for the storage network; however, it must be different across sites.
- Storage VLANs and storage networks are customizable for a single rack and must use only a private network for the storage network.

Admin network

Each cluster has a pod network that needs to communicate with each other in a Metro-DR setup. To achieve this communication, make sure that the pod network is different across the sites. By default, different values are available for site 1 and site 2 during installation, but you can override them.

- [Preparing the tiebreaker](#)
Planning and preparation to setup the tiebreaker.

Preparing the tiebreaker

Planning and preparation to setup the tiebreaker.

Important:

- Ensure that you install the `ncat` package for the tiebreaker.
- Ensure that you have entry for the `gpfs-tiebreaker` in the DNS server along with the IP that you choose for the tiebreaker.

Connect with your network administrator for the tiebreaker setup. You must connect the tiebreaker to the daemon network of the two OpenShift® Container Platform clusters.

- The Metro-DR configuration must be complete between the two sites.
- When you want to upgrade from IBM Fusion HCI 2.13.x Metro-DR setup to IBM Fusion HCI 2.14.0 Metro-DR setup, skip this procedure and upgrade your tiebreaker to IBM Storage Scale 5.2.3.9. For the procedure to upgrade, see [Upgrading the tiebreaker from IBM Storage Scale 5.2.3.x to 5.2.3.9](#).

• Secure Boot enabled system:

For RHEL, ensure either of the following for the IBM Storage Scale to work properly in a Secure Boot enabled system:

- Disable Secure Boot in BIOS.
- Sign into IBM Storage Scale kernel module manually.

For more information about how to check Secure Boot enablement, see <https://access.redhat.com/articles/5337691>.

- Hardware requirements are CPU 2 cores, Memory 4G, a raw disk with not less than 20 GB.
- Add entry in the Domain Name System (DNS) for the tie-breaker: `gpfs-tiebreaker`.
- For software requirements, see [Software requirements for IBM Storage Scale](#).
 - For RHEL, ensure either of the following for IBM Storage Scale to work properly in a Secure Boot enabled system:
 - Disable Secure Boot in BIOS.
 - Sign into IBM Storage Scale kernel module manually.
- For tiebreaker allowed ports, see [Firewall requirements](#).
- Software preparation:
 1. SSH to the tiebreaker VM.
 2. Run the following commands to install Python 3:

```
yum install python3
```

3. Download the IBM Storage Scale Data Management 5.2.3.9 from IBM Entitled System Support:

- a. Log in to IBM Entitled System Support - <https://www.ibm.com/servers/eserver/ess/landing/index.html>.
- b. Go to My entitled software, Software Downloads.
- c. In the Product, search for 5771-PP7 (IBM Fusion HCI) and click Add Product.
 - The **IBM Storage Scale Data Mgmt 5.2.3.9 x86 64 Linux install** is available for Storage Scale Data Management.
 - Select `Storage_Scale_Data_Management-5.2.3.9-x86_64-Linux.tar.gz` to download.

4. Extract the IBM Storage Scale package:

```
chmod +x Storage_Scale_Data_Management-5.2.3.9-x86_64-Linux.tar.gz
./Storage_Scale_Data_Management-5.2.3.9-x86_64-Linux.tar.gz
```

5. Go to `/usr/lpp/mmfs/5.2.3.9/ansible-toolkit` directory.
6. Run the following setup command to install Ansible.

```
./spectrumscale setup -s <Tiebreaker IP>
```

7. Create `/usr/lpp/mmfs/5.2.3.9/ansible-toolkit/ansible/vars/tiebreaker_nodedefinition.json` file.
8. Update the content of `tiebreaker_nodedefinition.json` as follows:

```
{
  "scale_cluster": {
    "scale_version": "5.2.3.9",
    "ssh_authorizedkeys": "<ssh_authorizedkeys>",
    "ssh_privatekey": "<ssh_privatekey>",
    "ssh_publickey": "<ssh_publickey>"
  },
  "tiebreaker_node": [
```

```
{
  "fqdn": "<Tiebreaker IP>"
}
]
```

<ssh_authorizedkeys>
Run the following command to get the `ssh_authorizedkeys` value:

```
oc get secret ibm-spectrum-scale-core-ssh-key-secret -n ibm-spectrum-scale -ojsonpath="{.data.ssh-authorizedkeys}"
```

<ssh_privatekey>
Run the following command to get the `ssh_privatekey` value:

```
oc get secret ibm-spectrum-scale-core-ssh-key-secret -n ibm-spectrum-scale -ojsonpath="{.data.ssh-privatekey}"
```

<ssh_publickey>
Run the following command to get the `ssh_publickey` value:

```
oc get secret ibm-spectrum-scale-core-ssh-key-secret -n ibm-spectrum-scale -ojsonpath="{.data.ssh-publickey}"
```

<Tiebreaker IP>
Enter your tiebreaker IP address.

9. Copy `playbook_tiebreakernode_install.yml` and `set_json_variables_tb.yml` from the sample directory to the Ansible directory:

```
cp /usr/lpp/mmfs/5.2.3.9/ansible-toolkit/ansible/sample/playbook_tiebreakernode_install.yml /usr/lpp/mmfs/5.2.3.9/ansible-toolkit/ansible/sample/set_json_variables_tb.yml /usr/lpp/mmfs/5.2.3.9/ansible-toolkit/ansible/
```

10. Run the following command to configure the SSH passwordless:

```
sed -i 's/scale_private_public_key_config: false/scale_private_public_key_config: true/g' /usr/lpp/mmfs/5.2.3.9/ansible-toolkit/ansible/playbook_tiebreakernode_install.yml
```

11. Go to directory `/usr/lpp/mmfs/5.2.3.9/ansible-toolkit/ansible/` and run the playbook to install the tiebreaker node:

```
ansible-playbook playbook_tiebreakernode_install.yml
```

Important:

- Change the port from default 22 to 12345. Otherwise, you cannot log in to the tiebreaker VM.
- If tiebreaker VM goes down, then you need to run the playbook again to install the tiebreaker node. After restart, the node port is automatically set to 22 because that is the default.

12. Run `lsblk` to get the device name of the raw disk attached to the tiebreaker VM. The device name gets used later to add the tiebreaker into the IBM Storage Scale cluster.

13. Run the following `echo` command to encode the disk name string:

```
echo "<Disk name eg: /dev/vda>" | base64
```

As a prerequisite to run `base64`, you must install `base64` or `jq`.

14. From either the site 1 or site 2, run the following command to patch the Metro-DR config secret to include the tiebreaker disk details:

```
oc patch secret isf-metrodr-config-secret -n ibm-spectrum-fusion-ns -p '{"data":{"TieBreakerDevice":"Encoded disk name from previous command"}}'
```

Note: Enter double quotes for the tiebreaker device name while you patch the Metro-DR config secrets.

15. Set up the tiebreaker. For the actual steps to set up, see [Upgrade and upsize considerations in Metro-DR](#) section.

Identify your resource allocation and management

Review system requirements and networking prerequisites to ensure your environment meets the resource allocation and management needs of IBM Fusion HCI before you install.

Use the following resources to confirm that your environment meets the resource allocation and management requirements before you proceed with installation:

- **Review recommended resources.** Review the resource allocation and management details for IBM Fusion HCI and its services to ensure efficient and effective operation.

After you confirm your resource allocation, review [Plan your networking and connectivity readiness](#) to complete your network planning before you install.

- **Review recommended resources**
System requirements provide the details of the resources allocation and management of the IBM Fusion HCI and its services to help ensure efficient and effective operation.

Review recommended resources

System requirements provide the details of the resources allocation and management of the IBM Fusion HCI and its services to help ensure efficient and effective operation.

System requirements outline the minimum and recommended specifications CPU, memory, and storage for a system to function correctly, including:

- Request - minimum requirements required for basic functions
- Limit - maximum requirements that are required for smooth and efficient operation

To ensure efficient and effective operation, the following resource allocation and management details are recommended for IBM Fusion HCI management software and its services, based on a cluster configuration with three control nodes and three compute nodes. Also, the resource sizing depends on the number of nodes for components that are marked as "Per node".

Important: Fusion Data Foundation can be deployed on Infra or worker nodes, whereas all other IBM Fusion services including Base must be deployed on worker nodes.

IBM Fusion management software

IBM Fusion	vCPU				Memory (GiB)				Storage (GiB)	
	Control node		Worker node		Control node		Worker node		Request	Limit
	Request	Limit	Request	Limit	Request	Limit	Request	Limit		
ibm-spectrum-fusion-ns namespace	5.5	12	0.5	3	5	16.5	0.6	2.5	500	NA
openshift-monitoring namespace	0.008	NA	NA	NA	0.2	NA	NA	NA	500	NA

Each additional multi-rack or expansion rack added to the system introduces four new switches, so increasing the overall capacity by four extra pods.

IBM Fusion	vCPU				Memory (GiB)				Storage (GiB)	
	Control node		Worker node		Control node		Worker node		Request	Limit
	Request	Limit	Request	Limit	Request	Limit	Request	Limit		
openshift-monitoring namespace	0.002 x 4	NA	NA	NA	0.1 x 4	NA	NA	NA	NA	NA

Fusion Data Foundation

The following table lists out the system requirements that must be met to install the Fusion Data Foundation service.

Component	vCPU			Memory (GiB)			Storage (GiB)
	Profile	Request	Limit	Profile	Request	Limit	
Fusion Data Foundation	Balanced	13 (number of storage drives x 2)	NA	Balanced	26	NA	50.5
MCG standalone	NA	3	NA	NA	15.5	NA	50.5

Important: Resource sizing might vary depending on the number of nodes for components that are marked as "Per node". By default, IBM Fusion HCI servers come with two disks. If you want to add more disks to your IBM Fusion HCI, the storage requirement changes based on the total disk count.

The following table lists out the system requirements that must be met for an additional worker node in the Fusion Data Foundation service.

Component	vCPU			Memory (GiB)			Storage (GiB)
	Profile	Request	Limit	Profile	Request	Limit	
Fusion Data Foundation	Balanced	13 + (number of storage drives x 2)	NA	Balanced	26 + (number of storage drives x 5)	NA	50.5
MCG standalone	NA	3	NA	NA	15.5	NA	50.5

Global Data Platform

The following table lists out the system requirements that must be met to install the Global Data Platform service.

To install the Global Data Platform using control nodes, the following requirements must be met:

Component	vCPU		Memory (GiB)		Storage (GiB)
	Request	Limit	Request	Limit	
Global Data Platform	10	NA	71	NA	25 per node
Global Data Platform remote mount	4	NA	11	NA	25 per node

To install the Global Data Platform using worker nodes, the following requirements must be met:

Component	vCPU			Memory (GiB)			Storage (GiB)
	Role	Request	Limit	Role	Request	Limit	
Global Data Platform	Storage	8	NA	Storage	64	NA	25
	Client	2	NA	Client	16	NA	
	AFM	16	NA	AFM	162	NA	
Global Data Platform remote mount	NA	2	NA	NA	5	NA	25

Backup & Restore

The following table lists out the system requirements that must be met to install the Backup & Restore service.

Component	vCPU				Memory (GiB)				Storage (GiB)	
	Control node		Worker node		Control node		Worker node		Request	Limit
	Request	Limit	Request	Limit	Request	Limit	Request	Limit		
Hub	NA	NA	4.91	31.1	NA	NA	17.91	42.76	Ephemeral: 3.35 PVC: 200	Ephemeral: 8.07 PVC: NA
Spoke	NA	NA	1.39	14	NA	NA	2.1	13.87	Ephemeral: 0.88 PVC: 10 minimum	Ephemeral: 3.15 PVC: NA

Important: Resource sizing might vary depending on the number of nodes for components that are marked as "Per node".

The following table lists out the system requirements that must be met for an additional job in the Backup & Restore service.

Component	vCPU		Memory (GiB)		Storage (GiB)	
	Request	Limit	Request	Limit	Request	Limit
Each additional node for Backup & Restore	0.05	4	0.24	2	0.02	0.5
(Beyond the first three) Applicable for both Hub and Spoke						

Per Job Additional Requirements	2	4	4	16	4.89	4.89
Data Mover (1 per PVC, max 5 per node)						
Per Job Additional Requirements	0.1	2	3.9	14.65	0.4	1.95
Legacy Restic Data Mover (1 per PVC, max 3 per node)						
Per Job Additional Requirements	0.5	4	0.5	4	4.89	4.89
Maintenance (after every job and once per day per application/policy combination)						

IBM Data Cataloging

The following table lists out the system requirements that must be met to install the IBM Data Cataloging service.

Component	vCPU				Memory (GiB)				Storage (GiB)	
	Control node		Worker node		Control node		Worker node		Request	Limit
	Request	Limit	Request	Limit	Request	Limit	Request	Limit		
IBM Data Cataloging	NA	NA	18	72	NA	NA	26	115	120	NA

Important: For IBM Data Cataloging service, no changes are required as the footprint on IBM Data Cataloging does not change for additional nodes.

Content-Aware Storage (CAS)

The following table lists out the system requirements that must be met to install the CAS service.

Note: For Content-Aware Storage with more than 12 TB of ingested data, contact IBM Sales representatives for your intended workloads.

Component	vCPUs	Memory	Storage
Content-Aware Storage with less than 12 TB of ingested data	Request: 9 Limit: 25	Request: 22 GiB Limit: 24 GiB	The minimum required filesystem size is 550 GB*
nv-ingest Requirements	Request: 30 Limit: 60	Request: 90 GiB Limit: 290 GiB	100 GB
docling_multimodal - Additional requirements	Request: 4.5 Limit: 21	Request: 13 GiB Limit: 44 GiB	100 GB
Minimum requirements for each additional Collection	Request: 1 Limit: 2	Request: 10 GiB Limit: 10 GiB	1 GB

* For more information about IBM Spectrum Scale Container Native Storage Access, see [Hardware requirements for IBM Storage Scale Container Native Storage Access](#).

GPU resources

Configuration	GPU worker nodes	Non-GPU worker nodes	Production with Multi-Instance GPU (MIG)* enabled	Production without Multi-Instance GPU (MIG) enabled
Content-Aware Storage with less than 12 TB of ingested data	1	2	2 or more MIG Capable NVIDIA GPUs (A100 80 GB, H100, H200, RTX PRO 6000)	1 NVIDIA GPU for each NVIDIA NIM service** configured (L40S, A100 H100, H200, RTX PRO 6000)

* For more information about MIG, see [Configuring a Multi-Instance GPU \(MIG\) with CAS](#).

** For more information about the NVIDIA NIM services, see [Select NVIDIA Inference Microservices \(NIMs\)](#).

Installation prerequisites

Go through these general prerequisites and ensure that they are all met before you go ahead with your installation.

- A connection to the internet is needed to install the software that operates the IBM Fusion HCI appliance. If you plan to do an offline installation of IBM Fusion, mirror external-operators and OpenShift® Container Platform image repositories to your registry. For the actual steps, see [Enterprise registry for IBM Fusion HCI installation](#).
- IBM's delivery service removes the rack from the pallet, unpacks, and moves the rack to its final location on the data center floor. If you instruct to leave the pallet or rack packed in the staging area, then it is your responsibility to remove, unpack, and move the rack to its final location. Follow the printed manual to unbox the rack and locate it in your data center.
 - If client-provided rack is used, then the following system components are delivered in two boxes that are shipped on one or more pallets:
 - First box has four switches (two High-speed and two management) and all nodes
 - Second box have rails, cables, and manuals
- Ensure that IBM Fusion HCI is installed in a restricted access location, such that the area is accessible only to skilled and instructed persons with proper authorization.
- If you plan to use a custom certificate, follow the OpenShift Container Platform guidelines to create a certificate. Consider the following points for the chain of certificates:
 - Wildcard certificate must be the first certificate in the file.
 - Any intermediate certificates must follow the wildcard certificate.
 - End of the file must have a root CA certificate.

Note: Ensure that the certificate is well-known and not a self-signed certificate.
- Go through the [Confirm your data center readiness](#) topics and confirm whether your premise satisfies the requirements.
- The following are the high-level steps to set up and configure the hardware appliance:
 - You must unpack the appliance and locate it in your data center. For planning and prerequisites, see [Planning your installation](#).
 - If you purchased the system without an IBM rack, the IBM SSR unpacks the components from their boxes and installs them into the client-provided rack.
 - The Service Support Representative (SSR) assists you in network cabling and power connections by using the details that are provided by your network team.

3. The SSR assists you with the Network setup stage of the installation. The network setup includes the configuration of your network, such as high-speed switch and IP configuration. For more information, see [General requirements](#).
- If you plan to use a proxy server for internet access, then contact the IBM Support team. For more information about proxy configuration, see [Review proxy configuration guidance](#).
- The Container Network Interface (CNI) network (daemon network) is created for IBM Spectrum® Storage Scale Erasure Code Edition (ECE) core pods. By default, IP addresses are assigned for scale daemon network. You can override the default IP address before you begin the Final installation. For the procedure, see [Preventing Scale network IP conflicts](#).

Note: You can override the default IP addresses only before you start the Final Installation wizard.

- If you plan to install site 2 in a Metro-DR setup, ensure that the following prerequisites are met:
 - IBM Storage Scale on the site 1 is healthy and all IBM Storage Scale core pods are up and running.
 - Ensure that the disk count is same on site 1 and site 2.
 - Ensure that site 2 has the same supported OpenShift Container Platform version as site 1.

For general Metro-DR prerequisites, see [General Metro-DR prerequisites](#).

- If you installed IBM Fusion HCI in the previous version using offline or online installation mode, then ensure that you do not change the mode during the upgrade to the new version. To change the installation mode, reinstall IBM Fusion HCI.
- Run the command to pull the image and verify that you have access to the IBM Fusion HCI images.

Note: You can use either Podman or Docker to verify the access.

```
podman login cp.icr.io -u cp -p "CLIENT ENTITLEMENT KEY"
podman pull cp.icr.io/cp/isf/isf-validate-entitlement@sha256:1a0dbf7c537f02dc0091e3abebae0ccac83da6aa147529f5de49af0f23cd9e8e
```

If the pull is successful, then you have a valid entitlement for IBM Fusion HCI images.

- For a high availability cluster, you must have received three racks from IBM with a minimum of six nodes per rack. Also, you must buy a pair of spine switches from IBM. Cables of required length to attach the spine switches can be IBM provided or client that is provided.

Confirm your data center readiness

Selecting the correct site is the first step in planning your installation.

Determine whether you are constructing a new site or modifying an existing one. This section provides information on building location, structure, and space requirements for present and future needs.

Power and communication facilities must be available in the quantities required for operation. If these are inadequate, contact the utility company to determine whether additional services are available.

Include any exposure to pollution, flooding, radio or radar interference, and hazards from nearby industries in your installation plan. These factors can affect information technology equipment and recorded media.

Ensure that the IBM Fusion HCI appliance is installed in a restricted access location, accessible only to skilled and instructed persons with proper authorization.

- [Confirm data center facility and space readiness](#)
Confirm that your data center facility meets the space, structural, and location requirements before you install IBM Fusion HCI.
- [Confirm data center environmental readiness](#)
Confirm that your data center meets the cooling, vibration, noise, and electromagnetic requirements before you install IBM Fusion HCI.
- [Confirm data center safety and protection readiness](#)
Confirm that your data center meets the static electricity and data storage protection requirements before you install IBM Fusion HCI.
- [Confirm your power and infrastructure readiness](#)
Reliable electrical power is required for the proper functioning of your data processing equipment.

Confirm data center facility and space readiness

Confirm that your data center facility meets the space, structural, and location requirements before you install IBM Fusion HCI.

Use the following topics to confirm that your data center facility and space meet the requirements for IBM Fusion HCI installation:

- *Review space requirements* — Determine the floor area needed based on your system configuration, future expansion, and service clearance requirements.
- *Conduct a floor load assessment* — Calculate the floor loads to confirm that the building structure can support the weight of the equipment.
- *Identify computer room location* — Evaluate safety, fire prevention, and environmental factors when selecting the computer room location.
- [Review space requirements](#)
The floor area that is required for the equipment is determined by the specific systems to be installed, the location of columns, the floor loading capacity, and the provisions for future expansion.
- [Conduct a floor load assessment](#)
Use the following formulas to calculate the floor loads for the system.
- [Identify computer room location](#)
Computer room location is affected by several factors, such as considerations for safety and fire prevention.

Review space requirements

The floor area that is required for the equipment is determined by the specific systems to be installed, the location of columns, the floor loading capacity, and the provisions for future expansion.

When the amount of space is determined, allow more space for furniture, carts, and storage cabinets. Additional space, not necessarily in the computer area, is required for air conditioning, electrical, security systems, fire protection equipment, and storage of tapes, forms, and other supplies. Plan to store all combustible materials in properly designed and protected storage areas.

Additional space might be needed to access the system, for example, rack-door-opening clearance.

For information about floor loading and weight distribution for your system, see *Floor construction and floor loading* [Conduct a floor load assessment](#).

For more information about the depth, height, and width measurements of a IBM Fusion HCI, see [Planning for the rack](#).

Conduct a floor load assessment

Use the following formulas to calculate the floor loads for the system.

A floor loading assessment is the evaluation of the concrete subfloor, not the raised floor. The weight of the raised floor is considered in the floor loading formula.

The building floor must support the weight of the equipment to be installed. Although older devices might impose 345 kg/m² (75 lb/ft²) on the building floor, a typical system design imposes a load of no more than 340 kg/m² (70 lb/ft²). The following pounds-per-square-foot (lb/ft²) formula is used to calculate floor loading. For assistance with floor load evaluation, contact a structural engineer.

Floor Loading is: (machine weight + (15 lb/ft² x 0.5 svc clear) + (10 lb/ft² x total area))/ total area

- The floor loading should not exceed 240 kg/m² (50 lb/ft²) with a partition allowance of 100 kg/m² (20 lb/ft²) for a total floor load rating of 340 kg/m² (70 lb/ft²).
- The raised-floor weight plus the cable weight adds 50 kg/m² (10 lb/ft²) uniformly across the total area that is used in calculations and is included in the 340 kg/m² (70 lb/ft²) floor loading. The total area is defined as: machine area + 0.5 service clearance.
- When the service clearance area is also used to distribute machine weight (weight distribution/service clearance), 75 kg/m² (15 lb/ft²) is considered for personnel and equipment traffic. The distribution weight is applied over 0.5 of the clearance up to a maximum of 760 mm (30 in.) as measured from the machine frame.

Identify computer room location

Computer room location is affected by several factors, such as considerations for safety and fire prevention.

Before selecting a location for the computer, give attention to these guidelines:

- The computer room must be in a noncombustible or fire-resistant building or room.
- The computer room must not be above, below, or next to areas where hazardous materials or gases are stored, manufactured, or processed. If the computer must be located near such an area, take extra precautions to safeguard the area.
- If the computer room is below ground level, provide adequate drainage.

Safety consideration and fire prevention

Safety is a vital factor when planning computer installation. This consideration is reflected in the choice of the computer location, building materials used, fire prevention equipment, air conditioning and electrical systems, and personnel training.

If an inconsistency occurs between IBM recommendations and any local or national regulation, the more stringent of the recommendations or regulations must take precedence. The National Fire Protection Association standard, NFPA 75, provides guidelines for protection of information technology equipment. The customer is responsible for adherence to governmental regulations.

- Computer room walls must have a minimum of a 1-hour-fire-resistance rating and extend from the structural floor to the structural ceiling (slab-to-slab).
- In rooms used for critical operations, it is preferable to install processors in 1-hour-fire-rated rooms separate from the main computer room.
- If the computer room has one or more outside walls that are adjacent to a building that is susceptible to fire, consider taking the following precautionary actions:
 - Installing shatterproof windows in the computer room to improve the safety of personnel and equipment from flying debris and water damage. Usually, windows in the computer room are undesirable because of security concerns, and the negative effect they have on temperature control. They can cause excessive heating in the summer, and excessive cooling in the winter.
 - Installing sprinklers outside the windows to protect them with a blanket of water if a fire occurs in the adjacent area.
 - Sealing the windows with masonry.

- Where a false (or hung) ceiling or insulating material is to be added, ensure that it is a noncombustible or fire-resistant material. All duct work must be noncombustible. If combustible material is used in the space between the structural ceiling and the false ceiling, appropriate protection must be provided.
- A raised floor that is installed over the structural floor must be constructed of noncombustible or fire-retardant materials. If the structural floor is of combustible material, it must be protected by water sprinklers on the ceiling of the room below.

Note: Before the equipment is installed, the space between the raised and the structural floors must be cleared of debris. This space must also be checked periodically after installation to keep it free of accumulated dust, possible debris, and unused cables.

- The roof, ceiling, and floor above the computer room and the storage area for recorded media must be watertight. Liquid piping, roof drains, and other potential sources of liquid damage must be rerouted around the area.
- The space under the raised floor in the computer room must be provided with drainage to protect against flooding or trapped water.
- Waste material containers must be constructed of metal with a frame-suppressant lid.

Fire prevention equipment in a computer room

Fire prevention equipment in the computer room must be installed as an added safety measure. A fire suppression system is the responsibility of the customer. Your insurance underwriter, local fire marshall, and local building inspector are all parties that must be consulted in selecting a fire suppression system that provides the correct level of coverage and protection. IBM® designs and manufactures equipment to internal and external standards that require certain environments for reliable operation. Because IBM does not test any equipment for compatibility with fire suppression systems, IBM does not make compatibility claims of any kind nor does IBM provide recommendations on fire suppression systems.

- An early-warning fire detection system must be installed to protect the computer room and storage areas for recorded media. This system must activate both an audible and a visual alarm in the rooms and at a monitored central station.
- Portable carbon dioxide fire extinguishers, of suitable size and number, must be provided in the computer room for use on electrical equipment. Dry chemical extinguishers must not be used in the data center.
- Portable, pressurized-water extinguishers must be provided for combustible material such as paper.
- Extinguishers must be readily accessible to individuals in the area, and extinguisher locations must be marked so they are visible.
- Automatic sprinkler systems and gaseous total flooding systems are acceptable forms of fixed protection. For information on environmentally friendly gases for total flooding systems, consult NFPA 2001 titled Standard on Clean Agent Fire Extinguishing Systems.
- Special consideration must be used if you prefer a gaseous total flooding system. If a gaseous total flooding system is installed, include a time delay feature that allows investigation and evacuation from the covered area of the gaseous total flooding system. A cross-zoned detection system is suggested.
- The protected area must be evacuated whenever the gaseous total flooding system or its controls are being serviced. Additionally, a master Disarm switch, available for use by the system service personnel, is required. With the switch set in the off position, the detonators that are used to release the gaseous total flooding system must be made inoperative, even if the circuit fails elsewhere in the system. This switch must be placed in the off (manual) position before servicing begins to prevent possible accidental discharge of the gaseous total flooding system.
- Alternatives to ordinary wet pipe sprinkler systems might include dry pipe systems or preaction systems. Water flows into preaction systems only if triggered by smoke or heat detectors. The detection systems must be independent of gaseous total flooding system detection systems. The On-Off type of sprinkler head is not suggested because it is more prone to leakage.

To determine the proper fire protection required for the computer room, consult with your insurance underwriter and your local code authority.

Confirm data center environmental readiness

Confirm that your data center meets the cooling, vibration, noise, and electromagnetic requirements before you install IBM Fusion HCI.

Use the following topics to confirm that your data center environment meets the requirements for IBM Fusion HCI installation:

- *Review cooling requirements* — Ensure that your air conditioning system provides year-round temperature and humidity control to support equipment operation.
- *Review vibration guidance* — Plan for vibration and shock conditions in the data center to ensure equipment stability.
- *Review noise emission guidance* — Assess acoustic noise levels for your data processing equipment to meet installation standards.
- *Review electromagnetic guidance* — Plan for system installation in environments that have high electromagnetic-radiated fields.
- [Review cooling requirements](#)
The air conditioning system must provide year-round temperature and humidity control as a result of the heat dissipated during equipment operation.
- [Review vibration guidance](#)
Use this information to plan for possible vibration and shock in the data center.
- [Review noise emission guidance](#)
Acoustic noise emission data enables you to assess noise levels for your data processing equipment.
- [Review electromagnetic guidance](#)
Use this information to plan for system installation in an environment that has a high electromagnetic-radiated field.

Review cooling requirements

The air conditioning system must provide year-round temperature and humidity control as a result of the heat dissipated during equipment operation.

Heat dissipation ratings are given in the server specifications for each server. Air conditioning units must not be powered from the computer power panel because of the high starting current drawn by their compressor units. The feeder line for the air conditioning system and the computer room power must not be in the same conduit.

Consider the following factors when you determine the air conditioning capacity necessary for installation:

- Information technology equipment heat dissipation
- Number of personnel
- Lighting requirements
- Amount of fresh air introduced
- Possible reheating of circulated air
- Heat conduction through outer walls and windows
- Ceiling height
- Area of floors
- Number and placement of door openings
- Number and height of partitions

Most servers are air-cooled by internal blowers. A separate air conditioning system is suggested for data processing installation. A separate system might be required for small systems or individual servers that are intended for operation when the building air conditioning system is not adequate or is not operational. Server heat dissipation loads are given on the server specifications for each server. See the environmental requirements in the server specifications for your server.

Review vibration guidance

Use this information to plan for possible vibration and shock in the data center.

It might be necessary to install the information technology equipment in an area subject to minor vibration. The following information supplies vibration and shock limits for your equipment and some basic definitions concerning vibration. The vibration levels normally present in computer-room and industrial installations are well within the indicated levels.

However, mounting the equipment in racks, stackers, or similar equipment might increase the risk of vibration-related problems. It is important to consult the manufacturer of such equipment to ensure that vibration factors do not exceed the specifications that are provided in the following tables.

Some useful definitions of vibration follow:

Acceleration

Normally measured in g multiples of the acceleration because of the force of gravity. If the frequency is also known for a sine wave, acceleration can be calculated from displacement. (g: The unit of acceleration caused by the force of gravity.)

Continuous

The presence of vibration over an extended period and cause a sustained resonant response in the equipment.

Displacement

Magnitude of the wave shape; normally given in peak-to-peak displacement in English or metric units:

- Normally used to measure floor vibration at low frequencies
 - If the frequency is also known, it can be converted to displacement g for a sine wave.
- Note: Many measuring instruments can convert displacement to go for either sinusoidal or complex wave shapes.

Peak

The maximum value of a sinusoidal or random vibration. This can be expressed as peak-to-peak in cases of sinusoidal vibration displacement.

Random

A complex vibration wave form varying in amplitude and frequency content.

rms (root mean square)

The long-term average of the acceleration or amplitude values. Normally used as a measure of overall vibration for random vibration.

Shock

Intermittent inputs that occur and then decay to zero prior to a recurrence of the event. Typical examples are foot traffic, fork lifts in aisles, and external events such as railroad, highway traffic, or construction activities (including blasting).

Sinusoidal

Vibration with the characteristic shape of the classical sine wave (for example, 60-Hz AC power).

Transient

Vibrations that are intermittent and do not cause a sustained resonant response in the equipment.

If you need to make any calculations or require information regarding the previous definitions, consult a mechanical engineer, a vibration consulting engineer, or your seller.

The three classes of a vibration environment are shown in the following table.

Table 1. Vibration environment

Class	Vibration environment
V1	Floor-mounted machines in an office environment
V2	Table-top and wall-mounted machines
V3	Heavy industrial and mobile equipment

A summary of the vibration limits for each of the three classes is shown in the following table. A legend follows the table.

Note: Vibration levels at any discrete frequency should not exceed a level of 1/2 the g rms values for the class that is listed in the following table.

Table 2. Operational vibration and shock limits

Class	g rms	g peak	Mils	Shock
V1 L	0.10	0.30	3.4	3 g at 3 ms
V1 H	0.05	0.15	1.7	3 g at 3 ms
V2	0.10	0.30	3.4	3 g at 3 ms
V3	0.27	0.80	9.4	application dependent

L

Light with weight less than 600 kg

H

Heavy with weight equal to or greater than 600 kg

g rms

Overall average g level over the 5 to 500 Hz frequency range

g peak

Maximum real-time instantaneous peak value of the vibration time history wave form (excluding events that are defined as shocks).

Mils

Peak-to-peak displacement of a discrete frequency in the 5 to 17 Hz range. One mil equals 0.001 inch

Shock

Amplitude and pulse width of a classical 1/2 sine shock pulse

The values that are given in the Operational vibration and shock limits table are based on worst-case field data measured at customer installations for current and previously released products. The vibration and shock environment does not exceed these values except for abnormal cases involving earthquakes or direct impacts. Your seller can contact the IBM® Standards Authority for Vibration and Shock in case of specific technical questions.

Earthquakes

Special frame-strengthening features might be required in earthquake prone areas. Local codes might require the information technology equipment to be tied down to the concrete floor. If sufficient information on equipment tie down is not provided in the product's physical planning documentation, consult with your seller.

Review noise emission guidance

Acoustic noise emission data enables you to assess noise levels for your data processing equipment.

Acoustic noise emission data on IBM® products is provided for the benefit of installation planners and consultants to help predict acoustical noise levels in data centers and other installations of information technology and telecommunications equipment. Such noise declarations also enable you to compare noise levels of one product to

another and to compare the levels to any applicable specifications. The format of the data that is provided conforms to ISO 9296: Acoustics - Declared Noise Emission Values of Computer and Business Equipment. The measurement procedures used to acquire the data conform to International Standard ISO 7779 and its American National Standard equivalent ANSI S12.10.

The following terms are used to present acoustical data.

- **L_{WAd}** is the declared (upper limit) A-weighted sound power level for a random sample of machines.
- **L_{pAm}** is the mean value of the A-weighted sound pressure levels either at the operator position or at the bystander (1-meter) positions for a random sample of machines.
- **L_{pA>m}** is the mean value of the space-averaged sound-pressure-emission levels at the 1-meter positions for a random sample of machines.

Acoustical treatment of data centers or other rooms, in which the equipment is installed, is suggested to achieve lower noise levels. Lower noise levels tend to enhance employee productivity and avoid mental fatigue, improve communications, reduce employee complaints, and generally improve employee comfort. Proper room design, including the use of acoustical treatment, might require the services of a specialist in acoustics.

The total noise level of an installation with information technology and telecommunications equipment is an accumulation of all the noise sources in the room. This level is affected by the physical arrangement of the products on the floor, the sound reflective (or absorptive) characteristics of the room surfaces, and the noise from other data center support equipment such as air conditioning units and backup power equipment. Noise levels might be reduced with proper spacing and orientation of the various noise-emitting equipment. Provide sufficient space around such machines. The farther apart they can be placed, the lower the overall room noise is.

In smaller installations, such as small offices and general business areas, pay additional attention to the location of equipment relative to the work areas of the employees. At work areas, consider locating computers next to the desk rather than on top of it. Small systems must be located as far away from personnel as possible. Locate nearby work areas away from the exhaust of computer equipment.

The use of absorptive materials can reduce the overall noise level in most installations. Effective and economical sound reduction can be achieved by using a sound-absorptive ceiling. The use of acoustically absorbing free-standing barriers can reduce the direct noise, increase room absorption and provide privacy. The use of absorptive material, such as carpeting on the floor, results in further reduction of the sound level in the room. Any carpeting that is used in a computer room must meet the electrical continuity requirements that are stated in *Static electricity and floor resistance*. To prevent computer room noise from reaching adjacent office areas, walls must be constructed from the structural floor to the structural ceiling. Also, ensure that doors and walls are properly sealed. Acoustical treatment of overhead ducts might further reduce noise that is transmitted to or from other rooms.

Many IBM large system products are offered with optional acoustical front and rear doors to help attenuate the noise of the product itself. If noise exposure is a concern for the installation planners or employees, inquiries must be made to IBM on the availability of such product options.

Review electromagnetic guidance

Use this information to plan for system installation in an environment that has a high electromagnetic-radiated field.

Information technology equipment installation might occasionally be planned in an area that has a high electromagnetic-radiated field environment. This condition results when the information technology equipment is near a radio frequency source such as a radio-transmitting antenna (AM, FM, TV, or two-core radio), civilian and military radar, and certain industrial machines (rf induction heaters, rf arc welders, and insulation testers). If any of these sources are near the proposed site, a planning review might be appropriate to assess the environment and determine whether any special installation or product considerations are advisable to reduce interference. Consult your seller. Workstations that are located near devices like transformers or buried electrical conduits can experience jitter on the workstation display in the presence of strong magnetic fields.

Most products can tolerate low-frequency to very-high-frequency rf levels of 3 volts per meter. Field strengths greater than 3 volts per meter might cause operational or serviceability problems. Products have different tolerance levels to electromagnetic-radiated fields in different frequency ranges. Radar (frequency of 1300 MHz, and 2800 MHz) signals with field strengths of a maximum of 5 volts per meter are acceptable. If problems occur, reorientation of the system or selective shielding might be required.

Two-core radio or cellular telephone usage must be properly controlled in the computer room. To reduce the likelihood of a problem, the following suggestions must be considered when operating such equipment:

- Keep hand-held transmitters (for example, walkie-talkies, radio paging, and cellular telephones) a minimum of 1.5 m (5 ft) from information technology equipment.
- Use only an operator-controlled transmitting device (no automatic transmissions). Develop specific rules, such as do not transmit within 1.5 m (5 ft) of a fully covered operating system. If covers are open, do not transmit.
- Choose the minimum output power that accomplishes your communication needs.

Extremely low frequency (ELF) fields

Except for some video display cathode ray tubes (CRT), most information technology equipment is tolerant of extremely low frequency (ELF) electromagnetic fields. The video displays that use cathode ray tubes are more sensitive because they use electromagnetic fields to position the electron beam in normal operation. The extremely low frequency range covers frequencies between 0 - 300 Hz. It is also referred to as electrical power frequency because most world electrical power is generated at either 50 or 60 Hz.

Many products tolerate ELF electromagnetic fields in the following ranges:

- Cathode ray tube video display: 15 - 20 milligauss
- Liquid crystal display (LCD): 10 Gauss
- Magnetic tape equipment: 20 Gauss
- Disk drive equipment: 20 Gauss
- Processors or systems: 20 Gauss

Typical information technology centers exhibit an ambient electromagnetic field of 3 - 8 milligauss. Some equipment within a center might, under normal operation, produce fields in excess of 100 milligauss. Examples of equipment that produces large magnetic fields include: power distribution units, electric motors, electrical transformers, laser printers, and uninterruptible power systems. However, magnetic field density decreases rapidly with distance. If a CRT display is located near equipment that produces large electromagnetic fields, the display might exhibit distortion such as poor focus, change in image shape or slight motion in static display images. Moving the CRT away from the equipment might remedy the problem.

Confirm data center safety and protection readiness

Confirm that your data center meets the static electricity and data storage protection requirements before you install IBM Fusion HCI.

Use the following topics to confirm that your data center meets safety and protection requirements for IBM Fusion HCI installation:

- *Review static electricity guidance* — Follow guidelines to minimize static electricity buildup in the data center, including floor resistance and grounding requirements.
- *Review data storage protection guidance* — Apply special safety considerations for storing data and materials, including fire protection and off-site storage planning.
- [Review static electricity guidance](#)
Use these guidelines to minimize static electricity buildup in the data center.
- [Review data storage protection guidance](#)
Special safety considerations are required when storing data or other material.

Review static electricity guidance

Use these guidelines to minimize static electricity buildup in the data center.

Floor covering material can contribute to the buildup of high static electrical charges as a result of the motion of people, carts, and furniture in contact with the floor material. Abrupt discharge of the static charges causes discomfort to personnel and might cause malfunction of electronic equipment.

The following list explains how to minimize static buildup and discharge:

- Maintain the relative humidity of the room within the system operating limits. Choose a control point that normally keeps the humidity between 35 percent and 60 percent. See [Review cooling requirements](#) for more information.
- Provide a conductive path to the ground from a metallic raised floor structure including the metal panels.
- Ground the raised floor metallic support structure (stringer, pedestals) to building steel at several places within the room. The number of ground points is based on the size of the room. The larger the room, the more ground points are required.
- Ensure that the maximum resistance for the flooring system is 2×10^{10} ohms, measured between the floor surface and the building (or an applicable ground reference). Flooring material with a lower resistance further decreases static buildup and discharge. For safety, the floor covering and flooring system should provide a resistance of no less than 150 kilohms when measured between any two points on the floor space 1 m (3 ft) apart.
- Maintenance of antistatic floor coverings (carpet and tile) should be in agreement with the individual supplier's recommendations. Carpeted floor coverings must meet electrical conductivity requirements. Use only antistatic materials with low-propensity ratings.
- Use ESD-resistant furniture with conductive casters to prevent static buildup.

Measuring floor resistance

The following equipment is required for measuring floor resistance:

- A test instrument similar to an AEMC-1000 megohmmeter is required for measuring floor conductivity.

The following figure shows the typical test connection to measure floor conductivity.

Figure 1. Typical test connection to measure floor conductivity

Review data storage protection guidance

Special safety considerations are required when storing data or other material.

Consider the following factors:

- Any data or material that is stored in the computer room, whether in the form of magnetic tapes, paper tapes, cards, or paper forms, must be limited to the minimum needed for safe, efficient operation and must be enclosed in metal cabinets or fire-resistant containers when not in use.
- For security purposes, and protection against fire, a separate room for material storage is strongly suggested. This room must be constructed of fire-resistant material (minimum 2-hour-fire-resistance rating). An approved fixed extinguishing system is suggested. Fixed extinguishing systems include automatic sprinklers and approved total flooding gaseous systems.

If continuity of operation is critical, plan a remote storage location for vital records if a disaster occurs. Key considerations in the choice of an off-site location for data storage are that the area is:

- Not subject to the same risk that might occur in the computer room.
- Suitable for long-term storage of hardcopy records and magnetic media files.

Air conditioning systems

In most installations, the computer area is controlled by a separate air conditioning system. Therefore, emergency power-off switches for the equipment and air conditioning must be placed in convenient locations, preferably near the console operator and next to the main exit doors. For more information, see the National Fire Protection Association standard, NFPA 70 article 645.

- When the regular building air conditioning system is used, with supplemental units in the computer area, the supplemental units would then be handled as previously stated. The regular building air conditioning system must have an audible alarm to alert maintenance personnel of an emergency.
- Fire dampers must be located in all air ducts at fire walls.
- The air filters in the air conditioning system must contain noncombustible or self-extinguishing material.

Electrical systems

Provide a mainline disconnect control for the computer equipment at a remote location. The remote controls must be in a convenient location, preferably near the console operator and next to the main exit doors. They must be next to the power-off switch for the air conditioning system and must be properly marked. A light must be installed to indicate when power is on. The National Electric Code (NFPA 70) article 645 states that a single disconnecting means to control both the electronic equipment and the HVAC system is permitted.

- If continuity of operation is essential, a standby power source must be installed.
- It is advisable to install an automatic battery-operated lighting unit to illuminate an area if a power or lighting circuit failure occurs. This unit is wired to and controlled by the lighting circuit.
- Watertight connectors are suggested under raised floors because of the moisture exposures (water pipe leaks, high humidity levels) under raised floors.

Confirm your power and infrastructure readiness

Reliable electrical power is required for the proper functioning of your data processing equipment.

IBM® information technology equipment requires a reliable electrical power source that is free from interference or disturbance. Electrical power companies generally supply power of sufficient quality. The Power quality, Voltage and frequency limits, Power load, and Power source topics provide the guidance and specifications that are needed to meet the requirements of the equipment. Qualified personnel must ensure that the electrical power distribution system is safe and meets local and national codes. They must also ensure that the voltage that is measured at the power receptacle is within the specified tolerance for the equipment. In addition, a separate power feeder is required for items such as lighting and air conditioning. A properly installed electrical power system helps to provide for reliable operation of your IBM equipment.

Other factors to consider when planning and installing the electrical system include a means of providing a low impedance conducting path to ground (path to earth) and lightning protection. Depending on the geographical location, special considerations may be required for lightning protection. Your electrical contractor should meet all local and national electrical code requirements. Building electrical power is normally derived from a three-phase power distribution system. General office areas are normally provided with single-phase power outlets, and data processing rooms are provided with three-phase power.

Some IBM IT equipment and devices may require standard three-phase power; others may require single-phase power. The power requirements for each device are specified in the individual system specifications for that system. Nominal voltage, plugs, receptacles, and in some cases, conduit and back boxes are listed in the specific system specifications. Refer to the respective system specifications to determine the power requirements. Ensure that existing branch circuit outlets are the correct type and are properly grounded.

- [Power quality](#)
The quality of electrical power significantly impacts the performance of sensitive electronic equipment. These guidelines ensure that quality electrical power is provided to your data center.
- [Voltage and frequency limits](#)
Voltage and frequency limits must be maintained to ensure proper functioning of your system.
- [Power load](#)
A preliminary sizing for total power load can be obtained by adding the total power requirements for all devices to be connected.
- [Power source](#)
These guidelines help to ensure that your data center has a quality power source.
- [Dual-power installation configurations](#)
These dual-power installation configurations allow you to use the fully-redundant power features of your system.

Power quality

The quality of electrical power significantly impacts the performance of sensitive electronic equipment. These guidelines ensure that quality electrical power is provided to your data center.

IBM® equipment can tolerate some power disturbances or transients. However, large disturbances can cause equipment power failures or errors. Transients can come into the site on the power utility company lines but are often caused by electrical equipment that is installed in the building. For example, transients can be produced by welders, cranes, motors, induction heaters, elevators, copy machines, and other office equipment. The best way to prevent problems that are caused by power disturbances is to have transient-producing equipment on a separate power service than the one that supplies power to your information technology equipment.

Ground or earth

When used in reference to electrical power systems, Ground is a conducting connection between an electrical circuit and the earth or some conducting body that serves in place of the earth. The term ground is the most common name that is used, however it is also referred to as earth or terra in several international geographies. In this topic, these terms and other local language equivalents are interchangeable.

Ground is a critical component of an electrical power distribution system. A properly installed ground system allows for safe operation of equipment that is connected to the electrical power source under normal and electrical or equipment fault conditions. The life safety function of ground and grounding methods is addressed by the appropriate local and national electrical wiring codes. In the United States, this code is known as the National Electric Code or publication 70 of the National Fire Protection Association. Many countries have adopted the National Electric Code or have developed an equivalent code.

The National Electric Code and its equivalents have a primary objective to provide safe operation of electrical power distribution systems and electrical equipment installations. Compliance with these codes does not guarantee efficient operation of equipment connected to the power distribution systems. When sensitive electronic equipment is connected, there are often times when additional ground connections may be required. Typically, additional ground connections are recommended when there is a concern for high frequency or radio frequency (RF) interference, which may impact electronic circuits. These additional ground requirements are found with the installation documentation for specific equipment. Additional ground requirements may also be recommendations from engineering or data center evaluations, reviews or surveys. Local or national codes allow for these additional grounds to be installed.

Grounding

IBM equipment, unless double insulated, has power cords containing an insulated grounding conductor (color-coded green or green with yellow stripe) that connects the frame of the equipment to the ground terminal at the power receptacle. The power receptacles for IBM equipment are identified in the equipment documentation and should match the equipment power plug. In some cases, there may be options for different manufacturer equivalent receptacles. IBM equipment plugs should not be changed or altered to match existing connectors or receptacles. To do so may create a safety hazard and void product warranty. The connectors or receptacles for IBM equipment should be installed to a branch circuit with an equipment grounding conductor, connected to the grounding bus bar in the branch-circuit distribution panel. The grounding bus bar in the panel should then be connected back to the service entrance or suitable building ground by an equipment grounding conductor.

Information technology equipment must be properly grounded. It is recommended that an insulated green wire ground, the same size as the phase wire, be installed between the branch circuit panel and the receptacle.

For personnel safety, the ground must have a sufficiently low impedance to limit the voltage to the ground and to facilitate the operation of protective devices in the circuit. For example, the ground path shall not exceed 1 ohm for 120-volt, 20-ampere branch circuit devices.

The ground path impedance limit is 0.5 ohms for 120 volt branch circuits that are protected by 30 ampere circuit breakers. The limit is 0.1 ohms for 120 volt 60 to 100 ampere circuits.

All grounds entering the room should be interconnected somewhere within the building to provide a common ground potential. This includes any separate power sources, lighting and convenience outlets, and other grounded objects, such as building steel, plumbing, and duct work.

The equipment grounding conductor must be electrically attached to both the enclosure of the computer power center and the connector grounding terminal. Conduit must not be used as the only grounding means, and it must be connected in parallel with any grounding conductors that it contains.

Figure 1. Transient grounding plate

Transient grounding

To minimize the effects of high-frequency electrical noise, the branch circuit power panel servicing the equipment should be mounted in contact with bare building steel or connected to it by a short length of cable. If this is not possible, a metal area of at least 1 m² (10 ft²) in contact with masonry can be used. The plate should be connected to the green-conductor common.

Figure 2. Transient grounding plate

The preferred connection is with a braided strap. If a braided strap is not available, the connection should consist of no. 12 AWG (3.3 mm or 0.0051 in.) or larger conductor and should not be more than 1.5 m (5 ft) long. To minimize this length, the preferred connection of this braided strap or conductor is to the nearest portion of the enclosure on the panel, if the enclosure is electrically continuous from the green-conductor common point to this point of connection.

The raised-floor-supporting substructure can be used as a substitute for the transient plate if the structure has a consistently low-impedance path. If the raised floor has stringers or other subframing that makes electrical connection between the pedestals, the floor itself can be used for the signal reference plane. Some raised floors are stringerless and the floor tiles lock into isolated pedestals by gravity alone. If there is no reliable electrical connection between the pedestals, a signal reference grid can be constructed by connecting the pedestals together with conductors. A minimal grid would interconnect every other pedestal in the immediate area of the power panel and extend at least 3 m (10 ft) in all directions.

Figure 3. Transient grounding using the raised floor support structure

Figure 4. Signal reference grid

Stranded bare or insulated conductor of at least no. 8 AWG (8 mm or 0.0124 in.) copper is required. This conductor provides a low-impedance path and is strong enough to make physical damage unlikely. Any connection method is acceptable as long as it provides a reliable electrical and mechanical connection.

A customer's self-contained, separately derived power system (computer power centers, transformers, motor generators), installed on a raised floor, has the same requirements.

Voltage and frequency limits

Voltage and frequency limits must be maintained to ensure proper functioning of your system.

The phase-to-phase steady-state voltage must be maintained within plus six percent to minus 10 percent of the normal rated voltage, which is measured at the receptacle when the system is operating. A voltage surge or sag condition must not exceed plus 15 percent or minus 18 percent of the nominal voltage and must return to within a steady-state tolerance of plus 6 percent or minus 10 percent of normal rated voltage within 0.5 second.

Some systems might require special considerations and might have more or less restrictive specifications. See the individual system specifications for actual requirements. Because of the possibility of brownouts (planned voltage reduction by the utility company) or other marginal voltage conditions, installing a voltage monitor might be advisable.

The phase frequency must be maintained at 50 or 60 Hz $\pm$ 0.5 Hz.

The value of any of the three phase-to-phase equipment voltages in the three-phase system must not differ by more than 2.5 percent from the arithmetic average of the three voltages. All three line-to-line voltages must be within the limits previously specified.

The maximum total harmonic content of the power system voltage waveforms on the equipment feeder must not exceed 5 percent with the equipment operating.

Power load

A preliminary sizing for total power load can be obtained by adding the total power requirements for all devices to be connected.

For a more precise analysis of power distribution system requirements, you can request an IBM® System Power Profile Program printout from your seller. The System Power Profile Program, controlled and operated by the service office installation planning representative, provides a vector analysis rather than an arithmetic summation of total power. The vector analysis takes into consideration power factor and phase relationships. In addition, it considers waveform distortions caused by the load and inrush requirements. Additional capacity should be planned for future expansion. Contact your service office installation planning representative for information on how to obtain a System Power Profile.

Primary power problem areas

Your system is designed to operate on the normal power supplied by most electrical utility companies. However, possible computer malfunctions can be caused by outside (radiated or conducted) transient electrical noise signals being superimposed on the power line to the computer. To guard against this interference, power distribution design should comply with the specifications discussed in this topic.

Failures caused by the power source are basically of three types:

- Power line disturbances, such as, short duration dips in voltage and prolonged outages. If the frequency of such power failures is not acceptable for your operation, installing standby or buffered power might be necessary.
- Transient electrical noise superimposed on power lines might be caused by a variety of industrial, medical, communication, or other equipment:
 - Within the computing facilities
 - Adjacent to the computing facilities
 - In the vicinity of the power company's distribution lines

Switching large electrical loads can cause problems, even though the source is on a different branch circuit. If you suspect such a condition, it might be advisable to provide a separate, dedicated feeder or transformer for your system directly from your power source.

If the transient-producing devices have been eliminated from the feeder and the computer room power panel and power line disturbances are still present, it might be necessary for you to install isolation equipment (for example, transformers, motor generators, or other power conditioning equipment).

Lightning protection

Installing lightning protection devices is recommended on the computer power source when:

- The primary power is supplied by an overhead power service.
- The utility company installs lightning protectors on the primary power source.

- The area is subject to electrical storms or an equivalent type of power surge.

Lightning protection for communication wiring

Be sure to install lightning protection devices to protect communication wiring and equipment from surges and transients induced into the communication wiring. In any area subject to lightning, surge suppressors should be installed at each end of every outdoor cable installation, whether installed above the ground (aerial) or buried below the ground.

Information about lightning surge suppressors for communication wiring systems and recommended installation methods for outdoor communication cables can be found in the manuals for the specific type of data processing system that is being considered.

Power source

These guidelines help to ensure that your data center has a quality power source.

The primary power source is normally a wye-type or delta-type, three-phase service coming from a service entrance or a separately derived source with appropriate overcurrent protection and suitable ground (service entrance or building ground). A three-phase, five-wire power distribution system should be provided for flexibility in your data processing installation. However, depending on the type of equipment that is installed, a single-phase distribution system might be sufficient. The five wire system enables you to provide power for three-phase line-to-line, single phase line-to-line, and single phase line-to-neutral. The five wires consist of three phase conductors, one neutral conductor, and one insulated equipment grounding conductor (green, or green with yellow trace).

Conduit must not be used as the only grounding means.

Power panel feeders

Ensure that the feeder wires to the branch-circuit distribution panel are large enough to handle the total system power load. For optimal results, ensure that these feeders service no other loads. See [Power quality](#) for more information.

Branch circuits

The computer branch circuit panel should be in an unobstructed, well-lighted area in the computer room.

The individual branch circuits on the panel should be protected by suitable circuit breakers properly rated according to manufacturer specifications and applicable codes. Each circuit breaker should be labeled to identify the branch circuit it is controlling. The receptacle should also be labeled.

Where a branch circuit and receptacle are installed to service your system, it is recommended that the grounding conductor of the branch circuit is insulated and equal in size to the phase conductors. The grounding conductor is an insulated, dedicated-equipment-grounding conductor, not the neutral.

Branch circuit receptacles that are installed under a raised floor should be within 0.9 m (3 ft) of the system that they supply power to. If the branch circuits are contained in a metallic conduit, either rigid or nonrigid, the conduit system should be grounded. This is accomplished by bonding the conduit to the power distribution panel, which in turn, is tied to the building or transformer ground.

Power cords are supplied in 4.3 m (14 ft) lengths unless otherwise noted in the system specifications. The length is measured from the exit symbol on the plan views. Some power plugs furnished by your seller are watertight, and should be located under the computer room raised floor.

Phase rotation

The three-phase power receptacles for some equipment, such as printers, must be wired for correct phase rotation. When looking at the face of the receptacle and counting clockwise from the ground pin, the sequence is phase 1, phase 2, and phase 3.

Emergency power control

A disconnecting means should be provided to disconnect the power from all electronic equipment in the computer room. This disconnecting means should be controlled from locations readily accessible to the operator at the principal exit doors. A similar disconnecting means to disconnect the air conditioning system serving this area should be available. Consult the local and national codes to determine the requirements for your installation. National Electric Code (NFPA 70) article 645 provides the requirements for this room EPO.

Convenience outlets

A suitable number of convenience outlets should be installed in the computer room and the Service Representative area for use by building maintenance personnel and service representatives. Convenience outlets should be on the lighting or other building circuits, not on the computer power panel or feeder. Under no circumstances are the service convenience outlets on your systems to be used for any purpose other than normal servicing.

Dual-power installation configurations

These dual-power installation configurations allow you to use the fully-redundant power features of your system.

Some models are designed with a fully redundant power system. The possible power installation configurations are listed as follows.

Dual-power installation: Redundant distribution panel and switch

This configuration requires that the system receives power from two separate power distribution panels. Each distribution panel receives power from a separate piece of building switch gear. This level of redundancy is not available in most facilities.

Figure 1.

Dual-power installation: Redundant distribution panel

This configuration requires that the system receives power from two separate power distribution panels. The two distribution panels receive power from the same piece of building switch gear. Most facilities should be able to achieve this level of redundancy.

Figure 2. Dual power installation - Redundant distribution panel

Single distribution panel: Dual circuit breakers

This configuration requires that the system receives power from two separate circuit breakers in a single power panel. This configuration does not make full use of the redundancy that is provided by the processor. However, it is acceptable if a second power distribution panel is not available.

Figure 3. Single distribution panel - Dual circuit breakers

Plan your networking and connectivity readiness

Before you install IBM Fusion HCI, review the network architecture, IP address assignment options, firewall rules, cable requirements, proxy settings, and Scale network configuration to ensure your environment is ready.

Complete the following networking and connectivity tasks before you begin the installation of IBM Fusion HCI:

- **Review IBM Fusion HCI network architecture.** Understand the switch-to-switch leaf topology that connects compute and storage nodes to your data center, including general requirements, firewall rules, and supported cable and transceiver options.
 - **Identify IP address assignment method.** Choose between static IP (recommended) and DHCP reservation for your hosts. Static IP eliminates the need for MAC-based reservations and simplifies ongoing network management.
 - **Configure sub-domains.** Set up the sub-domain configuration that IBM Fusion HCI requires before installation begins.
 - **Set up DHCP for IBM Fusion HCI.** If you use DHCP, update the Dynamic Host Configuration Protocol and DNS settings by using the values in your installation preparation worksheet.
 - **Set up static IP.** If you use static IP addressing, configure the appliance network interfaces by using the static IP values from your installation preparation worksheet.
 - **Set up DNS.** Configure Domain Name System settings for the appliance to ensure correct name resolution across your network.
 - **Review proxy configuration guidance.** If your installation connects through a proxy, review the proxy requirements and limitations, including considerations for disaster recovery, ACL, GPU nodes, and Call Home firewall sites.
 - **Prevent Scale network IP conflicts.** If the default Scale daemon IP addresses conflict with your workloads, configure an additional IPVLAN network for Scale core pods before you begin the final installation.
- [Review IBM Fusion HCI network architecture](#)
The IBM Fusion HCI network architecture connects compute and storage nodes to your data center through high-speed switches, forming a switch-to-switch leaf topology.
 - [Identify IP address assignment method](#)
IP address assignment is a critical settings on your network devices. You must properly assign IP addresses for your hosts so that it participates on your network. IBM Fusion offers you the option to choose between DHCP reservation-based IP management and Static IP (recommended) for your needs.
 - [Review proxy configuration guidance](#)
Proxy configuration is needed only in a connected install through proxy.
 - [Preventing Scale network IP conflicts](#)
This is an optional configuration and is only needed when the default scale daemon IPs conflicts with some of your workloads. An additional IPVLAN Container Network Interface (CNI) network named as daemon-network is created for scale core pods. By default, IP addresses are assigned for Scale daemon network. You can override the default IP addresses before you begin the Final installation of IBM Fusion HCI. If the default IPs are being overridden ensure that they are configured in a private subnet.

Review IBM Fusion HCI network architecture

The IBM Fusion HCI network architecture connects compute and storage nodes to your data center through high-speed switches, forming a switch-to-switch leaf topology.

The IBM Fusion HCI system contains two high-speed switches that connect to the data center network. The storage and compute nodes within the appliance are connected to the data center network indirectly through these high-speed switches, forming a switch-to-switch connection. This setup treats the appliance switches as leaf switches, recommending a connection to core switches for integration with the larger network.

Planning a Connection between IBM Fusion HCI and Your Network

IBM Fusion HCI is a hyperconverged infrastructure solution that combines compute, storage, and networking resources into a single, integrated platform. To integrate IBM Fusion HCI with your existing network, you need to plan a connection that ensures seamless communication and data exchange between the two environments.

Before establishing a connection, ensure that you have:

- A clear understanding of your network architecture and topology

- The necessary network infrastructure, including switches, routers, and firewalls
- IBM Fusion HCI hardware and software requirements met
- A plan for network segmentation and security

You can connect IBM Fusion HCI to your network as follows:

- Connect IBM Fusion HCI directly to your network by using a dedicated Ethernet cable.
 - Configure the network settings on IBM Fusion HCI to match your network configuration.
- After establishing a connection, you configure DHCP, DNS, and NTP server connections. For more information, see [General requirements](#).

Network connectivity for different storage options

The IBM Fusion HCI offers two storage options: Global Data Platform and Fusion Data Foundation. Understanding the network differences between these two options is crucial for effective planning.

Global Data Platform

- The uplink carries only the OpenShift® Bare Metal VLAN.
 - In a multi-rack setup, internal storage and management traffic also use the spine switches.
- Important: Global Data Platform supports expansion multi-rack configurations only.

Fusion Data Foundation

- The uplink carries both the OpenShift VLAN and the management or provisioning VLAN 4091.
- No spine switches are present in a Fusion Data Foundation rack.
- Fusion Data Foundation supports multiple rack configurations, including:
 - High-Availability (HA) multi-rack
 - Expansion multi-rack
 - 3 zone multi-rack
 - 2 zone + arbiter

For more information on Fusion Data Foundation network architecture, see [Deployment configurations](#). For high-availability multi-rack and expansion racks with storage type FDF prerequisites (also applicable to multi AZ racks), refer to [Network prerequisites for high-availability racks](#).

IBM Fusion HCI network configuration for SSR setup

After receiving the IBM Fusion HCI appliance, an IBM Systems Service Representative (SSR) visits your data center to set it up. To complete the setup, the SSR needs information about your internal network. Fill out the following [Planning Worksheet](#) and share it with your IBM representative.

- [General requirements](#)
To ensure a smooth installation of the IBM Fusion HCI in your data center, review the following network requirements and configuration options. This information is intended for your network administrator.
- [Firewall requirements](#)
IBM Fusion HCI requires outbound access to external sites for accessing image registries and sending telemetry data to IBM and Red Hat®. This outbound access can be optionally routed through a proxy server. Configure your data center's firewall rules or proxy access control list (ACL) to meet the requirements for IBM Fusion HCI.
- [Network cable requirements](#)
This topic has general network cable requirements.
- [Installing LACP spine switches](#)
Install and configure LACP-based spine switches (also referred to as aggregate switches) to interconnect multiple IBM Fusion HCI racks into a unified network fabric for multi-rack deployments.

General requirements

To ensure a smooth installation of the IBM Fusion HCI in your data center, review the following network requirements and configuration options. This information is intended for your network administrator.

Initial setup and network connection

The IBM Fusion HCI connects to your data center's network through two high-speed switches. These switches are linked to your core network through a single port channel, which serves as the gateway between the appliance and your network. This connection enables:

- Administration of the appliance and OpenShift®
- Network traffic in and out of the cluster

Pre-installation network preparation

Before the IBM Fusion HCI appliance installation, your network team must prepare your network. An IBM Systems Service Representative (SSR) performs the initial configuration of the appliance and connects it to your pre-configured network using the information you provide.

Important: Complete the planning worksheets to provide IBM Service Support Representative (SSR) with the IBM Fusion HCI network setup plan.

To download the worksheets, see [IBM Fusion HCI Installation worksheets](#).

When you fill the worksheet, check with your network team about whether the CIDR ranges that you plan to use are free on your network.

Pre-installation validation utilities

IBM Fusion HCI pre-installation validation utilities provide automated checks to verify environment readiness for IBM Fusion HCI deployments. These scripts validate critical software dependencies, network configuration, connectivity, credentials, and external access requirements, helping identify and resolve issues before installation.

IBM Fusion HCI Management software precheck and validation

The [openshift-fusion-mgmt-software-prechecks.py](#) script is an interactive pre-installation validation utility designed to assess readiness for IBM Fusion HCI management cluster deployment. The script guides users through environment-specific inputs and validates required software, registry access, credentials, certificates, and external connectivity for both connected and air-gapped installations.

The script validates the following areas to ensure installation readiness:

- Container registry validation
- Credential and configuration validation
- X.509 Certificate validation
- Network and endpoint connectivity
- Installation mode validation
- Validation result tracking and summarization
- Log generation for audit and troubleshooting

IBM Fusion HCI network precheck and validation

The [fusion-hci-network-prechecks.py](#) script is a network validation utility that verifies connectivity, configuration, and infrastructure readiness for IBM Fusion HCI deployments. The script supports both interactive and CLI execution modes and performs comprehensive network-level checks across addressing, name resolution, connectivity, and time synchronization.

The script includes the following network validation capabilities:

- IP configuration validation
- DNS validation
- Network connectivity validation
- NTP configuration and synchronization checks
- Network interface validation
- Parallel execution of validation tasks
- Input validation and error handling
- Logging and output reporting

Configuring DNS and DHCP

To set up an OpenShift cluster, you need to configure the Domain Name System (DNS) and Dynamic Host Configuration Protocol (DHCP) for each node in the appliance. It involves creating DHCP entries for each MAC address and setting up forward and reverse DNS entries for each IP address.

Before configuring DNS and DHCP, ensure that you have:

- Each node must have a pre-configured MAC address and a MAC address for the bootstrap VM.
- IBM provides a list of all MAC addresses for configuration purposes.

Follow the instructions to create DNS and DHCP entries:

Create DHCP entries

Create a DHCP entry for each MAC address provided by IBM. It ensures that each node and service node receives an IP address.

Create DNS entries

Create forward and reverse DNS entries for each IP address that is assigned to the nodes and service nodes.

The following are some key considerations while you create DNS and DHCP entries:

- Ensure that your DHCP server can provide infinite leases. It is required to set a permanent IP address for each node.
- Set the DHCP expiration time to 4294967295 seconds (as specified by RFC 2131) to enable infinite leases.
- In RHEL 8, `dhcpd` does not provide infinite leases. As an alternative, use `dnsmasq` to serve dynamic IP addresses with infinite lease times.

To serve dynamic IP addresses with infinite lease times using the provisioner node, it is recommended using `dnsmasq` instead of `dhcpd`.

For a detailed guide on setting up DNS and DHCP for IBM Fusion HCI, refer to [Setting up DHCP for IBM Fusion HCI](#).

Configuring static IP

To configure static IP, you need to obtain the following IP addresses:

- **Gateway IP:** The IP address of the gateway.
- **DNS IP:** The IP address of the DNS server.
- **Service node IP:** The IP address of the service node.

For a detailed guide on setting up static IP for IBM Fusion HCI, refer to [Setting up Static IP](#).

These IP addresses are used during the cluster configuration process.

Configuring NTP Server

Ensure that the network administrator has configured an NTP server that is connected to your network.

NTP server requirements

- The IBM Fusion HCI requires a connection to an NTP server to coordinate time across the nodes in the OpenShift cluster.
- Ensure that the NTP server is accessible on the network where the IBM Fusion HCI is connected.

Providing NTP server information

- Provide the IP address of the NTP server in the planning worksheet. The IBM SSR requires this information to complete the initial configuration of the appliance.
- You can provide multiple NTP servers as comma-separated values.

Note: According to Red Hat®, to maintain optimal synchronization in an OpenShift Container Platform cluster, use a minimum of four NTP servers. If four NTPs are not available, then use one or three NTPs servers but never two because it can introduce synchronization issues.

LACP topology

To ensure high availability and redundancy, it is recommended to configure the IBM Fusion HCI high-speed switches to connect to the data center switches using link aggregation.

Configuration recommendations

Use both uplink ports on each high-speed switch to connect to the data center switches. This configuration creates a total of four links, aggregated into a single port channel with four times the bandwidth. The uplink ports differ by switch vendor:

- Cumulus switches - ports 31 and 32

Benefits

- Provides redundancy and high availability: if any link or switch fails, traffic is automatically balanced between the remaining links.
- Increases bandwidth: the aggregated port channel has four times the bandwidth of a single link.

Switch configuration options

- **Recommended Configuration:** Use two high-speed switches, each connected to the data center switches with two ports (31 and 32).

- **Alternative Configuration:** If you prefer to use only one switch, combine data center switch 1 and data center switch 2 with four ports.

By following these configuration recommendations, you can ensure a reliable and high-bandwidth connection between the IBM Fusion HCI and the data center switches.

It is recommended to use an LACP topology to connect the IBM Fusion HCI switches to the data center switches.

Note: LACP is the preferred choice. Support is not available for non-LACP.

Link Aggregation Control Protocol (LACP) is an IEEE standard defined in IEEE 802.3ad to dynamically build an Etherchannel. IBM Fusion HCI configures link aggregation automatically based on the detected switch vendor:

- Cumulus switches - uses MLAG (Multi-Chassis Link Aggregation Group) with bond interfaces. The MLAG ID is internally derived from the Switch LAG ID.

For IBM Fusion HCI, the recommended LACP settings are as follows:

- Rate setting is Fast
- Mode is Active-Active setting

To know more about network cable requirements to connect the appliance switches to the data center switches, see [Network cable requirements](#).

VLAN planning

The IBM Fusion HCI System requires two VLANs for communication between the data center switches and the appliance high-speed switches.

Supported VLAN range

The IBM Fusion HCI System supports VLANs from 1 to 4094.

The following are the required VLANs:

OpenShift customer VLAN

- A default VLAN used to access OpenShift.
- Requires a name and ID, which must be recorded in the [planning worksheet](#) for initial configuration.
For example, **OpenShift-Customer** (name) and **100** (ID).

Native VLAN

- Handles discard traffic.
- Typically uses VLAN ID 1, but verify your data centers default ID.
For example: **Native** (name) and **1** (ID).

Important: The storage VLAN is applicable only for the Global Data Platform. Data Foundation does not contain a storage VLAN.

Storage VLAN

- Used by the internal 100G storage network.
- The default value is 3201, but can be changed during initial configuration.
For example: **Storage** (name) and **3201** (ID).

Reserved VLAN IDs

The following VLAN IDs are reserved and must not be used:

- VLAN 4091 (internal Provisioning network)
- VLANs 3725-3999 (internal switches).

VLAN naming conventions

- Ensure VLAN names are in lowercase.

- Verify that VLAN names contain only alphanumeric characters and hyphens (-).
- Interface names can be up to 15 characters long.
- The names must start and end with a letter or number.

Important considerations

- All internal VLANs used within the IBM Fusion HCI must have unique VLAN IDs.
- The system does not provide routing between VLANs; routing functions must be provided at the data center core network.
- It is recommended to configure the uplink in trunk mode rather than access mode as it allows addition of VLANs to the uplink.

Network for service node

Network overview for service node

The node supports three types of networks, namely provisioning network, Bare Metal network, and Customer DC network. Both provisioning network and Bare Metal network are mandatory and the Customer DC network is optional.

To connect the DC network directly to the service node, connect RJ45 network cable to service node slot 4 port 4. The Port 4 of the quad-port OpenShift Container Platform 1Gb NIC is used to connect the Service Node to the client network. IA Cat5e (or better) Ethernet cable with RJ45 connectors is needed to make the connection from the Service Node to the client switch. IBM does not provide this cable so you must arrange cat5e cable that is commonly available in any data center.

• Bare Metal network

Bare Metal node has two 100G ports (with Data Foundation rack), which internally connects to the high-speed switch of the rack. This network is used to reach the OpenShift cluster on the rack. This network is configured by the IBM Fusion HCI installation process.

• Provisioning network

It has two ports 1G Nic to connect to the provisioning network of the OpenShift. The device comes pre-wired and pre-configured right from the factory.

• Customer DC network

This network is used to access service node directly for maintenance and out of band management purposes. It is recommended that you provide an IP, gateway, subnetmask to the SSR at the time of initial setup. Also, check whether you filled in network planing sheet with the right details.

It has 1 GbE Nic that is used to connect to the customer data centre for out of band access.

For more information about the hardware configuration of the service node, see [Service node](#).

Prerequisites for service node

Ensure that you meet the following prerequisites for the service node:

- A separate VLAN must be available for the Customer DC connectivity to the service node.
- Ensure to provide the DHCP-assigned IP address to the bare metal network interface of the service node.
Note: The DHCP and DNS lookup and reverse lookup records are required for service node similar to other OpenShift nodes.
- Ensure that the following firewall ports are allowed for the service node:
 - Port 22 for SSH access.
 - Port 443, 3000, and 3900 for stage 2 user interface (the 443 and 3900 are allocated for IMM console access through port forwarding on service node if needed).

Network for multi-rack HA

Planning and prerequisites for high-availability multi-rack, 3-zone high-availability, and expansion racks:

- The provisioning network (VLAN 4091) and OpenShift Bare Metal network must be extended between the racks and must be on the same layer2 domain across all three racks or sites.
- The recommended uplink bandwidth requirement is 25G and higher.
- The latency must be in the range of less than 10 ms RTT. For more information, see [Guidance for OCP Deployments Spanning Multiple Sites](#).
- For Data Foundation multi-rack setup, ensure that you meet the following mandatory requirements from lab switches setup:
 1. The provisioner VLAN 4091 must be extended on all the intermediate switches between the racks.
 2. The OpenShift Container Platform VLAN must be extended on all the intermediate switches between the racks.
- Each rack must have the same number of storage nodes. Ensure that the number of NVMe drives are uniform across storage nodes in the multi-rack solution.

Network for two-availability-zone and arbiter node (2AZ and arbiter node) configuration

Ensure that the following network planning and prerequisites are met:

- Two IBM Fusion HCI are placed in two different zones, and the arbiter node is placed in a third zone.
- The latency between servers or zones must be less than 10 ms round-trip time (RTT). For more information, see [Guidance for OCP Deployments Spanning Multiple Sites](#).
Note: If you are planning a 2AZ and arbiter node deployment with latency higher than 10 ms RTT, contact [IBM Support](#).
- All nodes in both racks and the arbiter node must be of the same type. For example, if nodes in both racks are Dell type, the arbiter node must also be Dell type.
- The arbiter node is connected to the switch using the following ports:
 - 1G provisioning port
 - 1G IMM port
- OpenShift Container Platform VLANs and Provisioning VLANs (4091) are extended to all three zones for mutual discovery and communication.
- If you use DHCP, ensure that DHCP and DNS are configured for both racks and the arbiter node by following the instructions that are mentioned in [Setting up DHCP for IBM Fusion HCI](#) and [Setting up DNS](#).
- If you use static IP, ensure that static IP and DNS are configured for both racks and the arbiter node by following the instructions that are mentioned in [Setting up Static IP](#) and [Setting up DNS](#).
- All nodes of both racks and the arbiter node are powered on.
- The Stretch cluster (2 AZ) tile is selected, and a unique value in the Availability zone field are added for both racks during installation using the IBM Fusion HCI web console (stage 1).
Note: The keyword **arbiter** cannot be used as a Availability zone field value.

- Stage 1 deployment can start with any rack, which is considered as the first rack. After Stage 1 on the first rack completes, start Stage 1 on the last rack. During this process, the Arbiter node and the first rack are discovered. After Stage 1 completes on the last rack, all discovered zones appear on the final page. The order of the intermediate racks does not matter. Any rack can be treated as the last rack.
- The same number of SSD or NVMe disks are available across storage nodes.
- The firewall on the provisioner or service node is disabled. Otherwise, the racks and arbiter node cannot discover each other.

Network configurations for 2AZ and arbiter node are as follows:

Figure 1. Network configurations for Dell

Important: As shown in [Figure 1](#), four 1 GbE Ethernet cables with RJ45 connectors and two 100 GbE AOC cables with QSFP28 transceivers are provided to connect the arbiter node to the network. No additional cables are required from the client.

Figure 2. Network configurations for Lenovo

2AZ + Arbiter Connections

1. Rack 1 (Zone 1):

High-speed switch ports 31/32 must be connected to the customer-provided uplink, carrying the **OpenShift VLAN** and the **Provisioning VLAN (4091)** as a trunk.

2. Rack 2 (Zone 2):

High-speed switch ports 31/32 must be connected to the customer-provided uplink, carrying the **OpenShift VLAN** and the **Provisioning VLAN (4091)** as a trunk.

3. Arbiter Node Connectivity:

- **BMC (IMM):** Dedicated IMM port must connect to **access VLAN 4091**.
- **2x25 GbE NICs:**
 - Ports 1 & 2 → Configured as an **LACP (IEEE 802.3ad)** bond on **access VLAN 4091**
 - Customer switch port connected to Port 1 must have **LACP bypass** enabled to allow PXE boot.
- **4x1 GbE NICs:**
 - Port 1 → **Access VLAN 4091**
- **2x100 GbE NICs:**
 - Port 1 → Configured as an **LACP (IEEE 802.3ad)** bond on a **trunk port** carrying the **OpenShift management VLAN**.

Important: As shown in [Figure 2](#), two 1 GbE Ethernet cables with RJ45 connectors and two 100 GbE AOC cables with QSFP28 transceivers are provided to connect the arbiter node to the network. Two additional 1 GbE Ethernet cables are included as spares. The client must provide two 25 GbE cables with SFP28 connectors.

Network planning and prerequisites for remote support connection

Remote support is a service that enables IBM Support representative to remotely access your rack and accomplish essential tasks, such as installation, maintenance, and troubleshooting. To create a remote support connection, ensure that the additional configuration is required with a customers firewall or proxy, the following table describes required IP and port configuration.

Table 1. Ports, Relay Hosts, and IP Information

Hostname / GEO	IP	Ports
aos.us.ihost.com	72.15.208.234	443
Americas Broker (4.0 Sessions)	150.238.213.135	443
Americas Broker (4.0 Sessions)	72.15.223.60	443
Americas Broker (4.0 Sessions)	72.15.223.62	443

To a remote support connection to work, the customer must allow encrypted TLS outbound traffic for the server 72.15.223.60 on port 443, 150.238.213.135 on port 443 or 72.15.223.62 on port 443.

To use geographically specific relay servers and realize improved throughput, the customer must also allow encrypted non-SSL (TLS encryption) outbound traffic to one of the geographically specific relay servers:

- 72.15.208.234 aos.us.ihost.com (hosted in North America, best for most geographies)
- 150.238.213.135 aosback.us.ihost.com (hosted in North America, best for most geographies)
- 72.15.223.60 aosrelay1.us.ihost.com (hosted in North America, best for most geographies)
- 72.15.223.62 aosshats.us.ihost.com (hosted in North America, best for most geographies)

Remote support connection automatically chooses the broker, which provides the best end-to-end performance. All broker servers are available from all geographies, with performance typically better from the server closest to the customer system.

For more information about remote support, see [Remote support](#).

MTU requirement for Backup & Restore Hub and Spoke configuration

This prerequisite is applicable when you create a relationship between two IBM Fusion HCI OpenShift Container Platform clusters. If you plan to make one IBM Fusion HCI as Backup & Restore Hub and another as Spoke, then make sure that the following things are met before you install IBM Fusion HCI:

1. The same MTU (maximum transmission unit) values are set on both clusters.
2. Confirm with network admins that planned MTU value is supported by your data center infrastructure as well.
3. All the devices and routers between these two clusters are configured with the same MTU.

Planning for Hosted Control Plane

In the same CIDR range (number of clusters), you must have a set of free available IPs (no DHCP or DNS is required). It is based on the number of Hosted Control Plane clusters that you plan to create in the rack.

Planning and prerequisites for remote mount support

Ensure that the following prerequisites are met for remote mount support:

For IBM Storage Scale Erasure Code Edition (ECE)

- The storage VLAN (default 3201) must be available and configured on the customer network. If the default storage VLAN 3201 is not available on the customer network, contact [IBM Support](#) to change the default VLAN on IBM Fusion HCI.
- The default gateway from the storage VLAN must be configured and reachable from IBM Fusion HCI.
- The routing must be in place on the customer network from the storage gateway to the external IBM Storage Scale System
- The IBM Storage Scale System must also be configured to support MTU 9000 along with other devices en route router, switches. The default MTU of IBM Fusion HCI is 9000.

For Red Hat OpenShift Data Foundation

- The routing must be in place on the customer network from the storage gateway to the external IBM Storage Scale System
- The IBM Storage Scale System must also be configured to support MTU 9000 along with other devices en route router, switches. The default MTU of IBM Fusion HCI is 9000.

Configuring Spanning Tree Protocol (STP)

Primary recommendation: Disable STP on IBM Fusion HCI switches

For the highest stability and performance, disable STP on the IBM Fusion HCI leaf switches.

- Reason: The IBM Fusion HCI switches act as edge or leaf nodes in a controlled Multi-Chassis Link Aggregation (MLAG) configuration.
- Loop prevention: LACP (802.3ad) and the MLAG peer link manages redundancy and loop prevention.
- Safety: Since these leaf switches with no downstream switches are connected, the risk of a loop is localized to the server ports.

Alternative configuration for enabling STP

If your network policy requires STP to be enabled for all infrastructure, or if there is a risk of accidental loops from downstream patching, follow these strict configuration guidelines to ensure compatibility with the IBM Fusion HCI cluster.

Match the mode: RSTP (802.1w)

The IBM Fusion HCI switches strictly use RSTP. Your uplink switches must match with this configuration or you can use MSTP.

Note: Do not use Cisco's PVRST or PVST+ on the uplink, as the IBM Fusion HCI switches do not process per-VLAN BPDUs correctly, leading to blocked ports or 30 second listening or learning delays.

Root bridge placement

Configure the customer uplink or core switches as the STP root bridge. IBM Fusion HCI switches use a fixed priority of **61440** and must not become the root of the network topology.

Uplink port configuration

The ports on the customer switch connecting to the IBM Fusion HCI bond must be configured as normal (network) ports.

Ensure the following settings:

- BPDU Guard: Must be disabled on the uplink bond.
- BPDU Filter: Must be disabled. Enabling this setting prevents the network from detecting loops.
- PortFast or Edge: Must be disabled. These ports connect to other switches (the IBM Fusion HCI pair) and must perform the standard RSTP handshake.

Network definitions

This section provides a comprehensive overview of network definitions, including key terms and concepts.

Important: While you go through these definitions, different networking teams use different terminologies. For example, Mellanox or Cisco.

Use LACP aggregation

Whether the recommended LACP topology is being used.

Note: LACP is the preferred choice. Use the **no aggregation** topology only if LACP is not possible as it does not provide the redundancy most clients require.

Link name

The name to assign to the aggregated link created by the recommended LAG topology.

Lag ID

The default LAG ID is 250, and you only need to customize the ID if it is already in use on your network. A scenario where this might occur is if you have multiple IBM Fusion HCI appliances on the same network.

Spanning tree enabled

If you are not using the recommended LAG topology, specify whether spanning tree is enabled on the network or not.

OpenShift VLAN name

The name to assign to the OpenShift Customer VLAN.

OpenShift VLAN ID

The VLAN ID to assign to the OpenShift Customer VLAN.

VLAN

A virtual LAN (VLAN) is an isolated broadcast domain that is created within a switch. Each VLAN created within a switch is isolated from other VLANs. The network traffic can pass from one VLAN to another by adding a routing device. The routing functions must be provided at the data center core network.

Native VLAN ID

The VLAN ID to assign to the Native VLAN if you aren't using the default of 1.

Storage VLAN ID

The VLAN ID to assign to the 100G storage network if you aren't using the default of 3201. You might only normally customize this if you are configuring a Metro Disaster Recovery configuration between two IBM Fusion HCI clusters.

MLAG

A Multi-Chassis Link Aggregation Group (MLAG) allows for multi-system link aggregation and facilitates active-active uplinks of access layer switches. An MLAG with no Spanning Tree configured avoids the wasted bandwidth that is associated with links that are blocked by the spanning tree.

To ensure high availability for the system, IBM Fusion requires MLAG and link aggregation for the switches.

Switch LAG ID

This Switch LAG ID is used by high-speed switches inside the IBM Fusion rack, which is not related to the LACP ID on (external) switch. It is unique for each IBM Fusion rack and can be less than 250.

The high-speed switch (MLAG PAIR) that gets connected to customer switch must have a unique system MAC address (MLAG ID). This MLAG ID is used as source MAC address for traffic that is sourced from MLAG PAIR, such as STP BPDUs. The MLAG ID is internally derived from the Switch LAG ID. The specific Switch LAG ID is used as the last octet for "44:38:39:ff:00:xx".

Layer 2 connections

The connections from all the IBM Fusion high-speed switches to the data center core network and customer management network are all layer 2 connections. IBM Fusion supports the Link Aggregate Control Protocol (LACP) type of layer 2 aggregation.

The following characteristics describe layer 2 connections:

- Layer 2 is considered switching and is done at the hardware layer.
- Layer 2 is in the same broadcast domain or local network.
- Layer 2 finds adjacent partners by MAC address.

Layer 3 connections

IBM Fusion does not participate in any layer 3 routing or firewall functions. These functions are done in the data center core network.

The following characteristics describe layer 3 connections:

- Layer 3 is considered routing and is done at the software layer.
- Layer 3 knows how to traverse multiple networks (hops).
- Layer 3 finds adjacent partners by IP address.

Spanning tree

In the networking stages of the installation for IBM Fusion, an option to enable or disable the Spanning Tree is available. When you enable it, the spanning tree is enabled on the high-speed switches. By default, the option is disabled on these switches. The high-speed switches in the IBM Fusion rack support only rapid spanning-tree (RSTP) modes. It is also compatible with PVST and PVST+. Customer data networks that are running older spanning-tree methods (MST) are not supported.

Note: IBM Fusion sets the spanning-tree bridge priority to 32768 as the default value. To avoid IBM Fusion high-speed switches from becoming the spanning-tree root, the customer switch must have priority less than 32768. For more information, see [Spanning Tree and Rapid Spanning Tree - STP](#).

Port type

Specify whether you are using VLAN trunking or access ports.

Access

An access port provides access to a single VLAN only. Typically, the packets on an access port are raw Ethernet frames (untagged packets).

Trunk

A trunk connection is used to pass traffic from multiple VLANs between two switches. All trunks use the IEEE 802.1Q standard. This link can be a single wire or one of the aggregations methods.

Transceiver

Specify the type of cable that is being used to connect the HCI high-speed switches with your data center switches. See [Hardware Compatibility List](#).

NTP server

The IP address of the NTP server that is used by IBM Fusion HCI.

Aggregate links

Link aggregation is to combine multiple network connections in parallel.

The standard-based negotiation protocol, which is known as IEEE 802.1ax Link Aggregation Control Protocol (LACP), is a way to dynamically build an Etherchannel.

Firewall requirements

IBM Fusion HCI requires outbound access to external sites for accessing image registries and sending telemetry data to IBM and Red Hat®. This outbound access can be optionally routed through a proxy server. Configure your data center's firewall rules or proxy access control list (ACL) to meet the requirements for IBM Fusion HCI.

Inbound access for OpenShift cluster

The following lists inbound access for the OpenShift® cluster.

URL	Port	Function
API server and apps	TCP: 443 and 6443	Required for communication with OpenShift API server and apps URL

Outbound access for Red Hat OpenShift and IBM Fusion HCI image registries

The following lists outbound access for Red Hat OpenShift and IBM Fusion HCI image registries.

URL	Port	Function
icr.io Note: If you use a public network to access IBM Container Registry and your firewall does not support wildcards, add the following content delivery network (CDN) domains: dd0.icr.io dd2.icr.io dd4.icr.io dd6.icr.io Users that are located in China must also add the following domains: ddl-icr.ibm-zh.com dd3-icr.ibm-zh.com dd5-icr.ibm-zh.com dd7-icr.ibm-zh.com cp.icr.io	443	IBM Entitled Registry and IBM Cloud Paks foundational services catalog source
gcr.io	443	Images from Google Cloud's Container Registry
registry.redhat.io	443	Provides core container images
*.quay.io Note: If wildcard is not allowed, add cdn01.quay.io cdn02.quay.io cdn03.quay.io	443	Provides core container images
*.openshiftapps.com Note: If your firewall does not accept wildcard, then use the complete URL.	443	Provides Red Hat Enterprise Linux CoreOS (RHCOS) images
cert-api.access.redhat.com	443	Required for Telemetry
access.redhat.com	443	Required for Telemetry
api.access.redhat.com	443	Required for Telemetry
infogw.api.openshift.com	443	Required for Telemetry
console.redhat.com/api/ingress	443	Required for Telemetry and for insights-operator
cloud.redhat.com/api/ingress	443	Required for Telemetry and for insights-operator
mirror.openshift.com	443	Required to access mirrored installation content and images. This site is also a source of release image signatures, although the Cluster Version Operator needs only a single functioning source.
storage.googleapis.com/openshift-release	443	A source of release image signatures, although the Cluster Version Operator needs only a single functioning source.
.apps.<cluster_name>.<base_domain>	443	Required to access the default cluster routes unless you set an ingress wildcard during installation.
quayio-production-s3.s3.amazonaws.com	443	Required to access Quay image content in AWS.
api.openshift.com	443	Required both for your cluster token and to check whether updates are available for the cluster.
art-rhcos-ci.s3.amazonaws.com	443	Required to download Red Hat Enterprise Linux CoreOS (RHCOS) images.
console.redhat.com/openshift	443	Required for your cluster token.
cloud.redhat.com/openshift	443	Required for your cluster token.
registry.access.redhat.com	443	Required for odo CLI.
sso.redhat.com	443	The https://console.redhat.com/openshift site uses authentication from sso.redhat.com

Note: You can use the wildcard ***.quay.io** and ***.openshiftapps.com** instead of **cdn0 [1-3].quay.io** and **rhcos-redirector.apps.art.xq1c.pl.openshiftapps.com** in your allowlist.

The entries from row 4 till the end are from Red Hat OpenShift documentation. For the actual list from Red Hat OpenShift, see https://docs.redhat.com/en/documentation/openshift_container_platform/4.21/html/installation_configuration/configuring-firewall.

Note: If you are using a private image registry to mirror Red Hat OpenShift and IBM Fusion HCI images, then set the host and port of your registry (**<your registry host><your registry port>**).

Important: After you go online, do not remove the firewall settings or switch between online and offline; otherwise, your cluster might go down. An uninterrupted connection to the repository is needed for both online and offline.

Service node and remote support

For service node, ensure that firewall port 22 is allocated for SSH access.

The remote support works seamlessly with most firewalls. Usually, remote support connections are possible without any firewall reconfiguration. It requires access to outbound ports at both ends of a connection, so there is normally no need to open holes in firewalls. Remote support also supports configuring a proxy for communication.

Call Home

Configure your data center's firewall rules or proxy access control list (ACL) to allow the manual and automated Service and Support request feature to communicate with the servers. To configure firewall, consider the following points for planning and prerequisites:

- Source IP for Call Home outbound connections is the OpenShift control node.

- The Host name, IP, and port details of Call Home servers:

Table 1. IP addresses of the IBM call home servers

Host name	IP address	Ports	Protocol
esupport.ibm.com	192.148.6.11	443	https
ecurep.ibm.com	192.109.81.21	443	https

Important: Though the table gives IP address guidance, ensure that you check the following pages for latest information: [IP addresses](#) and <https://www.ibm.com/support/pages/node/6853429>.

Metro-DR

The following table lists outbound access from a IBM Fusion HCI cluster for Metro sync DR:

IP address	TCP or UDP or IP protocol	Additional detail
<TieBreaker IP address>	TCP: 1191 and 12345	Required for IBM Fusion HCI storage to talk to tiebreaker storage
<Other site storage network>	TCP: 1191 and 12345	Required for stretch cluster deployment across the sites.
<Other site Red Hat OpenShift network>	UDP: 4500	Required for IPsec encapsulation traffic.
<Other site Red Hat OpenShift network>	ESP IP protocol: 50	Required for IPsec tunnel.
<API and apps IP of the other site>	TCP: 443 and 6443	Required for OpenShift and IBM Fusion management software stack to stay in sync.
<Other site storage network>	ICMP (ICMP ECHO (ping))	Required for stretch cluster deployment across the sites.

The following UDP port is required to be allowed only when there is a NAT device between the two site.

IP address	TCP or UDP or IP protocol	Additional detail
<Other site master nodes>	UDP: 4490	Required for NAT traversal discovery.

The following table lists outbound access from tiebreaker VM for Metro sync DR:

IP address	TCP	Additional detail
<IBM Fusion storage network of both sites>	TCP: 1191 and 12345	Required for tiebreaker storage to talk to IBM Fusion HCI storage.

For more information firewall details, see [General Metro-DR prerequisites](#).

Scale (GDP) ephemeral ports

Range	Protocol	Service name	Components involved in communication
60000 - 61000	TCP	GPFS ephemeral port range	Intra-cluster

The ephemeral port range is automatically set to 60000-61000. Firewall ports must be opened according to the defined ephemeral port range. If commands such as **mmismgr** and **mmcrfs** hangs, it indicates that the ephemeral port range is not configured correctly.

As mentioned in this topic, pods use port 12345 for ssh. If it is for a different source or destination, then mention accordingly.

For more information about Scale port number recommendation, see [Scale documentation](#).

Network cable requirements

This topic has general network cable requirements.

Note: IBM Fusion HCI does not include any cables or transceivers for connecting the system to external switches. If you need cables and transceivers for external connections, then explicitly add them to an order.

Network cable requirements

Connect port 31 or both ports 31 and 32 of both IBM Fusion HCI high-speed switches to the data center switches. The supported uplink speeds are 1, 10, 25, 40, and 100 GbE for Cumulus high-speed switches. The ports on the 100G high-speed switches are 100 GbE QSFP28 ports.

Purchase the needed DAC/AOC/QSFP and fibre cables from IBM or another supplier depending on your needs. Discuss with your network administrators or consult an IBM Support representative before you purchase the cables (minimum of 2). If you plan to use both 31 and 32 ports, then you must purchase four cables.

The following table lists cable and transceiver options for the 9155-S01 high-speed switch:

Feature Code (FC) or Request for Price Quotation (RPQ)	Description	Purpose	Country of Origin (COO)	Part Number (PN)
FC EB49	A connector that supports plugging a SFP28 transceiver into a QSFP28 port.	To adapt a QSFP28 100GbE port so that a SFP28 25GbE transceiver can be plugged into it.	ID	01FT845
FC EB57	A 40GbE QSFP+ base-SR4 optical transceiver with MPO connector.	To connect a IBM Fusion HCI 100 GbE switch port to a 40GbE client network port (cable must be supplied separately).	TH	78P6916
FC EB59	A 100GbE QSFP28 MTP/MPO SR4 850nm optical transceiver.	To connect a IBM Fusion HCI 100 GbE switch port to a 100GbE client network port (cable must be supplied separately).	CN	78P4988
FC AKBP	A 200GbE SR4 QSFP56 850nm optical transceiver with MPO-12 connector.	To connect a IBM Fusion HCI 200 GbE switch port to a 200GbE client network port (cable must be supplied separately).	CN	78P7682
FC EB5T	A 10 meter QSFP28 Ethernet active optical cable with integrated transceivers.	To connect a IBM Fusion HCI 100 GbE port to your 100 GbE switch port. These are AOC cables and come with integrated 100GbE transceivers at both ends of the cable.	TH	01FT724
FC EB5W	A 30 meter QSFP28 Ethernet active optical cable with integrated transceivers.	To connect a IBM Fusion HCI 100 GbE port to your 100 GbE switch port. These are AOC cables and come with integrated 100GbE transceivers at both ends of the cable.	TH	01FT726

Feature Code (FC) or Request for Price Quotation (RPQ)	Description	Purpose	Country of Origin (COO)	Part Number (PN)
RPQ 8S1916	A 10GbE SFP+ SR optical transceiver.	Transceiver to connect a IBM Fusion HCI 100 GbE port to your 10 GbE network. The 10GbE cable must be supplied separately. To plug this transceiver into a IBM Fusion HCI 100GbE port, you must use the adapter FC EB49.	MY	78P6987
RPQ 8S1929	A 1 Gb optical transceiver for cables with RJ-45 connectors.	Transceiver to connect a IBM Fusion HCI 100 GbE port to your 1 GbE network. The 1 GbE cable must be supplied separately. To plug this transceiver into a IBM Fusion HCI 100GbE port, you must use the adapter FC EB49.	MY	03FP283
FC EB47	A 25GbE SFP28 optical transceiver with LC connector.	Transceiver to connect a IBM Fusion HCI 100 GbE port to your 25 GbE network. The 25 GbE cable must be supplied separately. To plug this transceiver into a IBM Fusion HCI 100GbE port, you must use the adapter FC EB49.	ID	78P5153
FC ECBD	A 5 meter LC-LC Fiber OM3 MMF cable.	This is only an optical cable and has no transceivers. Use this with transceiver that has an LC-type connector.	TW	45D4774
FC ECBE	A 25 meter LC-LC Fiber OM3 MMF cable.	This is only an optical cable and has no transceivers. Use it with transceiver that has an LC-type connector.	TW	15R8848

Installing LACP spine switches

Install and configure LACP-based spine switches (also referred to as aggregate switches) to interconnect multiple IBM Fusion HCI racks into a unified network fabric for multi-rack deployments.

Before you begin

1. Ensure that the aggregate switches are at the same os/firmware level as that of rack tor switches.
2. Ensure that if the default mac address `44:38:39:ff:01:00` is changed then it is updated accordingly in the commands list available in the next section.
3. Stage 1 is not performed yet.

About this task

The steps are applicable only for fresh install and not for day2 operation.

Procedure

1. Log in to the aggregate switch using default credentials (username `cumulus` and password `cumulus`).
Use the serial connection.
2. Generate unique passwords for users ISFUSER, CEUSER and cumulus for both the aggregate switches and replace the password in placeholders [isfuser-password], [ceuser-password] , [cumulus-password] in the following commands list. While you generate the passwords, see [NVIDIA documentation](#).
3. Save the generated passwords in someplace as you may need them later while you create the secrets.
4. Run the following commands.
The assumption here is that OpenShift® Container Platform vlan is 7 and Internal Management Vlan is 4091, bonding ports connected to rack-1 tors are 1, 2 and bonding ports connected to rack-2 tors are 5, 6.

Before applying commands:

- a. If OpenShift Container Platform VLAN/ Internal management VLAN is different, then replace the VLAN ID in the command list before execution.
- b. In the set of commands for last section `#Configure Bond for Ports 27,28,29,30,31 & 32 (LACP Uplink)`, add commands only for the configured ports, For example if the uplinks configured are only 27 and 28 then the last section is as follows:

```
nv set interface <linkname> type bond
nv set interface <linkname> bond member swp27
nv set interface <linkname> bond member swp28
nv set interface <linkname> bridge domain br_default
nv set interface <linkname> bridge domain br_default vlan 7
nv set interface <linkname> bridge domain br_default vlan 4091
nv set interface <linkname> bridge domain br_default untagged 1
nv set interface <linkname> bond mlag enable on
nv set interface <linkname> mlag id 3030
```

- c. Configuration on aggregate switch 1:

```
nv set system hostname agg-switch1

nv set bridge domain br_default stp state down
nv set bridge domain br_default type vlan-aware

nv set interface eth0 ip address 169.253.254.200
nv set interface eth0 ip vrf mgmt
nv set interface eth0 type eth

#PEERLINK
nv set interface peerlink type peerlink
nv set interface peerlink bond member swp25
nv set interface peerlink bond member swp26
```

```

#Set MLAG
nv set mlag backup 169.254.3.2 vrf mgmt
nv set mlag mac-address 44:38:39:ff:01:00
nv set mlag peer-ip linklocal
nv set mlag priority 1000
nv set mlag init-delay 100

# Vlans on bridge
nv set bridge domain br_default vlan 7,4091

# Trunk VLANs over peerlink
nv set interface peerlink bridge domain br_default
nv set interface peerlink bridge domain br_default vlan 7
nv set interface peerlink bridge domain br_default vlan 4091

#Configure Bonds for Ports 1-24 (LACP with Trunking) based on number of racks
nv set interface swp1-2 type swp
nv set interface bond1 type bond
nv set interface bond1 bond member swp1, swp2
nv set interface bond1 bridge domain br_default
nv set interface bond1 bridge domain br_default vlan 7
nv set interface bond1 bridge domain br_default vlan 4091
nv set interface bond1 bond mlag enable on
nv set interface bond1 mlag id 2001

nv set interface swp5-6 type swp
nv set interface bond2 type bond
nv set interface bond2 bond member swp5,swp6
nv set interface bond2 bridge domain br_default
nv set interface bond2 bridge domain br_default vlan 7
nv set interface bond2 bridge domain br_default vlan 4091
nv set interface bond2 bond mlag enable on
nv set interface bond2 mlag id 2002

nv config apply -y
nv config save

nv set interface <linkname> mlag id 3030

```

6. After completing the configuration of aggregate switches, proceed with stage1. During stage1 select the ports as both 31 and 32 for uplinks. After completing the stage1 on all the racks that are part of cluster, perform stage2 from the base rack. After stage2 is complete, do the following steps to add aggregate switches to Fusion UI:
Populate information as mentioned in the following for the aggregate switches, generate it for both the aggregate switches and then add it to kickstart, the example commands have reference to rack gen2009 and is for both the switches, update it accordingly based on the cluster. Update the values of location, IP and other switch specific details. The location to be used in the

Openshift UI -> Workloads -> ConfigMaps -> kickstart-gen2009 (under namespace ibm-spectrum-fusion-ns) -> yaml -> data->switches-> {}

```

{
  "boot_version": "5.6.0",
  "ibmMTM": "9155-S04",
  "ibmSerialNumber": "GEN200925",
  "images": {
    "active": "5.6.0",
    "standby": "5.6.0"
  },
  "ipv4": "169.253.254.200",
  "location": "RU25",
  "macAddr": "FC:6A:1C:04:58:C0",
  "manufacturer": "Nvidia",

      "switch_type": "spine_network_switch",
      "vendor": "Nvidia"
    }
  ]
}

```

7. Create the following secrets for both aggregate switches agg-switch1 and agg-switch2, add the details to a yaml file and run `oc apply -f <file-name.yaml>`. While creating the files, update the credentials information using the details generate in previous steps.

```

kind: Secret
apiVersion: v1
metadata:
  name: agg-switch1-gen2009-secret
  namespace: ibm-spectrum-fusion-ns
data:
  ceUserName: <>
  ceUserPasswrd: <>
  defaultUserPasswrd: <>
  isfmgmtUserPasswrd: <>
  ceUserGroup: nvapply
  defaultUserGroup: admin
  isfmgmtUserName: <>
  defaultUserName: <>
  isfmgmtUserGroup: nvapply

```

```

kind: Secret
apiVersion: v1
metadata:
  name: agg-switch2-gen2009-secret
  namespace: ibm-spectrum-fusion-ns
data:
  ceUserName: <>
  ceUserPasswrd: <>
  defaultUserPasswrd: <>
  isfmgmtUserPasswrd: <>
  ceUserGroup: nvapply
  defaultUserGroup: admin
  isfmgmtUserName: <>
  defaultUserName: <>
  isfmgmtUserGroup: nvapply

```

8. On day2, when upgrade of aggregate switches is required, do the following steps to perform manual upgrade of aggregate switches.
- Ensure the serial connection is present for both the aggregate switches before starting upgrade.
 - Login to one of the aggregate switch using the credentials from the secret and save the current running configuration using command.

```
nv config save
```

- Copy the file `/etc/nvue.d/startup.yaml` to some location outside of aggregate switch.
- Fetch the image using artifactory URL and place it on the switch using command. I

```
nv action fetch system image http://<url>/cumulus-linux-5.11.1-mlx-amd64.bin
```

Instead of using `nv fetch` command if the image is manually copied to the switch then move it to location `/var/images`.

- Run the following command:

```
nv action install system image files
    cumulus-linux-5.11.1-mlx-amd64.bin
```

To install new firmware, if there is any issue, then force the install using the following command:

```
nv action install system image files cumulus-linux-5.11.1-mlx-amd64.bin force
```

- Set the boot partition using command and reboot the switch using command `reboot`.

```
nv action boot-next system image other
```

- After the switch is rebooted, login to the switch using the serial connection with default credentials (username `cumulus` and password `cumulus`), copy the backed up file back to the switch to location `/home/cumulus`, and then run command.

```
nv config patch /home/cumulus/startup.yaml; nv config apply -y
```

- Fetch the user credentials from the aggregate switch secrets present in `ibm-spectrum-fusion-ns` from openshift CLI/ GUI and run the following commands to create required users.

```

sudo adduser --disabled-password --gecos "" ISFUSER --ingroup nvapply --force-badname
sudo usermod -G nvapply,sudo ISFUSER
echo 'ISFUSER ALL=(ALL) NOPASSWD:ALL' >> /etc/sudoers
echo 'ISFUSER:<isfuser-password>' | sudo chpasswd

sudo usermod -G nvapply,sudo cumulus
echo 'cumulus ALL=(ALL) NOPASSWD:ALL' >> /etc/sudoers
echo 'cumulus:<cumulus-password>' | sudo chpasswd

sudo adduser --disabled-password --gecos "" CEUSER --ingroup nvapply --force-badname
sudo usermod -G nvapply,sudo CEUSER
echo 'CEUSER ALL=(ALL) NOPASSWD:ALL' >> /etc/sudoers
echo 'CEUSER:<ceuser-password>' | sudo chpasswd

```

- Repeat the steps 2-8 on the other aggregate switch to complete the upgrade process.
- Cabling for aggregate switches:

Spine switch L2 LACP-Based design for Multi-Rack DF:

Configuration commands on hspeed switches for connecting to aggregate switches. These commands are executed automatically during stage1 when both the ports 31 and 32 are selected as part of link. Incase if there is any need to execute manually then the following are the commands for reference.

```

nv set interface <linkname> type bond
nv set interface <linkname> bond member swp31
nv set interface <linkname> bond member swp32
nv set interface <linkname> bridge domain br_default
nv set interface <linkname> bridge domain br_default vlan 7
nv set interface <linkname> bridge domain br_default vlan 4091
nv set interface <linkname> bridge domain br_default untagged 1
nv set interface <linkname> bond mlag enable on
nv set interface <linkname> mlag id 3030
nv config apply -y
nv config save

```

Identify IP address assignment method

IP address assignment is a critical settings on your network devices. You must properly assign IP addresses for your hosts so that it participates on your network. IBM Fusion offers you the option to choose between DHCP reservation-based IP management and Static IP (recommended) for your needs.

Static

These addresses do not change that makes it easy to find on the network. The static IP option eliminates the need to create Mac based reservations in DHCP server of your data center.

Dynamic

Automatically assigned to network devices from a Dynamic Host Configuration Protocol (DHCP) server. You must create Mac based reservations in DHCP server of your data center.

Advantages of Static IP address assignment method

Before you select your IP address assignment method, consider the following advantages of the Static IP method:

- The Static IP addresses method requires less configuration effort, as you only need to set up DNS. Unlike the Dynamic IP addresses method, you do not have to configure the DHCP.
- When you scale out by adding new nodes, the effort is minimal as you only need to set up DNS. Unlike the Dynamic IP addresses method, there is no need to configure the DHCP for each new node.
- In the event of a NIC replacement in the field, a new MAC address is assigned, which requires an update to the DHCP configuration. However, with Static IP addresses, this step is eliminated, as the IP address remains unchanged.
- If your network does not have a dedicated DHCP server or it is mounted as an add-on service, then the Static IP addresses option eliminates the need for DHCP deployment.
- [Configuring sub-domains](#)
A network administrator must configure a subdomain or sub-zone where the canonical name extension is the cluster name.
- [Setting up DHCP for IBM Fusion HCI](#)
As a prerequisite to IBM Fusion HCI installation, update Dynamic Host Configuration Protocol (DHCP) and Domain Name System (DNS) with the information that is detailed in the planning worksheet for your system.
- [Setting up DNS](#)
Steps to set up the DNS server for IBM Fusion HCI appliance. It is applicable for both static and DHCP.
- [Setting up Static IP](#)
Steps to set up the static IP for IBM Fusion HCI appliance.

Configuring sub-domains

A network administrator must configure a subdomain or sub-zone where the canonical name extension is the cluster name.

```
<cluster_name>.<base_domain>
```

For example:

```
test-cluster.example.com
```

Red Hat® OpenShift® Container Platform includes functionality that uses cluster membership information to generate A/AAAA records. This resolves the node names to their IP addresses. After the nodes are registered with the API, the cluster can disperse node information without using `CoreDNS-mDNS`. This eliminates the network traffic that is associated with multicast DNS.

Setting up DHCP for IBM Fusion HCI

As a prerequisite to IBM Fusion HCI installation, update Dynamic Host Configuration Protocol (DHCP) and Domain Name System (DNS) with the information that is detailed in the planning worksheet for your system.

Before you begin

Download the installation preparation worksheet and review the network preparation section. To download the worksheets, see [IBM Fusion HCI Installation worksheets](#).

- Ensure that you have the MAC addresses from your IBM Technical Seller with whom you engaged with. If you do not have your IBM Technical Seller contact information, see the planning worksheets for contact details.
To download the worksheets, see [IBM Fusion HCI Installation worksheets](#).
- The sample files that are used in this section are based on standard DNS/DHCP services available on Red Hat® Enterprise Linux 8.

About this task

Important: If you are using static IP, then you do not have to do a DHCP setup.

You can access IBM Fusion OpenShift® Container Platform cluster nodes on your network. As such, each cluster node requires an IP address that is accessible on this network. During installation, each cluster node obtains its IP address from an external DHCP server based on the MAC address of the cluster node. As a prerequisite for IBM Fusion HCI installation, you must reserve few IP addresses for OpenShift:

Note: All these IPs must be in the same range.

- One IP address for the OpenShift API server endpoint

For example:

- API in DNS lookup file.

```
api IN A 10.44.100.143
```

- API in DNS reverse lookup file.

```
143 IN PTR api.isf.mycompany.com.
```

- One IP address for the wildcard ingress endpoint (to access your workloads)

For example, ingress in DNS.

```
; Ingress LB (apps)
*.apps IN A 10.44.100.144
```

- One IP address for each cluster node (control, compute, AFM, and GPU nodes)
- One IP address for the bootstrap node (it is temporary and is only required during the OpenShift Container Platform installation)

For example:

- Bootstrap in DHCP.

```
host bootstrap.isf.mycompany.com { option host-name "bootstrap.isf.mycompany.com"; hardware ethernet
00:16:3e:e0:31:65; fixed-address 10.44.100.151; }
```

- Bootstrap in DNS lookup.

```
bootstrap IN A 10.44.100.151
```

- Bootstrap in DNS reverse lookup.

```
151 IN PTR bootstrap.isf.mycompany.com.
```

Note:

- For each cluster node and the bootstrap node, you must add DHCP reservations to your DHCP configuration.

A single sample DHCP reservation record for a cluster node looks similar to the following example:

```
host control-1-ru2.isf.mycompany.com { option host-name "control-1-ru2.isf.mycompany.com"; hardware ethernet 04:3f:72:f7:2f:76;
fixed-address 10.44.100.145; }
```

IBM provides the node's hostname (for example, control-1-ru2) and hardware Ethernet (MAC) address and you cannot change them. The fixed-address that you provide is the IP address that gets assigned to the cluster node.

A fully functional DNS environment is a requirement for IBM Fusion HCI and OpenShift Enterprise to work correctly. Adding entries into the /etc/hosts file is not enough because that file is not copied into containers that are running on the platform. For more information about DHCP and DNS, see [OpenShift documentation](#).

Mapping of rack unit with OpenShift host name in a single rack with 9155-C10, 9155-C14, 9155-G03 servers:

For rack that supports 9155-C00, 9155-C01, 9155-C04, 9155-C05, 9155-G02, 9155-G03, and 9155-F01 servers, see [IBM Fusion HCI 2.8.x documentation](#) for host name conventions.

For rack that supports 9155-C010, 9155-C014, G03, and Service node, use the following table as reference for host name conventions:

Rack unit	Host name	Node type
RU2	control-1-ru2.<domainname>	Storage or compute-only
RU3	control-1-ru3.<domainname>	Storage or compute-only
RU4	control-1-ru4.<domainname>	Storage or compute-only
RU5	compute-1-ru5.<domainname>	Storage or compute-only
RU6	compute-1-ru6.<domainname>	Storage or compute-only
RU7	compute-1-ru7.<domainname>	Storage or compute-only
RU23	servicenode-1.<domainname>	Service node

After RU7 any type of nodes can be installed on the next available RU. The naming convention is based on the RU number in the format **compute-1-ru<x>**.<domainname>.

Mapping of rack unit with OpenShift host name for a high availability multi rack cluster:

Rack unit	Host name			Node type
	Rack 1	Rack 2	Rack 3	
RU2	control-1-ru2.<domainname>	control-2-ru2.<domainname>	control-3-ru2.<domainname>	Storage or compute-only
RU3	compute-1-ru3.<domainname>	compute-2-ru3.<domainname>	compute-3-ru3.<domainname>	Storage or compute-only
RU4	compute-1-ru4.<domainname>	compute-2-ru4.<domainname>	compute-3-ru4.<domainname>	Storage or compute-only
RU5	compute-1-ru5.<domainname>	compute-2-ru5.<domainname>	compute-3-ru5.<domainname>	Storage or compute-only
RU6	compute-1-ru6.<domainname>	compute-2-ru6.<domainname>	compute-3-ru6.<domainname>	Storage or compute-only
RU7	compute-1-ru7.<domainname>	compute-2-ru7.<domainname>	compute-3-ru7.<domainname>	Storage or compute-only
RU23	servicenode-1.<domainname>	compute-2-ru23.<domainname>	compute-3-ru23.<domainname>	Compute-only and Service node in base rack

After RU7 any type of nodes can be installed on the next available RU. The naming convention is based on the RU number in the format **compute-1-ru<x>**.<domainname>. In a multi-rack setup, the service node can be added to any one of the racks.

Important: Ensure that in a two-availability-zone and arbiter node (2AZ and arbiter node) configuration, the arbiter node hostname is configured as **arbiter-999**.<domainname>.

Procedure

- Place your DHCP servers in the same VLAN as IBM Fusion HCI unless the DHCP relay agent is used.

2. Verify whether the DNS server is accessible from outside the IBM Fusion HCI by using either the `ping <server-ipaddress>` or the `nslookup <server-ipaddress>` command.
Note: The DNS server can be anywhere but must be reachable, that is, the installation and cluster must have access to your network.
 3. After the verification is complete, set up DHCP reservation for each node. For more information about setting up the DHCP, see [Setting up DHCP](#).
 4. Set up the DNS reservation for each node. For more information about setting up the DNS, see [Setting up DNS](#).
Here, ensure that you use the same `domain-name-servers` value and option host name that you used in DHCP configuration as they are interconnected. Ensure that the fixed addresses that you configure here is same in DHCP as well.
Note: Ensure that the subdomain consists of lowercase alphanumeric characters, '-' or '.', and starts and ends with an alphanumeric character. For example, `example.com`. The regex used for validation is `'a-z0-9?(\.a-z0-9?)*'`,"
- [Setting up DHCP](#)
Steps to set up the DHCP server for IBM Fusion HCI appliance.

Setting up DHCP

Steps to set up the DHCP server for IBM Fusion HCI appliance.

About this task

Important: If you are using static IP, then you do not have to do a DHCP setup.

All storage and GPU nodes in the IBM Fusion appliance must be in the same network segment (subnet). The nodes must have access to a DHCP server to provide IP addresses and other network parameters, for example, default gateway and DNS address.

Note: The samples in this procedure are based on Red Hat® Enterprise Linux. If you are on Microsoft® Linux®, then use equivalent commands.

Use the DHCP server to provide all the nodes of the OpenShift® cluster that you are about to install, with IP information that corresponds to the mac address of the node. It is the reason for you to use fixed-address directive for DHCP to statically map all the mac addresses of the nodes to the required IP addresses. Also, the DHCP server must provide these DHCP options in its DHCP responses for the nodes to be configured correctly:

```
option routers
option broadcast-address
option subnet-mask
option domain-name-servers
option domain-name
option domain-search
option host-name
```

Note: For the host-name option, it must be full FQDN value.

Procedure

1. Edit `/etc/dhcp/dhcpd.conf` file to update values for routers, broadcast-address, subnet-mask, domain-name-servers.

Note: The following sample `dhcpd.conf` (DHCP configuration file) provides bootstrap IP addresses for the control nodes and computes nodes in the `10.44.100.0/24` subnet. In this example, the OpenShift cluster name is `isf` and the DNS domain is `mycompany.com`. Together, the cluster name and domain name form the cluster subdomain. The MAC addresses are provided by IBM.

```
authoritative;
ddns-update-style interim;
default-lease-time 489776228;
max-lease-time 489776228;

option domain-name-servers      10.44.100.142;

subnet 10.44.100.128 netmask 255.255.255.128 {
    interface bond0;
    option routers                10.44.100.129;
    option broadcast-address      10.44.100.255;
    option subnet-mask           255.255.255.128;
    group {
        option domain-name        "isf.mycompany.com";
        option domain-search      "isf.mycompany.com";
        host control-1-ru2.isf.mycompany.com { option host-name "control-1-ru2.isf.mycompany.com"; hardware
ethernet 04:3f:72:f7:2f:76; fixed-address 10.44.100.145; }
        host control-1-ru3.isf.mycompany.com { option host-name "control-1-ru3.isf.mycompany.com"; hardware
ethernet 04:3f:72:f7:31:2e; fixed-address 10.44.100.146; }
        host control-1-ru4.isf.mycompany.com { option host-name "control-1-ru4.isf.mycompany.com"; hardware
ethernet 04:3f:72:f5:a7:2a; fixed-address 10.44.100.147; }

        host compute-1-ru5.isf.mycompany.com { option host-name "compute-1-ru5.isf.mycompany.com"; hardware
ethernet 04:3f:72:f5:a7:26; fixed-address 10.44.100.148; }
        host compute-1-ru6.isf.mycompany.com { option host-name "compute-1-ru6.isf.mycompany.com"; hardware
ethernet 04:3f:72:f5:a7:16; fixed-address 10.44.100.149; }
        host compute-1-ru7.isf.mycompany.com { option host-name "compute-1-ru7.isf.mycompany.com"; hardware
ethernet b8:59:9f:e4:46:6e; fixed-address 10.44.100.150; }

        # The compute-1-ru23.isf.mycompany.com is for service node
        host servicenode-1.gen2003.mycompany.com { option host-name "servicenode-1.gen2003.mycompany.com"; hardware
ethernet a0:88:c2:e5:fc:74; fixed-address 10.0.20.222;
    }

    deny unknown-clients;
}
```

Note: Here, the same `domain-name-servers` value and option host name must be used when you configure in DNS as they are interconnected. Ensure that the fixed addresses that you configure here must be the same in DNS as well.

This example is for a single rack. If you want to configure DHCP for a high availability multi rack cluster or expansion rack, then add rest of the nodes in the cluster according to your host name. For more information about the hostname, see [Setting up DHCP for IBM Fusion HCI](#).

If you want to configure using dnsmasq:

```
user=dnsmasq
group=dnsmasq
interface=ens19
domain=isf.mycompany.com
dhcp-range=10.10.9.10,10.10.9.127,9.9.9.0,infinite
conf-dir=/etc/dnsmasq.d,.rpmnew,.rpmsave,.rpmorig

dhcp-host=08:c0:eb:ff:40:66,control-0,10.10.9.12,infinite,set:control-0
dhcp-option=tag:control-0,12,control-0.isf.mycompany.com

dhcp-host=08:c0:eb:ff:43:36,control-1,10.10.9.13,infinite,set:control-1
dhcp-option=tag:control-1,12,control-1.isf.mycompany.com

dhcp-host=08:c0:eb:ff:40:86,control-2,10.10.9.14,infinite,set:control-2
dhcp-option=tag:control-2,12,control-2.isf.mycompany.com

dhcp-host=08:c0:eb:ff:2f:86,compute-0,10.10.9.15,infinite,set:compute-0
dhcp-option=tag:compute-0,12,compute-0.isf.mycompany.com

dhcp-host=08:c0:eb:ff:3e:92,compute-1,10.10.9.16,infinite,set:compute-1
dhcp-option=tag:compute-1,12,compute-1.isf.mycompany.com

dhcp-host=08:c0:eb:ff:30:42,compute-2,10.10.9.17,infinite,set:compute-2
dhcp-option=tag:compute-2,12,compute-2.isf.mycompany.com

dhcp-host=08:c0:eb:cb:09:2e,compute-13,10.10.9.18,infinite,set:compute-13
dhcp-option=tag:compute-13,12,compute-13.isf.mycompany.com

dhcp-host=08:c0:eb:cb:08:8e,compute-14,10.10.9.19,infinite,set:compute-14
dhcp-option=tag:compute-14,12,compute-14.isf.mycompany.com

dhcp-host=b8:ce:f6:74:ef:d6,compute-15,10.10.9.20,infinite,set:compute-15
dhcp-option=tag:compute-15,12,compute-15.isf.mycompany.com

dhcp-host=08:c0:eb:ff:31:66,compute-16,10.10.9.21,infinite,set:compute-16
dhcp-option=tag:compute-16,12,compute-16.isf.mycompany.com

address=/api.isf.mycompany.com/10.10.9.6
address=/api-int.isf.mycompany.com/10.10.9.6
address=/apps.isf.mycompany.com/10.10.9.7
```

2. After you update the configuration file, restart the service for the changes to take effect.

For example, on Linux®, run the following command:

```
sudo /etc/init.d/dnsmasq restart
```

or

```
sudo systemctl restart network-manager
```

Note: The first command works on RHEL 7 or lower. For RHEL 8 or higher, use **sudo systemctl restart network-manager/**

Setting up DNS

Steps to set up the DNS server for IBM Fusion HCI appliance. It is applicable for both static and DHCP.

Before you begin

- Ensure that the VIP address for Ingress and API are in the same subnet as machine CIDR.
- For IBM Fusion HCI with static IP, configure DNS server to disallow **nslookup** on IP range **169.253.0.0/24**. This IP range belongs to the provisioning network and DNS must not try to resolve it. On Linux named server do the following configuration changes:

1. Edit **/etc/named.conf** to add the following content:

```
zone "253.169.in-addr.arpa" {
    type master;
    file "/var/named/db.blocked-253.169";
};
```

2. Create zone config file **/var/named/db.blocked-253.169** and add the following configuration:

```
$TTL 86400
@ IN SOA localhost. root.localhost. (
    1          ; Serial
    3600       ; Refresh
    1800       ; Retry
    604800     ; Expire
    86400 )    ; Minimum

IN NS localhost.
```

3. Run the following command to restart the named server:

```
sudo systemctl restart named
```

4. Test whether the `nslookup` on the IP range returns no response:

```
nslookup 169.253.2.53 <DNS server IP>
```

Output:

```
** server can't find 53.2.253.169.in-addr.arpa: NXDOMAIN
```

About this task

Forward and reverse lookup must match to ensure that no network spoofing exists. It is a security issue where the hostname points to a wrong IP address. For MAC address, IBM Fusion HCI installation needs static IPs for its nodes and each node has its own specific hostname. To facilitate this requirement, DHCP is setup to map MAC address with an IP and hostname. In DNS service, similar mapping is configured between IP and hostname and vice-verse.

Note: The samples in this procedure are based on Red Hat® Enterprise Linux. If you are on Microsoft® Linux®, then use equivalent commands.

Procedure

1. Run the following command to suspend updates to all dynamic zones:

```
rndc freeze
```

2. Edit your forward lookup (zonefile.db) at /var/named/ folder:

Note: Forward look up returns the IP address of a hostname.

Samples forward lookup file:

```
$TTL 1W
@      IN      SOA      ns1.isf.mycompany.com. root (
                                2021052608      ; serial
                                3H                ; refresh (3 hours)
                                30M               ; retry (30 minutes)
                                2W                ; expiry (2 weeks)
                                1W )             ; minimum (1 week)
      IN      NS       ns1.isf.mycompany.com.
      IN      MX 10    smtp.isf.mycompany.com.
;
ns1     IN      A       10.9.20.17
smtp    IN      A       10.9.20.17
;
api     IN      A       10.9.20.127
;
; Ingress LB (apps)
*.apps  IN      A       10.9.20.128
;
bootstrap IN A 10.0.20.135
;
; Create entries for the master nodes
control-1-ru2 IN A 10.9.20.129
control-1-ru3 IN A 10.9.20.130
control-1-ru4 IN A 10.9.20.131
;
; Create entries for the worker nodes
compute-1-ru5 IN A 10.9.20.132
compute-1-ru6 IN A 10.9.20.133
compute-1-ru7 IN A 10.9.20.134
servicenode-1 IN A 10.9.20.222
;
;
;EOF
```

Note: The servicenode-<rackid> is used for servicenode hostname and for single rack it is always 1. For multi rack, it depends on the rackid used for the base rack.

3. Edit the reverse lookup file (reverse.db) at /var/named/reverse.db folder.

Reverse look up returns the hostname of an IP address.

Sample reverse lookup file:

```
$TTL 1W
@      IN      SOA      ns1.isf.mycompany.com. root (
                                2021052608      ; serial
                                3H                ; refresh (3 hours)
                                30M               ; retry (30 minutes)
                                2W                ; expiry (2 weeks)
                                1W )             ; minimum (1 week)
      IN      NS       ns1.isf.mycompany.com.
; gen2003 rack
127    IN      PTR     api.isf.mycompany.com.
135    IN      PTR     bootstrap.isf.mycompany.com.
;
; syntax is "last octet" and the host must have fqdn with trailing dot
129    IN      PTR     control-1-ru2.isf.mycompany.com.
130    IN      PTR     control-1-ru3.isf.mycompany.com.
131    IN      PTR     control-1-ru4.isf.mycompany.com.
132    IN      PTR     compute-1-ru5.isf.mycompany.com.
133    IN      PTR     compute-1-ru6.isf.mycompany.com.
134    IN      PTR     compute-1-ru7.isf.mycompany.com.
```

```
222      IN      PTR      servicenode-1.isf.mycompany.com.
;
```

In this example, the IP addresses 10.9.20.127-222 points to the corresponding fully qualified domain name.

Note: Ensure that the subdomain consists of lowercase alphanumeric characters, '-' or '.', and starts and ends with an alphanumeric character. For example, `example.com`. The regex used for validation is `'a-z0-9?(\.a-z0-9?)*'`.

4. Ensure that your `named.conf` file in the `/etc` folder contains details of your forward and reverse lookup files.

Sample `named.conf` file:

```
[root@provisioner named]# cat /etc/named.conf

options {
    listen-on port 53 { any; };
    listen-on-v6 port 53 { ::1; };
    directory      "/var/named";
    dump-file       "/var/named/data/cache_dump.db";
    statistics-file "/var/named/data/named_stats.txt";
    memstatistics-file "/var/named/data/named_mem_stats.txt";
    allow-query     { any; };
    .....
    .....
##### Add what's between these comments #####
zone "isf.mycompany.com" IN {
    type      master;
    file      "zonefile.db";
};
zone "100.44.10.in-addr.arpa" IN {
    type      master;
    file      "reverse.db";
};
#####
include "/etc/named.rfc1912.zones";
include "/etc/named.root.key";
```

5. On the DNS server, run the following commands to open the firewall port for DNS:

```
firewall-cmd --zone=public --add-service=dns --permanent
firewall-cmd --reload
```

6. Restart the DNS service.

```
sudo systemctl restart named.service
```

Setting up Static IP

Steps to set up the static IP for IBM Fusion HCI appliance.

Before you begin

- Download the installation preparation worksheet and review the network preparation section. To download the worksheets, see [IBM Fusion HCI Installation worksheets](#).
- If you plan to use Static IP instead of DHCP, you must have selected the Static IP assignment method in Stage 1 of the installation.
- A fully functional DNS environment is a requirement for IBM Fusion HCI and OpenShift® Enterprise to work correctly. Adding entries into the `/etc/hosts` file is not enough because that file is not copied into containers that are running on the platform.

About this task

Important: If you are using static IP, then you do not have to do a DHCP setup.

Procedure

1. Place your static servers in the same VLAN as IBM Fusion HCI.
2. Verify whether the DNS server is accessible from outside the IBM Fusion HCI by using either the `ping <server-ipaddress>` or the `nslookup <server-ipaddress>` command.
Note: The DNS server can be anywhere but must be reachable, that is, the installation and cluster must have access to your network.
3. Set up the DNS reservation for each node. For more information about setting up the DNS, see [Setting up DNS](#).
Here, ensure that you use the same `domain-name-servers` value and option host name that you used in Static IP as they are interconnected. Ensure that the fixed addresses that you configure here is same in Static IP as well.

Review proxy configuration guidance

Proxy configuration is needed only in a connected install through proxy.

- Note: As a prerequisite, check the following points for proxy limitations:
 - Ensure that there are no restrictions on the maximum file size for download through proxy or that it must be adjusted adequately.
 - Ensure that there is enough bandwidth available, or otherwise installation might run into errors due to download timeouts
 - Ensure that there are no quotas or download limits set or adjusted appropriately, or else pods might get into a crash loop due to download limitations.
 - Do not use special characters in proxy credentials.

- If you plan to setup Metro-DR and both sites use proxy, then site1 API must be in the allowed list of site2 proxy and site2 API must be in the allowed list of site1 proxy.
- If you are going to install through your enterprise registry and that is also through your proxy, then add `http://<enterprise_registry_host_name>`
- If you plan to use a proxy server for internet access with IBM Fusion HCI for configuration, add the following list to access control list (ACL) on proxy server:
 - `registry.redhat.io`
 - `redhat.com`
 - `registry.connect.redhat.com`
 - `console.redhat.com`
 - `cloud.redhat.com`
 - `access.redhat.com`
 - `registry.access.redhat.com`
 - `api.access.redhat.com`
 - `quay.io`
 - `cdn.quay.io`
 - `cdn01.quay.io`
 - `cdn02.quay.io`
 - `cdn03.quay.io`
 - `cdn04.quay.io`
 - `cdn05.quay.io`
 - `cdn06.quay.io`
 - `sso.redhat.com`
 - `oauth-openshift.apps.<cluster_name>.<base_domain>`
 - `canary-openshift-ingress-canary.apps.<cluster_name>.<base_domain>`
 - `console-openshift-console.apps.<cluster_name>.<base_domain>`
 - `api.openshift.com`
 - `infogw.api.openshift.com`
 - `mirror.openshift.com`
 - `docker.com`
 - `docker.io`
 - `dseasb33srnrrn.cloudfront.net`
 - `rhc4tp-prod-z8cxf-image-registry-us-east-1-evenkyleffocxqvofrk.s3.dualstack.us-east-1.amazonaws.com`
 - `storage.googleapis.com`
 - `pkg-containers.githubusercontent.com`
 - `ghcr.io`
 - `www.okd.io`
- If your IBM Fusion appliance contains GPU nodes, you must configure the following sites:
 - `cloud.openshift.com`
 - `.nvcr.io`
 - `.d3c2pjnrr68kpx.cloudfront.net`
 - `containers.nvcr.io`
 - `authn.nvcr.io`
 - `api.ngc.nvidia.com`
 - `catalog.ngc.nvidia.com`
- The following firewall sites must be configured for IBM Cloud Container registry:
 - `icr.io`
 - `cp.icr.io`
 - `dd0.icr.io`
 - `dd2.icr.io`

If you are located in China, you must also allow the following hosts:

 - `dd1-icr.ibm-zh.com`
 - `dd3-icr.ibm-zh.com`
- The following firewall site must be configured for Metro-DR set up:
 - `gcr.io`
- The following firewall sites must be configured to interact with IBM or Red Hat® services:
 - <http://www.ibm.com>
 - <http://www.redhat.com>
- The following firewall sites must be configured for Call Home:
 - `www.ecurep.ibm.com`
 - `esupport.ibm.com`
- The following endpoints must be configured for Remote Support:
 - `aosrelay1.us.ihost.com`
 - `aosback.us.ihost.com`
 - `aoshats.us.ihost.com`

Preventing Scale network IP conflicts

This is an optional configuration and is only needed when the default scale daemon IPs conflicts with some of your workloads. An additional IPVLAN Container Network Interface (CNI) network named as daemon-network is created for scale core pods. By default, IP addresses are assigned for Scale daemon network. You can override the default IP addresses before you begin the Final installation of IBM Fusion HCI. If the default IPs are being overridden ensure that they are configured in a private subnet.

About this task

Scale core pods have two networks, namely admin and daemon network. Admin network is the default pod network and pod service domain, whereas the daemon network is used for communication between the Scale core pods.

Compute nodes parts of the Scale cluster are annotated to provide the daemon network name, IPv4 address, gateway, and optionally the machine address.

By default, for Scale daemon network, the private IPv4 addresses is in the range of 192.168.128.6 to 192.168.191.254. The default gateway for this network is 192.168.128.1. This default allocated IP range can be overridden if necessary.

Configuring the enterprise registry

Before you install IBM Storage Fusion HCI, confirm that you have the required access to the image registry and software entitlements for your deployment.

Before you run the installation wizard, confirm that your image registry is in place and that your software entitlements are active. Complete the following tasks:

- **Identify your registry strategy.** Choose between an online installation that pulls images directly from IBM and Red Hat registries, or an offline installation that requires you to mirror images to an enterprise registry before you install. If your environment has no internet access, set up the enterprise registry and mirror all required images before you proceed.
- **Activate your subscriptions and entitlements.** Activate your Red Hat® OpenShift® Container Platform subscriptions and IBM Fusion HCI software entitlements so that the installation wizard can access the required images and licenses.
- [Identify your registry strategy](#).
Identify the image registry strategy that suits your deployment before you install IBM Storage Fusion HCI.
- [Activate your subscriptions and entitlements](#)
Before you install IBM Storage Fusion HCI, activate your IBM software subscriptions and entitlements to ensure that your deployment is licensed and supported.

Identify your registry strategy

Identify the image registry strategy that suits your deployment before you install IBM Storage Fusion HCI.

Content and metadata for this topic will be provided.

- [Enterprise registry for IBM Fusion HCI installation](#)
During the installation process, IBM Fusion HCI installs Red Hat® OpenShift® Container Platform and IBM Fusion software using images that are hosted in the Red Hat and IBM entitled registries. If you want to use your enterprise registry, you can install both OpenShift and IBM Fusion HCI software from images that are maintained in a container registry that you manage.
- [Quay on IBM Fusion HCI](#)
How to setup Quay and S3 for Quay.
- [Converting a rack from internal registry to offline using enterprise registry](#)
Use the following instructions to convert a rack from internal registry to offline using enterprise registry on the IBM Fusion HCI cluster.
- [Converting a rack from online proxy to offline using external Quay](#)
Use the following instructions to convert a rack from online proxy to offline using external quay on the IBM Fusion HCI cluster.

Enterprise registry for IBM Fusion HCI installation

During the installation process, IBM Fusion HCI installs Red Hat® OpenShift® Container Platform and IBM Fusion software using images that are hosted in the Red Hat and IBM entitled registries. If you want to use your enterprise registry, you can install both OpenShift and IBM Fusion HCI software from images that are maintained in a container registry that you manage.

Though the installation experience of using your enterprise registry and IBM entitled and Red Hat registry are the same, you are responsible for setting up and populating your private enterprise registry. IBM Fusion supports both JFrog Artifactory and Quay enterprise registries.

These mirroring procedures guide you to download the images of IBM Fusion HCI and all its services at once or individually depending on your specific needs. Before you initiate the mirroring process, verify that all prerequisites are met to ensure its success, regardless of whether you choose the end-to-end procedure or selective procedure.

- [Mirroring prerequisites](#)
Complete the following prerequisites before you mirror images of IBM Fusion and its services.
- [End-to-end mirroring of IBM Fusion HCI and its services images to the enterprise registry](#)
If you are planning a disconnected or offline installation, then you must mirror images to your enterprise registry. You can use this procedure to complete an integrated mirroring of IBM Fusion HCI and its services **Backup & Restore**, **IBM Data Cataloging**, **IBM Software Hub**, and **Content-Aware Storage**. Otherwise, you can mirror them individually per your requirement.
- [Mirroring OpenShift Container Platform release images to enterprise registry](#)
Mirror the OpenShift Container Platform image repository to your registry to use during installation or upgrade.
- [Mirroring Red Hat operator images to enterprise registry](#)
Mirror the Red Hat operator images to your enterprise registry.
- [Mirroring individual images](#)
There may be scenarios wherein you may want to mirror individual images separately.
- [Troubleshooting and known issues in offline mirroring](#)
Issues can occur during the offline mirroring of images. This topic outlines known issues and offers troubleshooting guidance.

Mirroring prerequisites

Complete the following prerequisites before you mirror images of IBM Fusion and its services.

Prepare your mirroring host

- The mirror host must have access to the internet and enterprise registry.
- Ensure that you install the following tools on your system from where you can connect to Red Hat® registry and enterprise registry:
 - Install Docker or Podman to create, run, and maintain images.
If you are using self-signed certificate registry, then ensure that you have updated the container tools configuration with insecure registries to skip certificate validation. For more information about how to update, see [Update container tools configuration](#).
 - Install skopeo for Global Data Platform storage image copy operation. For more information to install skopeo, see <https://github.com/containers/skopeo>.
 - Install OC command tool from any of the Red Hat OpenShift® Container Platform cluster:
 1. Log in to the system from where you want to run commands.
 2. Log in to OpenShift Container Platform.
 3. Click bell icon and select Command line tools.
 4. Click the appropriate oc download option based on your operating system.Alternatively, you can also download the platform based oc client.
Note: For example, if the latest version is 4.20.28, then use the following link to download oc client for Linux platform:
https://mirror.openshift.com/pub/openshift-v4/x86_64/clients/ocp/4.20.28/openshift-client-linux-4.20.28.tar.gz.
- Install the **oc-mirror** CLI plug-in. For more information about **oc-mirror** CLI plug-in installation, see [Installing the oc-mirror OpenShift CLI plugin](#).
Note: Ensure that you install the **oc-mirror** CLI plug-in of **4.20.6** version due to RH bug.
- Download pull-secret.txt.
Note: After downloading the file, ensure it is saved with a **.json** file extension.
To download the pull-secret, see <https://console.redhat.com/openshift/install/pull-secret> and follow the instructions.

You can either use podman command to add private registry credentials to downloaded pull-secret.json or manually edit the downloaded **pull-secret** with registry credentials. For example:

```
podman login registryhost.com:443 --authfile="pull-secret.json"
```

Add a new section of key-value pair under **auths**. For example,

```
"<Your enterprise registry>:<port>": {  
  "auth": "<base64 encoded 'user_name:password'>",  
  "email": "<your email>" }
```

As a prerequisite to run base64, you must install base64 or jq.
See the following sample values:

```
{  
  "auths": {  
    "cloud.openshift.com": {  
      ....  
    }  
    "registryhost.com:443": {  
      "auth": "dXNlc19uYW11OnBhc3N3b3Jk",  
      "email": "user_name@ibm.com"  
    }  
  }  
}
```

Here, **user_name** and **password** are credentials to connect to enterprise registry.

Note: If you want to use multiple repositories, add an auth section for both repositories.

To authenticate to quay.io by using the username and password from the pull-secret, do the following steps:

1. Look for quay.io in the json and copy **auth**. Example:

```
"auths": {  
  "quay.io": {  
    "auth": "b3BlbnNoaWZ0LXJTCzOGY2YzNjNDM2ZWl0JRSdDUQU45RFBWVUNXM0VZQU1VVDBoQTU3VFM2RE1JMg==",  
    "email": <email-id>  
  }  
}
```

It is a base64 encoded value of **username:password**.

2. Get the username/password.

```
echo <auth-content> | base64 -decode
```

Example echo command:

```
echo "b3BlbnNoaWZ0LXJTCzOGY2YzNjNDM2ZWl0JRSdDUQU45RFBWVUNXM0VZQU1VVDBoQTU3VFM2RE1JMg==" | base64 -decode
```

Example output:

```
openshift-release+ocmaccess0ab5738f6c3c42:CXKR2TSBQH7TAN9
```

Here, **openshift-release+ocmaccess0ab5738f6c3c42** is the user name and **CXKR2TSBQH7TAN9** is the password.

Command line to get the username/password: `echo <auth-content> | base64 -decode`

- Ensure that you have entitlement key to access IBM Fusion HCI appliance images. For more information about entitlement key, see [Activating IBM Fusion HCI Software to be downloaded](#).

General prerequisites

- Before you proceed with mirroring, be aware of key considerations, known issues, and troubleshooting information. See [Troubleshooting and known issues in offline mirroring](#).

- Provide the port number as follows:

For installation

If you want to use the default port (443), then make sure you provide the port number.

For example, `<Your enterprise registry>:9443`.

If you want to use custom port, then provide the custom details.

To verify, log in to `your registry:port` by using docker or podman. Use the following **podman** command:

```
"podman login registryhost:registryport"
```

- The registry must have at least one directory path specified.

For example:

```
https://<enterprise registry host>:<enterprise registry port>/<mandatory root path>
```

- Ensure that your secure enterprise registry is already setup and ready for use. Support is available for Quay and registries with self signed certificate. Important: Always mirror the most recent images at any point in time to your registry before installation.
- Run a pull command in your network to test the network speed. If that time is more than 2 to 5 minutes, there may be an overall reduction in network speed that can cause installation failure. Example command:

```
time podman pull cp.icr.io/cp/isf/isf-compute-
operator@sha256:414275e851972db2b7172642f7f7827c42da14914061bd5d82ea0584e6ce7fc8
```

Single or multiple repositories

You can either host your images in a single repository or host your OpenShift and IBM Fusion images separately. Choose the latter option if you want to manage their OpenShift images separately from other software.

Single repository

If you want to use Single repository, mirror all the images to IBM Fusion images repository, so your `$LOCAL_OCP_REGISTRY` remains same as `$LOCAL_ISF_REGISTRY`.

Multiple repositories

If you want to use Multiple repositories, mirror the OpenShift images to the OpenShift images repository (`$LOCAL_OCP_REGISTRY`) and all other images to the IBM Fusion images repository (`$LOCAL_ISF_REGISTRY`).

Considerations for your enterprise registry

- There must not be a huge latency between cluster nodes and your enterprise registry. Slow image pull can cause OpenShift Container Platform installation to fail.
- You must have a container image registry that supports Docker v2-2 in the location that hosts the Red Hat OpenShift Container Platform cluster. For more information about image manifest, see [opm CLI reference](#).

Important: Artifactory is the recommended registry because it supports the following must have capabilities:

- Import and export
- Untagged images

JFrog Artifactory version 7.55.8 is tested on IBM Fusion HCI. The port that is specified in the URL is used to login and pull the images from the enterprise repository. For a secured enterprise registry, specify 443. If you do not provide the port value, then no default port is considered in its absence. The API key is the only supported authentication method.

- For disconnected installation, you need a firewall type proxy server and for an air break installation, the registry must have import and export capabilities.
- If you are using self-signed certificate registry, then ensure that you have updated the container tools configuration with insecure registries to skip certificate validation.

- For Podman, see <https://docs.podman.io/en/stable/markdown/podman-login.1.html>.
- For Docker, follow the steps to skip certificate validation:

- To trust the certificate in the Docker daemon:

For Linux, copy the `domain.crt` file to `/etc/docker/certs.d/myregistrydomain.com:5000/ca.crt` on your mirroring host, Where `domain.crt` is a self-generated certificate and `myregistrydomain.com` is your Docker registry and 5000 is port for registry.

- For configuring an insecure registry:

Note: It is insecure and not recommended.

Edit the `daemon.json` file that present in the default location of `/etc/docker/daemon.json` on the Linux Server.

If the `daemon.json` file does not exist, then create it. Ensure it contains the following contents:

```
{
  "insecure-registries" : ["myregistrydomain.com:5000"]
}
```

- Offline upgrade cons

The offline mirroring process includes applying `ImageDigestMirrorSet` or `ImageContentSourcePolicy` files to your cluster. Any changes to the IDMS or ICSP on clusters triggers a `MachineConfigPool` rollout, which can cause nodes to reboot. This includes adding, updating, or deleting IDMS or ICSP files. There are two options for offline upgrade mirroring:

Mirroring images to the same location as the previous offline installation

This gives the IDMS or ICSP files that are identical to your previous installation, and you can choose to not apply the IDMS or ICSP files or `oc apply` the file and OpenShift recognizes there is no change in content and exit gracefully.

Mirror images to a different location as the previous offline installation

Because the generated IDMS or ICSP is tailored specifically to the target offline registry, mirroring to a new location every time gives a different IDMS or ICSP every time. Applying a new IDMS or ICSP triggers the MCP rollout and contains the potential to reboot nodes, which can be disruptive to the health of the OpenShift cluster.

Additionally, if you have done multiple offline upgrades using this method, then your cluster likely have multiple ICSP or IDMS files, some of which are old and unused. Again, deleting a IDMS or ICSP can trigger a disruptive MCP rollout. It is recommended to not delete any IDMS or ICSP files from the cluster until you have completed your upgrade to your target version of IBM Fusion HCI.

However, it is recommended you to edit the generated IDMS and change the `metadata.name` to unique name to avoid overwriting an existing IDMS on your cluster.

End-to-end mirroring of IBM Fusion HCI and its services images to the enterprise registry

If you are planing a disconnected or offline installation, then you must mirror images to your enterprise registry. You can use this procedure to complete an integrated mirroring of IBM Fusion HCI and its services **Backup & Restore**, **IBM Data Cataloging**, **IBM Software Hub**, and **Content-Aware Storage**. Otherwise, you can mirror them individually per your requirement.

Before you begin

- Before you mirror, go through the prerequisites. See [Mirroring prerequisites](#).
- Use either podman or docker commands to login to the registries. The examples in the procedure used docker; if you are using podman, substitute `podman` for `docker` in the commands.
- Configure Common Environment Variables:
Important: Ensure that you review the [offline upgrade considerations](#) before proceeding with upgrade mirroring.
Define the following environment variables for your target container registry. These values are used in each of the subsequent steps to mirror all the related components.

```
export LOCAL_ISF_REGISTRY="<Your container registry host>:<port>"
export LOCAL_ISF_REPOSITORY="<Your image path>"
export TARGET_PATH="$LOCAL_ISF_REGISTRY/$LOCAL_ISF_REPOSITORY"
```

LOCAL_ISF_REGISTRY is your target container registry.

LOCAL_ISF_REPOSITORY is the image path in which you want to mirror the images. You can choose your own repository paths. For example, `hci-images/isf` or `hci-images`. See the following sample values:

```
export LOCAL_ISF_REGISTRY="registryhost.com:443"
export LOCAL_ISF_REPOSITORY="mirror-fusion-services-images"
export TARGET_PATH="$LOCAL_ISF_REGISTRY/$LOCAL_ISF_REPOSITORY"
```

About this task

Points to note about this task:

- Run all commands as root user.
- In the commands, replace `<your enterprise registry>` with your enterprise registry.
- Common tasks to complete this procedure.
 1. Install oc CLI plug-in. For steps to install, see [Mirroring prerequisites](#).
 2. Set common variables used by all subsequent mirroring steps, such as the target registry and target registry location.
 3. IBM Fusion complete installation:
Mirror and install IBM Fusion and its related services (Backup & Restore, IBM Data Cataloging, IBM Software Hub, and Content-Aware Storage). For steps, see [Procedure](#).
- IBM Fusion custom installation:
To perform a custom installation of IBM Fusion and its components, determine which components you want to install, and then see the following topics for installation instructions.
 - Mirror Red Hat® OpenShift® Container Platform release images. For more information, see [Mirroring OpenShift Container Platform release images to enterprise registry](#).
 - Mirror images for Red Hat operator. For more information, see [Mirroring Red Hat operator images to enterprise registry](#).
 - IBM Fusion HCI images. For more information, see [Mirroring IBM Fusion HCI images](#).
 - Mirror Global Data Platform images. For more information, see [Mirroring IBM Storage Scale images](#).
 - Mirror Fusion Data Foundation images. For more information, see [Fusion Data Foundation images](#).
 - Mirror Backup & Restore images. For more information, see [Mirroring Backup & Restore images](#).
 - Mirror IBM Data Cataloging images. For more information, see [Mirroring IBM Data Cataloging images](#).
 - Mirror IBM Software Hub images. For more information, see [Mirroring IBM Software Hub, watsonx.ai, and watsonx Orchestrate images](#).
 - CAS images. For more information, see [Mirroring Content-Aware Storage \(CAS\) images](#).
- For Hosted Control Plane upgrades, follow the [step](#) described in the following procedure.

Procedure

Mirror IBM Fusion and related Backup & Restore, IBM Data Cataloging, IBM Software Hub, and CAS services.

1. Run the following command to login to the Docker registry with your Red Hat enterprise credentials:

```
docker login registry.redhat.io -u <Red Hat enterprise registry username> -p <Red Hat enterprise registry password>
```

Log in to the IBM Entitled Container Registry using the IBM entitlement key:

```
docker login cp.icr.io -u cp -p <your entitlement key>
```

Important:

- Ensure that your entitlement key for IBM Fusion HCI contains the correct entitlement.

- Ensure you review the [offline upgrade considerations](#) before proceeding with upgrade mirroring.
- Set the following environment variables:

```
export LOCAL_ISF_REGISTRY="<Your container registry host>:<port>"
export LOCAL_ISF_REPOSITORY="<Your image path>"
export TARGET_PATH="$LOCAL_ISF_REGISTRY/$LOCAL_ISF_REPOSITORY"
```

Note: Port is a non-mandatory value when setting the `LOCAL_ISF_REGISTRY` variable. You can ignore this if your enterprise registry is accessible and has a secure connection.

Sample value for without port:

```
export LOCAL_ISF_REGISTRY="registryhost.com"
```

See the following sample values:

```
export LOCAL_ISF_REGISTRY="registryhost.com:443"
export LOCAL_ISF_REPOSITORY="fusion-mirror"
```

`LOCAL_ISF_REGISTRY` is your entitlement registry.

`LOCAL_ISF_REPOSITORY` is the image path in which you want to mirror the images. You can choose your own repository paths. For example, `hci-images/isf` or `hci-images`.

2. Run the command to login to the Docker registry with your enterprise registry credentials.

```
docker login $LOCAL_ISF_REGISTRY -u <your enterprise registry username> -p <your enterprise registry password>
```

3. Ensure that the `redhat-oadp-operator` and `amq-streams` operator packages are present in your cluster.

Note: If you did not mirror `redhat-oadp-operator` and `amq-streams` from the Red Hat packages previously, follow the steps that are provided in the [Mirroring Red Hat operator images to enterprise registry](#).

Note:

- Run the following command to get list of mirrored Red Hat packages available on your cluster.

```
oc get packagemanifests | grep -i "Red Hat Operators"
```

- If you do not get `redhat-oadp-operator` and `amq-streams` operator packages from the previous step, then you must follow the step 1.
- Ensure that you also add existing packages along with new one in ImageSetConfiguration file. Otherwise, old packages can be lost from the Red Hat operator index image.

4. Create the image set configuration for IBM Fusion HCI.

`imageset-config-fusion.yaml`

```
cat << EOF > imageset-config-fusion.yaml
kind: ImageSetConfiguration
apiVersion: mirror.openshift.io/v2alpha1

EOF

```

- Run the following `oc-mirror` command to mirror the images.

```
oc mirror --v2 --config imageset-config-fusion.yaml --workspace file:/// docker://${TARGET_PATH} --dest-tls-verify=false
```

- Apply the IDMS file to your cluster:

Note: Replace the variable `$TARGET_PATH` with your registry details where images are mirrored.

```

apiVersion: config.openshift.io/v1
kind: ImageDigestMirrorSet
metadata:
  name: ibm-spectrum-fusion
spec:
  imageDigestMirrors:
  - mirrors:
    - $TARGET_PATH/cp
    source: cp.icr.io/cp
  - mirrors:
    - $TARGET_PATH/cpopen
    source: icr.io/cpopen
  - mirrors:
    - $TARGET_PATH/db2u
    source: icr.io/db2u
  - mirrors:
    - $TARGET_PATH/fusion-open/minio
    - $TARGET_PATH/minio
    source: quay.io/minio
  - mirrors:
    - $TARGET_PATH/openshift4
    source: registry.redhat.io/openshift4

```

- Create a `CatalogSource` (required only for upgrade).

Note: Replace the variable `$TARGET_PATH` with your registry details where images are mirrored.

```

apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: ibm-spectrum-fusion-catalog
  namespace: openshift-marketplace
spec:
  displayName: ibm-spectrum-fusion-2.14.0-linux-amd64
  publisher: IBM
  image: ${TARGET_PATH}/cpopen/isf-operator-
catalog@sha256:ffec2cdd438b1ee5f2b11a9f6964b8d892065c97ab5c74cc2b2b6edbeba148a9
  sourceType: grpc
  grpcPodConfig:
    nodeSelector:
      kubernetes.io/arch: amd64

```

- If you planned to install the IBM Data Cataloging service, then apply the following catalog source.

```

apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: ibm-spectrum-discover-catalog
  namespace: openshift-marketplace
spec:
  displayName: ibm-spectrum-discover-256.0.1
  publisher: IBM
  image: ${TARGET_PATH}/cpopen/ibm-spectrum-discover-operator-
catalog@sha256:3ada857fe322cf08f50be799a6194d5248fd0627f061098dab0511f5b277d89c
  sourceType: grpc

```

- If you planned to install the Content-Aware Storage service, then apply the following catalog source.

```

apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: ibm-cas-catalog
  namespace: openshift-marketplace
spec:
  displayName: ibm-cas-1.1.7-linux-amd64
  publisher: IBM
  image: ${TARGET_PATH}/cpopen/ibm-isf-cas-operator-
catalog@sha256:3ecc98df5ab3f6f26a36e7ed0e99030081ee7152cbf763531973081173e6e39d

```

```
sourceType: grpc
grpcPodConfig:
  nodeSelector:
    kubernetes.io/arch: amd64
```

10. Hosted Control Plane upgrade:

- To upgrade Hosted Control Planes, mirror the IBM Fusion image of the upgradeable version. For more information, see [Mirroring IBM Fusion images](#).
- After mirroring, apply the generated IBM Fusion catalog source in IBM Fusion HCI base cluster.

Note: Verify whether mirror of IBM Fusion images is added in the `HostedCluster` custom resource (CR).

What to do next

After you complete the end-to-end mirroring of IBM Fusion HCI and its services images to the enterprise registry, proceed with [Mirroring OpenShift Container Platform release images to enterprise registry](#).

Mirroring OpenShift Container Platform release images to enterprise registry

Mirror the OpenShift® Container Platform image repository to your registry to use during installation or upgrade.

Before you begin

- Before you mirror, go through the prerequisites. See [Mirroring prerequisites](#).
- Ensure that you go through the *Before you begin* section and *About the task* section of [End-to-end mirroring of IBM Fusion HCI and its services images to the enterprise registry](#).
- Use either `podman` or `docker` commands to login to the registries. The examples in the procedure used `docker`; if you are using `podman`, substitute `podman` for `docker` in the commands.

About this task

For more information about Red Hat® OpenShift Container Platform, see [Red Hat OpenShift Documentation](#).

Procedure

1. Set the following environment variables:

```
export LOCAL_ISF_REGISTRY="<Your enterprise registry host>:<port>"
export LOCAL_ISF_REPOSITORY="<Your image path>"
export TARGET_PATH="$LOCAL_ISF_REGISTRY/$LOCAL_ISF_REPOSITORY"
export OCP_VERSION="<your selected OCP version>"
export OCP_MIN_VERSION=$(echo $OCP_VERSION | cut -d'.' -f1,2)
echo "$TARGET_PATH"
```

For 2.14.0 fresh installation, the OCP_VERSION values are 4.22.9 or 4.20.28.

2. Run the command to login to the Docker registry with your enterprise registry credentials.

```
podman login $LOCAL_ISF_REGISTRY -u <your enterprise registry username> -p <your enterprise registry password>
```

3. Create an image set configuration file for the OpenShift Container Platform.

```
cat << EOF > ocp-hcp-imageset.yaml
apiVersion: mirror.openshift.io/v2alpha1
kind: ImageSetConfiguration
mirror:
  platform:
    channels:
      - name: stable-$OCP_MIN_VERSION
        minVersion: $OCP_VERSION
        maxVersion: $OCP_VERSION
        type: ocp
      # Add below "kubeVirtContainer: true" only if you are planning to install HCP clusters and Mirror the 4.20.10 for
      hosted clusters due to a known RH limitation stated in following note
      - name: stable-4.20
        minVersion: 4.20.10
        maxVersion: 4.20.10
        type: ocp
        kubeVirtContainer: true
    architectures:
      - "multi"
    graph: true
EOF
```

For example:

```
apiVersion: mirror.openshift.io/v2alpha1
kind: ImageSetConfiguration
mirror:
  platform:
    channels:
      - name: stable-4.22
        minVersion: 4.22.8
        maxVersion: 4.22.8
        type: ocp
      # Add below "kubeVirtContainer: true" only if you are planning to install HCP clusters and Mirror the 4.20.10 for
```

```
hosted clusters due to a known RH limitation stated in following note
- name: stable-4.20
  minVersion: 4.20.10
  maxVersion: 4.20.10
  type: ocp
  kubeVirtContainer: true
  architectures:
  - "multi"
  graph: true
```

Note:

- In case of Bare Metal Hosted Control Plane deployment, remove `kubeVirtContainer: true` flag.
- For offline virtualized Hosted Control Plane deployments on Red Hat OpenShift Container Platform 4.21 and later, you must also mirror the Red Hat OpenShift Container Platform 4.20.10 release payload in multi-architecture format due to a known Red Hat limitation. For more information, see [Deploying hosted control planes on OpenShift Virtualization in a disconnected environment](#).

4. Run the command to create catalog mirror images:

```
oc-mirror --v2 --config ocp-hcp-imageset.yaml --workspace file:/// docker://$TARGET_PATH --remove-signatures=false --dest-tls-verify=false
```

It might take 10 - 15 minutes to complete.

Example output:

```
[INFO] : === Results ===
[INFO] : . Generating IDMS file...
[INFO] : mirror-file/working-dir/cluster-resources/idms-oc-mirror.yaml file created
[INFO] : Generating ITMS file...
[INFO] : mirror-file/working-dir/cluster-resources/itms-oc-mirror.yaml file created
[INFO] : No catalogs mirrored. Skipping CatalogSource file generation.
[INFO] : No catalogs mirrored. Skipping ClusterCatalog file generation.
[INFO] : Generating Signature Configmap...
[INFO] : mirror-file/working-dir/cluster-resources/signature-configmap.json file created
[INFO] : mirror-file/working-dir/cluster-resources/signature-configmap.yaml file created
```

5. Upon successful execution, apply the generated IDMS configuration to the cluster.

Example IDMS:

```
apiVersion: config.openshift.io/v1
kind: ImageDigestMirrorSet
metadata:
  name: idms-release-0
spec:
  imageDigestMirrors:
  - mirrors:
    - $TARGET_PATH/openshift/release
    source: quay.io/openshift-release-dev/ocp-v4.0-art-dev
  - mirrors:
    - $TARGET_PATH/openshift/release-images
    source: quay.io/openshift-release-dev/ocp-release
```

What to do next

After you complete with mirroring OpenShift Container Platform release images to enterprise registry, proceed with [Mirroring Red Hat operator images to enterprise registry](#).

Mirroring Red Hat operator images to enterprise registry

Mirror the Red Hat® operator images to your enterprise registry.

Before you begin

- Before you mirror, go through the prerequisites. See [Mirroring prerequisites](#).
- Use either Podman or docker commands to login to the registries. The examples in the procedure used docker; if you are using Podman, substitute `podman` for `docker` in the commands.
- Ensure that you install the `oc-mirror` OpenShift CLI plug-in. For more information about `oc-mirror` OpenShift CLI plug-in installation, see [Installing the oc-mirror OpenShift® CLI plug-in](#).
- Ensure that you must use the recent enterprise registry images for mirroring.

Procedure

1. Log in to `registry.redhat.io` and `registry.connect.redhat.com`, and run the following command to login to the Docker registry with your Red Hat enterprise credentials:

```
registry.redhat.io
```

```
podman login registry.redhat.io -u <Red Hat enterprise registry username> -p <Red Hat enterprise registry password>
```

```
registry.connect.redhat.com
```

```
podman login registry.connect.redhat.com -u <Red Hat enterprise registry username> -p <Red Hat enterprise registry password>
```

Set the following environment variables:

```
export LOCAL_ISF_REGISTRY="<Your enterprise registry host>:<port>"
export LOCAL_ISF_REPOSITORY="<Your image path>"
export TARGET_PATH="$LOCAL_ISF_REGISTRY/$LOCAL_ISF_REPOSITORY"
export OCP_VERSION="<your selected 4.x version>"
echo "$TARGET_PATH"
```

Note:

- The Red Hat OpenShift Container Platform version variable value must be the same as the version you used during the OpenShift mirroring. For example, if you mirror Red Hat OpenShift Container Platform 4.20 images, then set the OCP_VERSION value as 4.20.
- Port is a non-mandatory value when you set the LOCAL_ISF_REGISTRY variable. You can ignore this if your enterprise registry is accessible and has a secure connection.

Sample value for without port:

```
export LOCAL_ISF_REGISTRY="registryhost.com"
```

See the following sample values:

```
export LOCAL_ISF_REGISTRY="registryhost.com:443"
export LOCAL_ISF_REPOSITORY="fusion-mirror"
```

LOCAL_ISF_REGISTRY is your entitlement registry.

LOCAL_ISF_REPOSITORY is the image path in which you want to mirror the images. You can choose your own repository paths. For example, hci- images/isf or hci-images

2. Run the command to login to the Docker registry with your enterprise registry credentials.

```
podman login $LOCAL_ISF_REGISTRY -u <your enterprise registry username> -p <your enterprise registry password>
```

3. Create an image set configuration file for Red Hat packages that are required for IBM Fusion installation.

For example:

```
cat << EOF > imageset-config-redhatoperator.yaml
kind: ImageSetConfiguration
apiVersion: mirror.openshift.io/v2alpha1
mirror:
  operators:
    - catalog: registry.redhat.io/redhat/certified-operator-index:v$OCP_VERSION
      packages:
        - name: cloudnative-pg
        - name: ibm-storage-odf-operator
      channels:
        - name: stable-v1.9
    - name: ibm-block-csi-operator
      defaultChannel: "stable-1.13.2"
      channels:
        - name: stable-1.13.2
    - catalog: registry.redhat.io/redhat/redhat-operator-index:v$OCP_VERSION
      packages:
        - name: kubernetes-nmstate-operator
        - name: redhat-oadp-operator
      channels:
        - name: stable-1.4
          minVersion: "1.4.2-0"
        - name: stable
          minVersion: "1.5.0-0"
    - name: amq-streams
      channels:
        - name: stable
          minVersion: "3.0.0-0"
    - name: nfd
    - name: node-maintenance-operator
    - name: rhods-operator
    - name: openshift-cert-manager-operator
    - name: kubevirt-hyperconverged
    - name: metallb-operator
    - name: multicluster-engine
    - name: local-storage-operator
    - name: lvms-operator
    - name: kernel-module-management
    - name: openshift-gitops-operator
    - name: submariner
    - name: advanced-cluster-management
  additionalImages:
    - name: registry.redhat.io/ubi9/ubi:latest
    - name: registry.redhat.io/ubi9/ubi-minimal:latest
    - name: registry.redhat.io/ubi9/ubi-micro:latest
    - name: registry.redhat.io/openshift4/driver-toolkit-rhel9:v$OCP_VERSION
EOF
```

Note:

- The self-node-remediation operator is used to enable automatic workload failover in case of unplanned node unavailability.
- The redhat-oadp-operator and amq-streams packages are required to install the Red Hat OADP operator and AMQ Streams operator. It is a prerequisite to deploy the IBM Backup & Restore service. If you plan to use the IBM Backup & Restore service, retain them in the commands, or else you can skip them.
- The local-storage-operator and lvms-operator packages are required to install the Fusion Data Foundation service. If you plan to use the Fusion Data Foundation service, retain them in the commands, or else you can skip them.
- The ibm-storage-odf-operator and ibm-block-csi-operator packages are required for Fusion Data Foundation 4.19 and 4.20. If you plan to use the Fusion Data Foundation service, retain them in the commands, or else you can skip them.
- The amq-streams package is required to install the IBM Data Cataloging service. If you plan to use the IBM Data Cataloging service, retain it in the commands, or else you can skip it.

- The **kubevirt-hyperconverged** is required to install the OpenShift virtualization operator.
- The **cloudnative-pg** package is required to install the CAS service. If you plan to use the CAS service, add it in the commands, or else you can skip it.
- The **kubevirt-hyperconverged**, **metallb-operator**, and **multiclustere-engine** operators are required to deploy Hosted Control Plane clusters.
- The **node-maintenance-operator** is required for node maintenance operations on both the Hub and Hosted Control Plane clusters.
- The **kubernetes-nmstate-operator** package is required for Stage2 that manages node network configuration
- The **node-feature-discovery (nfd)** package is required when the cluster contains GPU nodes or specialized hardware that needs to be discovered and labeled. Essential for GPU-enabled workloads and hardware accelerated services.
- The **rhods-operator** package is required for Software Hub and IBM watsonx services.
- The **openshift-cert-manager-operator** package is required for Software Hub and IBM watsonx services to manage TLS certificates and secure communications between service components.
- The **kernel-module-management** package is required to build and load the AMD GPU out-of-tree kernel module on GPU worker nodes. Include it when your cluster has AMD GPU nodes or when you plan to add AMD GPU nodes.
- The **openshift4/driver-toolkit-rhel9** additional image is required by the Kernel Module Management (KMM) operator to compile the AMD GPU driver module. Include it when you are mirroring for AMD GPU nodes.

4. Run the following **oc** command to mirror the images from the specified image set configuration to a specified registry:

```
oc mirror --v2 --config imageset-config-redhatoperator.yaml --workspace file:///./ docker://${TARGET_PATH} --dest-tls-verify=false
```

This can take 1-2 hours to complete.

Example output:

```
Rendering catalog image "<TARGET_PATH>/redhat/redhat-operator-index:v4.16" with file-based catalog
Writing image mapping to oc-mirror-workspace/results-1693810862/mapping.txt
Writing CatalogSource manifests to oc-mirror-workspace/results-1693810862
Writing ICSP manifests to oc-mirror-workspace/results-1693810862
```

5. Important: You can run steps 5, 6, and 7 only when the cluster is up for a freshly installed rack.
Apply the generated **ImageDigestMirrorSet** to the cluster:

```
oc apply -f working-dir/cluster-resources/idms-oc-mirror.yaml
```

Example **ImageDigestMirrorSet**:

```
apiVersion: config.openshift.io/v1
kind: ImageDigestMirrorSet
metadata:
  name: idms-operator-0
spec:
  imageDigestMirrors:
  - mirrors:
    - registryhost.com:8443/mirrorimages/mirror-rh-images/migration-toolkit-virtualization
    source: registry.redhat.io/migration-toolkit-virtualization

    source: registry.redhat.io/container-native-virtualization
  - mirrors:
    - registryhost.com:8443/mirrorimages/mirror-rh-images/rhaii-early-access
    source: registry.redhat.io/rhaii-early-access
  - mirrors:
    - registryhost.com:8443/mirrorimages/mirror-rh-images/lvms4
    source: registry.redhat.io/lvms4
  - mirrors:
    - registryhost.com:8443/mirrorimages/mirror-rh-images/rhaiis
    source: registry.redhat.io/rhaiis
  - mirrors:
    - registryhost.com:8443/mirrorimages/mirror-rh-images/rhelai1
    source: registry.redhat.io/rhelai1
  - mirrors:
    - registryhost.com:8443/mirrorimages/mirror-rh-images/ubi9
    source: registry.redhat.io/ubi9
```

```

- mirrors:
  - registryhost.com:8443/mirrorimages/mirror-rh-images/ubi8
    source: registry.redhat.io/ubi8
- mirrors:
  - registryhost.com:8443/mirrorimages/mirror-rh-images/cluster-observability-operator
    source: registry.redhat.io/cluster-observability-operator
- mirrors:
  - registryhost.com:8443/mirrorimages/mirror-rh-images/openshift-service-mesh
    source: registry.redhat.io/openshift-service-mesh
- mirrors:
  - registryhost.com:8443/mirrorimages/mirror-rh-images/rhel8
    source: registry.redhat.io/rhel8

```

6. Apply the generated `CatalogSource` to the cluster:

```

oc apply -f catalogSource-cs-redhat-operator-index.yaml
oc apply -f catalogSource-cs-certified-operator-index.yaml

```

For example:

```

oc apply -f working-dir/cluster-resources/cs-redhat-operator-index-v4-20.yaml

```

7. For offline environments, update the `redhat-operators` `CatalogSource` image with the following mirrored image:

```

apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: redhat-operators
  namespace: openshift-marketplace
spec:
  displayName: Red Hat Operators
  image: $TARGET_PATH/redhat/redhat-operator-index:v$OCP_VERSION
  publisher: Red Hat
  sourceType: grpc

```

Mirroring individual images

There may be scenarios wherein you may want to mirror individual images separately.

You may choose to mirror individual images to suit customized requirements, manage resource usage, or greater control over the mirroring.

- [Mirroring IBM Fusion HCI images](#)
Mirror the IBM Fusion HCI images to your enterprise registry.
- [Mirroring IBM Storage Scale images](#)
Mirror the IBM Storage Scale images to your enterprise registry.
- [Mirroring Fusion Data Foundation images](#)
Mirror the Fusion Data Foundation images deployed on Red Hat OpenShift Container Platform to your enterprise registry by using `ImageDigestMirrorSet`.
- [Mirroring Backup & Restore images](#)
Mirror the Backup & Restore images to your enterprise registry.
- [Mirroring IBM Data Cataloging images](#)
Mirror the IBM Data Cataloging images to your enterprise registry.
- [Mirroring Content-Aware Storage \(CAS\) images](#)
IBM Fusion HCI supports a range of CAS versions, and it can upgrade independently of IBM Fusion HCI within a certain range. In 2.14.0, the supported CAS version range is any version < v1.1.0. You can run this procedure multiple times to upgrade to each newer version of CAS within the supported range.
- [Mirroring IBM Software Hub, watsonx.ai, and watsonx Orchestrate images](#)
Mirror the IBM Software Hub, watsonx.ai, watsonx Orchestrate, and Red Hat OpenShift AI images to your enterprise registry.

Mirroring IBM Fusion HCI images

Mirror the IBM Fusion HCI images to your enterprise registry.

Before you begin

1. Before you mirror, go through the prerequisites. See [Mirroring prerequisites](#).
2. Use either Podman or docker commands to login to the registries. The examples in the procedure used docker; if you are using Podman, substitute `podman` for `docker` in the commands.
3. For more information about the version support, see [IBM Fusion HCI support matrix](#).

About this task

Use this procedure only necessary if you plan to mirror specific sub-components of IBM Fusion HCI instead of following the full end-to-end mirroring instructions. For more information about the end-to-end mirroring of and all its services, see [End-to-end mirroring of IBM Fusion HCI and its services images to the enterprise registry](#).

The following are the high-level tasks for mirroring:

- Log in to the relevant Docker registries.
- Define some convenience variables that are used to configure and mirror the Fusion base component.
- Run the `oc-mirror` CLI tool that mirrors the Fusion base components.
- Run the mirroring steps for the additional components you want to include in your installation.

Note: If you choose to mirror specific sub-components, it is recommended that you use the same **TARGET_PATH** variable so that all the components mirror in the same location, and the generated **ImageDigestMirrorSet** is same across all components.

Procedure

1. Run the following command to login to the Docker registry with your Red Hat® enterprise credentials:

```
docker login registry.redhat.io -u <Red Hat enterprise registry username> -p <Red Hat enterprise registry password>
```

Log in to the IBM Entitled Container Registry using the IBM entitlement key:

```
docker login cp.icr.io -u cp -p <your entitlement key>
```

Important:

- Ensure that your entitlement key for IBM Fusion HCI contains the correct entitlement.
- Ensure that you review the [offline upgrade considerations](#) before proceeding with upgrade mirroring.

Set the following environment variables:

```
export LOCAL_ISF_REGISTRY="<Your container registry host>:<port>"
export LOCAL_ISF_REPOSITORY="<Your image path>"
export TARGET_PATH="$LOCAL_ISF_REGISTRY/$LOCAL_ISF_REPOSITORY"
```

Note: Port is a non-mandatory value when setting the **LOCAL_ISF_REGISTRY** variable. You can ignore this if your enterprise registry is accessible and has a secure connection.

Sample value for without port:

```
export LOCAL_ISF_REGISTRY="registryhost.com"
```

See the following sample values:

```
export LOCAL_ISF_REGISTRY="registryhost.com:443"
export LOCAL_ISF_REPOSITORY="fusion-mirror"
```

LOCAL_ISF_REGISTRY is your entitlement registry.

LOCAL_ISF_REPOSITORY is the image path in which you want to mirror the images. You can choose your own repository paths. For example, hci- images /isf or hci- images.

2. Run the command to login to the Docker registry with your enterprise registry credentials.

```
docker login $LOCAL_ISF_REGISTRY -u <your enterprise registry username> -p <your enterprise registry password>
```

3. Create the image set configuration for IBM Fusion HCI.

imageset-config-fusion.yaml

```
cat << EOF > imageset-config-fusion.yaml
kind: ImageSetConfiguration
apiVersion: mirror.openshift.io/v2alpha1
mirror:
  operators:
    - catalog: icr.io/cpopen/isf-operator-catalog@sha256:ffec2cdd438b1ee5f2b11a9f6964b8d892065c97ab5c74cc2b2b6edbeba148a9
      packages:
        - name: isf-operator
          channels:
            - name: v2.0
              minVersion: 2.14.0
              maxVersion: 2.14.0
      additionalImages:
        - name: cp.icr.io/cp/fusion-hci/isf-validate-entitlement@sha256:1a0dbf7c537f02dc0091e3abebae0ccac83da6aa147529f5de49af0f23cd9e8e
        - name: icr.io/cpopen/isf-operator-catalog:2.14.0-26559@sha256:ffec2cdd438b1ee5f2b11a9f6964b8d892065c97ab5c74cc2b2b6edbeba148a9
EOF
```

4. Run the following oc-mirror command to mirror the images.

```
oc mirror --v2 --config imageset-config-fusion.yaml --workspace file:///./ docker://${TARGET_PATH} --dest-tls-verify=false
```

5. Important: You can run steps 5 and 6 only when the cluster is up for a freshly installed rack.

Apply the IDMS file to your cluster:

Note: Replace the variable **\$TARGET_PATH** with your registry details where images are mirrored.

```
apiVersion: config.openshift.io/v1
kind: ImageDigestMirrorSet
metadata:
  name: ibm-spectrum-fusion
spec:
  imageDigestMirrors:
    - mirrors:
        - $TARGET_PATH/cp
      source: cp.icr.io/cp
    - mirrors:
        - $TARGET_PATH/cpopen
      source: icr.io/cpopen
    - mirrors:
        - $TARGET_PATH/openshift4
      source: registry.redhat.io/openshift4
```

6. Create a **CatalogSource** (required only for upgrade).

Note: Replace the variable **\$TARGET_PATH** with your registry details where images are mirrored.

```

apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: ibm-spectrum-fusion-catalog
  namespace: openshift-marketplace
spec:
  displayName: ibm-spectrum-fusion-2.14.0-linux-amd64
  publisher: IBM
  image: ${TARGET_PATH}/cpopen/isf-operator-
catalog@sha256:ffec2cdd438b1ee5f2b11a9f6964b8d892065c97ab5c74cc2b2b6edbeba148a9
  sourceType: grpc
  grpcPodConfig:
    nodeSelector:
      kubernetes.io/arch: amd64

```

7. Follow the steps to mirror the Usage Metering Service (UMS):
 Important: This step is required for mirroring IBM Fusion HCI images. Do not skip.
 a. Create the image set configuration for UMS.

```

cat << EOF > imageset-config-ums.yaml
kind: ImageSetConfiguration
apiVersion: mirror.openshift.io/v2alpha1
mirror:
  operators:
    - catalog: icr.io/cpopen/ibm-usage-metering-operator-
catalog@sha256:b80738a02914c0eb08af87a7bc63226bf2b65de7add92156cc8d14673707b4dc
  packages:
    - name: ibm-usage-metering-operator
      channels:
        - name: v1.0
      full: true
  additionalImages:
    - name: icr.io/cpopen/ibm-usage-metering-operator-catalog:1.0.6-
26559@sha256:b80738a02914c0eb08af87a7bc63226bf2b65de7add92156cc8d14673707b4dc
EOF

```

- b. Run the following oc command to mirror the images.

```

oc mirror --v2 --config imageset-config-ums.yaml --workspace file:/// docker://${TARGET_PATH} --dest-tls-
verify=false

```

- c. Important: You can run this step only when the cluster is up for a freshly installed rack.
 Apply the `ImageDigestMirrorSet` file to your cluster:
 Note: Replace the variable `$TARGET_PATH` with your registry details where images are mirrored.

```

apiVersion: config.openshift.io/v1
kind: ImageDigestMirrorSet
metadata:
  name: ibm-usage-metering
spec:
  imageDigestMirrors:
    - mirrors:
        - ${TARGET_PATH}/cpopen
      source: icr.io/cpopen

```

In case of any failure, refer [Troubleshooting and known issues](#) in offline mirroring to get the resolution steps.

8. Important: Mirror the Node Feature Discovery (NFD) and NVIDIA GPU Operator or AMD GPU Operator images only if your cluster has GPU worker nodes or if you plan to add GPU worker nodes in the future.
 Follow the steps to mirror the NFD catalog source:
 Note:

- If the cluster already contains an existing `redhat-operators` catalog source, perform the mirroring using the same path that is specified in that catalog source.
 - Verify the `<ocp-version>` installed on the cluster.
- a. Run the following command to check the package name of the NFD operator:

```

oc-mirror list operators --catalog=registry.redhat.io/redhat/redhat-operator-index:v<ocp-version> --version=<ocp-
version>

```

Here, `<ocp-version>` refers to OpenShift® version installed on the cluster.

For example:

```

oc-mirror list operators --catalog=registry.redhat.io/redhat/redhat-operator-index:v4.12 --version=4.12

```

- b. Run the following commands to create the `imageset-config-nfd.yaml`.

```

oc mirror init --registry ${TARGET_PATH}/oc-mirror-nfd-metadata > imageset-config-nfd.yaml

```

- c. Edit the `imageset-config-nfd.yaml` file as follows:

- Set `skipTLS` to true.
- Set catalog to `registry.redhat.io/redhat/redhat-operator-index:v<ocp-version>`. Here, `<ocp-version>` refers to OpenShift version installed on the cluster.
 For example:

```
registry.redhat.io/redhat/redhat-operator-index:v4.12
```

 (assuming 4.12 is installed on the cluster)
- Set the packages name to `nfd`.
 For example:

```

kind: ImageSetConfiguration
apiVersion: mirror.openshift.io/v1alpha2
storageConfig:
  registry:
    imageURL: ${TARGET_PATH}/oc-mirror-nfd-metadata
    skipTLS: true
mirror:
  operators:
  - catalog: registry.redhat.io/redhat/redhat-operator-index:v<OCP_VERSION>
  packages:
  - name: nfd
  additionalImages:
  - name: registry.redhat.io/ubi8/ubi:latest
  helm: {}

```

Note: If Red Hat operator catalog is running on your cluster, prune and push all earlier packages, including the NFD. Otherwise, old packages get lost from the Red Hat operator index image. For more information about Red Hat operator images, see [Mirroring Red Hat operator images to enterprise registry](#).

d. Run the following command to mirror the image set to the private mirror registry:

```
oc-mirror --dest-skip-tls=true --config=./imageset-config-nfd.yaml docker://${TARGET_PATH}
```

This command generates an output directory, for example:

```
oc-mirror-workspace/results-1670391296/
```

The directory contains **mapping.txt**, **CatalogSource manifests**, and **ImageContentSourcePolicy (ICSP) manifests**. Example output:

```

Rendering catalog image
"ec2-3-16-218-255.us-east-2.compute.amazonaws.com:5000/redhat/redhat-operator-index:v4.11"
with file-based catalog

Writing image mapping to oc-mirror-workspace/results-1670391296/mapping.txt
Writing CatalogSource manifests to oc-mirror-workspace/results-1670391296
Writing ICSP manifests to oc-mirror-workspace/results-1670391296

```

e. Important:

- You can run steps 8.e, 8.f, and 8.g only when the cluster is up for a freshly installed rack.
- If the **redhat-operators** catalog source exists in the cluster, then skip the following step.

Rename the generated catalog source name to **redhat-operators** from **cs-redhat-operator-index**.

```

kind: CatalogSource
metadata:
  name: cs-redhat-operator-index --> change to redhat-operators
  namespace: openshift-marketplace

```

Apply this edited catalogsource yaml file using following command:

```
oc apply oc-mirror-workspace/results-1759765853/catalogSource-cs-redhat-operator-index.yaml
```

f. Convert the generated ICSPs (generic-0, operator-0, and release-0) to IDMS equivalents.

Sample IDMS.yaml:

```

---
apiVersion: config.openshift.io/v1
kind: ImageDigestMirrorSet
metadata:
  name: generic-0
spec:
  imageDigestMirrors:
  - mirrors:
    - ${TARGET_PATH}/ubi8
    source: registry.redhat.io/ubi8
---
apiVersion: config.openshift.io/v1
kind: ImageDigestMirrorSet
metadata:
  labels:
    operators.openshift.org/catalog: "true"
  name: operator-0
spec:
  imageDigestMirrors:
  - mirrors:
    - ${TARGET_PATH}/openshift4
    source: registry.redhat.io/openshift4
---
apiVersion: config.openshift.io/v1
kind: ImageDigestMirrorSet
metadata:
  name: release-0
spec:
  imageDigestMirrors:
  - mirrors:
    - ${TARGET_PATH}/openshift/release
    source: quay.io/openshift-release-dev/ocp-v4.0-art-dev
  - mirrors:
    - ${TARGET_PATH}/openshift/release-images
    source: quay.io/openshift-release-dev/ocp-release

```

Apply these three IDMSs on the cluster using following command:

```
oc apply -f imageDigestMirrorSet.yaml
```

- g. Create and apply the ITMS equivalent for the generated ICSP operator-0.
For example:

```
apiVersion: config.openshift.io/v1
kind: ImageTagMirrorSet
metadata:
  name: operator-0
spec:
  imageTagMirrors:
    - mirrors:
        - '${TARGET_PATH}/openshift4'
      source: registry.redhat.io/openshift4
```

Apply this ITMS using following command:

```
oc apply -f imageTagMirrorSet.yaml
```

- h. Search for the `ose-cluster-nfd-rhel9-operator` image in the mapping.txt file:
For example:

```
registry.redhat.io/openshift4/ose-cluster-nfd-rhel9-
operator@sha256:ce25bd4baaf2c29e3212c69e243c943e4eb507dad4a85a7b040dafb427920523=${TARGET_PATH}/openshift4/ose-
cluster-nfd-rhel9-operator:54e0411b
```

Mirror the image for `ose-cluster-nfd-rhel9-operator` in digest format into the private registry.

```
skopeo copy --all --dest-tls-verify=false \docker://registry.redhat.io/openshift4/ose-cluster-nfd-rhel9-
operator@sha256:ce25bd4baaf2c29e3212c69e243c943e4eb507dad4a85a7b040dafb427920523 \
  docker://${TARGET_PATH}/openshift4/ose-cluster-nfd-rhel9-
operator@sha256:ce25bd4baaf2c29e3212c69e243c943e4eb507dad4a85a7b040dafb427920523
```

- i. Mirror the images required by the NFD custom resource. For procedure, follow Steps 1 and 2 from the [Red Hat documentation](#).
9. Follow the steps to mirror the GPU catalog source to install the NVIDIA GPU operator:
a. Run the following command to check for the correct package name for the GPU operator.

```
oc-mirror list operators --catalog=registry.redhat.io/redhat/certified-operator-index:v<ocp-version> --version=<ocp-
version>
oc-mirror list operators --catalog=registry.redhat.io/redhat/certified-operator-index:v<ocp-version> --package=gpu-
operator-certified
```

Example output:

NAME	DISPLAY NAME	DEFAULT CHANNEL
gpu-operator-certified	NVIDIA GPU Operator	v25.3

PACKAGE	CHANNEL	HEAD
gpu-operator-certified	stable	gpu-operator-certified.v25.3.4
gpu-operator-certified	v1.10	gpu-operator-certified.v1.10.1
gpu-operator-certified	v1.11	gpu-operator-certified.v1.11.1
gpu-operator-certified	v25.3	gpu-operator-certified.v25.3.4

- b. Run the following command to create the `imageset-config-gpu.yaml` file.

```
oc-mirror init --registry ${TARGET_PATH}/oc-mirror-gpu-metadata > imageset-config-gpu.yaml
```

- c. Edit the `imageset-config-gpu.yaml` file as follows:

- Set `skipTLS` to true.
 - Set catalog to `registry.redhat.io/redhat/certified-operator-index:v<ocp-version>`.
 - Set packages name to `gpu-operator-certified`.
- For example:

```
kind: ImageSetConfiguration
apiVersion: mirror.openshift.io/v1alpha2
storageConfig:
  registry:
    imageURL: ${TARGET_PATH}/oc-mirror-gpu-metadata
    skipTLS: true
  mirror:
    platform:
      channels:
        - name: stable-<ocp-version>
          type: ocp
      operators:
        - catalog: registry.redhat.io/redhat/certified-operator-index:v<ocp-version>
          packages:
            - name: gpu-operator-certified
      additionalImages:
        - name: registry.redhat.io/ubi8/ubi:latest
    helm: {}
```

To mirror only v25.3.4, make the same edits as the preceding example and also specify the minversion value:

```
kind: ImageSetConfiguration
apiVersion: mirror.openshift.io/v1alpha2
storageConfig:
  registry:
    imageURL: ${TARGET_PATH}/oc-mirror-gpu-metadata
    skipTLS: true
  mirror:
    platform:
      channels:
        - name: stable-<ocp-version>
          type: ocp
      operators:
```

```

- catalog: registry.redhat.io/redhat/certified-operator-index:v<ocp-version>
packages:
- name: gpu-operator-certified
  minversion: "25.3.4"
additionalImages:
- name: registry.redhat.io/ubi8/ubi:latest
helm: {}

```

d. Run the following command to mirror the GPU operator catalog source.

```

oc-mirror --dest-skip-tls=true --skip-missing --continue-on-error --config=./imageset-config-gpu.yaml
docker://${TARGET_PATH}

```

The `oc-mirror` tool generates a folder similar to `oc-mirror-workspace/results-<ID>`.

e. Important: You can run steps 9.e, 9.f, and 9.g only when the cluster is up for a freshly installed rack.

Run the following command to create the catalog source for the GPU operator.

Note: Before applying the YAML, edit the name of the catalog source with `certified-operator`.

```

oc apply oc-mirror-workspace/results-<ID>/catalogSource-cs-certified-operator-index.yaml

```

f. Create and apply the equivalent IDMS for all the generated ICSPs in the path `oc-mirror-workspace/results-1759765853/imageContentSourcePolicy.yaml`.

g. Create and apply the equivalent ITMS for the generated operator-0 ICSP.

Note: Update the ICSP names to reflect GPU-specific configurations. For example, rename `operator-0` to `operator-0-gpu`.

```

# cat oc-mirror-workspace/results-<ID>/imageContentSourcePolicy.yaml
---
apiVersion: operator.openshift.io/v1alpha1
kind: ImageContentSourcePolicy
metadata:
  name: generic-0
spec:
  repositoryDigestMirrors:
  - mirrors:
    - ${TARGET_PATH}/ubi8
    source: registry.redhat.io/ubi8
---
apiVersion: operator.openshift.io/v1alpha1
kind: ImageContentSourcePolicy
metadata:
  labels:
    operators.openshift.org/catalog: "true"
  name: operator-0
spec:
  repositoryDigestMirrors:
  - mirrors:
    - ${TARGET_PATH}/nvidia
    source: nvcr.io/nvidia
  - mirrors:
    - ${TARGET_PATH}/nvidia
    source: registry.connect.redhat.com/nvidia
---
apiVersion: operator.openshift.io/v1alpha1
kind: ImageContentSourcePolicy
metadata:
  name: release-0
spec:
  repositoryDigestMirrors:
  - mirrors:
    - ${TARGET_PATH}/openshift/release
    source: quay.io/openshift-release-dev/ocp-v4.0-art-dev
  - mirrors:
    - ${TARGET_PATH}/openshift/release-images
    source: quay.io/openshift-release-dev/ocp-release

```

h. Use the `skopeo` CLI tool to copy the NVIDIA driver image from `nvcr.io` to your mirror registry, by running the following command:

```

skopeo copy \
docker://nvcr.io/nvidia/driver:<GPU Driver versions>-rhcos<ocp_version> \
docker://${TARGET_PATH}/nvidia/driver:<GPU Driver versions>-rhcos<ocp_version>

```

For example:

```

skopeo copy \
docker://nvcr.io/nvidia/driver:580.82.07-rhcos<ocp_version> \
docker://${TARGET_PATH}/nvidia/driver:580.82.07-rhcos<ocp_version>

```

10. Important: Mirror AMD GPU Operator images only if your cluster has AMD GPU worker nodes or if you plan to add AMD GPU worker nodes in the future.

Mirror the AMD GPU Operator catalog and related images for an offline or disconnected cluster.

Before you begin: check for existing `CatalogSources`

Before mirroring, check whether `CatalogSource` resources named `redhat-operators` or `certified-operators` exist in your cluster:

```

oc get catalogsource -n openshift-marketplace \
redhat-operators certified-operators \
-o custom-columns="NAME:.metadata.name,IMAGE:.spec.image" 2>/dev/null

```

Note: Use the target path present in existing `redhat-operators` and `certified-operators` `CatalogSources` as the `TARGET_PATH` for AMD GPU Operator mirroring. This ensures that all AMD GPU images are stored in the same registry location from which the cluster is configured to pull images.

a. Set environment variables

Replace the placeholder values with values specific to your environment before running any command.

Variable	Description	Example value
TARGET_PATH	Base registry path derived from existing CatalogSources (see above), or set to your enterprise registry	myregistry.example.com:5000/fusion-mirror
OCF_VERSION	Full OpenShift version (major.minor used for catalog index)	4.20.26
AMD_DRIVER_VERSION	AMD GPU driver version. IBM Fusion HCI Supports 31.40.	31.40
RHEL_VERSION	RHEL version of your cluster nodes	9.6

```
export TARGET_PATH="myregistry.example.com:5000/fusion-mirror"
export OCF_VERSION="4.20.26"           # replace with your OCF version
export AMD_DRIVER_VERSION="31.40"
export RHEL_VERSION="9.6"             # or "9.8" depending on OCF version
```

```
# Derived variables
export REDHAT_VERSION=$(echo $OCF_VERSION | cut -d'.' -f1,2)
export AMD_GPU_DRIVER_TAG="coreos-{$RHEL_VERSION}-{$AMD_DRIVER_VERSION}"
```

b. Mirror the AMD GPU Operator catalog (oc mirror)

This step mirrors the `amd-gpu-operator` (alpha channel) from the `certified-operator-index`, and `kernel-module-management` (KMM, stable channel) together with UBI 9 and the OpenShift Driver Toolkit from the `redhat-operator-index`.

Create the ImageSet configuration files.

AMD GPU Operator catalog (`certified-operator-index`):

```
cat > imageset-amd-gpu.yaml << EOF
kind: ImageSetConfiguration
apiVersion: mirror.openshift.io/v2alpha1
mirror:
  operators:
    - catalog: registry.redhat.io/redhat/certified-operator-index:v${REDHAT_VERSION}
      packages:
        - name: amd-gpu-operator
          channels:
            - name: alpha
EOF
```

KMM, UBI 9, and Driver Toolkit (`redhat-operator-index`):

```
cat > imageset-redhat-amd-gpu.yaml << EOF
kind: ImageSetConfiguration
apiVersion: mirror.openshift.io/v2alpha1
mirror:
  operators:
    - catalog: registry.redhat.io/redhat/redhat-operator-index:v${REDHAT_VERSION}
      packages:
        - name: kernel-module-management
          channels:
            - name: stable
  additionalImages:
    - name: registry.redhat.io/ubi9/ubi:latest
    - name: registry.redhat.io/ubi9/ubi-minimal:latest
    - name: registry.redhat.io/openshift4/driver-toolkit-rhel9:v${REDHAT_VERSION}
EOF
```

Run `oc mirror` for both imagesets:

```
oc mirror --v2 \
  --config imageset-amd-gpu.yaml \
  --workspace=file:/// \
  docker://${TARGET_PATH} \
  --dest-tls-verify=false

oc mirror --v2 \
  --config imageset-redhat-amd-gpu.yaml \
  --workspace=file:/// \
  docker://${TARGET_PATH} \
  --dest-tls-verify=false
```

When complete, `oc mirror` writes YAML manifests into a `working-dir/` directory. These are applied in step 4.

c. Mirror the ROCm additional images (skopeo)

The AMD GPU Operator requires several ROCm images that are not distributed through the Red Hat catalog. Mirror them individually using `skopeo copy`.

Resolve the latest versioned tags:

```
# Resolve latest stable semver tag
resolve_latest_semver_tag() {
  local repo="$1"
  skopeo list-tags "docker://docker.io/rocm/${repo}" 2>/dev/null \
    | jq -r '.Tags[] | select(test("^[0-9]") and (test("beta|alpha|rc") | not))' \
    | sort -V | tail -1
}

# Resolve latest rhubi-<version> tag (k8s-device-plugin, k8s-node-labeler)
resolve_latest_rhubi_tag() {
  local repo="$1"
  skopeo list-tags "docker://docker.io/rocm/${repo}" 2>/dev/null \
    | jq -r '.Tags[] | select(test("^[0-9]") and (test("beta|alpha|rc") | not))' \
    | sort -V | tail -1
}
```

```
GPU_OPERATOR_TAG=$(resolve_latest_semver_tag "gpu-operator")
METRICS_TAG=$(resolve_latest_semver_tag "device-metrics-exporter")
TEST_RUNNER_TAG=$(resolve_latest_semver_tag "test-runner")
DEV_CFG_TAG=$(resolve_latest_semver_tag "device-config-manager")
K8S_PLUGIN_TAG=$(resolve_latest_rhubi_tag "k8s-device-plugin")
K8S_LABELLER_TAG=$(resolve_latest_rhubi_tag "k8s-node-labeler")
```

```
echo "gpu-operator:           ${GPU_OPERATOR_TAG}"
echo "device-metrics-exporter: ${METRICS_TAG}"
echo "test-runner:            ${TEST_RUNNER_TAG}"
echo "device-config-manager:   ${DEV_CFG_TAG}"
echo "k8s-device-plugin:       ${K8S_PLUGIN_TAG}"
echo "k8s-node-labeler:        ${K8S_LABELLER_TAG}"
```

Important: If any variable above is empty, that image has no stable versioned tag available. Do not proceed until you resolve a valid tag.
Mirror each image:

```
skopeo copy --all \
  docker://docker.io/rocm/gpu-operator:${GPU_OPERATOR_TAG} \
  docker://${TARGET_PATH}/rocm/gpu-operator:${GPU_OPERATOR_TAG}

skopeo copy --all \
  docker://docker.io/rocm/gpu-operator-utils:latest \
  docker://${TARGET_PATH}/rocm/gpu-operator-utils:latest

skopeo copy --all \
  docker://docker.io/busybox:1.36 \
  docker://${TARGET_PATH}/busybox:1.36

skopeo copy --all \
  docker://docker.io/rocm/device-metrics-exporter:${METRICS_TAG} \
  docker://${TARGET_PATH}/rocm/device-metrics-exporter:${METRICS_TAG}

skopeo copy --all \
  docker://docker.io/rocm/test-runner:${TEST_RUNNER_TAG} \
  docker://${TARGET_PATH}/rocm/test-runner:${TEST_RUNNER_TAG}

skopeo copy --all \
  docker://docker.io/rocm/device-config-manager:${DEV_CFG_TAG} \
  docker://${TARGET_PATH}/rocm/device-config-manager:${DEV_CFG_TAG}

skopeo copy --all \
  docker://docker.io/rocm/rocm-terminal:latest \
  docker://${TARGET_PATH}/rocm/rocm-terminal:latest

skopeo copy --all \
  docker://docker.io/rocm/k8s-device-plugin:${K8S_PLUGIN_TAG} \
  docker://${TARGET_PATH}/rocm/k8s-device-plugin:${K8S_PLUGIN_TAG}

skopeo copy --all \
  docker://docker.io/rocm/k8s-node-labeler:${K8S_LABELLER_TAG} \
  docker://${TARGET_PATH}/rocm/k8s-node-labeler:${K8S_LABELLER_TAG}

skopeo copy --all \
  docker://quay.io/argoproj/workflow-controller:v4.0.3 \
  docker://${TARGET_PATH}/argoproj/workflow-controller:v4.0.3

# AMD GPU driver, tag format: coreos-<RHEL_VERSION>-<AMD_DRIVER_VERSION>
# Example: coreos-9.6-31.40
skopeo copy --all \
  docker://docker.io/rocm/amdgpu-driver:${AMD_GPU_DRIVER_TAG} \
  docker://${TARGET_PATH}/rocm/amdgpu-driver:${AMD_GPU_DRIVER_TAG}
```

Note: IBM Fusion HCI Supports AMD driver version 31.40.

- d. Apply the `oc mirror` generated manifests

Apply the `ImageDigestMirrorSet` and `CatalogSource` resources that are written by `oc mirror` into the working-dir/ directory:

```
oc apply -f working-dir/cluster-resources/
```

This creates the IDMS resources that redirect digest-based image pulls to your enterprise registry, and creates `CatalogSource` resources that points to the mirrored catalog index images.

- e. Rename the `CatalogSource` resources

Note: Skip this step if the pre-step check already found `CatalogSources` named `redhat-operators` and `certified-operators` running in your cluster. Those names are already correct. Renaming is not needed.

If the `CatalogSources` did not exist before you started, `oc mirror` created them with auto-generated names. The AMD GPU Operator and KMM Operator subscriptions require the catalog sources to be named exactly `certified-operators` and `redhat-operators`. Rename them as follows.

For the certified operator index (must be named `certified-operators`):

```
oc get catalogsource <auto-generated-certified-name> \
  -n openshift-marketplace -o json \
  | jq '.metadata.name = "certified-operators"
    | del(.metadata.resourceVersion,
      .metadata.uid,
      .metadata.creationTimestamp,
      .metadata.generation)' \
  | oc apply -f -

oc delete catalogsource <auto-generated-certified-name> -n openshift-marketplace
```

For the Red Hat operator index (must be named `redhat-operators`):

```
oc get catalogsource <auto-generated-redhat-name> \
  -n openshift-marketplace -o json \
  | jq '.metadata.name = "redhat-operators"
    | del(.metadata.resourceVersion,
      .metadata.uid,
      .metadata.creationTimestamp,
      .metadata.generation)' \
  | oc apply -f -

oc delete catalogsource <auto-generated-redhat-name> -n openshift-marketplace
```

Verify both CatalogSources are present and in READY state:

```
oc get catalogsource -n openshift-marketplace
```

Expected output includes:

NAME	DISPLAY	TYPE	PUBLISHER	AGE	STATE
certified-operators	...			...	READY
redhat-operators	...			...	READY

f. Apply the AMD GPU ImageTagMirrorSet

The `ImageDigestMirrorSet` resources from step 4 handle digest-based pulls. Also, the following `ImageTagMirrorSet` redirects tag-based pulls for all ROCm and supporting images that are mirrored in step 3.

Note:

IBM Fusion HCI Automatically creates this resource (named `amd-gpu-op`) when it installs the AMD GPU Operator in offline mode. If it exists, skip this step:

```
oc get imagetagmirrorset amd-gpu-op
```

Replace `${TARGET_PATH}` with the value set in step 1, then apply:

```
cat > itms-amd-gpu-op.yaml << EOF
apiVersion: config.openshift.io/v1
kind: ImageTagMirrorSet
metadata:
  name: amd-gpu-op
spec:
  imageTagMirrors:
  - mirrors:
    - ${TARGET_PATH}/rocm
    source: docker.io/rocm
  - mirrors:
    - ${TARGET_PATH}/amd
    source: registry.connect.redhat.com/amd
  - mirrors:
    - ${TARGET_PATH}/kmm
    source: registry.redhat.io/kmm
  - mirrors:
    - ${TARGET_PATH}/ubi9
    source: registry.redhat.io/ubi9
  - mirrors:
    - ${TARGET_PATH}/openshift4
    source: registry.redhat.io/openshift4
  - mirrors:
    - ${TARGET_PATH}
    source: docker.io/library
EOF

oc apply -f itms-amd-gpu-op.yaml
```

Important:

Applying an `ImageTagMirrorSet` triggers a rolling reboot of all cluster nodes through the Machine Config Operator (MCO). Wait for all nodes to return to Ready status before proceeding:

```
oc wait mcp worker --for condition=Updated --timeout=30m
```

Source	Mirrored to	Images covered
docker.io/rocm	TARGET_PATH/rocm	All ROCm images: gpu-operator, device-metrics-exporter, k8s-device-plugin, amdgpu-driver, etc.
registry.connect.redhat.com/amd	TARGET_PATH/amd	AMD GPU Operator bundle images from Red Hat Connect
registry.redhat.io/kmm	TARGET_PATH/kmm	KMM operator images
registry.redhat.io/ubi9	TARGET_PATH/ubi9	UBI 9 base images that are used by KMM driver build
registry.redhat.io/openshift4	TARGET_PATH/openshift4	OpenShift Driver Toolkit that is used by KMM module builds
docker.io/library	TARGET_PATH	busybox init container

Mirroring IBM Storage Scale images

Mirror the IBM Storage Scale images to your enterprise registry.

Before you begin

- Use this [procedure](#) to mirror IBM Storage Scale images to enable the Global Data Platform or Global Data Platform Remote Mount service in IBM Fusion HCI on Red Hat® OpenShift® Container Platform 4.20 or earlier.
- For Red Hat OpenShift Container Platform 4.21:

IBM Storage Scale Container Native Storage Access (CNSA) is integrated with Fusion Data Foundation through the remote mount feature.

To enable the Global Data Platform Remote Mount service in IBM Fusion HCI:

1. Mirror the Fusion Data Foundation images as described in [Mirroring Fusion Data Foundation images](#).
 2. Mirror the IBM Storage Scale 6.0.1.0 images as described in [Mirroring IBM Storage Scale 6.0.1.0 images](#).
- Before you mirror, go through the prerequisites. See [Mirroring prerequisites](#).
 - Use either podman or docker commands to login to the registries. The examples in the procedure used docker. If you are using podman, substitute **podman** for **docker** in the commands.
 - For more information about the version support, see [IBM Fusion HCI support matrix](#).
 - For more information on offline setup for network restricted Red Hat OpenShift Container Platform clusters, see [Air-gaped installs](#).

Procedure

1. Log in to the IBM Entitled Container Registry by using the IBM entitlement key:

```
docker login cp.icr.io -u cp -p <your entitlement key>
```

Note: Your entitlement key for IBM Fusion HCI must contain the correct entitlement.

Set the following environment variables:

```
export LOCAL_ISF_REGISTRY="<<Your enterprise registry host>:<port>"
export LOCAL_ISF_REPOSITORY="<<Your image path>"
IFS='/' read -r NAMESPACE PREFIX << "$LOCAL_ISF_REPOSITORY"
if [[ "$PREFIX" != "" ]]; then export TARGET_PATH="$LOCAL_ISF_REGISTRY/$NAMESPACE/$PREFIX"; export REPO_PREFIX=$(echo
"$PREFIX" | sed -r 's/\/-/-g')-; export NAMESPACE="$NAMESPACE"; else export TARGET_PATH="$LOCAL_ISF_REGISTRY/$NAMESPACE";
export REPO_PREFIX=""; fi
#verify both variables set correctly
echo "$TARGET_PATH"
echo "$NAMESPACE"
echo "$REPO_PREFIX"
```

Note: Port is a non-mandatory value when you set the **LOCAL_ISF_REGISTRY** variable. If your enterprise registry is accessible and has a secure connection, ignore it.

Sample value for without port:

```
export LOCAL_ISF_REGISTRY="registryhost.com"
```

See the following sample values:

```
export LOCAL_ISF_REGISTRY="registryhost.com:443"
export LOCAL_ISF_REPOSITORY="fusion-mirror"
```

LOCAL_ISF_REGISTRY is your entitlement registry.

LOCAL_ISF_REPOSITORY is the image path in which you want to mirror the images.

2. Run the command to login to the Docker registry with your enterprise registry credentials.

```
docker login $LOCAL_ISF_REGISTRY -u <your enterprise registry username> -p <your enterprise registry password> --tls-verify=false
```

3. From the mirroring host, run the following commands to copy the IBM Storage Scale images to the artifactory and quay registry:

- a. Global Data Platform 5.2.3.9

- Artifactory:

```
skopeo copy --all --preserve-digests docker://cp.icr.io/cp/gpfs/erasure-code/ibm-spectrum-scale-

```

Note: All commands must be successful.

4. In the OpenShift Container Platform cluster, add `ImageDigestMirrorSet`.

Note:

- Replace the variable `$TARGET_PATH` with your registry details where images are mirrored.
- Do not add white spaces while you update the mirror paths. If you want to do so, add values within double quotation marks. For example, if the new path where the images are mirrored is `registryhost.com:443/!sf-new-path`, then encapsulate within double quotation marks ("") while you edit to avoid

white spaces in the line.

```
- mirrors:
  - "registryhost.com:443/isf-new-path"
  - registryhost.com:443/old-path
  source: cp.icr.io/cp/spectrum/scale

apiVersion: config.openshift.io/v1
kind: ImageDigestMirrorSet
metadata:
  name: isf-scale-idms
spec:
  imageDigestMirrors:
    - mirrors:
      - $TARGET_PATH
      source: cp.icr.io/cp/spectrum/scale
    - mirrors:
      - $TARGET_PATH
      source: cp.icr.io/cp/gpfs
    - mirrors:
      - $TARGET_PATH
      source: icr.io/cpopen
```

Note: Ensure that you use **ImageTagMirrorSet** only when you upgrade the IBM Storage Scale.

```
apiVersion: config.openshift.io/v1
kind: ImageTagMirrorSet
metadata:
  name: isf-scale-itms
spec:
  imageTagMirrors:
    - mirrors:
      - $TARGET_PATH/submariner
      source: quay.io/submariner
    - mirrors:
      - $TARGET_PATH/kubebuilder/kube-rbac-proxy
      source: gcr.io/kubebuilder/kube-rbac-proxy
```

- **Mirroring IBM Storage Scale 6.0.1.0 images**

Mirror IBM Storage Scale 6.0.1.0 images to your enterprise registry for installation in a disconnected environment by using the **oc-mirror** plug-in.

Mirroring IBM Storage Scale 6.0.1.0 images

Mirror IBM Storage Scale 6.0.1.0 images to your enterprise registry for installation in a disconnected environment by using the **oc-mirror** plug-in.

Before you begin

Before you mirror images, review the prerequisites in [Mirroring prerequisites](#).

- Ensure that Red Hat® OpenShift® Container Platform version 4.21 is installed.
- Ensure that the Red Hat operator images are mirrored. For more information, see [Mirroring Red Hat operator images to enterprise registry](#).
- Ensure that the Fusion Data Foundation images are mirrored. For more information, see [Mirroring Fusion Data Foundation images](#).
- Use either the **podman** or **docker** commands to log in to the registries. The examples in this procedure use **docker**. If you use **podman**, replace **docker** with **podman** in the commands.
- For more information about offline setup for network-restricted Red Hat OpenShift Container Platform clusters, see [Air-gaped installs](#).

Procedure

1. Log in to the IBM Entitled Container Registry by using your IBM entitlement key:

Command example:

```
docker login cp.icr.io -u cp -p <your entitlement key>
```

2. Set the following environment variables:

Command example:

```
export LOCAL_ISF_REGISTRY=<your enterprise registry host>:<port>
export LOCAL_ISF_REPOSITORY=<your image path>
export TARGET_PATH=$LOCAL_ISF_REGISTRY/$LOCAL_ISF_REPOSITORY
```

3. Log in to your enterprise registry:

Command example:

```
docker login $LOCAL_ISF_REGISTRY -u <your enterprise registry username> -p <your enterprise registry password>
```

4. Create the image set configuration for Fusion Data Foundation.

Command example where Fusion Data Foundation version is 4.21.7:

```
cat << EOF > image-set-config.yaml
kind: ImageSetConfiguration
apiVersion: mirror.openshift.io/v1alpha2
mirror:
  additionalImages:
    - name: cp.icr.io/cp/gpfs/csi/csi-
```

```

EOF

```

- Run the following command to mirror the images:
Command example:

```
oc mirror --v2 --config image-set-config.yaml --workspace file:/// docker://${TARGET_PATH} --dest-tls-verify=false
```

- Create an `ImageDigestMirrorSet` custom resource named `isf-fdf-idms.yaml`.
Important: Replace `$TARGET_PATH` with the registry path where the images are mirrored.
Command example:

```

apiVersion: config.openshift.io/v1
kind: ImageDigestMirrorSet
metadata:
  name: ibm-spectrum-scale-dme-bundle
spec:
  imageDigestMirrors:
    - mirrors:
      - $TARGET_PATH/cp
      source: cp.icr.io/cp
    - mirrors:
      - $TARGET_PATH/cpopen
      source: icr.io/cpopen

```

- Apply the `ImageDigestMirrorSet` configuration.
Command example:

```
oc apply -f isf-fdf-idms.yaml
```

- Verify that the images are pulled from your internal registry and that the operator pod is in the Running state.
Command example:

```
kubectl get pods -lapp.kubernetes.io/name=operator -n ibm-spectrum-scale
```

Example output:

NAME	READY	STATUS	RESTARTS	AGE
ibm-spectrum-scale-controller-manager-64d548f576-znrgc	1/1	Running	0	37m

Mirroring Fusion Data Foundation images

Mirror the Fusion Data Foundation images deployed on Red Hat® OpenShift® Container Platform to your enterprise registry by using `ImageDigestMirrorSet`.

Before you begin

- Use this [procedure](#) to mirror Fusion Data Foundation images to enable the Fusion Data Foundation service in IBM Fusion HCI.
- To enable the Global Data Platform Remote Mount service in IBM Fusion HCI on Red Hat OpenShift Container Platform 4.21:
 - Use this [procedure](#) to mirror the Fusion Data Foundation images.
 - Mirror the IBM Storage Scale 6.0.1.0 images as described in [Mirroring IBM Storage Scale 6.0.1.0 images](#).
- Ensure that you mirror the required Red Hat operator images for Fusion Data Foundation. For more information, see [Mirroring Red Hat operator images to enterprise registry](#).

- Before you mirror, go through the prerequisites. See [Mirroring prerequisites](#).
- Use either podman or docker commands to login to the registries. The examples in the procedure used docker; if you are using podman, substitute `podman` for `docker` in the commands.
- For more information about the version support, see [IBM Fusion HCI support matrix](#).

About this task

The Fusion Data Foundation 4.16 with Red Hat OpenShift Container Platform 4.16 is used in the procedure as an example. Replace it with your appropriate supported version.

Procedure

1. Run the following command to login to Docker registry with your Red Hat® enterprise credentials:

```
docker login registry.redhat.io -u <Red Hat enterprise registry username> -p <Red Hat enterprise registry password>
```

2. Log in to the IBM Entitled Container Registry by using the IBM entitlement key:

```
docker login cp.icr.io -u cp -p <your entitlement key>
```

Note: Ensure that your entitlement key for IBM Fusion HCI contains the correct entitlement.
Set the following environment variables:

```
export LOCAL_ISF_REGISTRY="<Your enterprise registry host>:<port>"
export LOCAL_ISF_REPOSITORY="<Your image path>"
export TARGET_PATH="$LOCAL_ISF_REGISTRY/$LOCAL_ISF_REPOSITORY"
export OCP_VERSION="<Your ocp version, eg 4.16>"
```

Note: Port is a non-mandatory value when you set the `LOCAL_ISF_REGISTRY` variable. If your enterprise registry is accessible and has a secure connection, then you can ignore it.

Sample value for without port:

```
export LOCAL_ISF_REGISTRY="registryhost.com"
```

See the following sample values:

```
export LOCAL_ISF_REGISTRY="registryhost.com:443"
export LOCAL_ISF_REPOSITORY="fusion-mirror"
```

`LOCAL_ISF_REGISTRY` is your entitlement registry.

`LOCAL_ISF_REPOSITORY` is the image path in which you want to mirror the images.

3. Run the command to login to the Docker registry with your enterprise registry credentials:

```
docker login $LOCAL_ISF_REGISTRY -u <your enterprise registry username> -p <your enterprise registry password>
```

4. Create the image set configuration for Fusion Data Foundation.

If you are using Fusion Data Foundation 4.22, then use the following image set configuration:

```
imageset-config-fdf.yaml
```

```
cat << EOF > imageset-config-fdf.yaml
kind: ImageSetConfiguration
apiVersion: mirror.openshift.io/v2alpha1
mirror:
  operators:
  - catalog: icr.io/cpopen/isf-data-foundation-catalog:v$OCP_VERSION
    packages:
      - name: "cephcsi-operator"
      - name: "mcg-operator"
      - name: "ocs-operator"
      - name: "odf-csi-addons-operator"
      - name: "odf-operator"
      - name: "ocs-client-operator"
      - name: "odf-prometheus-operator"
      - name: "recipe"
      - name: "rook-ceph-operator"
      - name: "odf-dependencies"
      - name: "odf-external-snapshotter-operator"
      - name: "ibm-spectrum-scale-operator"
      - name: "cnsa-dependencies"
      - name: "ceph-volsync-plugin-operator"
      - name: "ocs-tls-profiles"
      - name: "odf-multicluster-orchestrator"          # Required for Regional-DR configuration
      - name: "odr-cluster-operator"                  # Required for Regional-DR configuration
      - name: "odr-hub-operator"                      # Required for Regional-DR configuration
      - name: "odr-volsync-plugin-operator"            # Required for Regional-DR configuration
EOF
```

If you are using Fusion Data Foundation 4.21, then use the following image set configuration:

```
imageset-config-fdf.yaml
```

```
cat << EOF > imageset-config-fdf.yaml
kind: ImageSetConfiguration
apiVersion: mirror.openshift.io/v2alpha1
mirror:
  operators:
```

```

- catalog: icr.io/cpopen/isf-data-foundation-catalog:v$OCP_VERSION
packages:
  - name: "cephcsi-operator"
  - name: "mcg-operator"
  - name: "ocs-operator"
  - name: "odf-csi-addons-operator"
  - name: "odf-operator"
  - name: "ocs-client-operator"
  - name: "odf-prometheus-operator"
  - name: "recipe"
  - name: "rook-ceph-operator"
  - name: "odf-dependencies"
  - name: "odf-external-snapshotter-operator"
  - name: "ibm-spectrum-scale-operator"
  - name: "cnsa-dependencies"
  - name: "odf-multicluster-orchestrator"          # Required for Regional-DR configuration
  - name: "odr-cluster-operator"                  # Required for Regional-DR configuration
  - name: "odr-hub-operator"                      # Required for Regional-DR configuration
EOF

```

If you are using Fusion Data Foundation 4.20, then use the following image set configuration:

imageset-config-fdf.yaml

```

cat << EOF > imageset-config-fdf.yaml
kind: ImageSetConfiguration
apiVersion: mirror.openshift.io/v2alpha1
mirror:
  operators:
  - catalog: icr.io/cpopen/isf-data-foundation-catalog:v$OCP_VERSION
    packages:
      - name: "cephcsi-operator"
      - name: "mcg-operator"
      - name: "ocs-operator"
      - name: "odf-csi-addons-operator"
      - name: "odf-operator"
      - name: "ocs-client-operator"
      - name: "odf-prometheus-operator"
      - name: "recipe"
      - name: "rook-ceph-operator"
      - name: "odf-dependencies"
      - name: "odf-external-snapshotter-operator"
      - name: "odf-multicluster-orchestrator"          # Required for Regional-DR configuration
      - name: "odr-cluster-operator"                  # Required for Regional-DR configuration
      - name: "odr-hub-operator"                      # Required for Regional-DR configuration
EOF

```

If you are using Fusion Data Foundation 4.18 and 4.19, then use the following image set configuration:

imageset-config-fdf.yaml

```

cat << EOF > imageset-config-fdf.yaml
kind: ImageSetConfiguration
apiVersion: mirror.openshift.io/v2alpha1
mirror:
  operators:
  - catalog: icr.io/cpopen/isf-data-foundation-catalog:v$OCP_VERSION
    packages:
      - name: "cephcsi-operator"
      - name: "mcg-operator"
      - name: "ocs-operator"
      - name: "odf-csi-addons-operator"
      - name: "odf-operator"
      - name: "ocs-client-operator"
      - name: "odf-prometheus-operator"
      - name: "recipe"
      - name: "rook-ceph-operator"
      - name: "odf-dependencies"
      - name: "odf-multicluster-orchestrator"          # Required for Regional-DR configuration
      - name: "odr-cluster-operator"                  # Required for Regional-DR configuration
      - name: "odr-hub-operator"                      # Required for Regional-DR configuration
EOF

```

5. Run the following oc command to mirror the images.

```
oc mirror --v2 --config imageset-config-fdf.yaml --workspace file:/// ./ docker:///${TARGET_PATH} --dest-tls-verify=false
```

6. Run the following command to check whether the image got successfully mirrored to the registry:

Note: If you are using a self signed registry, then export the `SSL_CERT_DIR=/root/quay-install/quay-rootCA` before running this command. The `/root/quay-install/quay-rootCA` path is where certificates are placed. For more information, see [Red Hat solution](#).

```
oc mirror list operators --catalog $TARGET_PATH/cpopen/isf-data-foundation-catalog:v$OCP_VERSION
```

Sample output:

WARN[0033] DEPRECATION NOTICE:

Sqlite-based catalogs and their related subcommands are deprecated. Support for them will be removed in a future release. Please migrate to the new file-based catalog format.

NAME	DISPLAY NAME	DEFAULT	CHANNEL
mcg-operator	NooBaa	Operator	stable-4.16
ocs-client-operator	OpenShift Data Foundation	Client	stable-4.16

ocs-operator	Container	Storage	stable-4.16
odf-csi-addons-operator	CSI	Addons	stable-4.16
odf-multicluster-orchestrator	Multicluster	Orchestrator	stable-4.16
odf-operator	IBM Fusion	Data Foundation	stable-4.16
odr-cluster-operator	DR Cluster	Operator	stable-4.16
odr-hub-operator	DR Hub	Operator	stable-4.16

7. Ensure that the local-storage-operator and lvms-operator operator packages are present in your cluster.

Note: If you have not mirrored local-storage-operator and lvms-operator from the Red Hat packages previously, then follow the steps that are provided in the [Mirroring Red Hat operator images to enterprise registry](#).

Note:

- For the regional disaster recovery (Regional-DR) setup, create the following image set configuration for the local storage operator:

```
cat << EOF > imageset-config-lso.yaml
kind: ImageSetConfiguration
apiVersion: mirror.openshift.io/v2alpha1
mirror:
  operators:
    - catalog: registry.redhat.io/redhat/redhat-operator-index:v$OCP_VERSION
      packages:
        - name: "multicluster-engine"
        - name: "local-storage-operator"
        - name: "lvms-operator"
        - name: "redhat-oadp-operator"
        - name: "openshift-gitops-operator"
        - name: "submariner"
        - name: "advanced-cluster-management"
EOF
```

- Run the following **OC** command to mirror the images.

```
oc mirror --config imageset-config-lso.yaml docker://$${TARGET_PATH} --dest-skip-tls --ignore-history
```

8. Note: You can run steps 8, 9, and 10 only when the cluster is up for a freshly installed rack.

Create an **ImageDigestMirrorSet** custom resource for Fusion Data Foundation. Apply the configuration by running the command:

```
oc apply -f isf-fdf-idms.yaml
```

See the following **ImageDigestMirrorSet**:

Note: Replace the variable **\$TARGET_PATH** with your registry details where images are mirrored.

```
apiVersion: config.openshift.io/v1
kind: ImageDigestMirrorSet
metadata:
  labels:
    operators.openshift.org/catalog: "true"
  name: isf-fdf-idms
spec:
  imageDigestMirrors:
    - mirrors:
      - $TARGET_PATH/openshift4
      source: registry.redhat.io/openshift4
    - mirrors:
      - $TARGET_PATH/redhat
      source: registry.redhat.io/redhat
    - mirrors:
      - $TARGET_PATH/rhel9
      source: registry.redhat.io/rhel9
    - mirrors:
      - $TARGET_PATH/rhel8
      source: registry.redhat.io/rhel8
    - mirrors:
      - $TARGET_PATH/cp/df
      source: cp.icr.io/cp/df
    - mirrors:
      - $TARGET_PATH/cpopen
      source: cp.icr.io/cpopen
    - mirrors:
      - $TARGET_PATH/cpopen
      source: icr.io/cpopen
    - mirrors:
      - $TARGET_PATH/cp/df/ceph
      source: cp.icr.io/cp/df/ceph
    - mirrors:
      - $TARGET_PATH/odf4
      source: registry.redhat.io/odf4
    - mirrors:
      - $TARGET_PATH/lvms4
      source: registry.redhat.io/lvms4
    - mirrors:
      - $TARGET_PATH/rhceph
      source: registry.redhat.io/rhceph
    - mirrors:
      - $TARGET_PATH/cp/gpfs
      source: cp.icr.io/cp/gpfs
    - mirrors:
      - $TARGET_PATH/cp/gpfs/csi
      source: cp.icr.io/cp/gpfs/csi
```

```
- mirrors:
- $TARGET_PATH/cp/gpfs/data-management
source: cp.icr.io/cp/gpfs/data-management
```

9. Create a `CatalogSource` named `redhat-operators`. Apply the `CatalogSource` by running the command:

```
oc apply -f redhat-operators-catalogsource.yaml
```

Note: Do this step when the Fusion Data Foundation uses the local disk.

```
apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: redhat-operators
  namespace: openshift-marketplace
spec:
  displayName: Red Hat Operators
  image: $TARGET_PATH/redhat/redhat-operator-index:v$OCP_VERSION
  publisher: Red Hat
  sourceType: grpc
```

10. Create an `ImageTagMirrorSet` for Fusion Data Foundation. Apply the configuration by running the command:

```
oc apply -f isf-fdf-imagetagmirrorset.yaml
```

See the following `ImageDigestMirrorSet`:

```
apiVersion: config.openshift.io/v1
kind: ImageTagMirrorSet
metadata:
  name: isf-fdf
spec:
  imageTagMirrors:
  - mirrors:
    - $TARGET_PATH/cpopen/isf-data-foundation-catalog
    source: icr.io/cpopen/isf-data-foundation-catalog
    mirrorSourcePolicy: AllowContactingSource
```

What to do next

- To enable the Global Data Platform Remote Mount service in IBM Fusion HCI on Red Hat OpenShift Container Platform 4.21, mirror the IBM Storage Scale 6.0.1.0 images as described in [Mirroring IBM Storage Scale 6.0.1.0 images](#).
- For the RDR setup, if you want to install the multicluster engine operator in an offline system or a disconnected environment, see [Installing in a disconnected environment](#) in *Red Hat Advanced Cluster Management for Kubernetes* documentation.

Mirroring Backup & Restore images

Mirror the Backup & Restore images to your enterprise registry.

Before you begin

- Before you mirror, go through the prerequisites. See [Mirroring prerequisites](#).
- Use either podman or docker commands to login to the registries. The examples in the procedure used docker; if you are using podman, substitute `podman` for `docker` in the commands.
- For more information about the version support, see [IBM Fusion HCI support matrix](#).

About this task

High level steps to mirror Backup & Restore service:

- Log in to the relevant Docker registries
- Define variables to configure and mirror the Backup & Restore component of IBM Fusion HCI.
- Run the `oc-mirror` CLI tool to mirror the Backup & Restore components.

Note:

- Use this procedure only necessary if you plan to mirror specific sub-components of IBM Fusion instead of following the full end-to-end mirroring instructions. For more information about the end-to-end mirroring of IBM Fusion and all its services, see [End-to-end mirroring of IBM Fusion HCI and its services images to the enterprise registry](#).
- If you choose to mirror specific sub-components, use the same `TARGET_PATH` variable so that all the components mirror into the same location, and the generated `ImageDigestMirrorSet` remains the same across all components.
- For more information about Air gap setup for network restricted Red Hat® OpenShift® Container Platform clusters, see [Offline setup for network restricted Red Hat OpenShift Container Platform clusters](#).

Procedure

- Log in to your Docker registry:
 - Run the following command to login to the Docker registry with your Red Hat enterprise credentials:

```
docker login registry.redhat.io -u <Red Hat enterprise registry username> -p <Red Hat enterprise registry password>
```
 - To authenticate to [quay.io](#) by using the username and password from the pull-secret, do the following steps:

- i. Download the pull-secret, see <https://console.redhat.com/openshift/install/pull-secret> and follow the instructions.
See the following sample values:

```
"auths": {
  "quay.io": {
    "auth": "b3BlbnNoaWZ0LXJtczOGY2YzNjNDM2ZWl0JRSdDUQU45RFBWVUNXM0VZQU1VVDBOQTU3VFM2RE1JMg==",
    "email": <email-id>
  }
}
```

- ii. Get the username/password:

```
echo <auth-content> | base64 -decode
```

Example echo command:

```
echo "b3BlbnNoaWZ0LXJtczOGY2YzNjNDM2ZWl0JRSdDUQU45RFBWVUNXM0VZQU1VVDBOQTU3VFM2RE1JMg==" | base64 -decode
```

Example output:

```
openshift-release+ocmaccess0ab5738f6c3c42:CXKR2TSBQH7TAN9
```

Here, `openshift-release+ocmaccess0ab5738f6c3c42` is the user name and `CXKR2TSBQH7TAN9` is the password.

- c. Log in to the IBM Entitled Container Registry using the IBM entitlement key.

```
docker login cp.icr.io -u cp -p <your entitlement key>
```

Note: Ensure that your entitlement key for IBM Fusion HCI contains the correct entitlement.

- d. Set the following environment variables:

Important: Ensure you review the [offline upgrade considerations](#) before proceeding with upgrade mirroring.

```
export LOCAL_ISF_REGISTRY=<Your enterprise registry host>:<port>
export LOCAL_ISF_REPOSITORY=<Your image path>
export TARGET_PATH=$LOCAL_ISF_REGISTRY/$LOCAL_ISF_REPOSITORY
echo "$TARGET_PATH"
```

Note: Port is a non-mandatory value when setting the `LOCAL_ISF_REGISTRY` variable. You can ignore this if your enterprise registry is accessible and has a secure connection.

Sample value without port:

```
export LOCAL_ISF_REGISTRY="registryhost.com"
export LOCAL_ISF_REGISTRY="registryhost.com:443"
export LOCAL_ISF_REPOSITORY="fusion-mirror"
```

- e. Run the command to login to the Docker registry with your enterprise registry credentials.

```
docker login $LOCAL_ISF_REGISTRY -u <your enterprise registry username> -p <your enterprise registry password>
```

`LOCAL_ISF_REGISTRY` is your entitlement registry.

`LOCAL_ISF_REPOSITORY` is the image path in which you want to mirror the images. You can choose your own repository paths. For example, `hci-images/isf` or `hci-images`.

2. Ensure that the `redhat-oadp-operator` and `amq-streams` operator packages are present in your cluster.

Note: If you have not mirrored `redhat-oadp-operator` and `amq-streams` from the Red Hat packages previously, then follow the steps that are provided in the [Mirroring Red Hat operator images to enterprise registry](#).

Note:

- Run the following command to get list of mirrored Red Hat packages available on your cluster.

```
oc get packagemanifests | grep -i "Red Hat Operators"
```

- If you do not get `redhat-oadp-operator` and `amq-streams` operator packages from the previous step, then you must follow the step [2](#).
- Ensure that you also add existing packages along with new one in ImageSetConfiguration file. Otherwise, old packages can be lost from the Red Hat operator index image.

3. Run the command to login to the Docker registry with your enterprise registry credentials.

For docker users:

```
docker login $LOCAL_ISF_REGISTRY -u <your enterprise registry username> -p <your enterprise registry password>
```

For podman users:

```
podman login $LOCAL_ISF_REGISTRY -u <your enterprise registry username> -p <your enterprise registry password>
```

4. Create the image set configuration for Backup & Restore.

```
cat << EOF > imageset-config-bnr.yaml
kind: ImageSetConfiguration
apiVersion: mirror.openshift.io/v2alpha1
mirror:
  operators:
    - catalog: icr.io/cpopen/idp-server-operator-
catalog@sha256:1cda52f948d2fa351a72e28fb0f8faf53f04ccc8da3d071d4dbc694027272d87
  packages:
    - name: guardian-dm-operator
      channels:
        - name: v2.0
    - name: guardian-dp-operator
      channels:
        - name: v2.0
```

```

- name: guardian-mongo-operator
  channels:
    - name: v2.0
- name: ibm-dataprotectionagent
  channels:
    - name: v2.0
- name: ibm-dataprotectionserver
  channels:
    - name: v2.0
- name: redis-operator
  channels:
    - name: v2.0
full: true
additionalImages:
- name: icr.io/cpopen/idp-server-operator-catalog:2.14.0-
26559@sha256:1cda52f948d2fa351a72e28fb0f8faf53f04ccc8da3d071d4dbc694027272d87
- name: icr.io/fusion-open/minio/minio@sha256:14cea493d9a34af32f524e538b8346cf79f3321eff8e708c1e2960462bd8936e
blockedImages:
- name: quay.io/minio/minio@sha256:14cea493d9a34af32f524e538b8346cf79f3321eff8e708c1e2960462bd8936e
EOF

```

5. Run the following `oc-mirror` command to mirror the images.

```
oc mirror --v2 --config imageset-config-bnr.yaml --workspace file:/// docker://${TARGET_PATH} --dest-tls-verify=false
```

6. Important: You can run step 5 only when the cluster is up for a freshly installed rack.

Apply the `ImageDigestMirrorSet` file to your cluster:

Note: Replace the variable `$TARGET_PATH` with your registry details where images are mirrored.

```

apiVersion: config.openshift.io/v1
kind: ImageDigestMirrorSet
metadata:
  name: ibm-fusion-bnr
spec:
  imageDigestMirrors:
    - mirrors:
      - ${TARGET_PATH}/cp
      source: cp.icr.io/cp
    - mirrors:
      - ${TARGET_PATH}/cpopen
      source: icr.io/cpopen
    - mirrors:
      - ${TARGET_PATH}/fusion-open/minio
      - ${TARGET_PATH}/minio
      source: quay.io/minio
    - mirrors:
      - ${TARGET_PATH}/openshift4
      source: registry.redhat.io/openshift4

```

In case of any failure, refer [Troubleshooting and known issues](#) in offline mirroring to get the resolution steps.

Mirroring IBM Data Cataloging images

Mirror the IBM Data Cataloging images to your enterprise registry.

Before you begin

- Before you mirror, go through the prerequisites. See [Mirroring prerequisites](#).
- Use either podman or docker commands to login to the registries. The examples in the procedure used docker; if you are using podman, substitute `podman` for `docker` in the commands.
- For more information about the version support, see [IBM Fusion HCI support matrix](#).
- Ensure that you install the `oc-mirror` OpenShift CLI plug-in. For more information about `oc-mirror` OpenShift CLI plug-in installation, see [Installing the oc-mirror OpenShift® CLI plug-in](#).

About this task

For more information about Air gap setup for network restricted Red Hat® OpenShift Container Platform clusters, see [Offline setup for network restricted Red Hat OpenShift Container Platform clusters](#).

Note:

- This procedure is only necessary if you plan to enable the IBM Data Cataloging IBM Fusion HCI service.
- The destination registry where all IBM Data Cataloging images are going to be copied need to support both OCI (`application/vnd.oci.image.manifest.v1+json`) and Docker V2 (`application/vnd.docker.distribution.manifest.v2+json`) manifest types.

Use this procedure only necessary if you plan to mirror specific sub-components of IBM Fusion HCI instead of following the full end-to-end mirroring instructions. For more information about the end-to-end mirroring of and all its services, see [End-to-end mirroring of IBM Fusion HCI and its services images to the enterprise registry](#).

High level tasks of this procedure:

1. Log in to the relevant Docker registries.
2. Define some convenience variables used to configure and mirror the Data Cataloging component of Fusion.
3. Run the `oc-mirror` CLI tool mirrors the Data Cataloging components.

Note: If you choose to mirror specific sub-components, it is recommended that you use the same `TARGET_PATH` variable so that all the components mirror in the same location, and the generated `ImageDigestMirrorSet` is same across all components.

Procedure

1. Ensure that the `amq-streams` operator package is present in your cluster.

Note: If you have not mirrored `amq-streams` from the Red Hat packages previously, then follow the steps that are provided in the [Mirroring Red Hat operator images to enterprise registry](#).

Note:

- Run the following command to get list of mirrored Red Hat packages available on your cluster.

```
oc get packagemanifests | grep -i "Red Hat Operators"
```

- If you do not get `redhat-oadp-operator` operator package from the previous step, then you must follow the step [1](#).
- Ensure that you also add existing packages along with new one in ImageSetConfiguration file. Otherwise, old packages can be lost from the Red Hat operator index image.

2. Run the following command to login the Red Hat enterprise registry and the IBM Entitled Container Registry using your credentials.

Note: Ensure that your entitlement key for IBM Fusion contains the correct entitlement.

For docker users:

```
docker login registry.redhat.io -u <Red Hat enterprise registry username> -p <Red Hat enterprise registry password>
```

```
docker login cp.icr.io -u cp -p <your entitlement key>
```

For podman users:

```
podman login registry.redhat.io -u <Red Hat enterprise registry username> -p <Red Hat enterprise registry password>
```

```
podman login cp.icr.io -u cp -p <Your entitlement key>
```

3. Set the following environment variable.

Important: Ensure you review the [offline upgrade considerations](#) before proceeding with upgrade mirroring.

```
export LOCAL_ISF_REGISTRY=<Your enterprise registry host>:<port>
export LOCAL_ISF_REPOSITORY=<Your image path>
export TARGET_PATH="$LOCAL_ISF_REGISTRY/$LOCAL_ISF_REPOSITORY"
```

`LOCAL_ISF_REGISTRY` is your entitlement registry.

`LOCAL_ISF_REGISTRY` is the registry image path in which you want to mirror the images. You can choose your own repository paths. For example, `hci-images/isf` or `hci-images`.

4. Run the command to login to the Docker registry with your enterprise registry credentials.

For docker users:

```
docker login $LOCAL_ISF_REGISTRY -u <your enterprise registry username> -p <your enterprise registry password>
```

For podman users:

```
podman login $LOCAL_ISF_REGISTRY -u <your enterprise registry username> -p <your enterprise registry password>
```

5. Create the image set configuration for IBM Data Cataloging.

```
cat << EOF > imageset-config-dcs.yaml
kind: ImageSetConfiguration
apiVersion: mirror.openshift.io/v2alpha1
mirror:
  additionalImages:
  - name: cp.icr.io/cp/dcs/auth@sha256:5a5b41ac93f0e55ccbb6335e1ec69cf09c0a4b08ab66744effe9ad7ce379422e
  - name: cp.icr.io/cp/dcs/connmgr-scheduler@sha256:22482b9f236ecf91ab0c5fa5d81e0c6596edde6db4b63d261080edee5dde2fb8
  - name: cp.icr.io/cp/dcs/connmgr-scheduler@sha256:d192ccc3d21e2227e4887b63bef6a962e7d36d4a3e9fa92b4256b05fd8d8c6a6d
  - name: cp.icr.io/cp/dcs/connmgr@sha256:7818fc0690c149821bca845ad9fabaf6512137f97b84e9ccfa7f9b939d06012

EOF

```

- Run the following `oc-mirror` command to mirror the images.

```
oc mirror --v2 --config imageset-config-dcs.yaml --workspace file:/// docker://${TARGET_PATH} --dest-tls-verify=false
```

- Important: You can run steps 7 and 8 only when the cluster is up for a freshly installed rack.
Apply the `ImageDigestMirrorSet` file to your cluster:
Note: Replace the variable `$TARGET_PATH` with your registry details where images are mirrored.

```

apiVersion: config.openshift.io/v1
kind: ImageDigestMirrorSet
metadata:
  name: ibm-spectrum-discover
spec:
  imageDigestMirrors:
  - mirrors:
    - ${TARGET_PATH}/cp
    source: cp.icr.io/cp
  - mirrors:
    - ${TARGET_PATH}/cpopen
    source: icr.io/cpopen
  - mirrors:
    - ${TARGET_PATH}/db2u
    source: icr.io/db2u

```

In case of any failure, refer [Troubleshooting and known issues](#) in offline mirroring to get the resolution steps.

- Apply the following `catalogsource` to the cluster:

```

apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: ibm-spectrum-discover-catalog
  namespace: openshift-marketplace
spec:
  displayName: ibm-spectrum-discover-256.0.1
  publisher: IBM
  image: ${TARGET_PATH}/cpopen/ibm-spectrum-discover-operator-catalog@sha256:3ada857fe322cf08f50be799a6194d5248fd0627f061098dab0511f5b277d89c
  sourceType: grpc

```

Mirroring Content-Aware Storage (CAS) images

IBM Fusion HCI supports a range of CAS versions, and it can upgrade independently of IBM Fusion HCI within a certain range. In 2.14.0, the supported CAS version range is any version < v1.1.0. You can run this procedure multiple times to upgrade to each newer version of CAS within the supported range.

Before you begin

- Before you mirror, go through the prerequisites. See [Mirroring prerequisites](#).
- Use either podman or docker commands to login to the registries. The examples in the procedure used docker; if you are using podman, substitute **podman** for **docker** in the commands.
- For more information about the version support, see [IBM Fusion HCI support matrix](#).

About this task

High level steps to mirror CAS service:

1. Log in to the relevant Docker registries
2. Define variables to configure and mirror the CAS component of IBM Fusion HCI.
3. Run the **oc-mirror** CLI tool to mirror the CAS components.

Note:

- Use this procedure when you want to upgrade your offline CAS installation to a newer version, without having to upgrade the IBM Fusion installation.
- If you choose to mirror specific sub-components, use the same TARGET_PATH variable so that all the components mirror into the same location, and the generated **ImageDigestMirrorSet** remains the same across all components.
- For more information about Air gap setup for network restricted Red Hat® OpenShift® Container Platform clusters, see [Offline setup for network restricted Red Hat OpenShift Container Platform clusters](#).

Procedure

1. Log in to your Docker registry:

- a. Run the following command to login to the Docker registry with your Red Hat enterprise credentials:

```
docker login registry.redhat.io -u <Red Hat enterprise registry username> -p <Red Hat enterprise registry password>
```

- b. Log in to the IBM Entitled Container Registry using the IBM entitlement key.

```
docker login cp.icr.io -u cp -p <your entitlement key>
```

Note: Ensure that your entitlement key for IBM Fusion HCI contains the correct entitlement.

- c. Set the following environment variables:

```
export LOCAL_ISF_REGISTRY="<Your enterprise registry host>:<port>"
export LOCAL_ISF_REPOSITORY="<Your image path>"
export TARGET_PATH="$LOCAL_ISF_REGISTRY/$LOCAL_ISF_REPOSITORY"
echo "$TARGET_PATH"
```

Note: Port is a non-mandatory value when setting the **LOCAL_ISF_REGISTRY** variable. You can ignore this if your enterprise registry is accessible and has a secure connection.

Sample value without port:

```
export LOCAL_ISF_REGISTRY="registryhost.com"

export LOCAL_ISF_REGISTRY="registryhost.com:443"
export LOCAL_ISF_REPOSITORY="fusion-mirror"
```

- d. Run the command to login to the Docker registry with your enterprise registry credentials.

```
docker login $LOCAL_ISF_REGISTRY -u <your enterprise registry username> -p <your enterprise registry password>
```

LOCAL_ISF_REGISTRY is your entitlement registry.

LOCAL_ISF_REPOSITORY is the image path in which you want to mirror the images. You can choose your own repository paths. For example, hci-images/isf or hci-images.

2. Create the image set configuration for CAS.

```
cat << EOF > imageset-config-cas.yaml
kind: ImageSetConfiguration
apiVersion: mirror.openshift.io/v2alpha1
mirror:
  operators:
  - catalog: icr.io/cpopen/ibm-isf-cas-operator-
    catalog@sha256:3ecc98df5ab3f6f26a36e7ed0e99030081ee7152cbf763531973081173e6e39d
  packages:
  - name: ibm-isf-cas-operator
    channels:
    - name: fusion-2.14
    - name: v1.0
    - name: v1.1
    full: true
  additionalImages:
  - name: icr.io/cpopen/ibm-isf-cas-operator-catalog:1.1.7-
    26559@sha256:3ecc98df5ab3f6f26a36e7ed0e99030081ee7152cbf763531973081173e6e39d
EOF
```

3. Run the following **oc-mirror** command to mirror the images.

```
oc mirror --v2 --config imageset-config-cas.yaml --workspace file:/// docker://${TARGET_PATH} --dest-tls-verify=false
```

4. Apply the `ImageDigestMirrorSet` file to your cluster:

Note: Replace the variable `$TARGET_PATH` with your registry details where images are mirrored.

```
apiVersion: config.openshift.io/v1
kind: ImageDigestMirrorSet
metadata:
  name: isf-cas
spec:
  imageDigestMirrors:
  - mirrors:
    - ${TARGET_PATH}/cp
    source: cp.icr.io/cp
  - mirrors:
    - ${TARGET_PATH}/cpopen
    source: icr.io/cpopen
  - mirrors:
    - ${TARGET_PATH}/openshift4
    source: registry.redhat.io/openshift4
```

In case of any failure, refer [Troubleshooting and known issues](#) in offline mirroring to get the resolution steps.

Note: After applying the catalog source, it gets deleted automatically and it recreates once CAS is deployed.

There is no need to apply the generated catalog-source.yaml file in this directory as Fusion applies the CatalogSource for CAS.

5. Apply the following catalog source to the cluster.

```
apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: ibm-cas-catalog
  namespace: openshift-marketplace
spec:
  displayName: ibm-cas-1.1.7-linux-amd64
  publisher: IBM
  image: ${TARGET_PATH}/cpopen/ibm-isf-cas-operator-

Mirroring IBM Software Hub, watsonx.ai, and watsonx Orchestrate images

Mirror the IBM Software Hub, watsonx.ai, watsonx Orchestrate, and Red Hat® OpenShift® AI images to your enterprise registry.

Before you begin

- Before you mirror, go through the prerequisites. See [Mirroring prerequisites](#).
- Use either podman or docker commands to login to the registries. The examples in the procedure used docker; if you are using podman, substitute `podman` for `docker` in the commands.
- For more information about the version support, see [IBM Fusion HCI support matrix](#).
- Ensure that you install the `oc-mirror` OpenShift CLI plug-in. For more information about `oc-mirror` OpenShift CLI plug-in installation, see [Installing the oc-mirror OpenShift CLI plugin](#).

About this task

For more information about Air gap setup for network restricted Red Hat OpenShift Container Platform clusters, see [Offline setup for network restricted Red Hat OpenShift Container Platform clusters](#).

Note:

- This procedure is only necessary if you plan to enable the IBM Software Hub, watsonx.ai, watsonx Orchestrate, and Red Hat OpenShift AI services of IBM Fusion HCI.
- If you choose to mirror specific sub-components, it is recommended that you use the same `TARGET_PATH` variable so that all the components mirror in the same location, and the generated `ImageDigestMirrorSet` is same across all components.

Procedure

1. Log in to the IBM Entitled Container Registry using the IBM entitlement key:

```
docker login cp.icr.io -u cp -p <your entitlement key>
```

Set the following environment variables:

```
export LOCAL_ISF_REGISTRY="<Your container registry host>:<port>"
export LOCAL_ISF_REPOSITORY="<Your image path>"
export TARGET_PATH="$LOCAL_ISF_REGISTRY/$LOCAL_ISF_REPOSITORY"
```

See the following sample values:

```
export LOCAL_ISF_REGISTRY="registryhost.com:443"
export LOCAL_ISF_REPOSITORY="fusion-mirror"
```

`LOCAL_ISF_REGISTRY` is your entitlement registry.

LOCAL_ISF_REPOSITORY is the image path in which you want to mirror the images. You can choose your own repository paths. For example, hci-images/isf or hci-images.

- Run the following command to login to the docker registry with your enterprise registry credentials:

```
docker login $LOCAL_ISF_REGISTRY -u <your enterprise registry username> -p <your enterprise registry password>
```

- Mirror the following mandatory IBM Software Hub components to your private registry:

IBM Software Hub

- **ibm-licensing**
- **cpfs**
- **cpd_platform**
- **ibm-cert-manager**

watsonx.ai

- **watsonx_ai**

watsonx Orchestrate

- **watsonx_orchestrate**

For detailed mirroring procedures and prerequisites of the services, see [Preparing to run IBM Software Hub installs from a private container registry](#).

- Download and install the following tools on your machine:

- casectl** from [Cloud Pak Open Content](#).
- cpd-cli** from [Cloud Pak for Data command line interface](#).
Clone this [Github repository](#) to your machine.

- Run the following commands to download the required cases for AI services:

```
export COMPONENTS="cpfs,cpd_platform,ibm-licensing,ibm-cert-manager,watsonx_ai,watsonx_orchestrate"
cpd-cli manage case-download \
  --components="${COMPONENTS}" \
  --release=5.4.0
```

After executing the case-download command, you should see list of cases required for **ai-services** in the path **/cpd-cli-workspace/olm-utils-workspace/work/offline/5.4.0/.ibm-pak/data/cases**.

You can also verify by running the following command:

```
ls cpd-cli-workspace/olm-utils-workspace/work/offline/5.4.0/.ibm-pak/data/cases/
```

ibm-ccs	ibm-cp-datacore	ibm-etcd-operator	ibm-redis-cp
ibm-watsonx-ai-ifm	ibm-wsl		
ibm-cert-manager	ibm-data-governor	ibm-licensing	ibm-watson-assistant
ibm-watsonx-data	ibm-wsl-runtimes		
ibm-cloud-native-postgresql	ibm-datarefinery	ibm-opensearch-operator	ibm-watson-gateway-
operator	ibm-watsonx-orchestrate	ibm-zen	
ibm-cp-common-services	ibm-elasticsearch-operator	ibm-rabbitmq-operator	ibm-watsonx-ai
ibm-wml-cpd			

To know the versions of all of these cases, run the following command:

```
for d in */; do
  echo "==== $d ====="
  ls "$d"
  echo
done
```

- After the CASE files are downloaded, they must be mirrored to the private container registry with the appropriate versions.

- Create the CASE repository only once using the first command.

```
./casectl repo create --repoPath /<some-path>/temp
```

- Run these commands for each CASE along with its version.

```
./casectl repo update --repoPath /<some-path>/temp --addCase ~/.ibm-
pak/data/cases/<casename>/<caseversion>/<casename>-<caseversion>.tgz
./casectl repo updateoci --repoPath /<some-path>/temp --addCase <casename> --addCaseVersion <caseversion> --
artifactRegistry <private-artifactory-path>:<port>
```

Here **<casename>** refers to the name of each case, and **<caseversion>** is the version of that particular case. You should have obtained a list of versions for each case from the previous step [5](#).

<some-path> is some random path to use based on the requirements.

For example:

```
./casectl repo create --repoPath /Documents/temp
```

```
./casectl repo update --repoPath /Documents/temp --addCase ~/.ibm-pak/data/cases/ibm-cert-manager/4.2.23/ibm-cert-
manager-4.2.23.tgz
```

```
./casectl repo updateoci --repoPath /Documents/temp --addCase ibm-cert-manager --addCaseVersion 4.2.23 --
artifactRegistry <private-registry-path>
```

- The **ibm-cp-common-services** CASE directory contains additional dependent CASE packages that must also be mirrored. To access these packages, navigate to the **/cpd-cli-workspace/olm-utils-workspace/work/offline/5.4.0/.ibm-pak/data/cases/ibm-cp-common-services/<ibm-cp-common-services-version>** path, where **<ibm-cp-common-services-version>** represents the CASE version of **ibm-cp-common-services**.

For an example:

```
% cd ibm-cp-common-services
ibm-cp-common-services % ls
4.19.2
ibm-cp-common-services % cd 4.19.2
4.19.2 % ls
caseDependencyMapping.csv                               ibm-cs-iam-4.18.1+20260812.100000-airgap-
metadata.yaml                                           ibm-cs-install-4.19.2+20260819.100000.tgz
charts                                                  ibm-cs-iam-4.18.1+20260812.100000-charts.csv
ibm-events-operator-5.2.1-airgap-metadata.yaml         ibm-cs-iam-4.18.1+20260812.100000-images.csv
component-set-config.yaml                               ibm-cs-iam-4.18.1+20260812.100000.tgz
ibm-events-operator-5.2.1-charts.csv                  ibm-cs-install-4.19.2+20260819.100000-airgap-
ibm-cp-common-services-4.19.2+20260819.100000-airgap-metadata.yaml  ibm-cs-install-4.19.2+20260819.100000-charts.csv
ibm-events-operator-5.2.1-images.csv                  ibm-cs-install-4.19.2+20260819.100000-images.csv
ibm-cp-common-services-4.19.2+20260819.100000-charts.csv
metadata.yaml                                           ibm-events-operator-5.2.1.tgz
ibm-cp-common-services-4.19.2+20260819.100000-images.csv
resourceIndexes                                         ibm-cs-install-4.19.2+20260819.100000-images.csv
ibm-cp-common-services-4.19.2+20260819.100000.tgz
```

From the output, consider only the `.tgz` files and exclude the main `ibm-cp-common-services` CASE archive. The following are the additional CASE archives that must be mirrored:

```
ibm-events-operator-5.2.1.tgz
ibm-cs-iam-4.18.1+20260812.100000.tgz
ibm-cs-install-4.19.2+20260819.100000.tgz
ibm-cp-common-services-4.19.2+20260819.100000.tgz
```

For each of the `.tgz` files found in the directory, run the following commands:

```
./casectl repo update --repoPath /Documents/temp --addCase ~/.ibm-pak/data/cases/ibm-cp-common-services/<filename>.tgz

./casectl repo updateoci --repoPath /Documents/temp --addCase <casename> --addCaseVersion <caseversion> --
artifactRegistry <private-registry-path>
```

Here, `<casename>` represents the name of the case contained within the `.tgz` files, and `<caseversion>` represents the version of these supplementary cases. Derive the `<casename>` and `<caseversion>` from the `.tgz` file in the following manner:

File name	Case name	Case version
ibm-cs-install-4.19.2.tgz	ibm-cs-install	4.19.2
ibm-cloud-native-postgresql-5.22.0+20251001.142254.2660.tgz	ibm-cloud-native-postgresql	5.22.0

8. Mirror images for Red Hat OpenShift AI as follows:

- Mirror images for Red Hat OpenShift AI version 2.2, which is required for installing IBM watsonx.ai and watsonx Orchestrate version 5.4.0. For detailed mirroring procedures and prerequisites, see [Mirroring images to a private registry for a disconnected installation](#).

9. Log in to your Docker registry as follows:

- a. Log in to the IBM Entitled Container Registry by using the IBM entitlement key:

```
docker login cp.icr.io -u cp -p <your entitlement key>
```

Note: Your entitlement key for IBM Fusion HCI must contain the correct entitlement.

Set the following environment variables:

```
export LOCAL_ISF_REGISTRY="<Your enterprise registry host>:<port>"
export LOCAL_ISF_REPOSITORY="<Your image path>"
export TARGET_PATH="$LOCAL_ISF_REGISTRY/$LOCAL_ISF_REPOSITORY"
echo "$TARGET_PATH"
export SRC_REGISTRY="cp.icr.io"
export SRC_NAMESPACE="fsh-dev"
export TAG="v1.0.7"
```

Note: Port is a non-mandatory value when you set the `LOCAL_ISF_REGISTRY` variable. If your enterprise registry is accessible and has a secure connection, ignore it.

Sample value for without port:

```
export LOCAL_ISF_REGISTRY="registryhost.com"
```

See the following sample values:

```
export LOCAL_ISF_REGISTRY="registryhost.com:443"
export LOCAL_ISF_REPOSITORY="fusion-mirror"
```

- b. Run the command to login to the Docker registry with your enterprise registry credentials.

```
docker login $LOCAL_ISF_REGISTRY -u <your enterprise registry username> -p <your enterprise registry password>
```

`LOCAL_ISF_REGISTRY` is your entitlement registry.

`LOCAL_ISF_REPOSITORY` is the image path in which you want to mirror the images. You can choose your own repository paths. For example, `hci-images/isf` or `hci-images`.

- c. Mirror operator catalog, image, and bundle.

- i. Copy operator catalog from source registry:

```
skopeo copy --all
"docker://${SRC_REGISTRY}/${SRC_NAMESPACE}/copen/ibm-fsh-operator-catalog:${TAG}"
"docker://${TARGET_PATH}/ibm-fsh-operator-catalog:${TAG}"
--tls-verify=false
```

- ii. Copy operator image from source registry:

```
skopeo copy --all
"docker://${SRC_REGISTRY}/${SRC_NAMESPACE}/cp/ibm-fsh-operator:${TAG}"
```

```
"docker://${TARGET_PATH}/ibm-fsh-operator:${TAG}"
--tls-verify=false
```

iii. Copy operator bundle from source registry:

```
skopeo copy --all
"docker://${SRC_REGISTRY}/${SRC_NAMESPACE}/copen/ibm-fsh-operator-bundle:${TAG}"
"docker://${TARGET_PATH}/ibm-fsh-operator-bundle:${TAG}"
--tls-verify=false
```

d. Apply the IDMS and ITMS objects to your cluster:

```
---
apiVersion: config.openshift.io/v1
kind: ImageDigestMirrorSet
metadata:
  name: ibm-fsh-idms
spec:
  imageDigestMirrors:
  - mirrors:
    - <Your enterprise registry host>:<port>/<Your mirror path>
    source: cp.icr.io/copen
  - mirrors:
    - <Your enterprise registry host>:<port>/<Your mirror path>
    source: icr.io/copen

---
apiVersion: config.openshift.io/v1
kind: ImageTagMirrorSet
metadata:
  name: ibm-fsh-itms
spec:
  imageTagMirrors:
  - mirrors:
    - <Your enterprise registry host>:<port>/<Your mirror path>
    source: cp.icr.io/cp
  - mirrors:
    - <Your enterprise registry host>:<port>/<Your mirror path>
    source: icr.io/copen
```

10. To access the private registry where the images are mirrored, log in using the `cpd-login` command. To do this, open a terminal in the `fsh-ai-operator-xxxx` pod within the `ibm-software-hub-operator` namespace and run the following command:

```
cpd-cli manage login-private-registry <private-registry-path>:<port> <username> <password>
```

11. To mirror the required images, run the following `skopeo` commands for `ibm-events-operator-catalog`, `ibm-events-operator-bundle`, and `kserve-controller`.

```
skopeo copy --all docker://icr.io/copen/ibm-events-operator-catalog:5.2.1 docker://$TARGET_PATH/ai-images/copen/ibm-
events-operator-catalog:5.2.1 --tls-verify=false
skopeo copy --all docker://icr.io/copen/ibm-events-operator-bundle:5.2.1 docker://$TARGET_PATH/ai-images/copen/ibm-
events-operator-bundle:5.2.1 --tls-verify=false
skopeo copy --all docker://quay.io/modh/kserve-
controller@sha256:67672b25f5e4c2ba5457d29f0c5ae5b7e0ec3b635bf58a79892306ddda30ac2a docker://$TARGET_PATH/ai-
images/rhoai/kserve-controller:sha256-67672b25f5e4c2ba5457d29f0c5ae5b7e0ec3b635bf58a79892306ddda30ac2a
skopeo copy --all docker://cp.icr.io/cp/cpd/ibm-slate-30m-
english@sha256:4d6b902d158dc946d7f3c7a0c373821e041a44b78267b319cb171cf71dba6355 docker://$TARGET_PATH/ai-
images/cp/cpd/ibm-slate-30m-english@sha256:4d6b902d158dc946d7f3c7a0c373821e041a44b78267b319cb171cf71dba6355
```

12. In the OpenShift Container Platform cluster, add `ImageDigestMirrorSet` and `ImageTagMirrorSet`:

ImageDigestMirrorSet (IDMS)

```
apiVersion: config.openshift.io/v1
kind: ImageDigestMirrorSet
metadata:
  name: ai-services-idms
spec:
  imageDigestMirrors:
  - mirrors:
    - <private-registry-path>:port/ai-images/cp
    source: cp.icr.io/cp
  - mirrors:
    - <private-registry-path>:port/ai-images/cp/cpd
    source: cp.icr.io/cp/cpd
  - mirrors:
    - <private-registry-path>:port/ai-images/copen
    source: icr.io/copen
  - mirrors:
    - <private-registry-path>:port/ai-images/db2u
    source: icr.io/db2u
  - mirrors:
    - <private-registry-path>:port/ai-images/copen/cpfs
    source: icr.io/copen/cpfs
  - mirrors:
    - <private-registry-path>:port/ai-images/copen
    source: cp.icr.io/copen
  - mirrors:
    - <private-registry-path>:port/ai-images/rhoai
    source: quay.io/modh
```

ImageTagMirrorSet (ITMS)

```
apiVersion: config.openshift.io/v1
kind: ImageTagMirrorSet
```

```

metadata:
  name: ai-service-itms
spec:
  imageTagMirrors:
    - mirrors:
      - <private-registry-path>:port/ai-images/cp
        source: cp.icr.io/cp
    - mirrors:
      - <private-registry-path>:port/ai-images/cp/cpd
        source: cp.icr.io/cp/cpd
    - mirrors:
      - <private-registry-path>:port/ai-images/cpopen
        source: icr.io/cpopen
    - mirrors:
      - <private-registry-path>:port/ai-images/db2u
        source: icr.io/db2u
    - mirrors:
      - <private-registry-path>:port/ai-images/cpopen/cpfs
        source: icr.io/cpopen/cpfs
    - mirrors:
      - <private-registry-path>:port/ai-images/cpopen
        source: cp.icr.io/cpopen
    - mirrors:
      - <private-registry-path>:port/ai-images/rhoai
        source: quay.io/modh

```

Troubleshooting and known issues in offline mirroring

Issues can occur during the offline mirroring of images. This topic outlines known issues and offers troubleshooting guidance.

oc-mirror command fails with unauthorized error

Problem statement

The **oc-mirror** command fails with an **unauthorized: access to the requested resource is not authorized** error.

Cause

The error occurs due to one of the following reasons:

- Insufficient authentication credentials for the registries mentioned in the command.
- Incorrect or missing secrets in the docker configuration file.

Resolution

Follow the steps to resolve the issue:

1. Ensure you are logged in to the registries mentioned in the **oc-mirror** command.
2. Verify that the `~/.docker/config.json` file contains the correct secrets for the registries.
 - If the file does not exist, create it manually.
 - Add the required registry credentials to the file.
3. After completing the preceding steps, retry the **oc-mirror** command. If the issue persists, review the registry credentials and docker configuration file for accuracy.

oc-mirror v2 fails with an error stat .: no such file or directory

Problem statement

The **oc-mirror** v2 fails with an error **stat .: no such file or directory**.

Resolution

As a resolution, install the **oc-mirror** CLI plug-in of **4.20.6** version.

Use the latest versions of the oc and oc-mirror tools

Problem statement

Issues may occur when you do not use the latest version of the **oc** CLI or **oc-mirror** plug in.

Diagnosis

Red Hat® has identified several library compatibility issues in the older versions of these tools, which are resolved in the latest releases. When you run older versions of **oc** or **oc-mirror** commands, you may encounter messages similar to the following examples.

```

oc: /lib/x86_64-linux-gnu/libc.so.6: version `GLIBC_2.33' not found (required by oc)
oc: /lib/x86_64-linux-gnu/libc.so.6: version `GLIBC_2.34' not found (required by oc)
oc: /lib/x86_64-linux-gnu/libc.so.6: version `GLIBC_2.32' not found (required by oc)

```

Resolution

Download the latest available **oc** CLI tool, even if it is a newer than your Red Hat OpenShift® version. The **oc** CLI is backward compatible with older OpenShift versions. For example, your **oc** CLI can be on version 4.17 while your OpenShift cluster remains on 4.14.

In addition, ensure you obtain the latest version of the **oc-mirror** plugin. The **oc-mirror** plugin need not match the **oc** CLI version and can even be newer. For example, you can use an **oc-mirror** plugin 4.17 with an **oc** CLI 4.16, even if your cluster is on 4.14.

Login to both source and target registries before mirroring images

Problem statement

You may encounter issues where some or all images fail to copy, resulting in errors related to either authorization or authentication requirements.

Diagnosis

If you encounter messages similar to the following examples, then it indicates that you must login to the specified registries:

- error: unable to retrieve source image cp.icr.io/cp/isf/isf-prereq-operator manifest sha256:1d062784dd6818297bd8275d139d0dd7ac6cd2ae6a4188bb3258bcdad8ccedf4:
Get "https://cp.icr.io/v2/cp/isf/isf-prereq-operator/manifests/sha256:1d062784dd6818297bd8275d139d0dd7ac6cd2ae6a4188bb3258bcdad8ccedf4":
unauthorized: Authorization required. See https://cloud.ibm.com/docs/Registry?topic=Registry-troubleshoot-auth-req
- Checking push permissions for docker-na-public.artifactory.swg-devops.com
error: error checking push permissions for docker-na-public.artifactory.swg-devops.com:
creating push check transport for docker-na-public.artifactory.swg-devops.com failed:
GET https://docker-na-public.artifactory.swg-devops.com/artifactory/api/docker/null/v2/token?scope=repository%3Aoffline%2A: Authentication is required

Resolution

As a resolution, log in to all the registries:

- registry.redhat.io
- icr.io
- quay.io
- Your target registry host

Also, create a `.docker/config.json` file in MGen with

- registry.redhat.io
- icr.io
- quay.io
- Your target registry host

If authorization errors persist even after logging, it indicates that your user does not have the right permissions to pull from the source registries or push to target registries. In such a case, contact your registry administrator regarding your user permissions

Check available disk space

Problem statement

If repeated retries of **oc-mirror** continue to fail, it is possible that the target registry has run out of disk space. Additionally, if you mirror to a local directory for offline install media, your local disk may be full.

Resolution

Check disk space usage and free up disk space if necessary.

Error with HTTP status: 504 Gateway Timeout or no space left on device

Problem statement

The **oc-mirror** operation may fail with an error message similar to the following example:

```
Rendering catalog image
"our.offline-registry.net/fusion-hci-2.9.0/cpopen/isf-operator-catalog:f34ee5" with file-based catalog
error: error rebuilding catalog images from file-based catalogs:
error regenerating the cache for our.offline-registry.net /fusion-hci-2.9.0/cpopen/isf-operator-catalog:f34ee5: exit status 1
```

Resolution

This is a known issue in the **oc-mirror** tool. For more information about how to resolve the issue, see the [Red Hat article](#).

Error with HTTP status: 502 Bad Gateway

Problem statement

The **oc-mirror** operation may fail with an error message similar to the following example:

```
error: unable to retrieve source image registry.redhat.io/amq-streams/kafka-35-rhel8 manifest sha256:e4b2073b3001502b3bd02275e
error: unable to retrieve source image registry.access.redhat.com/ubi8/openjdk-11 manifest sha256:d9739b266415be7c915daf3c61f8
error: an error occurred during planning
```

Resolution

As a resolution, retry the **oc-mirror** command.

Error with HTTP status: 504 Gateway Timeout or no space left on the device

Problem statement

The **oc-mirror** operation may fail with an error message similar to the following example:

```
error: unable to retrieve source image registry.redhat.io/amq-streams/kafka-35-rhel8 manifest #3 from manifest list: received
error: unable to retrieve source image registry.redhat.io/amq-streams/kafka-35-rhel8 manifest #1 from manifest list: received
error: unable to retrieve source image registry.redhat.io/amq-streams/kafka-35-rhel8 manifest #1 from manifest list: received
error: an error occurred during planning
```

Resolution

1. Run the following command:

```
rm -rf /root/.oc-mirror
```

2. Retry the **oc-mirror** command.

Quay on IBM Fusion HCI

How to setup Quay and S3 for Quay.

To setup Quay and S3 for Quay, see <https://access.redhat.com/products/red-hat-quay/>.

Also, when the local storage is Global Data Platform service, see [Data Foundation for MCG only](#).

When the local storage is Data Foundation service, you can use the Data Foundation service provided object storage. .

Converting a rack from internal registry to offline using enterprise registry

Use the following instructions to convert a rack from internal registry to offline using enterprise registry on the IBM Fusion HCI cluster.

Procedure

1. Mirror the images of the cluster to an external registry. For more information, see [Enterprise registry for IBM Fusion HCI installation](#).

Note: All images must be mirrored by using the same versions as those in the internal registry cluster.

2. Convert the rack from internal registry to offline:

- a. If the certificate is self-sign certificate or not a well-known authority signed certificate, add the certificate to the cluster manually:

Note: Replace the following variables with appropriate values:

- Replace **repo** with the enterprise registry where the images are mirrored.
- Replace **port** with the port number of the enterprise registry.
- Use **certificate.crt** as the file that contains the enterprise registry certificates.
- If the registry does not require a port, use **--from-file=[repo]=[certificate.crt]** instead.

```
oc create configmap registry-cas -n openshift-config --from-file=[repo]..[port]=[certificate.crt] --dry-run=client -o
yaml | oc apply -f -
```

- b. Update the required IDMS, ITMS, or **catalogsources** that are generated during step 1 in the cluster. This action triggers an MachineConfigPool (MCP) rollout. Wait for it to complete.
- c. Update the pull-secret in the cluster:
 - i. Go to OpenShift UI and search for secret **pull-secret** in the **openshift-config** namespace.
 - ii. Click the Actions dropdown and select Edit Secret.
 - iii. Click Add credentials and update the enterprise registry details.
 - iv. Click Remove credentials to delete the previous entry of the internal registry.
 - v. Click Save.This action triggers an MCP rollout. Wait for it to complete.

Results

The rack is converted from internal registry to offline using enterprise registry.

Converting a rack from online proxy to offline using external Quay

Use the following instructions to convert a rack from online proxy to offline using external quay on the IBM Fusion HCI cluster.

Procedure

1. Mirror the images of the cluster to an external repo. For more information, see [Enterprise registry for IBM Fusion HCI installation](#).

Note: Mirroring of all operators must be of the same version, as it is in the online cluster.

2. Remove cluster-wise proxy details:

Remove proxy details from **userconfig_secret**

- a. Log in to the OpenShift web console and go to Workloads > Secrets.
- b. Click userconfig-secret.
- c. From the Actions dropdown, select Edit Secret.
- d. Update the following values:
 - i. Set **isProxy** to **false**. The default value is **true** since the cluster is installed as proxy.
 - ii. Clear the values for **proxy_host**, **proxy_password**, **proxy_port**, and **proxy_username** (for example: **proxy_password=**'').

Remove proxy details from the proxy custom resource (CR):

- a. In the OpenShift web console, go to Administration > CustomResourceDefinitions, and search for **Proxy**.
- b. Click the **Proxy** named CR, and then click Instances.
- c. Click cluster and edit the YAML.
- d. Remove the proxy details under the **spec** section (**httpProxy**, **httpsProxy**, and **noProxy**), and save the changes.

This step triggers a Machine Config Pool (MCP) roll out. Allow the rollout to complete.

3. If the certificate is self-sign certificate or not a well-known authority signed certificate, add the certificate to the cluster manually:

```
oc create configmap registry-cas -n openshift-config --from-file=[repo]..[port]=[certificate.crt]
oc patch image.config.openshift.io/cluster --type=merge -p '{"spec":{"additionalTrustedCA":{"name":"registry-cas"}}}'
```

To verify that **registry-cas** is added to the nodes, follow these steps:

- a. Log in to the node:

```
oc debug node/[nodename]
```

- b. Run the following command on the node to switch to the host environment:

```
chroot /host
```

- c. Go to the certificates directory:

```
cd /etc/docker/certs.d
```

- d. List the contents of the directory:

```
ls
```

The certificate must be present in this directory.

4. Disable call home and AOS: In the offline system, call home is not supported. For more information, see [Disabling Call Home](#).

- a. In the IBM Fusion user interface, go to Settings > Support Toggle to disable remote support.
b. Click Edit for call home and disable the call home support.

Note:

- For offline system, call home can be enabled by configuring proxy for call home. For more information, see [Configuring Call Home with proxy](#).
- For offline system, AOS can be enabled by configuring proxy for AOS. For more information, see [Enabling remote support through user interface](#).

5. Convert the rack from online to offline:

- a. Add IDMS, ITMS, and catalog source for the offline repository, for IBM Fusion, Red Hat and services.
b. Add a new registry pull secret.
This action triggers a MCP rollout. Allow the rollout to complete.

- c. Remove online pull-secrets from the cluster.
This action triggers a MCP rollout. Allow the rollout to complete.

- d. Run the following command to disable the default catalog:

```
oc patch OperatorHub cluster --type=json -p='[{"op":"add","path":"/spec/disableAllDefaultSources","value":true}]'
```

6. Update **CatalogSource fusion-catalog** image to offline repo path for **isf-operator-catalog**.

```
spec:
  displayName: IBM Storage Fusion Catalog
  image:
```

Verify no issues are observed after updating **CatalogSource**.

Results

MCP is triggered and the cluster is converted to offline.

Activate your subscriptions and entitlements

Before you install IBM Storage Fusion HCI, activate your IBM software subscriptions and entitlements to ensure that your deployment is licensed and supported.

Content and metadata for this topic will be provided.

- [Activating Red Hat OpenShift Container Platform subscriptions purchased from IBM](#)
If you purchased your Red Hat® OpenShift® Container Platform subscription from IBM, then you must activate your OpenShift subscription with Red Hat and activate OpenShift support with IBM.
- [Activating IBM Fusion HCI Software to be downloaded](#)
You need IBM Fusion HCI software entitlement to access IBM Fusion HCI images that are used to install your IBM Fusion HCI appliance.
- [How to Activate NVIDIA AI Enterprise Subscriptions](#)
NVIDIA H100 NVL and H200 NVL GPUs are bundled with a five-year subscription to NVIDIA AI Enterprise.

Activating Red Hat OpenShift Container Platform subscriptions purchased from IBM

If you purchased your Red Hat® OpenShift® Container Platform subscription from IBM, then you must activate your OpenShift subscription with Red Hat and activate OpenShift support with IBM.

About this task

IBM Fusion HCI base cluster can be used with any of the four distributions of OpenShift: Red Hat OpenShift Virtualization Engine (OVE), OpenShift Kubernetes Engine (OKE), OpenShift Container Platform, or OpenShift Platform Plus (OPP). For more information about the subscriptions, see [Red Hat OpenShift distributions](#).

Procedure

1. Activate your OpenShift subscription with Red Hat.

Open an account in the Red Hat Customer Portal: <https://access.redhat.com/>. If you already have an account, you do not need to open a new account.

Contact Red Hat at openshift-orders@redhat.com, requesting OpenShift subscription activation. Provide your Red Hat Customer Portal id and IBM Software Order number for your OpenShift purchase in the email.

You can find the Order Number on your purchase invoice. The Order Number can be a 6-character number, and it can be similar to the following sample formats:

- LCxxxx
- LDxxxx
- A3xxxx
- A4xxxx

2. Activate OpenShift support with IBM.

Complete the following steps to accept the IBM support agreement:

- a. Access the Agreements for IBM Software Support Services website - www.ibm.biz/tss-agreements. On the website, select the Agreement for IBM Support for Commercial Open Source for the country or region in which the software is installed (Agreement).
- b. Print and read the Agreement. The Agreement terms govern the Service. By your ordering, making payment for, or using the Service, you accept the terms and Agreement without modification. Service becomes subject to this Agreement when IBM or your IBM Business Partner accepts your order or payment.

- **Red Hat OpenShift distributions**

IBM Fusion HCI base cluster can be used with any of the four distributions of OpenShift: Red Hat OpenShift Virtualization Engine (OVE), OpenShift Kubernetes Engine (OKE), OpenShift Container Platform, or OpenShift Platform Plus (OPP).

Red Hat OpenShift distributions

IBM Fusion HCI base cluster can be used with any of the four distributions of OpenShift®: Red Hat OpenShift Virtualization Engine (OVE), OpenShift Kubernetes Engine (OKE), OpenShift Container Platform, or OpenShift Platform Plus (OPP).

Important: You must follow the terms and conditions of Red Hat® to use these different distributions. For more information about these terms and conditions, see [Red Hat Subscription Guide](#).

Red Hat OpenShift Virtualization Engine (OVE)

For organizations that want to run and manage Virtual Machines (VMs) on the same platform as containers without a separate virtualization stack. For example, VMware.

IBM Fusion services permitted for use with OVE in support of virtual machines include:

- Fusion Data Foundation including MCG, Scale CNSA, Backup & Restore Spoke, Fusion Control Tower are permitted to run on infrastructure nodes.
- IBM Data Cataloging, Backup & Restore Hub and Fusion Base can be deployed as containers on OVE but must run on normal worker nodes.

OpenShift Kubernetes Engine (OKE)

For organizations who want a lightweight, Kubernetes-only platform with enterprise support.

Warning: IBM Fusion enables monitoring of user-defined objects at the time of installation. User-defined monitoring is not supported for users with OKE license. To remain compliant with your license agreement, disable user-defined monitoring. Continuing to use this feature can result in a violation of your contract. For more information on how to disable user-defined monitoring, see the [Red Hat documentation](#).

OpenShift Container Platform

To provide a full-featured enterprise container platform with DevOps tools, monitoring, networking, and security. Also, for enterprises with complex, multi-cluster, or hybrid cloud environments that need unified governance and security.

OpenShift Platform Plus

For enterprises with complex, multi-cluster, or hybrid cloud environments that need unified governance and security.

Activating IBM Fusion HCI Software to be downloaded

You need IBM Fusion HCI software entitlement to access IBM Fusion HCI images that are used to install your IBM Fusion HCI appliance.

Before you begin

The procedure that you use to generate your entitlement key depends on how your IBM Fusion HCI was ordered:

- If your IBM Fusion HCI was ordered as a hardware bundle (Machine Type **9155**), use the **Entitled Systems Support (ESS)** procedure.
 - If your IBM Fusion HCI was ordered as a software-only product via Passport Advantage (Machine Type **9855**), use the **Passport Advantage (PPA)** procedure. The *Before you begin* checklist items below (ICN, order number, and serial number) are not required for the PPA procedure; proceed directly to the *Passport Advantage (PPA)* section.
1. Sign up for an IBMid. If you already have an IBMid, skip this step. You can sign up for an IBMid here: <https://www.ibm.com/account/reg/us-en/signup?formid=urx-19776A>. It is a best practice to use your company email address for your IBMid.

2. If you are using the **ESS procedure (MT 9155)**, ensure that you have the following information. If you are using the **PPA procedure (MT 9855)**, skip this step and go directly to the *Passport Advantage (PPA)* section.

This information can be retrieved from the IBM Invoice of your IBM Fusion HCI purchase. You can request the invoice from your internal buyer, IBM Sales Representative, or your Business Partner. If you are a Business Partner, you can request the invoice from your Distributor.

- IBM Customer Number (ICN)
Clients can have multiple IBM Customer Numbers. You need the ICN that was used for your purchase of IBM Fusion HCI. Your seller or business partner can provide this number.
- Order number
It is also called an Internal Order Number. An Order number can be a 6-character number that might look like the following example formats:
 - LCxxxx
 - LDxxxx
 - A3xxxx
 - A4xxxx
- Serial number of a IBM Fusion HCI component:
Examples for 7-character serial numbers:
 - 85xxxxx
 - 78xxxxx
 - RMxxxxx
 - 66xxxxx
 - 68xxxxx

Method 1

Serial number of IBM Fusion HCI Software, 5771-PP7. You can find multiple 5771-PP7 serial numbers in the invoice, but you need only one of them to complete this process.

Method 2

Serial number of a IBM Fusion HCI hardware component. This method might be useful if you have your ICN but you do not have access to your IBM Invoice. IBM Fusion HCI hardware serial numbers can be found on the documents that are shipped with your IBM Fusion HCI. IBM Fusion HCI hardware components have machine type 9155. You find multiple serial numbers for 9155 components. You only need one serial number from one of the following components to proceed: 9155-C00, 9155-C01, 9155-C04, or 9155-C05.

Generate entitlement key

Use the procedure that matches how your IBM Fusion HCI was ordered: **ESS** for hardware orders (MT 9155) or **PPA** for software-only orders (MT 9855).

Entitled Systems Support (ESS)

Your purchase of IBM Fusion HCI Software, 5771-PP7, and IBM Fusion HCI hardware is recorded in the IBM Entitled Systems Support (ESS) portal (<https://www.ibm.com/servers/eserver/ess/landing/index.html>). For more information about the registration process, see <https://www.ibm.com/docs/en/entitled-systems-support>.

IBM Fusion HCI software is made available for installation into your OpenShift® cluster by using an entitlement key that is generated with your IBMid in My IBM (<https://www.ibm.com/account/us-en/>). The entitlement key grants access to IBM Fusion HCI software that resides in the IBM Container Registry (ICR).

To enable your IBMid to generate an entitlement key with permission to access IBM Fusion HCI software in the ICR, you must follow the procedure to register your IBM Fusion HCI purchase in the IBM Entitled Systems Support portal:

1. Go to website (<http://www.ibm.com/eserver/ess>) and click Log in.

2. When the login is complete, click My Profile avatar in the title bar and select Register Customer Number.
3. Select the country and enter your IBM Customer Number (ICN). If you receive a message that the ICN is already registered, no further action is required.
4. Register an IBM Fusion HCI serial number. Use one of the serial numbers from either Method 1 or Method 2 that is mentioned in the *Before you begin* section.
5. In Authentications, select Hardware or Software serial number and then enter the IBM Fusion HCI serial number.

Authentications (Select one of the following)

☐ Order number

☐ SWMA Contract number

☐ System number

☒ Hardware or Software serial number

Access to Software Download only

Submit

Cancel

6. Click Submit.
7. Log in to [IBM product services dashboard](#) with your IBMid.
8. Go to Entitlement keys.
9. Click Add new key to generate a key.
If you have an existing key, then click Copy to get the key and use.

10. Run the following commands to validate the key:

```
docker login cp.icr.io -u cp -p ${key}

docker pull cp.icr.io/cp/isf/isf-validate-
entitlement@sha256:1a0dbf7c537f02dc0091e3abebae0ccac83da6aa147529f5de49af0f23cd9e8e
```

Note: After you complete the registration, start to pull the images even if the entitlement does not show up in the [software container library](#).
For installation procedure, see [Installing IBM Fusion HCI](#).

Passport Advantage (PPA)

IBM Fusion HCI that is ordered as a software-only product (Machine Type 9855) uses Passport Advantage for entitlement. **ESS registration is not required and is not used for this purchase type.** The IBMid that you use must be linked to the IBM Customer Number (ICN) that was used to purchase the system.

To generate the entitlement key, follow these steps:

1. Log in to the [IBM container software library](#) with the IBMid that is linked to the ICN used to purchase your IBM Fusion HCI.
2. Go to Container software library > Passport Advantage Online.
3. Verify that an IBM Fusion subscription is present. If the subscription is not visible, contact your IBM Sales Representative or Business Partner to confirm that the entitlement is associated with your IBMid and ICN.
4. Go to Entitlement keys and click Add new key to generate a key. If you have an existing key, click Copy to use it.
5. Save the key to a secure location for future use.
6. Run the following commands to validate the key:

```
docker login cp.icr.io -u cp -p ${key}

docker pull cp.icr.io/cp/isf/isf-validate-
entitlement@sha256:1a0dbf7c537f02dc0091e3abebae0ccac83da6aa147529f5de49af0f23cd9e8e
```

How to Activate NVIDIA AI Enterprise Subscriptions

NVIDIA H100 NVL and H200 NVL GPUs are bundled with a five-year subscription to NVIDIA AI Enterprise.

You can activate your subscription by following the instructions here: [Activate your NVIDIA AI Enterprise License](#).

To activate your NVIDIA AI Enterprise license, you require the serial number of your NVL GPU. To find the serial number, log into the OpenShift® Cluster as an administrator and run the following command:

```
oc get cmo monitoring-compute-1-ru25 -o jsonpath='{.status.nodes[0].processorInfos}'
```

If you have L40S GPU, then you can use the 90-day evaluation licenses available directly from NVIDIA NGC™. See [NVIDIA AI Enterprise Trial](#).

Important: IBM does not provide support for NVIDIA AI Enterprise. You must work directly with NVIDIA to get support for your subscriptions.

Run the installation

Before you begin the installation of IBM Storage Fusion HCI, confirm that your environment meets all prerequisites and that your site, network, registry, and software access are ready.

After you confirm that all prerequisites in the planning sections are met, complete the following tasks to install IBM Fusion HCI:

- **Run the installation wizard.** Use the two-stage installation wizard to configure your network, set up your image registry, and initialize the OpenShift® cluster and IBM Fusion HCI management software.
- **Validate your installation.** Confirm that all components are running as expected and collect installation log files.
- **Install your services.** Enable the IBM Fusion HCI services that your workloads require.
- **Resolve installation issues.** If the installation encounters errors, use the troubleshooting topics to diagnose and fix the problem before you proceed.
- **Installing IBM Fusion HCI**
Use this procedure to install IBM Fusion HCI stage 2.
- **Validate your installation**
After you install IBM Storage Fusion HCI, validate that the installation completed successfully and that all components are running as expected.
- **Install your IBM Fusion HCI services**
In the service-based IBM Fusion HCI, choose the features that you want to deploy.
- **Resolve installation issues**
If your IBM Storage Fusion HCI installation does not complete successfully, use the following resources to diagnose and resolve common installation issues.

Installing IBM Fusion HCI

Use this procedure to install IBM Fusion HCI stage 2.

Before you begin

- IBM Fusion HCI requires Red Hat® OpenShift® Container Platform. If you purchased OpenShift subscriptions from IBM, see [Activating Red Hat OpenShift Container Platform subscriptions purchased from IBM](#). For the supported version of Red Hat OpenShift Container Platform, see [Support matrix](#). For other compatible OpenShift distributions, see [Red Hat OpenShift distributions](#).
 - Before the installation of IBM Fusion HCI, enable IBM Fusion HCI Software to be downloaded. For steps to enable, see [Activating IBM Fusion HCI Software to be downloaded](#).
 - Go through the installation prerequisites and ensure that they are all met before you go ahead with your installation. See [Installation prerequisites](#).
 - For two-availability-zone and arbiter node (2AZ and arbiter node) configuration, complete the network planning and meet all prerequisites mentioned in [Network for two-availability-zone and arbiter node \(2AZ and arbiter node\) configuration](#).
 - For the installation sequence in a disaster recovery setup, see [Installing IBM Fusion HCI in a Metro-DR setup](#).
 - To enable remote support so that the IBM Support team can assist with the installation, follow these steps:
 1. Go to the URL provided by your IBM Systems Support Representative (SSR).
The format of the URL is `https://<host IP address>:3000/isfsetup`.
 2. In Login, enter the Username and Password and click Log in.
The default credentials are Username `service-node-client` and Password `passw0rd`.
 3. In the License agreement window, select I accept the license agreement.
 4. In the title bar, click (?) (Help) and select Support.
 5. In the Support settings pane, enter the contact information, optional proxy server details, and enable the remote support option.
After you enable the remote support, you can start or stop remote sessions. For the actual procedure, see [Enabling remote support](#).
- If you have proxy connection, you can use this remote support feature for offline installation also.
- The rack discovery fails for HA MR with static IP. For more information about the workaround steps, see [Workaround for HA MR static IP](#).

About this task

IBM Fusion HCI comes with the bootstrapping software that is installed from the factory. The IBM support representative completes the initial verification and physically connects the system to network and power. Then, they conduct the network setup of the appliance (stage 1), which connects the appliance to the data center network. This procedure configures all the default nodes (three controllers and three compute nodes). If you ordered more nodes, then they get installed as well. For high available multi rack, the IBM support representative completes the initial verification and physically connects the three racks to network and power. Then, they conduct the network setup of the first two racks which are called auxiliary racks. Network setup of the third, also known as last rack, is done after the first two racks. The network setup validates hardware and wiring of rack and connects the rack to the data centre network. This procedure configures all the default nodes. During network setup of last rack, software collects network configuration details from first two racks automatically and shows consolidated appliance view. After the network setup (stage 1) is completed for all three racks, IBM SSR provides stage 2 URL so you can continue next phase of install that is explained in the following procedure.

Note: For basic guidance on stage 2 of installation in a disaster recovery setup, see [Installing IBM Fusion HCI in a Metro-DR setup](#).

Procedure

1. Go to the URL provided by your IBM Systems Support Representative (SSR).
The format of the URL is `https://<host IP address>:3000/isfsetup`.
Note: If you close your browser anytime before the completion of stage 2, then open the URL again to go back to its last state.
Important: Do not add, change, or remove any files at any time.
2. In Login, enter the Username and Password and click Log in.
The default credentials are Username `service-node-client` and Password `passw0rd`.
3. In the License agreement window, select I accept the license agreement.

4. In Create login, enter a new Username and Password for the service node.
In the Create login page, you are prompted to create a different username and password. You need to create new credentials because the default credentials are deleted as soon as the stage 2 installation begins. The password must be at least 8 characters long and include uppercase letters, lowercase letters, numbers, and special characters. After you change the password, use the new username for subsequent logins. If you enter an incorrect password for the same username more than six times within one minute, access to that username is locked out for the next 10 minutes.
5. Click Next.
6. Configure support assistance.
 - a. Enter contact information:
In the Contact information section, provide the primary support contact details:
 - i. Enter Company name.
 - ii. Enter Customer number.
 - iii. Enter Primary contact name.
 - iv. Enter Primary email address.
 - v. Enter Primary phone number:
 1. Select the country code.
 2. Enter the phone number.
 - b. Provide the data center location:
In the Data center section, enter the physical location details:
 - i. Enter Address line 1.
 - ii. Enter Address line 2 (optional).
 - iii. Enter City.
 - iv. Enter State/Province/Region.
 - v. Enter Zip/Postal code.
 - vi. Select the appropriate Country from the drop-down list.
 - c. Configure Call Home settings:
The Call Home feature enables automatic upload of telemetry and logs to IBM Support for faster issue resolution.
Select a Connection type:
 - Direct connection: Uses a direct internet connection to IBM Support.
 - Open proxy: Requires proxy host and port.
 - Basic authentication: Requires a proxy with username and password.
 - Certificate authentication: Requires certificate-based proxy authentication.
 For more information, see [Configuring Call Home with proxy](#).
 - d. Configure remote access:
The remote access feature enables secure, on-demand access for IBM Support to troubleshoot issues when required. Every session is initiated with explicit user approval.
 - i. Toggle Remote access to Enabled to allow support connectivity.
 - ii. Select a Connection type:
 - Direct connection: Uses a direct internet connection to IBM Support.
 - Open proxy: Requires proxy host and port.
 - Basic authentication: Requires a proxy with username and password.
7. Configure network:
The Network precheck page runs an automatic network check against all nodes in the appliance. It checks whether each node has an assigned IP address and hostname. If it is high-availability multi-rack, then you can see the nodes of all the three racks.
 - a. Check whether you can see all your nodes in Connected state.
In a high-availability cluster, it displays all the nodes present in all three racks. If you observe all your nodes in connected state, click Next and go to step [8](#). Any nodes that do not pass the network check shows in Disconnected status.
 - b. If one or more nodes are in a Disconnected state, do the following steps:

DHCP
DHCP, this error means that either DHCP or DNS is not configured for the node. For more information about the prerequisite, see [Setting up DHCP for IBM Fusion HCI](#) and [Setting up DNS](#).

Static
The DNS configuration of the nodes may have issues. For more information about the prerequisite, see [Setting up Static IP](#) and [Setting up DNS](#).
 - c. Work with your network team and confirm that the DHCP or Static and DNS are configured for all nodes in the appliance.
 - d. After you make all the changes, click Retry pre-check connection to initiate a new network check.
 - e. Click Next.
8. In the OpenShift version page, select the version of the OpenShift and click Next.
Important:
 - For Dell hardware, the OpenShift 4.20.28 and 4.22.9 versions are supported with only Data Foundation as a storage.
 - For Lenovo hardware, the OpenShift 4.20.28 and 4.22.9 versions are supported with Data Foundation as a storage, and only 4.20.28 is supported with Global Data Platform as a storage.
9. Set up your image registry:
If you want to use your private image registry, you can install both Red Hat OpenShift and IBM Fusion HCI software from images that are maintained in a container registry that you manage. If you do not want to use your enterprise registry, then skip this step to install Red Hat OpenShift Container Platform and IBM Fusion software by using either the images that are hosted in the Red Hat and IBM entitled registries, or the internal registry hosted within IBM Fusion HCI.
Important: Support is available for self signed, custom certificates, and certificates signed by a well-known CA authority. Also, the self-signed and ingress certificate must be RSA certificates.
 - a. Choose whether to use the Public image registry, Private image registry, or Internal registry option.

Choice	Procedure
Public image registry	To use the public image registry, you need a pull secret and an entitlement key. i. Enter the OpenShift Pull secret. It is an authorization token that stores Docker credentials that you can use to access a registry. Your cluster needs this secret to access and pull OpenShift images from the quay.io container registry. If you do not have a pull secret, click Get Pull secret. It takes you to https://cloud.redhat.com/openshift/install/pull-secret. ii. Enter the IBM entitlement key. It is a product code that is used to pull images from IBM Entitlement Registry. Your cluster needs this key to gain access to IBM Fusion images in the IBM Entitlement Registry. If you do not have a key, click Get Entitlement key. It takes you to IBM Container Library. For steps to obtain the key, see the Activating IBM Fusion HCI Software to be downloaded.

Choice	Procedure
Private image registry	If you select the Private image registry, then first mirror the Red Hat and IBM Fusion images to your private registry. For more information about mirroring, see End-to-end mirroring of IBM Fusion HCI and its services images to the enterprise registry. You can choose to host the Red Hat and IBM Fusion images in separate repositories, or use the same repository. - Single repository Enter the following details for the enterprise registry. - Enter the URL of the private registry in the Repository path. For example, <pre>https://<enterprise registry>:<custom port>/<mirrorpath></pre> If you want to use custom port, then provide the custom port details. - Enter the Username for the private registry. - Enter the API key/ Password for the private registry. - For Image repository, Registry certificate (Optional) section, provide a CA certificate to trust your private registry. If you select the option, then enter the following details: - Select whether the file upload method is File upload or Text input. - If you select File upload, drag and drop your file in the specified box. The maximum size of the file must be 1 MB and the supported file type is crt. - If you select Text input, enter the Custom certificate. - Multiple repositories Enter the following details for both OpenShift images repository and IBM Fusion images repository: - Enter the URL of the respective private image registry OpenShift images repository path or IBM Fusion images repository path in the Repository path field. For example, URLs for OpenShift and IBM Fusion images repository paths: <pre>https://<enterprise registry for IBM Fusion>:<custom port>/<mirrorpath> or https://<enterprise registry for Red Hat OpenShift>:<custom port>/<mirrorpath></pre> See the following sample values: <pre>https://registryhost.com:443/fusion-mirror or https://registryhost.com:443/mirror-ocp</pre> If private registry is configured with a custom port, then provide the port details in URL. - Enter the Username for the private registry. Ensure that this user has access to the private registry. - Enter the API key/ Password for the private registry. - Enter the Proxy server URL (Optional). In both the OpenShift and IBM Fusion image repository sections, this option allows you to specify an alternative registry URL where images are not mirrored to a location but accessible through a proxy URL. - For any of the Image repository > Registry certificate (Optional) section, provide a CA certificate to trust your private registry. If you select the option, then enter the following details: - Select whether the file upload method is File upload or Text input. - If you select File upload, drag and drop your file in the specified box. The maximum size of the file must be 1 MB and the supported file type is crt. - If you select Text input, enter the Custom certificate. Note: - It is applicable for both single and multiple repo sections. - The CA certificate is mandatory only for self-signed certificate registry. This certificate is used to trust your private registry. - Ensure the uploaded CA certificate has external constraint set to true. Run the following openssl command to verify: <pre>openssl x509 -in ssl.cert -noout -ext basicConstraints</pre> Expected output: <pre>`X509v3 Basic Constraints: CA:TRUE`</pre>
Internal registry	If you select the Internal registry option, no images need to be mirrored initially. Select the Internal registry tile and click Next to proceed with installation. The images and internal registry is validated and can take around 30-60 seconds before you proceed to the next page. Note: - If you select the Internal registry for installation, you must mirror the images within three months from the start of installation. - Follow the instructions in Converting a rack from internal registry to offline using enterprise registry to mirror the images and update the pull secret in your cluster. - Only Stage2, Fusion Data Foundation, and Global Data Platform Remote Mount service can be installed by using the Internal registry option. To use other services, you must mirror the required images to the enterprise registry by following the steps mentioned in Converting a rack from internal registry to offline using enterprise registry.

b. Select Connect through a proxy option in Proxy Settings to provide proxy server details to access to your network and image registries.

Enter the IP and port for the proxy server in the Host address and Port fields. If your proxy requires authentication, then enter a Username and Password.

c. Click Next.

If there are any missing images, then an error message is displayed. Click the View details link to know the details of the missing images. Correct the missing image error and click Next. This error can also occur when the IBM Fusion or the OpenShift server is temporarily down.

10. Configure network - OpenShift network and storage network.

The Network settings page shows the OpenShift network to setup OpenShift, and the storage configuration for the internal storage network of IBM Fusion.

To enter values and customize network, see [Network configuration](#).

11. Optional: Ingress certificate:

On the Ingress certificate page, you can optionally configure a custom certificate for OpenShift.

a. Click the Configure now toggle to off to configure OpenShift with a self-signed certificate.

By default, the Configure now toggle is set to on. However, it is recommended that you upload a certificate that is provided by Certificate Authority (CA). Applying a custom certificate during the installation ensures that the certificate is used immediately by OpenShift. If you do not apply custom certificate during installation, then you can do it later from OpenShift. For more information about how to apply custom certificate from OpenShift, see [Ingress Operator in OpenShift](#).

Important: Support is available for self signed, custom certificates, and certificates signed by a well known CA authority. Also, the self-signed and ingress certificate must be RSA certificates.

- b. Drag and drop to upload a .crt file of a size that does not exceed 1 MB or enter the details as text input.
- c. Enter the Private key and click Next. The OpenShift initialization page gets displayed.
- d. Click Finish.

12. Cluster initialization and next steps.

The final step of this phase of installation is to create a three node Red Hat OpenShift cluster and install IBM Fusion software. This minimal cluster is used in the next phase of the installation to orchestrate building out the cluster and configuring storage for IBM Fusion HCI.

- a. Monitor the progress of the OpenShift cluster.

In case of failures, collect logs to analyze the errors. Click Learn more link to see details about the error and steps to troubleshoot the issue. After you fix the issue, click Retry. If you need to change any information entered in previous install steps, click Change install settings.

After the OpenShift cluster gets successfully created, you can view the credentials for the OpenShift cluster.

- b. In the Next steps, > Download and save credentials section, click Download Password and CoreOS key to download and save the kubeadmin password and CoreOS key.

Important: If the Download Credentials step fails during stage 2 installation, see [Contacting IBM Support](#).

Note down the credentials before the installation proceeds with the next phase as you cannot access the OpenShift cluster without these credentials. It is also essential for debugging, system recovery, and reimaging or resetting. In the Downloading Password and CoreOS key window, confirm that you have saved the Password and CoreOS key, and click Continue.

Note: For security reasons, after you download the password and CoreOS key, all the files that have credentials get deleted, such as kickstart, inventory. If there is a failure, then an error message is displayed with details. Fix the error and click Retry link. If retry does not solve the problem, see [Delete files from provisioned node](#).

A window displays the progress of the deletion of all the sensitive service node files. After completion, the window closes automatically and returns to the final page of the installation.

- c. To retrieve the password from the downloaded file in the future, run the following commands:

- i. Go to the Downloads folder:

```
cd ~/Downloads
```

- ii. List the files in the folder:

```
ls -ltr
```

- iii. Extract the contents of ocpkeys compressed file.

- iv. Go to the auth folder:

```
cd clusterconfigs/auth
```

- v. Open kubeadmin-password in edit mode and copy the password:

```
vi kubeadmin-password
```

- vi. Go to the extracted folder /install, save the CoreOS Key:

```
id_rsa
```

- vii. In the installation folder, id_rsa is a CoreOS key that can be used to connect to CoreOS nodes. The folder also includes isfconfig sub folder where you can get the configuration data of the rack. Do not make updates to these files and keep it in safe location for future reference.

- d. In the Login section, copy the Username and Password and save it. Use it to log in to IBM Fusion HCI and Red Hat OpenShift. These credentials are configured as single sign-on between Red Hat OpenShift and IBM Fusion.

Note: After you save the password and download the ocpkey.zip file, the URL points you to the OCP address. If your URL does not automatically point to the OCP address, then check the *Network Preparation* tab in your TDA installation worksheet to ensure that the DNS wildcard domain name is added to the DNS server. Test your connectivity with <https://DNSentryingressendpointipaddress>.

- e. Click IBM Fusion to go to the IBM Fusion HCI user interface.

The login page of the IBM Fusion HCI console displays in a new browser tab.

- f. Enter the credentials that you noted down and click Log in to resume with the installation of other Fusion services.

Note: If there are any issues to access the console, then verify that your DNS server has a wildcard DNS A/AAAA or CNAME record that refers to OpenShift ingress. Test your connectivity <cluster_name>.<base_domain> with https://console-ibm-storage-fusion-ns.apps.<cluster_name>.<base_domain>.

If you encounter errors in the OpenShift installation wizard, see [Installation issues](#). If you encounter errors in the Provisioning and software installation wizard, check the logs. For more information about accessing these logs, see [Collecting log files of final installation](#).

Important: If there arises a need to redeploy IBM Fusion HCI stage 2 installation in the future, contact [Contact IBM Support](#).

What to do next

- Set up a non-kubeadmin cluster-admin user and disable the temporary kubeadmin user. Set up an identity provider for the OpenShift Container Platform cluster. For more information about the management, see [User management](#).
- To verify the installation, see [Validating IBM Fusion HCI installation](#).
- To add more nodes and configure storage, see [Scaling the cluster](#).
- For high-availability cluster, go to IBM Fusion HCI user interface and view rack details. For the procedure to view rack details, see [Adding expansion racks](#).
- For the 2AZ and arbiter node configuration, go to Compute > Nodes in the OpenShift Container Platform web console, and verify that nodes of the cluster have the following names and roles:

Table 1. Nodes of 2AZ and arbiter node deployment

Names	Roles
arbiter-999.<domain.com>	control-plane, master, worker
control-1-ru2.<domain.com>	control-plane, master, worker
control-2-ru2.<domain.com>	control-plane, master, worker

After verifying the nodes, configure Fusion Data Foundation storage by following the instructions mentioned in [Two availability zones and arbiter node configuration with Fusion Data Foundation](#).

- Configure Global Data Platform service or Fusion Data Foundation service before you install additional services. IBM Fusion HCI does not support both Global Data Platform and Fusion Data Foundation services to coexist.

Important:

- The high-availability setup of IBM Fusion HCI does not support Fusion Data Foundation storage option.
- If either Global Data Platform or Fusion Data Foundation are not configured or are configured but are not in a healthy state, then a few pods, like logcollector, might remain in a pending state. The pods come into a running state automatically after the storage is configured and is in a healthy state.

For the procedure to install and work with services, see [Fusion services](#).

- If your cluster is using Fusion Data Foundation for storage, ensure you specify the appropriate storage class as mentioned in the following snippet:

```
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: image-registry-storage
spec:
  storageClassName: ocs-storagecluster-cephfs
  accessModes:
    - ReadWriteMany
  resources:
    requests:
      storage: <desired-storage-size>
```

Replace **desired-storage-size** with the amount of storage you want to allocate. For example, 500Gi, 1Ti.

For Global Data Platform, you can proceed with the default storage class that is available on your cluster.

- Optionally, after the storage is available, configure the OpenShift Container Platform internal image registry. For the procedure to configure, see *Changing the image registry's management state* section and *Configuring registry storage for bare metal and other manual installations* section of [OpenShift documentation](#). Run the following command to make this registry accessible outside the cluster.

```
oc patch configs.imageregistry.operator.openshift.io/cluster --patch '{"spec":{"defaultRoute":true}}' --type=merge
```

- If you want to install Noobaa service, then install Red Hat OpenShift Data Foundation and deploy it as Multicloud Object Gateway (MCG) only mode to provide object service. For the procedure, see [Installing Data Foundation for MCG only](#).
- In a Metro-DR setup, run the following command on both site1 and site2 when stage 2 on site 2 is complete:

Site 1

```
oc -n ibm-spectrum-scale-csi create configmap ibm-spectrum-scale-csi-config --from-literal=VAR_DRIVER_DISCOVER_CG_FILESET=DISABLED
```

Site 2

```
create namespace oc new-project ibm-spectrum-scale-csi

oc -n ibm-spectrum-scale-csi create configmap ibm-spectrum-scale-csi-config --from-literal=VAR_DRIVER_DISCOVER_CG_FILESET=DISABLED
```

- [Network configuration](#)
Steps to configure the Red Hat OpenShift network and storage network. Use the defaults as is and customize only for any special CIDRs network requirements.
- [Installing IBM Fusion HCI in a Metro-DR setup](#)
Use the sequence mentioned in this procedure to install IBM Fusion HCI with Metro-DR setup.

Network configuration

Steps to configure the Red Hat® OpenShift® network and storage network. Use the defaults as is and customize only for any special CIDRs network requirements.

About this task

The Network settings page shows the OpenShift network to setup OpenShift and the storage configuration for the internal storage network of IBM Fusion. You can use the default values in this page and customize values only whenever you have specific network requirements. In the OpenShift network section, you can override the default network CIDRs, which might collide with the data center networks. Also, it provides the flexibility to choose your own range during network planning.

Important:

- If you choose to edit the default values, ensure you remember the following points:
 - The CIDRs defined for the OpenShift network and Storage network do not overlap.
 - Each CIDR is large enough to handle nodes and workloads.
 - All IPs are unused by other systems on the network.
- For high-availability multi rack is only supported with Data Foundation storage and not with Global Data Platform.

Procedure

1. For Metro-DR setup, select whether it is the First cluster or Second cluster.
Note: Metro-DR solution is only supported on Global Data Platform storage.
If it is the second cluster, enter the value for Network configuration snippet:
 - a. Log in to the user interface of the first cluster.
 - b. Go to Disaster Recovery > Overview.
 - c. In the Get started section, copy the network snippet.
 - d. Go back to the installation page of the second cluster and paste it in Network configuration.

During the Metro-DR stretch cluster installation on a secondary site, enable ping on ports 1191 and 12345. For more information about ports that must be enabled with pings, see [IBM Storage Scale port usage](#).

2. In the OpenShift network section, enter the following network configuration for Red Hat OpenShift.

Important:

- 100.64.0.0/16 is reserved for **v4InternalSubnet** by OVN and must not be used for CIDR in OpenShift Container Platform installation.
- Use unique network values for Metro-DR clusters. The following values are pre-populated with unique values. If you want to change these values, ensure that the network setting used between the two Metro-DR sites are not duplicated.
 - a. Enter Pod network CIDR. It is the IP address pools from which pod IP addresses are allocated. The default value is 10.128.0.0/14.
Note: The Pod network CIDR must be different between site 1 and site 2 of Metro-DR.
 - b. Enter Pod network Host Prefix. It is the subnet prefix length to assign to each individual node.
For example, if **hostPrefix** is set to 23, then each node is assigned a /23 subnet out of the given CIDR. A **hostPrefix** value of 23 provides $510 (2^{(32 - 23)} - 2)$ pod IP addresses. The default value is 23.
 - c. Enter Service network CIDR. It is the IP address pool for the services. The default value is 172.30.0.0/16.
Note: The Service network CIDR must be different between site 1 and site 2 of Metro-DR.
 - d. In the Network MTU section, select either of the following values:
 - 9000 MTU is recommended option to maximize performance of features like Hosted Control Plane and Regional Disaster Recovery.
 - 1500 MTU is the default option for older switches to connect IBM Fusion HCI to external networks. Check with you network administrator to understand whether this option is supported.

Important: Ensure that the MTU setting is the same for both clusters in a Metro-DR relationship. The chosen MTU must be same on the complete network infrastructure where the traffic from or to is expected in the cluster.

3. In the Storage network section, enter the following network configuration details for the internal storage network:

Note: The CIDR address, Gateway address, and IP address range must be unique across site 1 and site 2. This is only available in case of Global Data Platform.

- a. Enter CIDR address. It is the network subnet that is used for the multus additional storage network of the scale core pods. The default value is 192.168.128.0/18.
The list of reserved CIDRs are 169.254.169.0/29 and 100.88.0.0/16.
- b. For list of all reserved ranges, see [Red Hat Documentation](#).
- c. Enter the Gateway address. It is the gateway address for the scale core Pods on the multus additional storage network that connects to the other site in a Metro-DR.
Note: In Metro-DR, the gateway must be pre-configured in the customer data center.
- d. Enter the IP address range. It is the IP address pools from which scale core pod IP addresses are allocated for the multus additional storage network. The default range is 192.168.128.11 - 192.168.191.254.
- e. Click Next to go to the Custom certificate wizard page.

Installing IBM Fusion HCI in a Metro-DR setup

Use the sequence mentioned in this procedure to install IBM Fusion HCI with Metro-DR setup.

Before you begin

- For general Metro-DR prerequisites, see [General Metro-DR prerequisites](#).
- For tiebreaker prerequisites, see [Preparing the tiebreaker](#).

Important: Contact [IBM support](#) before you begin the installation of Metro-DR deployment.

About this task

During the installation planning, you can enable disaster recovery for your rack in either of these methods:

- If you already set up your first rack as Site 1. During the installation of Site 2, connect it to Site 1 in a Metro-DR relationship.
- You already got a standalone rack set up but not designated it as Site 1. During the installation of Site 2, use the connection snippet of Site 1 to establish a Metro-DR relationship between the two racks.

Procedure

1. Note: Perform Day 2 operations, such as expanding capacity by upsizing or adding nodes, only after the Metro-DR is successfully established and stable.
Install site 1.
For the procedure to install, see the single rack installation procedure in [Installing IBM Fusion HCI](#).
2. Install site 2.
For the procedure to install, see the single rack installation procedure in [Installing IBM Fusion HCI](#).
3. For Metro-DR, set up the Tiebreaker. For the tiebreaker procedure, see [Preparing the tiebreaker](#).

What to do next

Metro-DR

Set up Metro-DR, Enable applications for Metro-DR, Failover applications from site 1 to site 2, and Failback applications from the mirrored site to the original site.
For the procedure, see [Metro-DR configuration for Global Data Platform](#).

Validate your installation

After you install IBM Storage Fusion HCI, validate that the installation completed successfully and that all components are running as expected.

- [Validating IBM Fusion HCI installation](#)

After the IBM Fusion HCI is installed, validate the success of the installation.

- [Collecting log files of final installation](#)

Three operators get involved in the final installation. The **Installer** operator adds compute nodes to the OpenShift® Container Platform cluster, and orchestrates the overall final installation. The **Storage** operator installs the IBM Storage Scale cluster.

Validating IBM Fusion HCI installation

After the IBM Fusion HCI is installed, validate the success of the installation.

Verify the IBM Fusion HCI installation

Validate IBM Fusion HCI installation from the IBM Fusion user interface

1. Log in to IBM Fusion user interface by using the default user credentials: **Kubadmin/<password generated during the installation of IBM Fusion>**.
Note: The default user has cluster administrator privileges. A single sign-on exists between the IBM Fusion user interface and the OpenShift® management console.
2. Go to Infrastructure > Overview and check the health of the nodes and switches. For more information about how to monitor the status, see [Monitoring hardware from IBM Fusion HCI user interface](#).

Validate IBM Fusion operator from the OpenShift management console

1. Log in to the OpenShift web console.
2. Go to Overview page and in the dashboard check the status of your Cluster in the Status section. A green check mark indicates that the cluster is healthy.
3. From the menu navigation, click Operators > Installed Operators.
4. From the Installed Operators list, click IBM Fusion operator. The Details tab is open by default.
5. In the Details tab, check whether the Status is set to Succeeded.
6. From the menu navigation, click Compute > Nodes.
7. Check whether the default 6 nodes are available and are in Ready status. If you ordered more than six nodes, also verify their availability and statuses.
Note: If the default 6 nodes are not in the Ready state, configure them. For more information, see [Configuring nodes for management](#).

Collecting log files of final installation

Three operators get involved in the final installation. The **Installer** operator adds compute nodes to the OpenShift® Container Platform cluster, and orchestrates the overall final installation. The **Storage** operator installs the IBM Storage Scale cluster.

See these steps to get the IBM Fusion log file of all these three operators.

1. Log in to the cluster with the correct permissions to access the **ibm-spectrum-fusion-ns** namespace resource.
2. Run the following command to go to the **ibm-spectrum-fusion-ns** namespace:

```
oc project ibm-spectrum-fusion-ns
```

The following message is displayed as an output:

```
Now using project "ibm-spectrum-fusion-ns" on server "https://api.racke.mydomain.com:6443".
```

3. Run the following command to get the **Installer** operator Pod's name:

```
oc get po -l control-plane=isf-installer-operator
```

A sample result of this command is as follows.

NAME	READY	STATUS	RESTARTS	AGE
isf-installer-operator-controller-manager-58546db557-qrcrn	2/2	Running	0	6h29m

Run the following command to get the **Installer** operator log information:

```
oc logs <Installer operator Pod's name> manager > ./installer-operator.log
```

A sample command is as follows:

```
oc logs isf-installer-operator-controller-manager-58546db557-qrcrn manager > ./installer-operator.log
```

isf-installer-operator-controller-manager-58546db557-qrcrn is the **Installer** operator Pod's name. Replace this value with your **Installer** operator Pod's name. The value of the container name is always **manager**.

4. Run the following command to get the **Storage** operator Pod's name:

```
oc get po -l control-plane=isf-storage-operator
```

A sample result of this command is as follows.

NAME	READY	STATUS	RESTARTS	AGE
isf-storage-operator-controller-manager-7c6f945c97-bv7mp	2/2	Running	0	6h29m

Run the following command to get the **Storage** operator log information:

```
oc logs <Storage operator Pod's name> manager > ./storage-operator.log
```

A sample command is as follows.

```
oc logs isf-storage-operator-controller-manager-7c6f945c97-bv7mp manager > ./storage-operator.log
```

`isf-storage-operator-controller-manager-7c6f945c97-bv7mp` is the **Storage** operator Pod's name. Replace this value with your **Storage** operator Pod's name. The value of the container name is always **manager**.

5. Run the following command to get the **BackupRestore** operator Pod's name:

```
oc get po -l control-plane=isf-bkprstr-operator
```

A sample result of this command is as follows.

NAME	READY	STATUS	RESTARTS	AGE
isf-bkprstr-operator-controller-manager-55b646456f-kcxcf	2/2	Running	0	6h29m

Run the following command to get the **BackupRestore** operator log information:

```
oc logs <BackupRestore operator Pod's name> manager > ./bkprstr-operator.log
```

A sample command is as follows:

```
oc logs isf-bkprstr-operator-controller-manager-55b646456f-kcxcf manager > ./bkprstr-operator.log
```

`isf-bkprstr-operator-controller-manager-55b646456f-kcxcf` is the **BackupRestore** operator Pod's name. Replace this value with your **BackupRestore** operator Pod's name. The value of the container name is always **manager**.

Install your IBM Fusion HCI services

In the service-based IBM Fusion HCI , choose the features that you want to deploy.

For an overview on each of these services, see [Fusion services](#).

As an administrator, you can install or enable the required services from the user interface, but make sure you meet the resource requirements of individual services.

In the Available section of the Services page, first install and configure Data Foundation service or Global Data Platform service as your storage. You can install Additional services only after you configure storage.

IBM Fusion supports preferred storage class selection during service installation by allowing each service to define an ordered list of storage classes in its FSD. The IBM Fusion UI reads this list, automatically selects the preferred storage class that exists in the cluster, and proceeds with installation without user input. If none of the preferred storage classes are available, the UI enables manual selection and records the user's choice in the service FSD.

You can also manage the upgrade of these IBM Fusion services from the user interface. For steps to upgrade in IBM Fusion HCI, see [Upgrading IBM Fusion HCI services](#). Note: All IBM Fusion services are supported on the Bare Metal platform of IBM Fusion HCI.

Resolve installation issues

If your IBM Storage Fusion HCI installation does not complete successfully, use the following resources to diagnose and resolve common installation issues.

- [Installation issues](#)
Use the troubleshooting tips and tricks in IBM Fusion installation.

Installation issues

Use the troubleshooting tips and tricks in IBM Fusion installation.

Note: To log in to the provisioner node, as a kni user, SSH to service node. It is the same host that the IBM Service Support Representative (SSR) provided you before the stage 2 of the installation: `https://<host IP address>:3000/isfsetup`. For the actual step, see [Installation procedure](#).

HA MR with static IP

Problem statement

The rack discovery fails for HA MR with static IP.

Resolution

For HA MR static IP setup, do the following workaround:

1. After you finish the stage 1 installation of rack 1, log in to the provisioning node RHEL.
2. Run the following command to change the directory:

```
cd /home/kni/isfconfig
```

3. Run the following command to copy the JSON file:

```
cp computeNodesDNSResult.json nodesDHCPResult.json
```

4. Complete the stage 1 installation of rack 2.
5. Log in to the provisioning node RHEL.
6. Run the following command to change the directory:

```
cd /home/kni/isfconfig
```

7. Run the following command to copy the JSON file:

```
cp computeNodesDNSResult.json nodesDHCPResult.json
```

8. In stage1 of rack3 (last rack of HA MR), go till the stage where all nodes are discovered and before you click Next to start the discovery of the neighboring rack.
9. Log in to provisioning node RHEL
10. Run the following command to change the directory:

```
cd /home/kni/isfconfig
```

11. Run the following command to copy the JSON file:

```
cp computeNodesDNSResult.json nodesDHCPResult.json
```

12. Go back to the stage 1 installation of rack 3 and click Next to start the rack discovery.

Red Hat OpenShift Container Platform cluster degradation

Problem statement

You might observe unpredictable Red Hat® OpenShift® Container Platform cluster degradation issues that include but not limited to severe performance and operator degradation issues.

Resolution

To avoid these issues, go through the Red Hat recommendations. For example, the following list has some of the high-level considerations (not all inclusive):

- Your cluster must have sufficient CPU and RAM resources that are allocated to etcd and compute nodes.
- The etcd disks must be high-performing with low read or write latency and high IOPs. You can use [FIO test](#) to check IOPS for etcd disks.
- There must not be high network latency among etcd members.

For more information and a complete list of considerations, see [Red Hat Documentation](#).

DeadlineExceeded error

If you notice that the operator installation or upgrade fails with **DeadlineExceeded error**, see [Operator installation or upgrade fails with DeadlineExceeded error](#).

Duplicate host entries in Stage2 Network pre-check page

Problem statement

When you retry stage 2, installation can fail due to multiple entries found for nodes in the list.
For example:

```
For node at RU5 the lookup of IP address from hostname compute-1-ru5.testdomain.com failed with error DNS lookup of hostname c
```

Resolution

1. Run the following command to verify duplicate entries:

```
sudo vim /etc/hosts
```

2. Remove all the duplicate entries from file and save it.
3. In the Network validation page, click Retry pre-check connection.

- [Troubleshooting installation issues](#)
Troubleshooting IBM Fusion HCI installation issues.
- [Operator installation or upgrade fails with DeadlineExceeded error](#)
IBM Cloud Paks foundational services operator ClusterServiceVersion (CSV) status shows Failed and its InstallPlan status shows Failed after the subscription gets created.

Troubleshooting installation issues

Troubleshooting IBM Fusion HCI installation issues.

Operator `OOMKilled` error in IBM Fusion namespace

Problem statement

The pods in the IBM Fusion namespace go into `CrashLoopBackOff` state with the `OOMKilled` error. To identify whether the pod is `OOMKilled`, go to the pod YAML and search for the word `OOMKilled`. If the pod is in `OOMKilled` state, perform the following resolution steps.

Resolution

Follow these steps to fix the `OOMKilled` pod:

1. Go to IBM Fusion `ClusterServiceVersion` object (Operators > Installed Operators > IBM Fusion operator > YAML tab).
2. Search for the deployment name of the `OOMKilled` pod from the list of deployments in the `clusterserviceversion` object under `spec.install.spec.deployments`.
3. In the specified deployment object, search for the container name `manager` under the `spec.template.spec.containers` and increase the memory limit in the `resources.limits.memory`.
After changing the limits in the IBM Fusion `clusterserviceversion`, the `OOMKilled` operator pod restarts with the new limits.
4. If the `OOMKilled` issue persists, follow steps 1 through 3 again.

Failed to pull SCA certs error on OpenShift Container Platform console

Problem statement

The following error may occur in `oc get co` command or on OpenShift® Container Platform console:

Failed to pull SCA certs from https://api.openshift.com/api/accounts_mgmt/v1/certificates: OCM API https://api.openshift.com/a

Resolution

For the resolution, see [Red Hat® customer portal](#).

Empty node list in Network precheck wizard

Problem statement

The Network validation wizard page (Network setup stage 1) of the IBM Fusion HCI installation can have an empty node list with the Finish button in enabled state. The InlineNotification status may also show a `Connection complete!` status with a green checkmark that suggests you can proceed to the next step. Similarly, Network precheck wizard page (Red Hat OpenShift installation stage 2) of IBM Fusion HCI may have an empty node list with the Next button enabled.

Resolution

1. If you run into this scenario, confirm that the nodes are connected before you proceed:
Check the response of the endpoint `<https://<host IP address>:3000/api/v1/verifyDHCP`
2. Find the failed nodes from the response.
3. Manually verify the configuration of the node in DHCP and DNS.
The IP addresses of the nodes can either be incorrect or not reachable.
4. Fix the issue and restart Network setup (stage 1) installation or Red Hat OpenShift installation (stage 2).

Nodes added as local host or local domain to Red Hat OpenShift Container Platform cluster

Resolution

If the Red Hat OpenShift installation fails, then retry OpenShift installation wizard. If problem persists, contact IBM Support.

ISF node exporter pod in container creating state

Problem statement

You might encounter `ISF node exporter` pod in `container creating` state at the end of stage 2 installation. An example pod in `container creating` state:

```
2022-05-16T12:06:07.538Z ERROR controller-runtime.manager.controller.node Reconciler error {"reconciler group": "storage.isf.i
```

Resolution

Ignore this message and proceed to work with next steps as the error gets resolved by itself.

ImagePull failure during an installation

Problem statement

The `ImagePull` failure can occur due to intermittent network or registry issues.

Resolution

If an `ImagePull` failure occurs due to intermittent network or registry issue during IBM Fusion HCI installation, then restart the pod and retry. If the issue persists, contact [IBM support](#).

Pull a container image from the `registry.connect.redhat.com`

Problem statement

If you pull a container image from the `registry.connect.redhat.com`, it redirects to AWS S3. It is a known issue in Red Hat.

Diagnostic steps

To verify the error message, do the following steps:

1. Log in to Red Hat OpenShift Container Platform control node.
2. Use the following commands to manually pull an image from `registry.connect.redhat.com`:

```
$ podman login registry.connect.redhat.com
$ podman pull registry.connect.redhat.com/seldonio/seldon-core-operator-bundle:latest
```

Note: An example image is used for illustration.

Resolution

A portion of the content is hosted on `registry.connect.redhat.com` by using the following AWS S3 bucket: `rhc4tp-prod-z8cxf-image-registry-us-east-1-evenkyleffocxqvofrk.s3.dualstack.us-east-1.amazonaws.com`. Allow this domain so that OpenShift Container Platform can access it in your firewall.

NVIDIA GPU operator validator pod failure on OpenShift 4.18.22 and 4.18.23

Problem statement

The NVIDIA GPU operator validator pod fails to initialize on OpenShift Container Platform versions 4.18.22 and 4.18.23 when using the `crun` container runtime. The pod fails with an `Init:CreateContainerError` message.

Note:

- This issue affects all versions of the NVIDIA GPU operator when deployed on the OpenShift Container Platform 4.18.22 and 4.18.23 versions.
- Clusters running OpenShift Container Platform versions before 4.18.22 or after 4.18.23 are not affected. Additionally, clusters that use `runc` as their default container runtime are also unaffected.

Diagnosis

1. Run the following command to verify the OpenShift Container Platform version.

```
oc version
```

2. Run the following command to check the container runtime used on the nodes, and check the `default_runtime` value in `/etc/crio/crio.conf`.

```
oc debug node/<node_name>
```

Example output:

```
$ oc debug node/nvd-srv-29.nvidia.example.com
Starting pod/nvd-srv-29nvidiaexamplecom-debug-fq54m ...
To use host binaries, run `chroot /host`
Pod IP: 10.0.0.1
If you don't see a command prompt, try pressing enter.
sh-5.1# chroot /host
sh-5.1# cat /etc/crio/crio.conf | grep default_runtime
# default runtime is the _name_ of the OCI runtime to be used as the default.
# default_runtime = "crun"
# If no runtime handler is provided, the "default_runtime" will be used.
# inherit_default_runtime = false
# - inherit_default_runtime (optional, bool): when true the runtime_path,
# inherit_default_runtime = false
```

If you see `default_runtime = "crun"` (or if it is commented and `crun` is default), then your node is using `crun`.

Clusters that use `runc` are not impacted

3. Run the following command to verify the status of the NVIDIA operator validator pod.

```
oc get pods -n nvidia-gpu-operator | grep validator
```

Example output:

```
nvidia-operator-validator-xxxxx 0/1 Init:CreateContainerError 0 2m
```

4. Run the following command to verify the pod events or logs for the error message.

```
oc describe pod <validator_pod_name> -n nvidia-gpu-operator
```

Example output:

```
error executing hook `/usr/local/nvidia/toolkit/nvidia-container-runtime-hook` (exit code: 1)
```

Resolution

To resolve this issue, upgrade the OpenShift cluster to version 4.18.24 or later, or to version 4.19.

NVIDIA CUDA validator pod stuck in `Init:CrashLoopBackOff` on OpenShift 4

Problem statement

After installing NVIDIA GPU operator version 25.10.0 or 25.3.4 on an OpenShift cluster, certain pods in the `nvidia-gpu-operator` namespace may fail to initialize, resulting in an unhealthy GPU operator.

1. The `nvidia-operator-validator` pod remains stuck in the `Init:2/4` state.
2. The `nvidia-cuda-validator` pod enters a state of `Init:CrashLoopBackOff`.
3. Although the `nvidia-driver-daemonset` pod is running, the CUDA validation phases fail.

Diagnosis

1. Run the following command to get an overview of the pod states in the **nvidia-gpu-operator** namespace:

```
oc get pods -n nvidia-gpu-operator -o wide
```

Check for the following symptoms:

- a. The **nvidia-operator-validator** pod remains stuck in the **Init:2/4** state.
 - b. The **nvidia-cuda-validator** pod enters a state of **Init:CrashLoopBackOff**.
2. Run the following command inside the driver **DaemonSet**:

```
oc exec <nvidia-driver-daemonset-pod> -n nvidia-gpu-operator -c nvidia-driver-ctr -- nvidia-smi
```

If **nvidia-smi** fails or cannot initialize the GPU, the kernel module may not be loading successfully.

3. Run the following command to check the validator pod logs:

```
oc logs <nvidia-cuda-validator-pod> -n nvidia-gpu-operator -c cuda-validation
```

Example failure message:

```
Failed to allocate device vector A (error code initialization error)!  
[Vector addition of 50000 elements]
```

Resolution

Follow the steps to resolve the issue:

1. Create a **MachineConfig** that adds **nokaslr** to the kernel arguments for the worker nodes.

For example:

```
apiVersion: machineconfiguration.openshift.io/v1  
kind: MachineConfig  
metadata:  
  labels:  
    machineconfiguration.openshift.io/role: worker  
  name: 99-disable-kaslr  
spec:  
  kernelArguments:  
    - nokaslr
```

Run the following command to apply it:

```
oc apply -f 99-disable-kaslr.yaml
```

2. Monitor the machine configuration pool state using the following command:

```
oc get mcp
```

The worker or GPU nodes automatically reboot to apply the new kernel argument. Wait until the MCP returns to **Updated=True** and **Degraded=False**.

3. After the nodes are back to **Ready** state, run the following command to verify that GPU components have recovered:

```
oc get pods -n nvidia-gpu-operator
```

Confirm the following:

- a. The **nvidia-operator-validator** pod is not stuck in the **Init:2/4** state.
 - b. The **nvidia-cuda-validator** pod is not in a **CrashLoopBackOff** state.
 - c. The driver pods are in a **Running** state.
4. After disabling KASLR and allowing nodes to reboot, all NVIDIA validation containers should initialize successfully, resolving the issue with validator pods being stuck.

Known issues

- During Red Hat OpenShift cluster creation, you cannot download logs but can monitor them on the user interface and download them after installation.
- If you observe an error **Configmap fusion platform not found in fusion namespace** in the prereq operator logs, then the error does not have any impact and can be ignored from the **isf-prereq-operator-controller-manager-xxxx** pod logs.
- If the Download Credentials step fails during stage 2 installation, contact [contact IBM Support](#).

Operator installation or upgrade fails with DeadlineExceeded error

IBM Cloud Paks foundational services operator ClusterServiceVersion (CSV) status shows Failed and its InstallPlan status shows Failed after the subscription gets created.

Symptom

The foundational services operator CSV status shows as **Failed**. On the Red Hat® OpenShift® Container Platform cluster console, you see an error message similar to the following message:

```
Bundle unpacking failed. Reason: DeadlineExceeded, and Message: Job was active longer than specified deadline".
```

The InstallPlan status also shows as **Failed**.

1. Get InstallPlans that have the **Failed** status.

```
oc get subscription <failed-operator-subscription> -n <operator-namespace> -o jsonpath='{.status.installPlanRef}'
```

See the following sample output:

```
{"apiVersion":"operators.coreos.com/v1alpha1","kind":"InstallPlan","name":"install-cpqk2","namespace":"cloudpak-control","reso
```

2. Confirm the status of the InstallPlan that you got in the previous command output.

```
oc get installplan install-cpqk2 -n cloudpak-control -o jsonpath='{.status.installPlanRef}'
```

Following is a sample output:

```
Failed
```

3. Inspect the InstallPlan.

```
oc get installplan install-cpqk2 -n cloudpak-control -o yaml | grep "unpack job not completed"
```

See the following sample output:

```
bundle unpacking failed. Reason: DeadlineExceeded, and Message: Job was active longer than specified deadline
```

Cause

Operator Lifecycle Manager (OLM) fails to unpack the operator bundle because the extract job failed (probably due to an issue of remote image access, or any other reason) and corrupted the configmap. Therefore, the operator manifest also most likely gets corrupted. When it is corrupted, any repeated installation attempts by using the same job and configmap fail.

In an air-gapped environment, in most cases the issue happens when the bundle image is unavailable in the private registry.

Resolution

For more information about how to resolve the issue, see [Operator installation or upgrade fails with DeadlineExceeded in Red Hat OpenShift Container Platform](#). Complete the following steps to resolve the issue:

1. Find the corresponding job and configmap in the namespace where the CatalogSource is deployed. Narrow down your search by using the operator name or any other keyword.

```
oc get job -n <catalog-namespace> -o json | jq -r '.items[] | select(.spec.template.spec.containers[].env[].value|contains("<failed-operator-name>")) | .metadata.name'
```

2. Delete the job and the corresponding configmap that you got in the previous command. In most cases, the job and configmap have the same name.

```
oc delete job <job-name> -n <catalog-namespace>
```

```
oc delete configmap <job-name> -n <catalog-namespace>
```

3. Delete the **Failed** InstallPlan.

```
oc delete installplan <operator-installplan-name> -n <operator-namespace>
```

4. Delete the subscription and CSV of the **Failed** operator.

```
oc delete subscription <name-of-the-operator-subscription> -n <operator-namespace>
```

```
oc delete csv <name-of-the-corresponding-CSV> -n <operator-namespace>
```

5. Delete the Operand Deployment Lifecycle Manager pod.

```
oc delete pod -l name=operand-deployment-lifecycle-manager -n <your-foundational-services-namespace>
```

Uninstalling services

You can uninstall IBM Fusion services by using the command line.

As a prerequisite to uninstallation of services, disable connections that are setup. For the actual procedure to disable, see [Disabling the connection](#).

Important: If you want to do a complete uninstallation, then uninstall all your installed services in the sequence mentioned in this topic and then uninstall IBM Fusion.

- [Disabling the connection](#)
Disable the connection between Hub and Spoke.
- [Uninstalling IBM Data Cataloging](#)
Steps to uninstall IBM Data Cataloging by using command line interface.
- [Uninstalling Backup & Restore](#)
Steps to uninstall IBM Fusion Backup & Restore by using command-line or command prompt interface.
- [Uninstalling Fusion Data Foundation](#)
Use the following steps to uninstall Fusion Data Foundation by using command line interface.

Disabling the connection

Disable the connection between Hub and Spoke.

About this task

In Hub and Spoke, there is a connection CR in each cluster that represents the connection to the another(remote) cluster. Delete connection CR in the Spoke or Hub. If the network is down, then use either method 1 or method 2 to manually delete the connection CR in another cluster also.

Important: Disabling a spoke connection results in the unassignment of policies from spoke applications, and no new backups are initiated subsequently. Custom Resources (CRs) of applications without backups are deleted, and these applications no longer appear in the user interface.

Method 1: Using command line or command prompt

Procedure

1. In the Spoke, use the following command to get all the connection CR:

```
oc get connection -n <fusion-namespace> -o=custom-  
columns='NAME:.metadata.name,ClusterName:.metadata.annotations.connection\.isf\.ibm\.com/cluster-name'
```

Example command:

```
oc get connection -n ibm-spectrum-fusion-ns -o=custom-  
columns='NAME:.metadata.name,ClusterName:.metadata.annotations.connection\.isf\.ibm\.com/cluster-name'
```

Example output:

NAME	ClusterName
connection-44ae8529aa	cp4d-vpc-98b7318c91b01bd72490e80cc2328915-0000.us-east.containers.appdomain.cloud

2. Check the **ClusterName** in connection CR, and delete the connection CR which has the same ClusterName with Hub:

```
oc delete connection <connection-name> -n <fusion-namespace>
```

Example command:

```
oc delete connection connection-44ae8529aa -n ibm-spectrum-fusion-ns
```

Method 2: By using OpenShift Container Platform console

Procedure

1. Log in to OpenShift Container Platform console.
2. Go to Administration > CustomResourceDefinitions > connections.application.isf.ibm.com > Instances.
3. Get the connection instance whose cluster name in the annotation is the same as the hub cluster name.
4. Delete this connection instance.

Uninstalling IBM Data Cataloging

Steps to uninstall IBM Data Cataloging by using command line interface.

Procedure

1. Run the following command and export IBM Fusion namespace as an environmental variable.

```
export FUSION_NS="<Fusion namespace>"
```

Important: Replace <Fusion namespace> with your namespace.

2. Run the following command to prevent catalog source creation.

```
oc -n ${FUSION_NS} patch fusion servicedefinition data-cataloging-service-definition --type='json' -p='[{"op": "replace",  
"path": "/spec/onboarding/serviceOperatorSubscription/triggerCatSrcCreate", "value": false}]'
```

3. Run the following command to scale down prerequisite operator.

```
oc -n ${FUSION_NS} scale --replicas=0 deployment/isf-prereq-operator-controller-manager
```

4. Run the following commands to delete all the IBM Data Cataloging workload, networking and storage resources.

```
oc project default  
export DCS_CR=$(oc get SpectrumDiscover -n ibm-data-cataloging -o jsonpath="{.items[*].metadata.name}")  
oc delete SpectrumDiscover ${DCS_CR} -n ibm-data-cataloging --timeout=2m --wait=true  
oc delete project ibm-data-cataloging --timeout=1m --wait=true
```

5. Run the following command to delete the IBM Fusion IBM Data Cataloging service instance object.

```
oc -n ${FUSION_NS} delete fusion serviceinstance data-cataloging-service-instance
```

6. Run the following command to delete the **SecurityContextConstraints** objects.

Important: The SCC objects are based on their namespace, and the namespace must be included in the name of the SCC object. The default namespace is **ibm-data-cataloging**, but you must change it if you use a different one.

```
oc delete securitycontextconstraints/isd-scc-ibm-data-cataloging  
oc delete securitycontextconstraints/ibm-data-cataloging-c-isd-scc
```

7. Run the following command to delete the IBM Data Cataloging **ConsoleLink** object.

```
oc delete consolelink/data-cataloging
```

8. Run the following command to delete IBM Data Cataloging **CustomResourceDefinitions** from the cluster.

```
oc delete customresourcedefinition/spectrumdiscovers.spectrum-discover.ibm.com  
oc delete customresourcedefinition/spectrumdiscoverapplications.spectrum-discover.ibm.com
```

9. Run the following command to scale up prerequisite operator.

```
oc -n ${FUSION_NS} scale --replicas=1 deployment/isf-prereq-operator-controller-manager
```

Uninstalling Backup & Restore

Steps to uninstall IBM Fusion Backup & Restore by using command-line or command prompt interface.

Before you begin

- Ensure you have the following installed:
 - Bash 5.0 or higher
 - OpenShift® Container Platform command line 4.14 or higher
 - jq 1.6 or higher version.

About this task

The uninstall-backup-restore.sh script has two optional arguments `-u` and `-d`. Use the `-u` argument to uninstall agent when the hub still exists.

Procedure

1. Log in to your cluster.
2. From your browser, go to this URL- <https://github.com/IBM/storage-fusion/blob/master/backup-restore/uninstall/uninstall-backup-restore.sh>.
3. Download uninstall-backup-restore.sh and run the script.

What to do next

Note: On the Topology page, it can take 10 minutes for the Connection Status of the spoke cluster to change from **Connected** to Unknown. Though in the Backedup applications page, you can see the previous application backups from the spoke cluster, no new backups are possible. After uninstall of agent or server, you may want to delete the connection from the system. You can remove the connection for a spoke from the hub user interface, but the agent user interface does not have this capability. When you try to remove a connection from a hub, check your firewall. For more information, see [Remove connections](#).

Uninstalling Fusion Data Foundation

Use the following steps to uninstall Fusion Data Foundation by using command line interface.

Before you begin

- Ensure that all workloads are stopped. Delete the associated persistent volume claims (PVCs) and clean up the namespace linked to it. Also, remove any other IBM Fusion services that use the Fusion Data Foundation service.
- If you are uninstalling Fusion Data Foundation 4.21 or later on Red Hat® OpenShift® Container Platform 4.21 or later, uninstall the Global Data Platform remote mount service if it is installed. For instructions, see [Uninstalling Global Data Platform remote mount](#).
- If your installed version of Fusion Data Foundation is a provider cluster and has hosted clusters, delete the hosted clusters before proceeding with the uninstallation. For the procedure to clean up, see [Cleaning up of a Hosted Control Plane cluster](#).

Procedure

1. Export the IBM Fusion HCI namespace as an environmental variable.

```
export FUSION_NS="<Storage Fusion namespace>"
```

Important: Replace `<Storage Fusion namespace>` with your namespace.

2. Scale the IBM Fusion HCI storage deployment to 0 replica.

```
oc scale deployment --replicas=0 isf-cns-operator-controller-manager -n "$FUSION_NS"
```

3. Delete the Fusion Data Foundation CR.

```
oc delete odmanager odmanager
oc delete odcluster odcluster -n "$FUSION_NS"
```

4. Remove monitoring stack from Fusion Data Foundation.
For more information, see [Removing monitoring stack from Fusion Data Foundation](#).
5. Delete the `isf-bkprstr-claim` PVC.

```
oc delete pvc isf-bkprstr-claim -n "$FUSION_NS"
```

6. Verify that the `logcollector` PVC exists and delete it if it is present.
 - a. Verify that the `logcollector` PVC exists.

```
oc get pvc logcollector -n "$FUSION_NS"
```

- b. If the `logcollector` PVC is present, delete it.

```
oc delete pvc logcollector -n "$FUSION_NS"
```

7. Uninstall steps for Fusion Data Foundation Service Consumer mode.

Note: This step is used to uninstall Fusion Data Foundation client mode. If the current cluster has one or more Hosted Control Plane clusters, make sure to clean all the Hosted Control Plane clusters. Use the `oc` login to the different Hosted Control Plane clusters.

a. Delete the `storageclassclaims`.

```
oc delete storageclassclaims --all
```

b. Delete the `storageclient` CR.

```
oc delete storageclient storageclient -n openshift-storage-client
```

c. Delete the finalizers from `CSIAddonsNode`.

```
for name in $(oc get CSIAddonsNode -n openshift-storage-client -o name);
do oc patch $name -p '{"metadata":{"finalizers":null}}' -n openshift-storage-client --type=merge;
done
```

d. Delete the `openshift-storage-client` namespace.

```
oc delete ns openshift-storage-client
```

8. Uninstall the Fusion Data Foundation. For uninstallation steps, see [Uninstalling Data foundation in Internal mode deployment](#) on the IBM Support page.

Important: Ensure that the `openshift-storage` namespace and all associated resources are deleted before you proceed to the next step.

9. Verify that the `ibm-spectrum-fusion-mgmt-sc` StorageClass exists and delete it if it is present.

a. Verify that the `ibm-spectrum-fusion-mgmt-sc` StorageClass exists.

```
oc get sc ibm-spectrum-fusion-mgmt-sc
```

b. If the `ibm-spectrum-fusion-mgmt-sc` StorageClass is present, delete it.

```
oc delete sc ibm-spectrum-fusion-mgmt-sc
```

10. Delete the Fusion Data Foundation Service Instance CR.

```
oc delete fusioninstance odfmanager -n "$FUSION_NS"
```

11. Delete the Fusion Data Foundation Catalog Source.

```
oc delete catalogsource isf-data-foundation-catalog -n openshift-marketplace
```

12. Recreate the `isf-bkprstr-claim` PVC and restore the deployment.

a. Recreate the `isf-bkprstr-claim` PVC.

```
oc apply -f - <<EOF
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: isf-bkprstr-claim
  namespace: ibm-spectrum-fusion-ns
spec:
  accessModes:
    - ReadWriteMany
  resources:
    requests:
      storage: 25Gi
  storageClassName: ibm-spectrum-fusion-mgmt-sc
  volumeMode: Filesystem
EOF
```

b. Scale the `isf-bkprstr` deployment to 1 replica.

```
oc scale deployment --replicas=1 isf-bkprstr-operator-controller-manager -n ibm-spectrum-fusion-ns
```

13. If you deleted the `logcollector` PVC in step [6.b](#), recreate it and restore the deployment.

a. Recreate the `logcollector` PVC.

```
oc apply -f - <<EOF
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: logcollector
  namespace: ibm-spectrum-fusion-ns
spec:
  accessModes:
    - ReadWriteMany
  resources:
    requests:
      storage: 25Gi
  storageClassName: ibm-spectrum-fusion-mgmt-sc
  volumeMode: Filesystem
EOF
```

b. Scale the `logcollector` deployment to 2 replicas.

```
oc scale deployment --replicas=2 logcollector -n ibm-spectrum-fusion-ns
```

14. Scale the IBM Fusion HCI storage deployment to 1 replica.

```
oc scale deployment --replicas=1 isf-cns-operator-controller-manager -n "$FUSION_NS"
```

- [Removing monitoring stack from Fusion Data Foundation](#)

Before you uninstall Fusion Data Foundation, remove the monitoring stack by editing the monitoring ConfigMap and deleting the PVCs in the `openshift-monitoring` namespace.

- [Uninstalling Global Data Platform remote mount](#)
Uninstall Global Data Platform remote mount resources from Fusion Data Foundation.

Removing monitoring stack from Fusion Data Foundation

Before you uninstall Fusion Data Foundation, remove the monitoring stack by editing the monitoring ConfigMap and deleting the PVCs in the `openshift-monitoring` namespace.

Before you begin

- The persistent volume claims (PVCs) that are created as part of configuring the monitoring stack are in the `openshift-monitoring` namespace.
- PVCs are configured to use the OpenShift® Container Platform monitoring stack. For more information, see Observability > Monitoring in [Red Hat® OpenShift Container Platform](#) product documentation.

Procedure

1. List the pods and PVCs that are currently running in the `openshift-monitoring` namespace.

```
oc get pod,pvc -n openshift-monitoring
```

NAME	READY	STATUS	RESTARTS	AGE
pod/alertmanager-main-0	3/3	Running	0	8d
pod/alertmanager-main-1	3/3	Running	0	8d
pod/alertmanager-main-2	3/3	Running	0	8d
pod/cluster-monitoring-operator-84457656d-pkrxm	1/1	Running	0	8d
pod/grafana-79ccf6689f-21128	2/2	Running	0	8d

2. Edit the monitoring ConfigMap.

```
oc -n openshift-monitoring edit configmap cluster-monitoring-config
```

3. Remove any `config` sections that reference the Fusion Data Foundation storage classes and save the file.

Before editing

```
[...]
apiVersion: v1
data:
  config.yaml: |
    alertmanagerMain:
      volumeClaimTemplate:
        metadata:

In this example, the `alertmanagerMain` and `prometheusK8s` pods that were consuming the PVCs are in the **Terminating** state. You can delete the PVCs after these pods are no longer using them.

- Delete all PVCs that are consuming the storage classes.

```
oc delete -n openshift-monitoring pvc <pvc-name> --wait=true --timeout=5m
```

<pvc-name> is the name of the PVC.

Uninstalling Global Data Platform remote mount

Uninstall Global Data Platform remote mount resources from Fusion Data Foundation.

Before you begin

- Remove all filesystems from the IBM Fusion HCI user interface.
- Run the following commands to define namespace environmental variables:

```
export FUSION_NS=ibm-spectrum-fusion-ns
export SCALE_NS=ibm-spectrum-scale
```

- Ensure that all applications that access the storage filesystem through the IBM Storage Scale Container Storage Interface Driver (CSI) are stopped.
- Do the following steps to remove all applications:
 - Stop all applications that access storage by using the IBM Storage Scale CSI driver.
 - Delete all Persistent Volume Claims (PVCs) and Persistent Volumes (PVs) created by the IBM Storage Scale CSI driver.

About this task

This procedure applies to uninstalling Global Data Platform remote mount resources from Fusion Data Foundation 4.21 or later on Red Hat® OpenShift® Container Platform 4.21 or later.

Important: Do not perform this procedure if Global Data Platform is installed as local storage.

Procedure

1. Complete the following steps to delete the IBM Fusion storage custom resources:

- a. If encryption is configured, delete the encryption custom resources.

Command example:

```
oc -n ${FUSION_NS} get EncryptionClient | grep -v NAME | awk '{print $1}' | xargs -I{} oc -n ${FUSION_NS} delete EncryptionClient {}
oc -n ${FUSION_NS} get EncryptionServer | grep -v NAME | awk '{print $1}' | xargs -I{} oc -n ${FUSION_NS} delete EncryptionServer {}
```

- b. Delete all filesystem custom resources.

Command example:

```
oc -n ${FUSION_NS} get ScaleCluster | grep -v NAME | awk '{print $1}' | xargs -I{} oc -n ${FUSION_NS} delete ScaleCluster {}
```

- c. Verify that all `EncryptionServer` and `EncryptionClient` custom resources are deleted from IBM Fusion namespace.

Command example:

```
oc -n ${FUSION_NS} get EncryptionServer
oc -n ${FUSION_NS} get EncryptionClient
```

- d. Verify that all the `ScaleCluster` custom resources are deleted from IBM Fusion namespace.

Command example:

```
oc -n ${FUSION_NS} get ScaleCluster
```

- e. Delete sample PersistentVolume templates.

Command example:

```
oc get pv -o name | grep 'ibm-spectrum-scale-fs-.*-template' | xargs -I{} oc delete {}
```

- f. Delete the `VolumeSnapshotClass`.

Command example:

```
oc get volumesnapshotclass | grep spectrumscale.csi.ibm.com | awk '{print $1}' | xargs -I{} oc delete volumesnapshotclass {}
```

2. Complete the following steps to delete IBM Storage Scale Container Native resources:

- a. Record the IBM Storage Scale cluster name.

Command example:

```
oc -n ${SCALE_NS} get daemon -o yaml | grep clusterName: | awk -F " " '{print $2}'
```

Example cluster name:

```
ibm-storage-fusion-xx.xxx.example.com
```

Note: Save the cluster name for later use.

- b. Delete the IBM Storage Scale Container Native cluster.

Command example:

```
oc delete cluster.scale.spectrum.ibm.com ibm-spectrum-scale
```

- c. Delete sample storage classes, PVCs, and PVs.

Command example:

```
oc -n ${SCALE_NS} get pvc -o name | grep pmcollector | xargs -I{} oc -n ${SCALE_NS} delete {}
oc delete sc -lapp.kubernetes.io/instance=ibm-spectrum-scale,app.kubernetes.io/name=pmcollector
oc delete pv -lapp.kubernetes.io/instance=ibm-spectrum-scale,app.kubernetes.io/name=pmcollector
```

3. Complete the following steps to delete IBM Storage Scale Container Native directories from nodes on which IBM Storage Scale is deployed:

- a. Identify the nodes on which IBM Storage Scale is deployed.

Command example:

```
kubectl get nodes -o jsonpath="{range .items[*]}{.metadata.name}{'\n'}"
```

Tip: Use the `nodeSelector` to limit the set of nodes to clean up, or run cleanup on all nodes.

- b. Create a debug pod to remove the kernel modules and host path volume mounted directories used by IBM Storage Scale Container Native.

Run the following command on each node:

Command example:

```
oc debug node/<openshift_node> -T -- chroot /host sh -c "rm -rf /var/mmfs; rm -rf /var/adm/ras; rmmmod tracedev mmfs26 mmfslinux;"
```

- c. Verify that no artifacts remain by running the following validation command:

Command example:

```
oc debug node/<openshift_node> -T -- chroot /host sh -c "ls /var/mmfs; ls /var/adm/ras; rmmmod tracedev mmfs26 mmfslinux;"
```

- d. Delete IBM Storage Scale node labels created by IBM Storage Scale Container Native operator.

Command example:

```
# clean up all 'scale.spectrum.ibm.com' labels on the nodes
kubectl get nodes -ojson | jq -r '.items[].metadata.labels' | \
grep scale.spectrum.ibm.com | sort | cut -d: -f1 | \
tr -d "\"" | uniq | xargs -I{} kubectl label nodes --all {} \-

# clean up 'scale' label on the nodes
oc label node --all scale.spectrum.ibm.com/role-
oc label node --all scale.spectrum.ibm.com/designation-
oc label node --all scale-
```

4. Complete the following steps on the remote IBM Storage Scale cluster to delete access permission:

Note: If your storage cluster is running on AWS ROSA, skip this step and revoke filesystem access directly from the storage cluster. For the procedure to revoke, see [Cleanup on AWS ROSA](#).

- a. Run the following command to query the name of the containerized client cluster:

Command example:

```
mmauth show all | grep <scale_cluster_name>
```

Replace <scale_cluster_name> with the cluster name recorded in step [2.a](#).

- b. Run the following command to remove the client cluster authorization:

Command example:

```
mmauth delete <scale_cluster_name>
```

5. Complete the following steps to disable Global Data Platform.

- a. Delete the **ScaleManager** custom resource.

Command example:

```
oc -n ${FUSION_NS} delete scalemanager scalemanager
```

- b. Delete the **ScaleManager** Fusion service instance.

Command example:

```
oc delete fusionserviceinstance scalemanager -n ibm-spectrum-fusion-ns
```

- c. Disable the Global Data Platform service.

Command example:

```
oc -n $SCALE_NS get csv | grep ibm-spectrum-scale-operator
oc -n $SCALE_NS get csv -o name | grep ibm-spectrum-scale-operator | xargs -r -I{} oc -n $SCALE_NS patch {} --
type=json -p='[{"op":"replace","path":"/spec/install/spec/deployments/0/spec/replicas","value":0}]'
```

Results

Global Data Platform remote mount resources are uninstalled from Fusion Data Foundation.

What to do next

If a complete cleanup is required, remove the Global Data Platform namespace and related custom resource definitions (CRDs) after the Fusion Data Foundation cleanup is complete. For the Fusion Data Foundation cleanup procedure, see [Uninstalling Fusion Data Foundation](#).

To uninstall the IBM Storage Scale Container Native operator and remove associated Kubernetes objects and namespaces, run the following commands:

```
oc delete project ibm-spectrum-scale --wait=true --timeout=5m
oc delete crd approvalrequests.scale.spectrum.ibm.com cachevolumeoperations.scale.spectrum.ibm.com
cachevolumes.scale.spectrum.ibm.com callhomes.scale.spectrum.ibm.com clusterinterconnects.scale.spectrum.ibm.com
clusters.scale.spectrum.ibm.com compressionjobs.scale.spectrum.ibm.com consistencygroups.scale.spectrum.ibm.com
daemons.scale.spectrum.ibm.com diskjobs.scale.spectrum.ibm.com dnsconfigs.scale.spectrum.ibm.com dnss.scale.spectrum.ibm.com
encryptionconfigs.scale.spectrum.ibm.com filesystemrecoverydata.scale.spectrum.ibm.com filesystems.scale.spectrum.ibm.com
grafanabridges.scale.spectrum.ibm.com guis.scale.spectrum.ibm.com localdisks.scale.spectrum.ibm.com
pmcollectors.scale.spectrum.ibm.com recoveryconfigstores.scale.spectrum.ibm.com recoverygroups.scale.spectrum.ibm.com
regionaldreexports.scale.spectrum.ibm.com regionaldrs.scale.spectrum.ibm.com remoteclusters.scale.spectrum.ibm.com
restripefsjobs.scale.spectrum.ibm.com stretchclusterinitnodes.scale.spectrum.ibm.com stretchclusters.scale.spectrum.ibm.com
stretchclustertiebreakers.scale.spectrum.ibm.com upgradeapprovals.scale.spectrum.ibm.com volumes.scale.spectrum.ibm.com
```

Storage

IBM Fusion offers a variety of storage options to meet the demands of high-performance workloads and fulfill the storage needs of virtual machines.

Fusion storage services

Depending on your workload requirements, choose between either of the following services:

- Fusion Data Foundation storage is optimized for container workload management, ensuring efficient orchestration and resource allocation.
- Global Data Platform, on the other hand, is designed for complex AI processing, providing enhanced computational power and scalability.

Fusion Data Foundation

Fusion Data Foundation is designed to provide persistent storage and cluster data management. It supports containerized environments and integrates seamlessly with Red Hat® OpenShift®. It supports file, block, and object storage, and provides a consistent storage experience across hybrid cloud environments. For more information about Fusion Data Foundation service, see [Fusion Data Foundation](#).

Object Storage

Multi-Cloud Gateway (MCG) is a highly customizable data gateway for object storage. It defines resources by using Custom Resource Definitions (CRDs), and provides data services such as caching, tiering, mirroring, deduplication, encryption, and compression over many storage resources including private and public cloud object storage, file systems, and container PV/PVC. IBM Fusion supports MCG through Fusion Data Foundation. You can install MCG from the Services page of IBM Fusion. For more information about how to manage and work with MCG, see [Managing hybrid and multicloud resource](#).

Global Data Platform

Global Data Platform is a clustered file system that provides concurrent access to a single file system or set of file systems from multiple nodes. The nodes can be SAN-attached, network-attached, a mixture of SAN-attached and network-attached, or in a shared-nothing cluster configuration. This enables high-performance access to this common set of data to support a scale-out solution or to provide a high availability platform. The IBM Storage Scale storage is designed for building a global data platform for AI, high-performance computing (HPC), advanced analytics, and other demanding workloads. It supports file and object storage for unstructured data. For more information about Global Data Platform service, see [Global Data Platform](#). For more information about IBM Storage Scale service, see [IBM Storage Scale documentation](#).

Object Storage

Multi-Cloud Gateway (MCG) in Global Data Platform is an on-prem deployment. If the Global Data Platform ECE is installed, then you can see the MCG tile for it.

Global Data Platform Remote Mount

The Global Data Platform remote mount enables you to connect to a remote IBM Storage Scale cluster as if it were part of your local cluster. This is particularly useful for distributed workloads and hybrid cloud environments. For more information about, see [Remote IBM Storage Scale storage cluster in IBM Fusion](#).

On Red Hat OpenShift Container Platform 4.20 or earlier and Fusion Data Foundation 4.20 or earlier, Fusion Data Foundation and the Global Data Platform remote mount service can be installed independently.

Starting with Red Hat OpenShift Container Platform 4.21 and Fusion Data Foundation 4.21 or later, install Fusion Data Foundation first. After installation, the Global Data Platform remote mount tile becomes available for configuration.

If you install Fusion Data Foundation as local storage, you must explicitly install and configure the remote mount service by using the Global Data Platform remote mount service tile. If you install Global Data Platform as local storage, the remote mount capability is available by default.

IBM Storage Ceph

When you install Fusion Data Foundation, you can connect or configure the Fusion Data Foundation with an external IBM Storage Ceph cluster to use it as a storage provider. As you connect and manage additional storage resources, you can scale your storage infrastructure as needed.

IBM FlashSystem

When you install Fusion Data Foundation, you can connect or configure the Fusion Data Foundation with an external IBM FlashSystem cluster to use it as a storage provider. As you connect and manage additional storage resources, you can scale your storage infrastructure as needed.

Combining these storage options

The different storage installation combinations that you can do using these options, see [Storage deployment combinations from the user interface](#).

- [Storage deployment combinations from the user interface](#)
The supported storage deployment options are Global Data Platform local, Global Data Platform remote mount, Fusion Data Foundation provider mode, and Global Data Platform with MCG only.
- [Deploying your workloads with Persistent volumes](#)
This section shows you how you can provision Persistent volumes for application data persistence on IBM Fusion HCI.

Storage deployment combinations from the user interface

The supported storage deployment options are Global Data Platform local, Global Data Platform remote mount, Fusion Data Foundation provider mode, and Global Data Platform with MCG only.

In the Services page of the IBM Fusion user interface, you can see only the services that can be deployed on the cluster. It is based on your current storage configuration. The different storage installation combinations are as follows:

- [Fusion Data Foundation service on IBM Fusion](#)
- [Fusion Data Foundation service with Global Data Platform remote mount](#)
- [Global Data Platform service](#)
- [Global Data Platform service with MCG only](#)

Note: The Global Data Platform remote mount capability is available only for the following deployment modes:

- Standalone rack with Global Data Platform storage (newly installed with IBM Fusion 2.10.0 or later)
- Standalone rack with FDF (upgraded to IBM Fusion 2.10.0 or later / newly installed with IBM Fusion 2.10.0 or later)

Fusion Data Foundation service on IBM Fusion

Install Fusion Data Foundation on provider mode. For the installation procedure, see [Installing Fusion Data Foundation](#).

Fusion Data Foundation service with Global Data Platform remote mount

1. Install Fusion Data Foundation on provider mode.
2. From the Available section of the Services page, install Global Data Platform remote mount. To know more about the remote mount, see [Connecting to remote IBM Storage Scale file systems](#). The Global Data Platform remote mount is available only for IBM Fusion HCI with Fusion Data Foundation. Ensure the previous step is complete before you start this step.
3. After the installation of Global Data Platform completes successfully and the service is in healthy state, go to Storage > Remote file systems and add remote file systems. For more information about the procedure to add file systems, see [Remote IBM Storage Scale storage cluster in IBM Fusion](#).

Global Data Platform service

1. Install Global Data Platform local. For the procedure to install, see [Installing Global Data Platform](#).
2. Configure Global Data Platform. For the procedure to configure, see [Configuring Global Data Platform local storage](#).

Global Data Platform service with MCG only

1. Install Global Data Platform local. For the procedure to install, see [Installing Global Data Platform](#). Multi-Cloud Gateway (MCG) in Global Data Platform is an on-prem deployment. If the Global Data Platform ECE is installed, then you can see the MCG tile for it.
2. Configure Global Data Platform. For the procedure to configure, see [Configuring Global Data Platform local storage](#).
3. Go to the Services page and install Data Foundation with MCG only from the Available section. For the procedure to install, see [Installing Data Foundation for MCG only](#).

Deploying your workloads with Persistent volumes

This section shows you how you can provision Persistent volumes for application data persistence on IBM Fusion HCI.

A PersistentVolume (PV) is a representation of storage volume in the IBM Fusion cluster that is provisioned by an administrator, or dynamically provisioned by Kubernetes, to fulfill a request made in a PersistentVolumeClaim (PVC).

PersistentVolume and PersistentVolumeClaim are independent of pod life cycles and preserve data through restarting, rescheduling, and even deleting Pods. For example, PersistentVolumes lets you store your WordPress platform data outside the containers. This way, even if the containers are deleted, their data persists.

With PersistentVolumeClaims, you can consume abstract storage resources. It is common that users need PersistentVolumes with varying properties, such as performance, for different problems. Cluster administrators need to be able to offer a variety of PersistentVolumes that differ in more ways than size and access modes, without exposing users to the details of how those volumes are implemented. For these needs, there is the *StorageClass* resource.

A PVC is a request for storage of a certain storage class by a user that can be fulfilled by a PV. There are two ways PVs may be provisioned: statically or dynamically.

This section explains how to deploy an application that uses PVs and PVCs to store data. A PersistentVolume (PV) is a piece of storage in the cluster that has been manually provisioned by an administrator, or dynamically provisioned by Kubernetes using a StorageClass. For example, WordPress with Persistent Volumes to access and work with the storage of your workloads.

Static

A cluster administrator creates a number of PVs. They carry the details of the real storage, which is available for use by cluster users. For more information on creating Static provisioning, see [Static provisioning of Persistent Volume in filesystem](#).

Dynamic

Dynamic volume provisioning allows storage volumes to be created on-demand. In dynamic provisioning when a PersistentVolumeClaim is created, a PersistentVolume is dynamically provisioned based on the StorageClass configuration. For more information on creating dynamic provisioning, see [Dynamic provisioning of Persistent Volume in filesystem](#).

Storage classes

The storage class options for and IBM Fusion HCI by using Container Storage Interface driver:

For more information about IBM Storage Scale Container Native, see <https://www.ibm.com/docs/en/scalecontainernative?topic=overview-introduction>.

For more information on how to create storage classes in IBM Spectrum® Storage Scale Erasure Code Edition (ECE) by using Container Network Interface (CNI), see [IBM Storage Scale Container Storage Interface Driver storage class](#).

The IBM Storage Scale Container Native Storage Access (CNSA) allows the deployment of the cluster file system in a Red Hat® OpenShift® cluster by using a remote mount attached file system.

- [Static provisioning of Persistent Volume in filesystem](#)
Persistent Volume storage that is statically provisioned by an administrator.
- [Dynamic provisioning of Persistent Volume in filesystem](#)
You can create and manage storage classes for dynamic provisioning of workloads.

Static provisioning of Persistent Volume in filesystem

Persistent Volume storage that is statically provisioned by an administrator.

1. Configure Persistent Volume manifest file with a `volumeHandle` as described in this example:

```

kind: PersistentVolume
apiVersion: v1
metadata:
  name: ibm-spectrum-fusion-pv-images
  labels:
    cns.isf.ibm.com/creator-fusion: ''
spec:
  capacity:
    storage: 10Gi
  csi:
    driver: spectrumscale.csi.ibm.com
    volumeHandle: 14544310586575975773;096E4651:61DFAFB3;path=/mnt/ibm-spectrum-scale-fs-mcgpfs3-14544310586575975773/images
  accessModes:
    - ReadWriteMany
  persistentVolumeReclaimPolicy: Retain
  volumeMode: Filesystem
status:
  phase: Available

```

Here, the name is `ibm-spectrum-fusion-pv-images2`. The storage capacity is 10Gi. The `volumeHandle` value is `14544310586575975773;096E4651:61DFAFB3;path=/mnt/ibm-spectrum-scale-fs-mcgpfs3-14544310586575975773/images`.

2. Run the following apply command to create a Persistent Volume:

```
kubectl apply -f pv.yaml
```

Note:

- IBM Fusion creates static Persistent Volume templates for each filesystem.
- For IBM Fusion, static Persistent Volume for fileset supports backup but does not support backup for normal file or directory. If backup must be taken for normal file or directory, use dynamic Persistent Volume.

It is not applicable for IBM Fusion HCI.

Dynamic provisioning of Persistent Volume in filesystem

You can create and manage storage classes for dynamic provisioning of workloads.

Storage classes in IBM Storage Scale

There are two versions of storage classes that you can use with IBM Storage Scale. The default version works with all versions of IBM Storage Scale. For storage class examples, see [Storage class \(version 1\)](#) and [Storage class \(version 2\)](#). For the storage class to use with IBM Cloud Paks, IBM Storage Scale version (All), see [Storage class to use with Cloud Paks](#).

Note: For IBM Storage Scale Container Storage Interface Driver volume expansion function, include `allowVolumeExpansion=true` in your Storage Classes. For information about how to set it in a storage class, see the example storage classes in this topic. For more information about volume expansion in CSI documentation, see [Volume expansion](#).

The IBM Fusion detects the version of IBM Storage Scale, and creates storage class for each filesystem.

Procedure to create and apply a storage class YAML:

1. Create the following YAML and store it in the location of your choice. Retain this YAML until you create the storage class.
2. Run the following command to apply it:

```
oc apply -f <filename>
```

Storage class(version 1)

The default version that works with all versions of IBM Storage Scale. Example storage class (version 1) for IBM Storage Scale version (All):

```

apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
  name: ibm-spectrum-scale-csi-fileset-dependent-new
  provisioner: spectrumscale.csi.ibm.com
parameters:
  volBackendFs: "ibm-spectrum-scale-fs-mcgpfs3-14544310586575975773"
  filesetType: "dependent"
  parentFileset: "primary-fileset-ibm-spectrum-scale-fs-mcgpfs3-14544310586575975773-2822920183822285462"
  reclaimPolicy: Delete
  allowVolumeExpansion: true

```

The file set path pattern is `primary-fileset-$FS_CR_NAME-$LocalClusterID`. If the fileset does not exist, then IBM Fusion creates it automatically from remote storage class.

For more information about the parameters, see [Storage class](#).

Storage class(version 2)

This second storage class version requires IBM Storage Scale on Storage Cluster. Example storage class(version 2) for IBM Storage Scale version >= 5.1.3:

```

apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
  name: ibm-spectrum-scale-csi-storageclass-version2
  provisioner: spectrumscale.csi.ibm.com

```

```
parameters:
  version: "2"
  volBackendFs: "mygpfs"
reclaimPolicy: Delete
allowVolumeExpansion: true
```

The optional parameter list depends on the storage class type.

For more information about the additional parameters, see [Volume expansion](#).

Storage classes in Fusion Data Foundation

There are two versions of storage classes that you can use with Fusion Data Foundation:

- Filesystem storage class `ibm-spectrum-fusion-mgmt-sc` and `ocs-storagecluster-cephfs`
- Block storage class `ocs-storagecluster-ceph-rbd`

Storage class to use with Cloud Paks

- [Storage class to use with Cloud Paks for IBM Storage Scale](#)
- [Storage class to use with Cloud Paks for Fusion Data Foundation](#)

IBM Storage Scale

The `ibm-storage-fusion-cp-sc` storage class is the default for use with IBM Cloud Paks, IBM Storage Scale (All). For IBM Cloud Paks, the permissions parameter is set to `shared: true` on the storage class.

The `ibm-storage-fusion-cp-sc` storage class is available for IBM Fusion:

NAME	PROVISIONER	RECLAIMPOLICY	VOLUMEBINDINGMODE	ALLOWVOLUMEEXPANSION	A
ibm-storage-fusion-cp-sc	spectrumscale.csi.ibm.com	Delete	Immediate	true	2

```
oc get sc ibm-storage-fusion-cp-sc -o yaml
```

```
allowVolumeExpansion: true
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
  creationTimestamp: "2023-08-06T13:07:55Z"
  name: ibm-storage-fusion-cp-sc
  resourceVersion: "4107984"
  uid: c8be0a2f-e379-4498-9051-ce8d4cde8d93
parameters:
  shared: "true"
  version: "2"
  volBackendFs: ibmspectrum-fs
provisioner: spectrumscale.csi.ibm.com
reclaimPolicy: Delete
volumeBindingMode: Immediate
```

Data Foundation

Fusion Data Foundation defines storage classes for ReadWriteAfter (RWO) access and ReadWriteMany (RWX) access separately.

During the installation of IBM Cloud Paks, the `--block_storage_class` option must point to block storage class that supports ReadWriteAfter (RWO) access, which is `ocs-storagecluster-ceph-rbd`. The `--file_storage_class` option must point to a file storage class that supports ReadWriteMany (RWX) access, which is `ocs-storagecluster-cephfs`.

Note: For supported IBM Cloud Paks versions, see [IBM Cloud Paks support for IBM Fusion](#).

Fusion services and capabilities

IBM Fusion Service provides scalable, integrated storage and data management solutions optimized for hybrid cloud and AI workloads on Red Hat® OpenShift®.

- [Fusion services](#)
IBM Fusion Service provides scalable, integrated storage and data management solutions optimized for hybrid cloud and AI workloads on Red Hat OpenShift.
- [Disaster recovery](#)
Disaster recovery offerings of IBM Fusion HCI.
- [High availability](#)
High availability ensures that system services and data remain accessible with minimal downtime by distributing compute, control, and storage components across independent failure domains.
- [Multi-cluster IBM Fusion HCI using Hosted Control Plane](#)
Create a Hosted Control Plane with Red Hat Red Hat OpenShift Virtualization clusters or Bare Metal clusters (both internal and external) on IBM Fusion HCI.
- [Red Hat Red Hat OpenShift Virtualization](#)
IBM Fusion enables the coexistence of containers and VMs, with Red Hat OpenShift Virtualization allowing VMs to be managed as Kubernetes resources. Beyond VM hosting, Fusion and Red Hat OpenShift Virtualization offer virtual machine mobility, backup and restore, and additional capabilities to ensure high availability and disaster recovery.
- [Advanced workloads](#)
IBM Fusion is built to provide enterprise ready deployments for IBM Cloud Paks, IBM watsonx, IBM Maximo®, and Db2 Warehouse.

Fusion services

IBM Fusion Service provides scalable, integrated storage and data management solutions optimized for hybrid cloud and AI workloads on Red Hat® OpenShift®.

IBM Fusion supports preferred storage class selection during service installation by allowing each service to define an ordered list of storage classes in its FSD. The IBM Fusion UI reads this list, automatically selects the preferred storage class that exists in the cluster, and proceeds with installation without user input. If none of the preferred storage classes are available, the UI enables manual selection and records the user's choice in the service FSD.

The available services in IBM Fusion are as follows:

Global Data Platform

The Global Data Platform in IBM Fusion is a unified data management solution that simplifies access, sharing, and management of data across diverse environments. It offers scalable storage optimized for hybrid cloud and AI workloads, ensuring seamless data availability and mobility across multiple locations. It is a software-defined file and object storage that enables organizations to build a global data platform for artificial intelligence (AI), high-performance computing (HPC), advanced analytics, and other demanding workloads.

The Global Data Platform storage type provides the following features:

- File storage
- High availability through capacity-efficient erasure coding
- Metro and regional disaster recovery
- CSI snapshot support with built-in application consistency
- Encryption at rest
- Ability to mount file systems hosted by remote IBM Storage Scale clusters.

Fusion Data Foundation

You can use Fusion Data Foundation as storage service in IBM Fusion HCI. It enables you to manage Fusion Data Foundation services, and to deploy and scale storage clusters. The Fusion Data Foundation storage type provides the following features:

- Block, file, and object storage
- High availability through automatic data replication
- Metro and regional disaster recovery
- CSI snapshot support
- Encryption at rest

For more information about Fusion Data Foundation service, see [Introduction to Fusion Data Foundation](#).

Backup & Restore

The Backup & Restore service provides the following features:

- Policy-driven backup of applications that run on Red Hat OpenShift
- Change block detection for Ceph RBD block volumes. It greatly reduces backup times for applications using block mode volumes, including OpenShift Virtualization VMs based on RBD block volumes.
- Orchestration of application consistent online backups through recipes
- Multi-cluster Backup & Restore by using a hub and spoke topology

The Backup & Restore provides application-centric backup and data recovery. To know more about the service and its architecture, see [Backup & Restore overview](#).

IBM Data Cataloging

The IBM Data Cataloging provides data insight for exabyte-scale heterogeneous file, object, backup, and archive storage on premises and in the cloud. The software connects to these data sources to rapidly ingest, consolidate, and index metadata for billions of files and objects. For more information about the IBM Data Cataloging service and its architecture, see [Data Cataloging](#).

Content-Aware Storage (CAS)

It uses natural language processing (NLP) and AI technologies to extract semantic meaning from unstructured data, such as text, charts, graphs, and images. It allows for more efficient data retrieval and integration with AI workflows, particularly in retrieval-augmented generation (RAG) processes. For more information about the CAS service, see [Content-Aware Storage \(CAS\)](#).

- [Fusion Data Foundation](#)
Use this documentation to install, configure, manage, monitor, and troubleshoot Fusion Data Foundation as part of IBM Fusion HCI 2.14.
- [Global Data Platform](#)
Learn how to install and configure Global Data Platform service.
- [Backup & Restore](#)
The Backup & Restore service protects your workloads with tailored backups by using a hub and spoke model. You can restore your data rapidly from local snapshots without having to rely on external storage. Backups can be transferred to external object storage solutions like IBM Cloud, Microsoft Azure, Amazon Web Services, and any S3-compliant object storage. It allows the protection of the IBM Fusion Backup & Restore service itself to a S3 bucket.
- [Data Cataloging](#)
Companies need the ability to use unstructured data to meet their business priorities.
- [Content-Aware Storage \(CAS\)](#)
The IBM Fusion Content-Aware Storage service is engineered to enhance the value of customers' AI applications, such as retrieval augmented generation (RAG) for faster time to insights, reduced cost, improved performance, enhanced security, and streamlined operations.
- [Software Hub](#)
The Software Hub is a comprehensive platform that simplifies the deployment and management of IBM software solutions, including IBM Software Hub, watsonx.ai and watsonx Orchestrate, on IBM Fusion HCI. It provides a streamlined and automated experience, reducing the complexity and manual effort associated with traditional deployment processes.

- [Lakehouse-Table \(Technology preview\)](#)
The Lakehouse-Table service is a Kubernetes-native solution for building and managing lakehouse infrastructure on IBM Fusion. It provides a simplified experience for administrators to provision and manage Data Lakehouse capabilities.
- [watsonx.data \(WXD\)](#)
The watsonx.data service delivers a complete, enterprise-ready data lakehouse platform in IBM Fusion.

Fusion Data Foundation

Use this documentation to install, configure, manage, monitor, and troubleshoot Fusion Data Foundation as part of IBM Fusion HCI 2.14.

The latest supported version is Fusion Data Foundation 4.22. For information about new features, enhancements, and known issues in this release, see the [Release notes](#).

IBM Fusion HCI 2.14 supports multiple versions of Fusion Data Foundation. For the list of supported versions and their compatibility with IBM Fusion HCI 2.14, see the [Support matrix](#).

Tip: IBM recommends running the most recent Fusion Data Foundation version that your IBM Fusion HCI release supports to access the latest features and security fixes.

- [Release notes](#)
Review the new features, enhancements, known issues, and deprecated features in the Fusion Data Foundation 4.22 release.
- [Introduction to Fusion Data Foundation](#)
IBM Fusion Data Foundation is a highly integrated collection of cloud storage and data services for Red Hat OpenShift Container Platform. It is available as a IBM Fusion storage service to facilitate simple deployment and management.
- [Installing Fusion Data Foundation](#)
The Fusion Data Foundation service provides a foundational data layer for applications to function and interact with data in a simplified, consistent, and scalable manner. The provider mode is similar to an external Data Foundation configuration. It acts as the provider and base storage on the host cluster. You can provision new clusters within a managed rack and consume storage from the central provider cluster.

Use this troubleshooting information to diagnose and resolve install, upgrade, and operational problems that are related to the Fusion Data Foundation service.

Release notes

Review the new features, enhancements, known issues, and deprecated features in the Fusion Data Foundation 4.22 release.

This release is based on Fusion Data Foundation 4.22, which is built on Red Hat® OpenShift® Container Platform 4.22. For details about new features, enhancements, known issues, and deprecated features in this release, see the topics in this section.

- [New features](#)

New features

Learn about the new features introduced in the Fusion Data Foundation 4.22 release.

- [S3 Vectors support](#)

S3 Vectors support

Fusion Data Foundation 4.22 introduces support for S3 Vectors in the Multicloud Object Gateway (MCG). Vector buckets enable you to store and manage vector embeddings natively in object storage, eliminating the need for an external vector database. This support is designed for machine learning (ML) and artificial intelligence (AI) workloads such as semantic search, recommendation systems, and natural language processing (NLP) applications. Vector data is stored on NamespaceStore Filesystem (NSFS)-backed storage using Lance, a modern columnar format optimized for ML workloads. Vector buckets are provisioned through the standard ObjectBucketClaim (OBC) workflow and managed using the AWS S3 Vectors CLI.

For more information, see [S3 Vectors in Multicloud Object Gateway](#).

Enhancements

- [Erasure coding](#)
- [2AZ and arbiter node topology](#)
- [Monitoring](#)
- [Disaster recovery](#)
- [Multicloud Object Gateway](#)
- [RADOS Object Gateway](#)

Erasure coding

Erasure coding support for Ceph File System (CephFS) file storage and RADOS Gateway (RGW) object storage

IBM Fusion HCI with Fusion Data Foundation 4.22 extends erasure coding support to include Ceph File System (CephFS) file storage and RADOS Gateway (RGW) object storage, in addition to the existing RADOS Block Device (RBD) block storage support introduced in IBM Fusion HCI 2.13. With this support, you can provision all three storage types: block, file, and object storage by using erasure coding on a single-rack IBM Fusion HCI system. Erasure coding can help improve usable storage capacity for workloads with different storage access patterns.

For more information, see [Configuring Fusion Data Foundation in provider mode](#).

Erasure coding support for expansion rack topology

IBM Fusion HCI with Fusion Data Foundation 4.22 extends erasure coding support to the expansion rack topology. You can now deploy a Fusion Data Foundation cluster in erasure coding mode on a base rack and expand storage and compute capacity by adding an expansion rack. The expansion rack uses a node failure domain, so storage nodes added through the expansion rack contribute to the total node count for the existing erasure coding profile.

For more information, see [Fusion Data Foundation storage compatibility across rack configurations](#).

2AZ and arbiter node topology

Hosted Control Plane support on 2AZ and arbiter node topology

IBM Fusion HCI 2.14 with Fusion Data Foundation 4.22 extends Hosted Control Plane support to the 2AZ and arbiter node topology. You can now deploy virtualized and bare metal hosted clusters on a 2AZ and arbiter node configuration. The control plane and etcd are distributed across all three control nodes, one per availability zone, so the cluster remains operational during a single AZ failure. LVM persistent storage for etcd is provisioned on control nodes using the LVM storage operator.

Regional-DR support for HCP workloads on 2AZ and arbiter node topology

IBM Fusion HCI 2.14 with Fusion Data Foundation 4.22 extends Regional-DR support to Hosted Control Plane workloads deployed on a 2 availability zone (AZ) and arbiter node topology. You can now protect applications and virtual machines (VMs) that consume erasure-coded block (EC Block) and erasure-coded file (EC File) storage across regional distances, pairing a 2AZ and arbiter primary site with a standalone single-rack secondary site. Red Hat® Advanced Cluster Management for Kubernetes (RHACM) orchestrates failover and failback between the two sites.

For configuration instructions, see [Configuring Regional-DR](#).

Monitoring

Clone count alert for client clusters in provider/consumer mode

Fusion Data Foundation 4.22 extends CSI RBD clone count monitoring to client clusters that are connected to a provider cluster in provider/consumer mode. A new **HighRBDCloneSnapshotCount** alert fires when the number of CSI RBD clones of a single source image on a client cluster exceeds the recommended soft limit. Exceeding this limit causes exponentially slower clone and flattening performance. The alert prompts users to switch to VolumeSnapshot-based cloning to avoid performance degradation.

For more information, see [HighRBDCloneSnapshotCount](#).

Disaster recovery

Transition to a vendor-agnostic DR operator

Fusion Data Foundation 4.22 rebrands the Red Hat OpenShift® Data Foundation Multicloud Orchestrator into a vendor-agnostic DR operator. The operator is renamed to Data Foundation Multicloud Orchestrator, removing Red Hat OpenShift Data Foundation-specific branding to support a broader range of storage platforms and disaster recovery configurations.

Monitoring disaster recovery relationships by using Topology view

Fusion Data Foundation 4.22 introduces a disaster recovery topology view that provides a visual, hierarchical representation of disaster recovery relationships across clusters and applications. You can use this view to quickly understand disaster recovery coverage, health, and dependencies without navigating multiple pages or inspecting configuration details.

For more information, see [Monitoring regional disaster recovery relationships and actions by using Topology view](#).

Regional-DR support for erasure-coded RBD and CephFS storage classes

Fusion Data Foundation 4.22 extends regional disaster recovery (Regional-DR) on IBM Fusion HCI to support applications that use erasure-coded CephFS file storage and RGW object storage, in addition to existing RBD block storage support introduced in IBM Fusion HCI 2.13. You can now provision all three storage types by using erasure coding: block, file, and object storage. Regional-DR between erasure-coded and non-erasure-coded storage classes is not supported.

For configuration instructions, see [Configuring Regional-DR](#).

Storage-agnostic disaster recovery for third-party vendors

Fusion Data Foundation 4.22 introduces a storage-agnostic DR framework in Ramen that decouples disaster recovery workflows from Red Hat OpenShift Data Foundation and Ceph-backed storage. Ramen abstracts the underlying storage layer and enables consistent disaster recovery operations across diverse

infrastructures. Any third-party storage vendor that provides an operator capable of reconciling the VolumeGroupReplication custom resources (CRs) can use Ramen to orchestrate DR policies, unplanned failovers, and planned relocations regardless of the storage platform.

For more information, see [Storage-agnostic disaster recovery for third-party vendors](#).

DryRun mode for testing failover [Technology preview]

Fusion Data Foundation 4.22 introduces DryRun mode, also known as Testing Failover, which enables you to validate disaster recovery procedures without disrupting your production application. This feature enables non-destructive failover testing by temporarily promoting the secondary cluster to verify readiness and data consistency while keeping the primary cluster completely untouched.

For more information, see [DryRun mode for testing failover \[Technology preview\]](#).

Important: Technology Preview features are not supported with production service level agreements (SLAs) and might not be functionally complete. Do not use Technology Preview features in production environments.

Multicloud Object Gateway

Object Bucket Claim support on hosted clusters

Fusion Data Foundation 4.22 extends object storage access to hosted (client) clusters in provider mode. On client clusters, you can now create and delete Object Bucket Claims (OBCs) using the NooBaa storage class distributed from the provider cluster, without requiring the storage administrator to provision buckets on their behalf. The resulting S3 credentials and relevant information are automatically propagated to the client cluster.

For more information, see [Object Bucket Claims on hosted clusters](#).

Object browser support on client clusters

Fusion Data Foundation 4.22 extends the object browser in the OpenShift Container Platform Web Console to client (hosted) clusters in provider mode. On client clusters, you can now browse and manage buckets, configure CORS rules and bucket policies, and perform data operations such as uploading, downloading, previewing, and sharing objects. Management operations are routed through an in-cluster Nginx reverse proxy on the client cluster. If the provider S3 Route certificate uses a private or custom certificate authority (CA), you must manually configure CA trust for the proxy. Data operations connect directly from the browser to the provider's S3 Route and require a one-time CORS enablement per bucket and browser trust of the provider's S3 certificate.

For more information, see [Object browser on client clusters](#).

Object bucket quota support for Object Bucket Claims

Fusion Data Foundation 4.22 introduces quota configuration support for Object Bucket Claims (OBCs) and buckets in the Multicloud Object Gateway (MCG). Quotas prevent resource exhaustion, optimize storage usage, and enable administrators to control storage consumption and ensure fair resource allocation across multiple applications.

For more information, see [Managing bucket quota](#).

Standardized Azure Identity configuration for Fusion Data Foundation

Fusion Data Foundation 4.22 introduces a standardized configuration workflow for Azure Identity on Azure Identity-enabled OpenShift clusters. This workflow provides a consistent and repeatable process that uses well-defined inputs and behavior, aligned with the common credential management flow. It simplifies deployment and reduces configuration complexity across operators that support Azure Identity. As a result, you can more easily adopt secure, token-based authentication with Azure services.

Configurable NooBaa operator log levels

Fusion Data Foundation 4.22 introduces a configurable `OPERATOR_LOG_LEVEL` environment variable that enables administrators to adjust NooBaa operator log verbosity to reduce log output during routine reconciliation loops.

[\(DFBUGS-4372\)](#)

RADOS Object Gateway

STS authentication for RADOS Object Gateway enabled by default

Fusion Data Foundation 4.22 enables Security Token Service (STS) token-based authentication for internal RADOS Object Gateway (RGW) instances by default. This change improves security and simplifies deployment by eliminating the need for manual STS configuration.

Disabling HTTP route for RADOS Object Gateway

Fusion Data Foundation 4.22 introduces the option to disable insecure HTTP access to the RADOS Object Gateway (RGW) by configuring the `disableHTTP` option in the StorageCluster custom resource. This configuration ensures that only secure HTTPS connections are allowed to access the RGW S3 endpoint. You can disable the HTTP route after the cluster is deployed.

For more information, see [Disabling the HTTP route for RADOS Object Gateway](#).

Known issues

Disaster recovery

UI cleanup message identifies the wrong cluster after aborting a discovered application dryRun test failover

When a dryRun test failover for a discovered application is aborted, the **failoverCluster** field is removed from the DRPlacementControl (DRPC) specification while the **DRPC status.phase** remains **FailedOver**. The UI derives the cleanup target cluster by finding the complement of the primary cluster, but since **getPrimaryClusterName()** returns undefined due to missing **spec.failoverCluster**, the cluster lookup defaults to the first cluster in the DRPolicy, which might be the original primary cluster instead of the actual failover target.

As a result, the UI cleanup message incorrectly directs you to delete application resources from the original primary cluster instead of the failover target cluster where the dryRun workload was deployed. Acting on this incorrect guidance could result in deleting the production workload.

Workaround:

Ignore the cluster name displayed in the UI cleanup message. Instead, identify the failover target cluster to which the dryRun test failover was triggered and delete the application resources from that cluster.

Result:

After cleaning up the workload from the correct failover target cluster, the application continues running only on the original primary managed cluster and data replication resumes, restoring the DR state for the application.

[\(DFBUGS-7998\)](#)

UI does not reflect DRPC progression updates during ApplicationSet dryRun test failover abort

When a dryRun test failover for an ApplicationSet workload is aborted, the DRPC progression correctly transitions through **Cleaning Up** and then **Completed**. However, the user interface does not recognize or display these progression updates during the abort workflow.

As a result, the UI continues to display a stale state, such as **TestingFailover** or **FailedOver**, instead of the actual DRPC progression. This can give you an inaccurate view of the dryRun abort and cleanup status.

Workaround:

Verify the actual DRPC progression by using the command line instead of relying on the UI status. For example, run `oc get drpc <name> -n <namespace> -o yaml` and review the DRPC progression details to confirm that the abort and cleanup completed successfully.

Result:

After the dryRun abort completes and the DRPC progression reaches **Completed**, the workload is removed from the failover cluster and normal disaster recovery protection resumes on the primary managed cluster.

[\(DFBUGS-8070\)](#)

CephFS VolSync PVCs can get stuck during disable DR

During disable DR for CephFS workloads protected by VolSync, Ramen deletes **ReplicationSource** (and related replication-group) objects without first removing their owner references from the PVCs, even when the disable-DR workflow requests that PVCs be preserved (**do-not-delete-pvc**). Kubernetes then marks the PVCs for deletion.

As a result, PersistentVolumeClaims (PVCs) can remain stuck in a **Terminating** state instead of staying **Bound**. Disable DR does not complete cleanly for affected CephFS deployments, and workloads might continue running while storage is left in an inconsistent lifecycle state.

Workaround:

Do not disable DR for CephFS VolSync workloads until a fix is available. If PVCs are already stuck in a **Terminating** state, recovery requires manual intervention. One recovery method is to use `kubectl patch` to remove the **ReplicationSource** and **ReplicationDestination** owner references from the PVCs during the disable-DR operation.

[\(DFBUGS-8196\)](#)

Ramen fails to detect updated SSL certificates for S3 connections

After an SSL certificate rotation on the S3 service, Ramen might not automatically detect newly added SSL certificates in the hub cluster. The Ramen pod continues to use the certificates that were loaded during startup, which can cause S3 connections to newly added clusters to fail.

This issue might surface as errors such as:

```
failed to list objects in bucket: code: RequestError, message: send request failed
```

Note that this error can occur due to various connection or access issues and should not always be interpreted as an SSL certificate problem.

Workaround:

Manually restart the Ramen pod on the hub cluster to trigger reinitialization of the S3 connections. This process allows Ramen to load and use the updated SSL certificates.

If you are using managed clusters:

- Update the certificates in the **managedClusters** configuration.
- Manually restart the Ramen pods in the managed clusters after the certificate rotation is complete.

[\(DFBUGS-2520\)](#)

CephBlockPoolRadosNamespace remains in **Progressing** state for custom **CephBlockPools** in an RDR configuration

When a custom **CephBlockPool** is created on a cluster configured for Regional Disaster Recovery (Regional-DR), the automatically created **CephBlockPoolRadosNamespace** resource (`<pool-name>-builtin-implicit`) can remain in the **Progressing** state indefinitely. This occurs because the MirroringController in the **ocs-operator** cannot enable mirroring on the **CephBlockPool** when the peer cluster bootstrap token is not yet available.

As a result, mirroring is not enabled on the **CephBlockPool** and the associated **CephBlockPoolRadosNamespace** does not transition to a healthy state.

Workaround:

If the **CephBlockPoolRadosNamespace** remains in the **Progressing** state and mirroring is not enabled on the **CephBlockPool**, restart the **ocs-operator** pod.

Result:

After the `ocs-operator` restarts, mirroring is enabled successfully on the `CephBlockPool` and the `CephBlockPoolRadosNamespace` transitions out of the `Progressing` state.

([DFBUGS-7981](#))

DRPCs protect all persistent volume claims created on the same namespace

The namespaces that host multiple disaster recovery (DR) protected workloads protect all the PVCs within the namespace for each DRPlacementControl resource in the same namespace on the hub cluster that does not specify and isolate PVCs based on the workload using its `spec.pvcSelector` field.

This results in PVCs that match the DRPlacementControl `spec.pvcSelector` across multiple workloads. Or, if the selector is missing across all workloads, replication management to potentially manage each PVC multiple times and cause data corruption or invalid operations based on individual DRPlacementControl actions.

Workaround:

Label PVCs that belong to a workload uniquely, and use the selected label as the DRPlacementControl `spec.pvcSelector` to disambiguate which DRPlacementControl protects and manages which subset of PVCs within a namespace. It is not possible to specify the `spec.pvcSelector` field for the DRPlacementControl using the user interface, hence the DRPlacementControl for such applications must be deleted and created using the command line.

Result:

PVCs are no longer managed by multiple DRPlacementControl resources and do not cause any operation and data inconsistencies.

([DFBUGS-1749](#))

Disabled `PeerReady` flag prevents changing the action to failover

The DR controller executes full reconciliation as and when needed. When a cluster becomes inaccessible, the DR controller performs a sanity check. If the workload is already relocated, this sanity check causes the `PeerReady` flag associated with the workload to be disabled, and the sanity check does not complete due to the cluster being offline. As a result, the disabled `PeerReady` flag prevents you from changing the action to failover.

Workaround:

Use the command-line interface to change the DR action to failover despite the disabled `PeerReady` flag.

([DFBUGS-665](#))

For discovered apps with CephFS, sync stop after failover

For CephFS-based workloads, synchronization of discovered applications may stop at some point after a failover or relocation. This can occur with a `Permission Denied` error reported in the `ReplicationSource` status.

Workaround:

- **For Non-Discovered Applications**

1. Delete the VolumeSnapshot.

```
oc delete volumesnapshot -n <vrg-namespace> <volumesnapshot-name>
```

The snapshot name usually starts with the PVC name followed by a timestamp.

2. Delete the VolSync Job.

```
oc delete job -n <vrg-namespace> <pvc-name>
```

The job name matches the PVC name.

- **For Discovered Applications**

Use the same steps, except `<namespace>` refers to the **application workload namespace**, not the VRG namespace.

- **For Workloads using Consistency Groups**

- Delete the ReplicationGroupSource:

```
oc delete replicationgroupsource -n
<namespace> <name>
```

- Delete all VolSync jobs in that namespace:

```
oc delete jobs --all -n
<namespace>
```

In this case, `<namespace>` refers to the namespace of the workload (either discovered or not), and `<name>` refers to the name of the ReplicationGroupSource resource.

([DFBUGS-2883](#))

DRPC progression completes without workload cleanup when aborting a CephFS dryRun test failover

For a CephFS discovered application that is in the `Deployed` state before a dryRun test failover is triggered, aborting the dryRun can cause the DRPlacementControl (DRPC) progression to transition from `TestingFailover` to `Completed` even though the workload has not been cleaned up from the failover cluster (test cluster).

This results in the CephFS discovered application continuing to run on both managed clusters simultaneously, which can leave the application's disaster recovery state inconsistent.

Workaround:

Delete the application from the failover cluster (test cluster) where the dryRun test failover was triggered.

Result:

After the application is removed from the failover cluster, the workload continues running only on the primary managed cluster. Data replication resumes after the cleanup is completed and the application's disaster recovery state is restored.

([DFBUGS-8115](#))

Submariner connectivity is degraded for CephFS mirroring in Regional DR deployments with hosted control plane clusters

In Regional Disaster Recovery (Regional-DR) deployments using KubeVirt-based Hosted Control Plane (HCP) clusters, the Submariner gateway public IP resolver fails to resolve the LoadBalancer IP in air-gapped environments. The Submariner gateway publishes an empty `publicIP` to the broker, causing the peer gateway to send NAT discovery packets to the unreachable private pod IP instead of the LoadBalancer virtual IP (VIP). As a result, the Submariner connection between clusters remains in a `Connecting` state, the overall Submariner status is `Degraded`, and CephFS mirroring fails.

([ACM-36616](#))

Multicloud Object Gateway

Unable to create new OBCs using Multicloud Object Gateway

When provisioning an NSFS bucket by using ObjectBucketClaim (OBC), the default filesystem path is expected to use the bucket name. However, if path is set in `OBC.Spec.AdditionalConfig`, it should take precedence. This behavior is currently inconsistent, resulting in failures when creating new OBCs.

([DFBUGS-3817](#))

Ceph

OSD pods restart during add capacity

OSD pods restart after performing cluster expansion by adding capacity to the cluster. However, no impact to the cluster is observed apart from pod restarting.

([DFBUGS-1426](#))

SELinux relabelling issue with a very high number of files

When attaching volumes to pods in Red Hat® OpenShift® Container Platform, the pods sometimes do not start or take an excessive amount of time to start. This behavior is generic and it is tied to how SELinux relabelling is handled by Kubelet. This issue is observed with any filesystem based volumes having very high file counts. In Fusion Data Foundation, the issue is seen when using CephFS based volumes with a very high number of files. There are multiple ways to work around this issue. Depending on your business needs you can choose one of the workarounds from the Red Hat knowledgebase article:

<https://access.redhat.com/solutions/6221251>.

([RFE-3327](#))

IBM Storage Scale

Scale Dashboard reports "Healthy" connection despite total storage I/O failure on worker nodes

The IBM Storage Scale Container Native (CNSA) operator fails to report a connection failure when the storage data path is severed between OpenShift worker nodes and the remote Scale cluster. While the data plane is functionally dead, the `RemoteCluster` custom resource (CR) and the Scale Dashboard UI continue to report a status of "Healthy/Available." This occurs because the health check relies solely on the reachability of the remote Scale REST API from the operator pod, ignoring the actual mount state and heartbeat status of the compute (daemon) pods on the worker nodes.

Workaround:

Perform manual verification by running `mmfscluster` from the CLI or run an `ls` command directly on the mount point to confirm the actual storage health and path status.

([DFBUGS-6498](#))

Fusion Data Foundation console

UI shows `WaitOnUserCleanup` even when automatic cleanup is enabled

The UI incorrectly displays the `WaitOnUserCleanup` status even when automatic cleanup is enabled for VMs. This occurs because the UI relies only on the `phase` and `progression` fields of the `DRPlacementControl` to determine cleanup behavior and does not evaluate the more granular `AutoCleanup` condition that explicitly indicates automatic cleanup.

Workaround:

There is no manual workaround required. This state is transient and clears automatically once the `progression` field advances to `Completed`. Manual cleanup should be avoided unless the `AutoCleanup` condition and its corresponding `reason` in the `DRPlacementControl` or VRG status indicate otherwise.

During automatic cleanup, the UI may briefly present a misleading status, which can cause temporary confusion until the cleanup completes.

([DFBUGS-5824](#))

DRPlacementControl shows `ProtectionError` even after successful relocation

When a relocation completes, the `DRPlacementControl` may continue to display a `ProtectionError` status. This occurs because the `Protected` condition in the `DRPlacementControl` status incorrectly reports an `Error` state, even though the relocation has finished (`phase: Relocated, progression: Completed`).

Workaround:

No direct workaround is available. Wait until retrying the `NoClusterDataConflict` condition is met.

The DR status in the UI remains in the `ProtectionError` state until the data conflict is resolved.

([DFBUGS-5823](#))

Upgrade

Upgrading from Fusion Data Foundation 4.21.z to 4.22.0 or 4.22.1 is not supported

If you upgrade from Fusion Data Foundation 4.21.z to 4.22, you must upgrade to Fusion Data Foundation 4.22.2 or later. Upgrades to Fusion Data Foundation 4.22.0 or 4.22.1 are not supported and fail.

([DFBUGS-11165](#))

Deprecated features

Learn about the deprecated features in the Fusion Data Foundation 4.22 release.

Deprecation notice for Metro-DR in external mode architectures

Metro-DR functionality based on external Fusion Data Foundation and IBM Storage Ceph architectures is deprecated as of release 4.22 and will be removed in version 5.1. Fusion Data Foundation 4.23 is the final release to support this configuration.

Starting with version 5.1, Metro-DR capabilities transition exclusively to a Provider-mode architecture within Fusion Data Foundation.

The impact and migration path are as follows:

Support lifecycle

Existing customers who use this technology can remain on version 4.23, which receives full support until its end of life (EOL) at the end of 2029.

Next steps

Customers who are planning future deployments or looking to upgrade beyond the 4.x lifecycle should plan a migration to the new Provider-mode Metro-DR architecture on Fusion Data Foundation.

Introduction to Fusion Data Foundation

IBM Fusion Data Foundation is a highly integrated collection of cloud storage and data services for Red Hat® OpenShift® Container Platform. It is available as a IBM Fusion storage service to facilitate simple deployment and management.

Fusion Data Foundation services are primarily made available to applications in the form of storage classes that represent the following components:

- Block storage devices, catering primarily to database workloads, for example, Red Hat OpenShift Container Platform logging and monitoring, and PostgreSQL. Important: Block storage should be used for any workload only when it does not require sharing the data across multiple containers.
- Shared and distributed file system, catering primarily to software development, messaging, and data aggregation workloads, for example, Jenkins build sources and artifacts, Wordpress uploaded content, Red Hat OpenShift Container Platform registry, and messaging using JBoss AMQ.
- Multicloud object storage, featuring a lightweight S3 API endpoint that can abstract the storage and retrieval of data from multiple cloud object stores.
- On-premises object storage, featuring a robust S3 API endpoint that scales to tens of petabytes and billions of objects, primarily targeting data intensive applications, for example, the storage and access of row, columnar, and semi-structured data with applications like Spark, Presto, Red Hat AMQ Streams (Kafka), and even machine learning frameworks like TensorFlow and Pytorch.

Note:

Running PostgreSQL workload on CephFS persistent volume is not supported and it is recommended to use RADOS Block Device (RBD) volume.

Fusion Data Foundation version 4.x integrates a collection of software projects, including:

- Ceph, providing block storage, a shared and distributed file system, and on-premises object storage.
- Ceph CSI, to manage provisioning and lifecycle of persistent volumes and claims.
- NooBaa, providing a Multicloud Object Gateway (MCG).
- Fusion Data Foundation, rook-ceph, and NooBaa operators to initialize and manage Fusion Data Foundation services.

Installing Fusion Data Foundation

The Fusion Data Foundation service provides a foundational data layer for applications to function and interact with data in a simplified, consistent, and scalable manner. The provider mode is similar to an external Data Foundation configuration. It acts as the provider and base storage on the host cluster. You can provision new clusters within a managed rack and consume storage from the central provider cluster.

Before you begin

- It is recommended to install the latest version of Fusion Data Foundation and OpenShift® Container Platform. For detailed storage comparability matrix, see [IBM Fusion support matrix](#).
- For Fusion Data Foundation 4.16, perform a fresh installation. Do not upgrade from versions 4.14 or 4.15.
- If you install Data Foundation, the Global Data Platform remote mount tile becomes available, but you must explicitly install and configure it. Important: If you install Fusion Data Foundation 4.21 or later and the Global Data Platform remote mount service is installed and configured, the service is automatically migrated to version 6.0.1.0. Review the supported [migration](#) scenarios before installation.
- If you install Data Foundation directly from the OpenShift Container Platform, then IBM Fusion HCI does not support its discovery.
- When LVM drives are available, IBM Fusion HCI automatically detects the presence of the control plane drives and configures them for LVM.
- Clean installation verification
 - Before installing Fusion Data Foundation, verify that there is no previously installed Fusion Data Foundation, Red Hat® OpenShift Data Foundation, OpenShift Container Storage, or Rook-Ceph in this OpenShift cluster:

1. Verify that the namespace `openshift-storage` does not exist.

- Run the following command to confirm that no storage resources exist:

```
oc get storagecluster -A; oc get cephcluster -A
```

- Run the following command to confirm that no nodes have storage labels:

```
oc get node -l cluster.ocs.openshift.io/openshift-storage=
```

Procedure

- Go to Services page in IBM Fusion user interface.
- In the Available section, click the Data Foundation tile.
- In the Storage providers section, click the Data Foundation tile to install and configure storage service.
Note: You cannot install other dependent services until you install and configure a storage service.
- In the Data Foundation page, go through the details about the service and click Install.
The IBM Fusion HCI supports both provider mode and MCG only mode.
- Choose the following options and click Install:
 - Automatic updates
Note: If you select Automatic updates, then IBM Fusion auto upgrades Fusion Data Foundation version. This upgrades Fusion Data Foundation service within the subscription channel.

For example, 4.16.x to 4.16.y. For storage support matrix, see [IBM Fusion support matrix](#).

The Fusion Data Foundation operator starts to deploy and you can see Data Foundation in the Installed section of the Services page. Initially, the status shows as Installing and progress of the installation is mentioned in percentage. After successful completion of the installation, the status changes to Running.

- To validate the installation, do the following steps in OpenShift Container Platform web console:
Go to Installed Operators to check whether the Fusion Data Foundation operator is listed and Status shows as Succeeded.
- Verify the Fusion Data Foundation service installation.
 - To verify the installation of Fusion Data Foundation on IBM Fusion, perform the checks specified in [Verify the installation](#).
 - Additionally, run the command to verify that Fusion Data Foundation service is installed successfully:

```
oc describe odffmanager/odffmanager -n <Fusionns>
```

Update <Fusions> with your namespace value.

Table 1. Install states Fusion Data Foundation service

Install State	Description
Installing	Fusion Data Foundation installation is ongoing, and there are no errors yet.
Failing	There is an installation error but IBM Fusion retries to install Fusion Data Foundation. If the problem is solved, this status changes to Installing or Completed .
Completed	Fusion Data Foundation installation completed successfully.

Table 2. Upgrade states Fusion Data Foundation service

Upgrade State	Description
Not started	Fusion Data Foundation upgrade has not started yet.
Upgrading	Fusion Data Foundation upgrade is ongoing, and there are no errors yet.
Failing	There is an installation error but IBM Fusion retries to upgrade Fusion Data Foundation. If the problem is solved, this status changes to Upgrading or Completed .
Completed	Fusion Data Foundation upgrade completed successfully.

Table 3. Health states Fusion Data Foundation service

State	Description
Installing	Fusion Data Foundation installation is ongoing.
Upgrading	Fusion Data Foundation upgrade is ongoing.
Healthy	Fusion Data Foundation installation completed successfully and the service is in normal state.
Degraded	Fusion Data Foundation installation completed successfully but the service is not in normal state.

- Validate the installation.

Verify the Fusion Data Foundation installation was completed successfully from the OpenShift Container Platform console:

- Go to Installed Operators to check whether the Fusion Data Foundation operator is listed and status is Succeeded.
- Verify pods from the Red HatOpenShift Container Platform web console:
 - Go to Workloads > Pods.
 - Select the **openshift-storage** namespace, where the Fusion Data Foundation is installed.
 - Check whether the following pods are running successfully:
 - csi-addons-controller-manager
 - ocs-metrics-exporter
 - ocs-operator
 - odf-console
 - odf-operator-controller-manager
 - rook-ceph-operator
 - ceph-csi-controller-manager
- Alternatively, you can verify the installation by running the OC commands:

```
oc get pod -n openshift-storage
```

A sample result of the OC command is as follows:

```
[root@fu40 ~]# oc get pod -n openshift-storage
NAME                                READY   STATUS    RESTARTS   AGE
csi-addons-controller-manager-bdb965b47-jvfhs   2/2     Running   0          119s
ocs-metrics-exporter-69cfc56fd9-jk49s          1/1     Running   0          2m45s
```

ocs-operator-6879c74556-pppj9	1/1	Running	0	2m46s
odf-console-849f64fdd7-rqd97	1/1	Running	0	3m3s
odf-operator-controller-manager-5bd4c85d6b-q8g2f	2/2	Running	0	3m3s
rook-ceph-operator-76699f976c-2zpm5	1/1	Running	0	2m46s

d. Ensure that all the pods are up and running.

e. Verify the Fusion Data Foundation status as follows:

- Click Operators > Install operators. Select the namespace in which IBM Fusion was installed from the Project tab.
- Select the IBM Fusion.
- Go to Fusion Service Instance tab and click odfmanager from the list.
- Open **YAML** tab and ensure that **.status.health** is Healthy.

f. Alternatively, you can verify the status by running the OC commands:

```
oc get fusionserviceinstances.service.isf.ibm.com -n ibm-spectrum-fusion-ns odfmanager -o
jsonpath='{.status.health}'
```

g. Verify the local storage operator pods:

- Click Operators > Install operators. Select the **ibm-spectrum-fusion-ns** namespace from the Project tab.
- Select the IBM Fusion.
- Go to Fusion Service Instance tab and click odfmanager from the list.
- Click **YAML** tab and check the **backingStorageType**.

```
- name: backingStorageType
  provided: true
  value: Provider
```

v. Alternatively, you can verify the backing storage type by running the oc commands.

```
oc get fusionserviceinstances.service.isf.ibm.com -n ibm-spectrum-fusion-ns odfmanager -o
jsonpath='{.spec.parameters}'
```

vi. Verify pods from the Red Hat OpenShift Container Platform web console:

- Go to Workloads > Pods.
- Select the **openshift-local-storage** namespace, where the local storage operator is installed.
- Check whether the following pods are running successfully: **local-storage-operator-xxxxx**
For example: **local-storage-operator-75c55cf57d-pfjcp**

vii. Ensure that all pods are running.

viii. Alternatively, you can verify the installation by running the oc commands:

```
oc get pod -n openshift-local-storage
```

A sample result of the oc command is as follows:

```
[root@fu40 ~]# oc get pod -n openshift-local-storage
NAME                                READY    STATUS    RESTARTS    AGE
local-storage-operator-75c55cf57d-pfjcp 1/1      Running   0            109s
```

What to do next

Configure local storage. For the procedure to configure, see [Configuring Fusion Data Foundation](#).

- [Fusion Data Foundation storage compatibility across rack configurations](#)
Describes the supported Fusion Data Foundation storage configurations across single-rack, multi-rack, and expansion-rack deployments in IBM Fusion HCI systems.
- [Installing a Fusion Data Foundation client](#)
Install a Fusion Data Foundation client on Red Hat OpenShift Container Platform to enable the cluster to access storage from a Fusion Data Foundation provider cluster without managing local storage.

Fusion Data Foundation storage compatibility across rack configurations

Describes the supported Fusion Data Foundation storage configurations across single-rack, multi-rack, and expansion-rack deployments in IBM Fusion HCI systems.

Table 1. Fusion Data Foundation storage compatibility across IBM Fusion HCI rack configurations

Deployment topology	Fusion Data Foundation provider mode	Fusion Data Foundation Provider mode failure domain tolerance	Disk upsize	Node Upsize	Node configuration
Standalone rack	Supported	Node	Supported	Supported	- A minimum of 3 storage nodes is required. - Disk size and type must be the same. - Erasure coding is supported on Red Hat® OpenShift® Container Platform and Fusion Data Foundation 4.21 or later for block (RBD) storage, and 4.22 or later for file (CephFS) and object (RGW) storage. The number of storage nodes must meet the minimum node requirement for the selected erasure coding profile (k + m nodes, where k is data chunks and m is parity chunks). For example, a 4+2 profile requires a minimum of 6 storage nodes, and an 8+2 profile requires a minimum of 10 storage nodes.

Deployment topology	Fusion Data Foundation provider mode	Fusion Data Foundation Provider mode failure domain tolerance	Disk upsize	Node Upsize	Node configuration
HA rack and 3 zone HA rack	Supported	Rack	Supported	Supported	- A minimum of 3 storage nodes is required in each rack. - All racks must maintain consistency in the number of nodes, disk sizes, and disk types. This uniformity requirement extends to all node or disk upscaling operations.
2 availability zone (AZ) + Arbiter node rack	Supported	Rack	Supported	Supported	- A minimum of 3 storage nodes is required in each rack. - Both racks must maintain consistency in the number of nodes, disk sizes, and disk types. This uniformity requirement extends to all node or disk upscaling operations.
Expansion rack	Supported	Node	Supported	Supported	- A minimum of 3 storage nodes is required in the base rack for an expansion rack configuration. When erasure coding is enabled, the base rack must meet the minimum node requirement of the selected erasure coding profile. - Disk size and type must be the same. - Erasure coding is supported on Red Hat OpenShift Container Platform 4.22 or later with Fusion Data Foundation 4.22 or later. When you first configure erasure coding on the base rack, the storage nodes in that rack must meet the minimum node requirement for the selected erasure coding profile (k + m nodes, where k is data chunks and m is parity chunks). For example, a 4+2 profile requires a minimum of 6 storage nodes, and an 8+2 profile requires a minimum of 10 storage nodes. Storage nodes added through an expansion rack contribute to the total node count for the existing profile. The erasure coding profile is set at initial deployment and does not change when you add an expansion rack. For example, a cluster configured with a 4+2 profile on 6 nodes remains a 4+2 profile after additional nodes are added through the expansion rack.

For more information about multi-rack configuration, see [Deployment configurations](#).

Installing a Fusion Data Foundation client

Install a Fusion Data Foundation client on Red Hat® OpenShift® Container Platform to enable the cluster to access storage from a Fusion Data Foundation provider cluster without managing local storage.

Before you begin

Before you begin, ensure that the following conditions are met:

- Provider and client clusters are running on Red Hat OpenShift Container Platform.
- The provider and client clusters are in the same network and can communicate with each other.
- The round-trip network latency between the two sites does not exceed 10 ms (RTT).
- Fusion Data Foundation is installed on the provider cluster.
- You have cluster administrator permissions.
- The OpenShift CLI (oc) is installed and configured.
- A mix of Red Hat OpenShift Data Foundation and Fusion Data Foundation client-provider configurations is not supported.

About this task

Fusion Data Foundation supports a provider–consumer architecture in which storage resources are managed on a provider cluster and consumed by one or more client clusters. In this configuration, the client cluster does not provision or manage local storage. Instead, it consumes storage exposed by the provider cluster.

In this model:

- The provider cluster hosts and exposes storage services.
- The client cluster connects to the provider cluster and consumes its storage.

This approach is useful when you want to:

- Centralize storage management in a provider cluster
- Enable multiple clusters to share centralized storage, isolated for each connected client
- Reduce infrastructure overhead on client clusters

Follow this procedure when:

- An OpenShift Container Platform cluster act as a Fusion Data Foundation client
- Storage is centralized and managed on a separate provider cluster
- The client cluster must consume storage without deploying or managing local storage

This task includes configuration steps on both the provider and the client clusters.

Procedure

1. Configure the provider cluster for external client access.
On the provider cluster, set up MetalLB, expose the provider endpoint, and generate the onboarding token. For instructions, see [Configuring the provider cluster for external client access](#).
2. Configure the client cluster to access provider storage.
Install the Fusion Data Foundation client and configure access to the provider storage. For instructions, see [Configuring the client cluster to access provider storage](#).

Results

- The client cluster is successfully connected to the provider cluster.
- Fusion Data Foundation storage classes are available to the client cluster.
- The provider cluster lists the client cluster as a registered storage consumer.
- [Configuring the provider cluster for external client access](#)
Configure the provider cluster to expose storage services and generate an onboarding token for client access.
- [Configuring the client cluster to access provider storage](#)
Install and configure the Fusion Data Foundation client on the client cluster to access storage from the provider cluster.

Configuring the provider cluster for external client access

Configure the provider cluster to expose storage services and generate an onboarding token for client access.

Procedure

1. Install the MetalLB operator.
To install the MetalLB operator, complete the following steps:
 - a. Log in to the Red Hat® OpenShift® Container Platform web console.
 - b. Go to the Ecosystem > Software Catalog page.
 - c. Scroll or type MetalLB into the Filter by keyword box.
 - d. Select MetalLB Operator from the results.
 - e. Click Install.
 - f. On the Install Operator page, complete the following configuration:
 - i. Select stable from the Update channel list.
 - ii. Select the required version from the Version list.
 - iii. For Installation mode, select All namespaces on the cluster (default).
 - iv. For Installed Namespace, select Operator recommended Namespace.
 - v. For Update approval, select either Automatic (recommended) or Manual.
 - g. Click Install.
 - h. Go to the Installed Operators page and confirm that:
 - The MetalLB Operator appears in the list
 - Status is Succeeded

2. Create a MetalLB instance.
Apply the following configuration:

```
apiVersion: metallb.io/v1beta1
kind: MetalLB
metadata:
  name: metallb
  namespace: metallb-system
```

3. Configure an IP address pool.
Define a range of IP addresses to be assigned by MetalLB:

```
apiVersion: metallb.io/v1beta1
kind: IPAddressPool
metadata:
  name: metallb
  namespace: metallb-system
spec:
  addresses:
  - 10.0.0.138-10.0.0.142
```

4. Create an L2 advertisement.
Apply the following configuration:

```
apiVersion: metallb.io/v1beta1
kind: L2Advertisement
metadata:
  name: l2advertisement
  namespace: metallb-system
spec:
  ipAddressPools:
  - metallb
```

5. Create a LoadBalancer service.
Expose the provider API using a LoadBalancer:

```
apiVersion: v1
kind: Service
```

```

metadata:
  name: ocs-provider-server-load-balancer
  namespace: openshift-storage
  annotations:
    metallb.universe.tf/ip-allocated-from-pool: metallb
spec:
  type: LoadBalancer
  selector:
    app: ocsProviderApiServer
  ports:
    - name: provider
      protocol: TCP
      port: 50051
      targetPort: ocs-provider
      nodePort: 30756

```

Important:

Record the LoadBalancer IP address and port. For example: `storageProviderEndpoint: 10.0.0.138:50051`. You need this information when onboarding the client cluster.

6. Create a storage consumer instance.

To create a storage consumer instance, complete the following steps:

- a. On the Red Hat OpenShift Container Platform web console, navigate to the Storage > Data Foundation > Storage Consumers page.
- b. Click Create Storage Consumer.
- c. Provide the required details, such as name and quota.
- d. Click Create.

7. Generate the onboarding token.

To generate the onboarding token of the created storage consumer instance, complete the following steps:

- a. Click the overflow menu  icon for the new storage consumer instance.
- b. Select Generate client onboarding token.
- c. Copy the onboarding token for use on the client cluster.

Results

The provider cluster is configured, and the onboarding token and LoadBalancer endpoint are available for onboarding the client cluster.

Configuring the client cluster to access provider storage

Install and configure the Fusion Data Foundation client on the client cluster to access storage from the provider cluster.

Procedure

1. Install IBM Fusion on the client cluster.

To install IBM Fusion on the client cluster, use the Red Hat® OpenShift® Container Platform web console. For example steps, see [Deploying IBM Fusion](#) in the *IBM Fusion* documentation. Make sure to use the documentation version that aligns with your setup.

2. Create the Fusion Data Foundation catalog if it is not already available.

Apply the following configuration:

```

apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: isf-data-foundation-catalog
  namespace: openshift-marketplace
spec:
  displayName: Data Foundation Catalog
  image: icr.io/cpopen/isf-data-foundation-catalog:v4.21
  publisher: IBM
  sourceType: grpc
  registryPoll:
    interval: 60m

```

Important:

The version `v4.21` in the `image` field is an example. Replace it with the appropriate version according to your deployment requirements.

The Fusion Data Foundation versions on the provider and client clusters must match the same minor version for onboarding to succeed. For example, a provider running version `4.21.z` supports onboarding only for clients running version `4.21.*` (any patch version). These are Fusion Data Foundation versions, not Red Hat OpenShift Container Platform versions.

3. Install the Fusion Data Foundation client operator.

To install the Fusion Data Foundation client operator, complete the following steps:

- a. On the Red Hat OpenShift Container Platform web console, navigate to the Ecosystem > Software Catalog page.
- b. Scroll or type **Fusion Data Foundation** into the Filter by keyword box.
- c. Select **IBM FusionData Foundation Client** from the results.
- d. Select stable-X.XX from the Channel list.
- e. Select the required version from the Version list.
- f. Click Install.
- g. Go to the Installed Operators page and confirm that:
 - The **IBM FusionData Foundation Client** appears in the list
 - Status is Succeeded

4. Verify that all pods are running in the `openshift-storage` namespace.

Command example:

```
oc get pods -n openshift-storage
```

5. Create a storage client.

To create a storage client, complete the following steps:

- Go to the Ecosystem > Installed Operators page.
- Select the installed Fusion Data Foundation client operator.
- Go to the Storage Client tab and click Create StorageClient.
- Provide the following values:
 - Name: Specify a name.
 - Data Foundation endpoint: Enter the LoadBalancer endpoint from the provider cluster.
 - Onboarding token: Paste the token generated on the provider cluster.
- Click Create.

6. Verify the following:

- On the Storage Client tab, storage client status is Connected.
- Go to Storage > StorageClasses, and verify that storage classes from the provider cluster are available.
- On the provider cluster, navigate to Storage > Data Foundation > Storage Consumers, and verify that the cluster ID, last heartbeat, and other fields are populated for the consumer.

Results

The client cluster is connected to the provider cluster and can use the provider storage.

Installing Data Foundation for MCG only

The IBM Fusion HCI supports MCG only mode.

Before you begin

Label at least two nodes:

- Validate whether the nodes have necessary `cluster.ocs.openshift.io/openshift-storage` label:

```
oc get node -l cluster.ocs.openshift.io/openshift-storage=
```

- If `No resources found` gets displayed, then it means that no node exists with the label. Run the following command to label at least two worker nodes for ensuring High Availability:

```
oc label node <worker-node-1> <worker-node-2> cluster.ocs.openshift.io/openshift-storage=''
```

- Validate label is applied to the nodes:

```
oc get node -l cluster.ocs.openshift.io/openshift-storage=
```

Example output:

NAME	STATUS	ROLES	AGE	VERSION
<worker-node-1>	Ready	worker	28d	v1.28.12+396c881
<worker-node-2>	Ready	worker	28d	v1.28.12+396c881

About this task

You must have a local Global Data Platform storage installed and in a running state. Otherwise, you cannot see the Data Foundation MCG Only tile for installation.

Multi-Cloud Gateway (MCG) in Global Data Platform is an on-prem deployment. If the Global Data Platform ECE is installed, then you can see the MCG tile for it.

Procedure

- Go to Services page in IBM Fusion user interface.
- In the Available section, click the Data Foundation MCG Only tile to install and configure storage service.
- In the Data Foundation page, go through the details about the service and click Install.

The IBM Fusion HCI supports both provider and MCG only modes.

The Fusion Data Foundation operator starts to deploy and you can see Data Foundation MCG Only in the Installed section of the Services page. Initially, the status shows as Installing and the progress of the installation is mentioned in percentage. After installation completes successfully, the status changes to Running.

- To verify, view Multi Cloud gateway in OpenShift®.

For more information about Multi Cloud gateway in OpenShift, see [Managing hybrid and multicloud resource](#).

Configuring Fusion Data Foundation

Configure Fusion Data Foundation to set up storage services that support scalable, resilient, and flexible data management for OpenShift® applications.

After the Fusion Data Foundation installation is complete, configure the storage system based on the device type selected during Fusion Data Foundation installation.

Fusion Data Foundation supports the following configuration mode:

Provider

In provider mode, you can run a local Fusion Data Foundation storage cluster that serves as the central storage provider for multiple consumer clusters. It functions similarly to an external Fusion Data Foundation configuration, where the provider cluster acts as the provider and base storage on the host cluster. You can provision new clusters within a managed rack and have them consume storage from the central provider cluster. This mode is available from IBM Fusion HCI 2.8.1 onward with Fusion Data Foundation 4.16. For instructions, see [Configuring Fusion Data Foundation in provider mode](#).

In this mode, Fusion Data Foundation is layered on Red Hat® OpenShift Service on bare metal and includes the Fusion Data Foundation provider. IBM Fusion HCI with Fusion Data Foundation supplies the base storage for all Hosted Control Plane-based clusters, as shown in the following figure:

Figure 1. Fusion Data Foundation provider mode

Fusion Data Foundation provider mode is a deployment configuration in which the OpenShift cluster running on bare metal serves local storage for OpenShift virtualization, standard applications, and hosted clusters that are running on top of OpenShift virtualization. Provider mode consists of two key components:

- **Provider** - The provider is a deployment mode for Fusion Data Foundation storage services, built on a minimum of three worker nodes using bare metal volumes. This mode allows external clusters to connect through the client operator. Fusion Data Foundation replicates data across these nodes, ensuring resilience and tolerance to node failures.
- **Client** - The client is a managed Container Storage Interface (CSI) deployment that connects to the provider to deliver a local storage class for hosted clusters.

For instructions on Fusion Data Foundation installation, see [Installing Fusion Data Foundation](#).

After completing the configuration, you can monitor capacity utilization and storage nodes, add nodes, and scale capacity as needed.

- [Configuring Fusion Data Foundation in provider mode](#)
Configure Fusion Data Foundation storage in IBM Fusion HCI for provider mode.
- [Viewing Fusion Data Foundation topology](#)
View the topology of your Fusion Data Foundation storage cluster, including the count, type, and status of Object Storage Devices (OSDs).

Configuring Fusion Data Foundation in provider mode

Configure Fusion Data Foundation storage in IBM Fusion HCI for provider mode.

About this task

The provider mode is similar to an external Data Foundation configuration. It acts as the provider and base storage on host cluster. You can provision new clusters within a managed rack and consume storage from the central provider cluster. Hosting multiple OpenShift® clusters within a single HCI rack improves cluster density and brings down cost.

The consumer can be deployed on the IBM Fusion HCI host cluster.

Important: If Fusion Data Foundation is not configured or is configured but are not in a healthy state, then a few pods, like logcollector, might remain in a pending state. The pods come into a running state automatically once storage is configured and in a healthy state.

Procedure

1. Go to the [Storage > Local storage](#) page.
2. Click [Configure storage](#).
3. In the [Configure storage](#) page, do the following configuration:
 - a. Under [Storage optimization](#) section, select one of the following options based on your workload requirements:
 - **Performance:** Optimizes for high-speed operations and fast recovery for performance-critical workloads.

Tip: This option is designed for workloads that require maximum performance and fast rebuild times. It provides higher read and write performance and faster rebuild and recovery times, but results in lower usable capacity. This option is ideal for databases, virtual machines, and applications that require low latency.

- **Storage efficiency:** Optimizes for strong data protection with maximum usable capacity.

Tip: This option uses erasure coding to significantly increase usable storage capacity compared to replication while maintaining strong data protection. Depending on the erasure coding profile, it provides approximately 67% usable capacity for 4+2 profile and 80% usable capacity for 8+2 profile, compared to approximately 33% usable capacity with triple replication. Rebuild times can be longer than the Performance option. This option is ideal for archival storage, backups, and workloads where capacity efficiency is paramount.

The Storage efficiency option is based on erasure coding, which improves usable capacity while maintaining strong data protection. Erasure coding splits data into k data chunks and m parity chunks, which are distributed across storage nodes. To support this configuration, the environment must have at least $k + m$ nodes. For optimal performance and availability, and better data protection during node maintenance operations such as node restart, drain, or replacement, deploy at least $k + m + 1$ nodes.

Examples:

- **4 data chunks + 2 parity chunks (4+2) profile:**
 - Minimum nodes: 6
 - Usable capacity: ~67% (2/3 of raw capacity)
 - Overhead: 1.5×
- **8 data chunks + 2 parity chunks (8+2) profile:**
 - Minimum nodes: 10
 - Usable capacity: ~80% of raw capacity
 - Overhead: 1.25×

Important:

- Erasure coding is supported for RADOS Block Device (RBD) block storage starting with Red Hat® OpenShift Container Platform and Fusion Data Foundation 4.21 or later.
- Erasure coding is supported for Ceph File System (CephFS) file storage and RADOS Gateway (RGW) object storage starting with Red Hat OpenShift Container Platform and Fusion Data Foundation 4.22 or later.
- For RGW object storage, erasure coding can be enabled only during cluster creation. For RBD and CephFS storage, erasure coding can be enabled either during cluster creation or later by creating a new storage class with a new pool.

- b. In the Nodes section, select a minimum of six nodes from the node table based on the recommendation.

By default, all available nodes are selected. If required, deselect nodes that you want to exclude from storage by clearing the corresponding check boxes.

The listed nodes are candidate nodes for selection as Fusion Data Foundation storage nodes. Both compute and control plane nodes that have available SSD or NVMe disks are displayed as candidate nodes in the table. To ensure balanced capacity utilization and performance, use the same number and size of disks across all Fusion Data Foundation storage nodes.

The node table includes the following details:

- Name
- Disks
- Disk size (TiB)
- vCPUs
- Memory (GB)

For High-Availability Multi-Rack configurations, the table also includes a Rack column.

When you configure storage for a High-Availability Multi-Rack configuration, select the same number of nodes from each rack. This configuration ensures that the Fusion Data Foundation cluster continues to operate even if one rack becomes unavailable.

For a two-availability-zone and arbiter node (2AZ and arbiter node) configuration:

- Select the same number of nodes from each zone.
- Select a minimum of two storage nodes from each zone.

Note: The Next button remains disabled if an uneven number of nodes are selected across zones or if fewer than two nodes are selected from each zone.

Based on your selection, the Summary section displays the usable capacity. The usable capacity includes raw capacity, number of nodes, CPUs, and memory. For example, the recommendation might be to select a minimum of six nodes with a usable capacity of 48 TiB.

- c. Click Next.

- d. In the Encryption settings section, select the location for the encryption key:

- Store the encryption key in a secret in the cluster: Stores the encryption key locally within the cluster as a Kubernetes secret.
- Store the encryption key in an external KMS: Stores the encryption key in an external Key Management System for enhanced security.
- None: Disables encryption for the storage configuration.

Note: On a FIPS-enabled cluster, you must enable encryption when configuring Fusion Data Foundation. Store the encryption key either on the cluster or in a user-managed external Vault to ensure compliance with FIPS requirements.

4. Click Configure.

The Data Foundation page displays Usable capacity, Health, and Storage nodes. After the configuration is complete, the Health section displays the health of the Storage cluster and Data resiliency.

Note: Setting up local storage may take around 45-50 minutes.

5. To validate the configuration, do the following steps:

- a. Log in to OpenShift Container Platform console.

- b. In the menu, go to Storage > StorageClasses.

- c. In the StorageClasses page, check whether you see the following storage classes:

- `ocs-storagecluster-cephfs` for Fusion Data Foundation storage file system
- `ocs-storagecluster-ceph-rbd` for Ceph's RADOS Block Devices (RBD) storage class. It is the default storage class.
- `openshift-storage.noobaa.io` storage class is for object storage. You can use it for MCG so that it gets generated either for the installation of Fusion Data Foundation or for Global Data Platform with Fusion Data Foundation MCG only mode.

What to do next

1. Create a `NetworkFenceClass` CR to fence and taint nodes, preventing volume corruption during non-graceful node shutdown. For instructions, see [Creating a NetworkFenceClass CR](#).
2. After the configuration is complete, you can view capacity utilization and storage nodes. You can add nodes to your storage configuration and scale its capacities. For instructions, see [Scaling the cluster](#).

- [Creating a NetworkFenceClass CR](#)
Create a **NetworkFenceClass** CR to fence and taint nodes during non-graceful node shutdown to prevent volume corruption.

Creating a NetworkFenceClass CR

Create a **NetworkFenceClass** CR to fence and taint nodes during non-graceful node shutdown to prevent volume corruption.

About this task

Note: Create one or more **NetworkFenceClass** CRs, depending on the number of storage clusters connected to the OpenShift® Container Platform cluster.

Procedure

1. Define a YAML file for the **NetworkFenceClass** CR and save it.
For example:

```
apiVersion: csiaddons.openshift.io/v1alpha1
kind: NetworkFenceClass
metadata:
  name: odf-networkfenceclass
spec:
  provisioner: openshift-storage.rbd.csi.ceph.com
  parameters:
    clusterID: openshift-storage
    csiaddons.openshift.io/networkfence-secret-name: rook-csi-rbd-node
    csiaddons.openshift.io/networkfence-secret-namespace: openshift-storage
```

Where,

- **provisioner**: Specifies the name of the storage provisioner.
- **parameters**: specifies storage provider-specific parameters.
- **csiaddons.openshift.io/networkfence-secret-name**: specifies the name of the secret that is required for network fencing. Fetch it from **parameters.csi.storage.k8s.io/node-stage-secret-name** field in the **ocs-storagecluster-ceph-rbd** StorageClass.
- **csiaddons.openshift.io/networkfence-secret-namespace**: specifies the namespace in which the secret is located. Fetch it from **parameters.csi.storage.k8s.io/node-stage-secret-namespace** field in the **ocs-storagecluster-ceph-rbd** StorageClass.

2. Verify the **csiaddonsnode** object details.

The **csiaddonsnode** object belongs to the daemonset pod (RBD) that has the IP address that needs to be fenced.

Command example:

```
oc get csiaddonsnode -n openshift-storage
```

Viewing Fusion Data Foundation topology

View the topology of your Fusion Data Foundation storage cluster, including the count, type, and status of Object Storage Devices (OSDs).

About this task

The topology provides a visual representation of the Fusion Data Foundation storage cluster at multiple levels of abstraction and enables interaction with each layer. It illustrates how the cluster components are organized and related, while offering visibility into Object Storage Devices (OSDs), including their count, type, and status.

Note: Starting with Fusion Data Foundation 4.22, the topology view includes a dedicated OSD information tab that provides comprehensive OSD-specific details for each node.

Procedure

1. In the OpenShift® Container Platform web console, go to **Storage > Data Foundation > Topology**.
The view shows the storage cluster and the topology groupings inside it. Nodes are depicted by circular entities within the topology groupings, which are indicated by dotted lines. The topology groupings are based on the cluster's topology configuration (for example, racks in bare metal or vSphere clusters, or zones in cloud-based clusters). The label of each item or resource contains basic information such as status, health, and alerts.
2. Select a node to view node details in the right-hand panel.
You can also access resources or deployments within a node by clicking the search or preview decorator icon.

The node details panel displays information about the OSDs running on that node, including:

- Number of OSDs on the node
- OSD disk type (for example, SSD, HDD)
- OSD status (for example, Running, Error, CrashLoopBackOff)

3. To view deployment details, click the preview decorator on a node.
A modal window appears above the node and displays all deployments associated with that node along with their statuses.
4. Click Back to main view in the upper left corner of the modal window to close it and return to the previous view.
5. Select a specific deployment to see more information about it.
All relevant data is shown in the side panel.
6. Click the Resources tab to view pod information.
This tab provides a deeper understanding of problems and offers granularity that aids in troubleshooting.
7. Click the OSD information tab to view detailed information about the OSDs.
This tab provides comprehensive OSD-specific details, including:

- OSD pod name and status
 - Disk device associated with each OSD
 - Device class (for example, SSD, HDD)
 - Resource utilization metrics
8. Click a pod link to view the pod information page on OpenShift Container Platform web console. The pod information page opens in a new window.

Preparing to connect to an external KMS server in Fusion Data Foundation

Procedure to prepare for the connection to an external KMS from Fusion Data Foundation.

Before you begin

- For external Key Management System (KMS), choose either HashiCorp Vault or Thales CipherTrust Manager.
- You must install Fusion Data Foundation from the Services page of the user interface and ensure that it is in running state. For the installation options and their procedures, see [Installing Fusion Data Foundation](#).
- For HashiCorp Vault, select an unique path name as the backend path that follows the naming convention. If you change this path name later, then the data becomes inaccessible.
- For Thales CipherTrust Manager, enable the Key Management Interoperability Protocol.
- Ensure that you are using signed certificates on your KMS servers.

About this task

Fusion Data Foundation supports cluster-wide encryption (encryption-at-rest) for all the disks and Multicloud Object Gateway operations in the storage cluster. The keys are stored using a Kubernetes secret or an external KMS. When you store the keys by using a Kubernetes secret, no need for you to do manual steps. You can enable cluster-wide encryption when you deploy Fusion Data Foundation.

This procedure provides steps (manual part) to initialize encryption configuration with KMS before you enable encryption. For HashiCorp Vault, you can choose either the token authentication method or the Kubernetes authentication method.

For additional reference, see [Red Hat® Data Foundation Data encryption options](#).

- [Enabling encryption with the token authentication using HashiCorp Vault\(manual part\)](#)
Configure token settings in vault server.
- [Enabling encryption with the Kubernetes authentication using HashiCorp Vault \(manual part\)](#)
Configure Kubernetes settings in vault server.
- [Enabling encryption using Thales CipherTrust Manager \(manual part\)](#)
Configure the Key Management Interoperability Protocol (KMIP) settings in Thales CipherTrust Manager server.

Enabling encryption with the token authentication using HashiCorp Vault(manual part)

Configure token settings in vault server.

Procedure

1. Enable the Key/Value (KV) backend path in Vault. Run the following command for Vault KV secret engine API, version 2, as it supports only version 2.

```
vault secrets enable -path=odf kv-v2
```

This is a one time settings. You can get the token from vault administrator directly, or you can login vault server and create a token with following steps. Use an unique path name as the backend path that follows the naming convention. You cannot change it later.

Note: The example uses backend path **odf**.

2. Create a policy with certain permission on the secret using the following commands.

```
echo '
path "odf/*" {
  capabilities = ["create", "read", "update", "delete", "list"]
}
path "sys/mounts" {
  capabilities = ["read"]
}' | vault policy write odf -
```

3. Create a token matching the policy.

```
vault token create -policy=odf -format json
```

Example output:

Take a note for the **auth.client_token**

```
# vault token create -policy=odf -format json
{
  "request_id": "e7103f23-c67c-2412-77b0-b92a728fd5fd",
  "lease_id": "",
```

```

"lease_duration": 0,
"renewable": false,
"data": null,
"warnings": null,
"auth": {
  "client_token": "hvs.CAESILkFSEnBgMgE0JxdbnBf_VUPxlvhCPTBBdx30j1bMfiMGh4KHGh2cy5QeFZVWnhOWGMxdlhvSU5YU0tNRjBBVGo",
  "accessor": "IFNbUOwWazg5cyiUZGVlvf5o",
  "policies": [
    "default",
    "odf"
  ],
  "token_policies": [
    "default",
    "odf"
  ],
  "identity_policies": null,
  "metadata": null,
  "orphan": false,
  "entity_id": "",
  "lease_duration": 2764800,
  "renewable": true,
  "mfa_requirement": null
}
}

```

Enabling encryption with the Kubernetes authentication using HashiCorp Vault (manual part)

Configure Kubernetes settings in vault server.

Procedure

1. Get the **VAULT_SA_SECRET_NAME** in OpenShift® Container Platform:

- a. For OpenShift Container Platform 4.14, identify the secret name associated with the **serviceaccount** (SA) created previously.

```
VAULT_SA_SECRET_NAME=$(oc -n openshift-storage get sa odf-vault-auth -o jsonpath="{.secrets[*]['name']}" | grep -o "[^[:space:]]*-token-[^[:space:]]*" )
```

Example output:

```
[root@fu40 ~]# echo $VAULT_SA_SECRET_NAME
odf-vault-auth-token-8kb2r
```

- b. For OpenShift Container Platform 4.15, assign a default value for `VAULT_SA_SECRET_NAME``

```
VAULT_SA_SECRET_NAME=odf-vault-auth-token
```

2. Get the parameters from OpenShift Container Platform cluster.

- a. Get **SA_JWT_TOKEN** and **SA_CA_CERT** from the secret.

```
SA_JWT_TOKEN=$(oc -n openshift-storage get secret "$VAULT_SA_SECRET_NAME" -o jsonpath="{.data.token}" | base64 --decode; echo)
```

- b. Get **SA_CA_CERT** from the secret.

```
SA_CA_CERT=$(oc -n openshift-storage get secret "$VAULT_SA_SECRET_NAME" -o jsonpath="{.data['ca.crt']}" | base64 --decode; echo)
```

- c. Retrieve the OpenShift Container Platform cluster endpoint **OCP_HOST**.

```
OCP_HOST=$(oc config view --minify --flatten -o jsonpath="{.clusters[0].cluster.server}")
```

- d. Fetch the service account issuer:

```
oc proxy &
proxy_pid=$!
issuer=$( curl --silent http://127.0.0.1:8001/.well-known/openid-configuration | jq -r .issuer)
kill $proxy_pid
```

Example output:

```
# oc proxy &
# proxy_pid=$!
# issuer=$( curl --silent http://127.0.0.1:8001/.well-known/openid-configuration | jq -r .issuer)
# echo $issuer
https://kubernetes.default.svc
# kill $proxy_pid
```

3. Apply the settings in the vault server.

- a. Use the information collected in the previous section to set up the Kubernetes authentication method in the vault server.

```
vault auth enable kubernetes
```

```
vault write auth/kubernetes/config \
  token_reviewer_jwt="$SA_JWT_TOKEN" \
  kubernetes_host="$OCP_HOST" \
```

```
kubernetes_ca_cert="$SA_CA_CERT" \
issuer="$issuer"
```

Example output:

```
# vault write auth/kubernetes/config \
> token_reviewer_jwt="$SA_JWT_TOKEN" \
> kubernetes_host="$OCF_HOST" \
> kubernetes_ca_cert="$SA_CA_CERT" \
> issuer="$issuer"
Success! Data written to: auth/kubernetes/config
```

- b. Enable the Key/Value (KV) backend path in Vault. For the vault KV secret engine API, see version 2. Use a unique path name as the backend path. The name should not be changed, and it should be consistent with the value of Backend Path input that present in the user interface.

```
vault secrets enable -path=<replace-with-the-backend-path> kv-v2
```

The example sample uses backend path odf.

```
vault secrets enable -path=odf kv-v2
```

- c. Create a policy to restrict users to perform a write or delete operation on the secret using the following commands.

```
echo '
path "odf/*" {
  capabilities = ["create", "read", "update", "delete", "list"]
}
path "sys/mounts" {
  capabilities = ["read"]
}' | vault policy write odf -
```

- d. Generate the `odf-rook-ceph-op` role using the following commands.

```
vault write auth/kubernetes/role/odf-rook-ceph-op \
  bound_service_account_names=rook-ceph-system,rook-ceph-osd,noobaa \
  bound_service_account_namespaces=openshift-storage \
  policies=odf \
  ttl=1440h
```

Example output:

```
# vault write auth/kubernetes/role/odf-rook-ceph-op \
> bound_service_account_names=rook-ceph-system,rook-ceph-osd,noobaa \
> bound_service_account_namespaces=openshift-storage \
> policies=odf \
> ttl=1440h
Success! Data written to: auth/kubernetes/role/odf-rook-ceph-op
```

The role `odf-rook-ceph-op` is previously input in the role field used when you configure the KMS connection details in the IBM Fusion user interface.

- e. Generate the `odf-rook-ceph-osd` role using the following commands.

```
vault write auth/kubernetes/role/odf-rook-ceph-osd \
  bound_service_account_names=rook-ceph-osd \
  bound_service_account_namespaces=openshift-storage \
  policies=odf \
  ttl=1440h
```

Example output:

```
# vault write auth/kubernetes/role/odf-rook-ceph-osd \
> bound_service_account_names=rook-ceph-osd \
> bound_service_account_namespaces=openshift-storage \
> policies=odf \
> ttl=1440h
Success! Data written to: auth/kubernetes/role/odf-rook-ceph-osd
```

- [Enabling key rotation for Kubernetes authentication](#)

Enabling key rotation for Kubernetes authentication helps to achieve the security common practices that require periodic encryption key rotation.

- [Disabling key rotation for Kubernetes authentication](#)

Key rotation for Kubernetes persistent volume claims (PVCs) can be disabled at the storage class level or for a specific PVC by updating the relevant annotations and patch settings.

Enabling key rotation for Kubernetes authentication

Enabling key rotation for Kubernetes authentication helps to achieve the security common practices that require periodic encryption key rotation.

To enable key rotation, add the annotation `keyrotation.csiaddons.openshift.io/schedule: <value>` to either Namespace, StorageClass, or PersistentVolumeClaim in order of precedence.

Set the `<value>` either `@hourly`, `@daily`, `@weekly`, `@monthly`, or `@yearly` based on your requirement. If the `<value>` is empty, `@weekly` is set by default.

Important: Only RADOS Block Device (RBD)-related volumes support key rotation.

Examples of enabling key rotation with the value `@weekly` are as follows:

Namespace

For example, run the following command to get the `default` namespace details:

```
oc get namespace default
```

Example output:

NAME	STATUS	AGE
default	Active	5d2h

Run the following command to enable the key rotation to the default namespace:

```
$ oc annotate namespace default "keyrotation.csiaddons.openshift.io/schedule=@weekly"
```

Example output:

```
namespace/default annotated
```

StorageClass

For example, run the following command to get the *rbd-sc* StorageClass details:

```
oc get storageclass rbd-sc
```

Example output:

NAME	PROVISIONER	RECLAIMPOLICY	VOLUMEBINDINGMODE	ALLOWVOLUMEEXPANSION	AGE
rbd-sc	rbd.csi.ceph.com	Delete	Immediate	true	5d2h

Run the following command to enable the key rotation to the *rbd-sc* StorageClass:

```
oc annotate storageclass rbd-sc "keyrotation.csiaddons.openshift.io/schedule=@weekly"
```

Example output:

```
storageclass.storage.k8s.io/rbd-sc annotated
```

PersistentVolumeClaim

For example, run the following command to get the *data-pvc* PersistentVolumeClaim details:

```
oc get pvc data-pvc
```

Example output:

NAME	STATUS	VOLUME	CAPACITY	ACCESS MODES	STORAGECLASS	AGE
data-pvc	Bound	pvc-f37b8582-4b04-4676-88dd-e1b95c6abf74	1Gi	RWO	default	20h

Run the following command to enable the key rotation to the *data-pvc* PersistentVolumeClaim:

```
oc annotate pvc data-pvc "keyrotation.csiaddons.openshift.io/schedule=@weekly"
```

Example output:

```
persistentvolumeclaim/data-pvc annotated
```

Replacing key rotation schedule

To replace the current key rotation schedule with a new one, follow these steps:

1. Run the following command to get the existing schedule details:

```
oc get encryptionkeyrotationcronjobs.csiaddons.openshift.io
```

Example output:

NAME	SCHEDULE	SUSPEND	ACTIVE	LASTSCHEDULE	AGE
data-pvc-1642663516	@weekly				3s

2. Run the following command to overwrite the existing schedule with a new one:

```
oc annotate pvc data-pvc "keyrotation.csiaddons.openshift.io/schedule=*/1 * * * * --overwrite=true"
```

Example output:

```
persistentvolumeclaim/data-pvc annotated
```

3. Run the following command to check whether the new schedule is set:

```
oc get encryptionkeyrotationcronjobs.csiaddons.openshift.io
```

Example output:

NAME	SCHEDULE	SUSPEND	ACTIVE	LASTSCHEDULE	AGE
data-pvc-1642664617	*/1 * * * *				3s

Disabling key rotation for Kubernetes authentication

Key rotation for Kubernetes persistent volume claims (PVCs) can be disabled at the storage class level or for a specific PVC by updating the relevant annotations and patch settings.

You can disable key rotation for the following:

- All the persistent volume claims (PVCs) of storage class
- A specific PVC

Disabling key rotation for all PVCs of a storage class

To disable key rotation for all PVCs, update the annotation of the storage class:

```
oc get storageclass rbd-sc
NAME      PROVISIONER      RECLAIMPOLICY   VOLUMEBINDINGMODE   ALLOWVOLUMEEXPANSION   AGE
rbd-sc    rbd.csi.ceph.com Delete           Immediate            true                    5d2h

oc annotate storageclass rbd-sc "keyrotation.csiaddons.openshift.io/enable: false"
storageclass.storage.k8s.io/rbd-sc annotated
```

Disabling key rotation for a specific persistent volume claim

1. Identify the `EncryptionKeyRotationCronJob` CR for the PVC you want to disable key rotation on:

```
oc get encryptionkeyrotationcronjob -o jsonpath='{range .items[?(@.spec.jobTemplate.spec.target.persistentVolumeClaim=="<PVC_NAME>")]}.metadata.name}{\n}{end}'
```

Where `<PVC_NAME>` is the name of the PVC that you want to disable.

2. Apply the following to the `EncryptionKeyRotationCronJob` CR from the previous step to disable the key rotation:

- a. Update the `csiaddons.openshift.io/state` annotation from `managed` to `unmanaged`:

```
oc annotate encryptionkeyrotationcronjob <encryptionkeyrotationcronjob_name> "csiaddons.openshift.io/state=unmanaged"
--overwrite=true
```

Where `<encryptionkeyrotationcronjob_name>` is the name of the `EncryptionKeyRotationCronJob` CR.

- b. Add `suspend: true` under the `spec` field:

```
oc patch encryptionkeyrotationcronjob <encryptionkeyrotationcronjob_name> -p '{"spec": {"suspend": true}}' --
type=merge.
```

3. Save and exit. The key rotation is disabled for the PVC.

Enabling encryption using Thales CipherTrust Manager (manual part)

Configure the Key Management Interoperability Protocol (KMIP) settings in Thales CipherTrust Manager server.

About this task

IBM Fusion HCI with IBM Spectrum® Storage Scale Erasure Code Edition (ECE) does not support the Thales or Vormetric CipherTrust Manager, and that the current encryption CR implementation in CNSA or IBM Fusion HCI works only with IBM Security GKLM (with simplified setup).

Procedure

1. If KMIP client does not exist, then create it.
 - a. From the Thales CipherTrust Manager user interface, select **Products**, **KMIP**, **Client Profile**, **Add Profile**.
 - b. Add the username location to the Common Name (CN) field during profile creation.
2. Create a token.
 - a. Go to **KMIP**, **Registration Token**, **New Registration Token**.
 - b. Copy the token for the next step.
3. Register the client.
 - a. Go to **KMIP**, **Registered Clients**, **Add Client**.
 - b. Specify the name.
 - c. Paste the Registration Token from the previous step.
 - d. Click **Save**.
4. To download the Private Key and Client Certificate, click **Save Private Key** and **Save Certificate** respectively.
5. Create a KMIP interface.
 - a. Go to **Admin Settings**, **Interfaces**, **Add Interface**.
 - b. Select **KMIP Key Management Interoperability Protocol** and click **Next**.
 - c. Select an available Port.
 - d. Select **Network Interface** as **all**.
 - e. Select **Interface Mode** for **TLS**. Verify client certificate and the username that is taken from the client certificate. The auth request is optional.
 - f. Select the CA to be used, and click **Save**.
6. To get the server CA certificate, click ellipsis overflow menu of the newly created interface, and click **Download Certificate**.
Whenever you configure encryption from the IBM Fusion user interface, use these downloaded files.

Managing hybrid and multicloud resource

Use this information to learn how to manage hybrid and multicloud resources.

The Multicloud Object Gateway (MCG) is a lightweight object storage service for OpenShift®, allowing users to start small and then scale as needed on-premise, in multiple clusters, and with cloud-native storage.

- [Accessing the Multicloud Object Gateway with your applications](#)
You can access the object service with any application targeting AWS S3 or code that uses AWS S3 Software Development Kit (SDK). Applications need to specify the Multicloud Object Gateway (MCG) endpoint, an access key, and a secret access key. You can use your terminal or the MCG command-line interface (CLI) to retrieve this information.
- [Adding storage resources for hybrid or Multicloud](#)
Understand how to add and edit storage resources for hybrid or Multicloud.
- [Creating and managing buckets using the object browser](#)
The object browser in the OpenShift Web Console enables you to create, view, and manage buckets and objects across different storage endpoints, including Multicloud Object Gateway (MCG) and internal mode RADOS Gateway (RGW) object storage.
- [Managing namespace buckets](#)
Namespace buckets let you connect data repositories on different providers together, so you can interact with all of your data through a single unified view. Add the object bucket associated with each provider to the namespace bucket, and access your data through the namespace bucket to see all of your object buckets at once. This lets you write to your preferred storage provider while reading from multiple other storage providers, greatly reducing the cost of migrating to a new storage provider. Use this information to add namespace buckets using command-line interface, YAML, and user interface and for information about sharing and accessing legacy data.
- [Securing Multicloud Object Gateway](#)
Ensure that the Multicloud Object Gateway is secure.
- [Mirroring data for hybrid and Multicloud buckets](#)
Create bucket classes to mirror data for hybrid and Multicloud buckets. Mirroring data can be setup by using the OpenShift UI, YAML, or MCG command-line interface.
- [Bucket policies in the Multicloud Object Gateway](#)
Fusion Data Foundation supports AWS S3 bucket policies. Bucket policies allow you to grant users access permissions for buckets and the objects in them. Use the information in this section to understand how to use bucket policies in Multicloud Object Gateway.
- [Bucket notification in Multicloud Object Gateway](#)
With bucket notification, you can send a notification to an external server whenever there is an event in the bucket.
- [Multicloud Object Gateway bucket replication](#)
Data replication from one Multicloud Object Gateway (MCG) bucket to another MCG bucket provides higher resiliency and better collaboration options. These buckets can be either data buckets or namespace buckets backed by any supported storage solution (S3, Azure, and so on). Replicate a bucket to another bucket and set replication policies using command-line interface and YAML.
- [Managing S3 Vectors](#)
S3 Vectors provide native vector-database storage capabilities within the Multicloud Object Gateway (MCG), enabling you to store and manage vector embeddings for machine learning and AI applications.
- [Object Bucket Claim](#)
An Object Bucket Claim can be used to request an S3 compatible bucket backend for your workloads. An object bucket claim creates a new bucket and an application account in NooBaa with permissions to the bucket, including a new access key and secret access key. The application account is allowed to access only a single bucket and can't create new buckets by default. Use this information to create, view, and delete object bucket claims.
- [Object Bucket Claims on hosted clusters](#)
Object Bucket Claims (OBCs) on hosted clusters enable application administrators to request S3-compatible object storage buckets directly from a client cluster that is connected to a Fusion Data Foundation 4.22 (or later) provider cluster.
- [Managing bucket quota](#)
Bucket quota allows you to set limits on the number of objects and total storage size for buckets in the Multicloud Object Gateway (MCG), helping prevent resource starvation and enabling better capacity planning and cost control.
- [Caching policy for object buckets](#)
A cache bucket is a namespace bucket with a hub target and a cache target. The hub target is an S3 compatible large object storage bucket. The cache bucket is the local Multicloud Object Gateway bucket. You can create a cache bucket that caches an AWS bucket or an IBM COS bucket.
- [Lifecycle bucket configuration in Multicloud Object Gateway](#)
Multicloud Object Gateway (MCG) lifecycle provides a way to reduce storage costs due to accumulated data objects.
- [Scaling Multicloud Object Gateway performance](#)
The Multicloud Object Gateway (MCG) performance may vary from one environment to another. In some cases, specific applications require faster performance which can be addressed by scaling S3 endpoints.
- [Accessing the RADOS Object Gateway S3 endpoint](#)
Users can access the RADOS Object Gateway (RGW) endpoint directly. The RGW route is created by default and is named `rook-ceph-rgw-ocs-storagecluster-cephobjectstore`.
- [Using TLS certificates for applications accessing RGW](#)
Fetch TLS certificates stored as Kubernetes secrets and configure applications to use them when accessing the RADOS Object Gateway (RGW) over a secure connection.
- [Using the security token service of Multicloud Object Gateway to assume the role of another user](#)
Multicloud Object Gateway (MCG) supports a security token service (STS) similar to the one provided by Amazon Web Services. This STS of the MCG authorizes a user to assume the role of another user.

Accessing the Multicloud Object Gateway with your applications

You can access the object service with any application targeting AWS S3 or code that uses AWS S3 Software Development Kit (SDK). Applications need to specify the Multicloud Object Gateway (MCG) endpoint, an access key, and a secret access key. You can use your terminal or the MCG command-line interface (CLI) to retrieve this information.

Accessing the MCG buckets using the virtual-hosted style

If the client application tries to access `https://<bucket-name>.s3-openshift-storage.apps.mycluster-cluster.qe.rh-ocs.com`, a DNS entry is needed for `mcg-test-bucket.s3-openshift-storage.apps.mycluster-cluster.qe.rh-ocs.com` to point to the S3 Service.

`<bucket-name>` is the name of the MCG bucket, for example: `https://mcg-test-bucket.s3-openshift-storage.apps.mycluster-cluster.qe.rh-ocs.com`.

Important: Ensure that you have a DNS entry in order to point the client application to the MCG buckets using the virtual-hosted style.

- [Accessing the Multicloud Object Gateway from the terminal](#)
Use this information to access the Multicloud Object Gateway from the terminal.
- [Accessing the Multicloud Object Gateway from the MCG command-line interface](#)
Use this information to access the Multicloud Object Gateway from the MCG command-line interface.
- [Support of Multicloud Object Gateway data bucket APIs](#)
The following table lists the Multicloud Object Gateway (MCG) data bucket APIs and their support levels.

Accessing the Multicloud Object Gateway from the terminal

Use this information to access the Multicloud Object Gateway from the terminal.

Before you begin

- A running Fusion Data Foundation Platform.
- Download the MCG command-line interface for easier management.

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-x86_64-rpms
```

```
yum install mcg
```

Note: Specify the appropriate architecture for enabling the repositories using the subscription manager.

- For IBM Power, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-ppc64le-rpms
```

- For IBM Z infrastructure, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-s390x-rpms
```

- Alternatively, you can install the MCG package from the RPMs found at [Download Red Hat® OpenShift® Data Foundation page](#).

Note: Choose the correct Product Variant according to your architecture.

Procedure

Run the **describe** command to view information about the Multicloud Object Gateway (MCG) endpoint, including its access key (AWS_ACCESS_KEY_ID value) and secret access key (AWS_SECRET_ACCESS_KEY value).

```
oc describe noobaa -n openshift-storage
```

Example output, where **(1)** is the access key (AWS_ACCESS_KEY_ID value), **(2)** is the secret access key (AWS_SECRET_ACCESS_KEY value), and **(3)** is the MCG endpoint

```

Welcome to NooBaa!
-----

Welcome to NooBaa!
-----
NooBaa Core Version:
NooBaa Operator Version:

Lets get started:

1. Connect to Management console:

Read your mgmt console login information (email & password) from secret: "noobaa-admin".

kubect1 get secret noobaa-admin -n openshift-storage -o json | jq '.data|map_values(@base64d)'

Open the management console service - take External IP/DNS or Node Port or use port forwarding:

kubect1 port-forward -n openshift-storage service/noobaa-mgmt 11443:443 &
open https://localhost:11443

2. Test S3 client:
```

```
kubectl port-forward -n openshift-storage service/s3 10443:443 &how
(1) NOOBAA_ACCESS_KEY=$(kubectl get secret noobaa-admin -n openshift-storage -o json | jq -r
'.data.AWS_ACCESS_KEY_ID|@base64d')
(2) NOOBAA_SECRET_KEY=$(kubectl get secret noobaa-admin -n openshift-storage -o json | jq -r
'.data.AWS_SECRET_ACCESS_KEY|@base64d')
alias s3='AWS_ACCESS_KEY_ID=$NOOBAA_ACCESS_KEY AWS_SECRET_ACCESS_KEY=$NOOBAA_SECRET_KEY aws --endpoint
https://localhost:10443 --no-verify-ssl s3'
s3 ls
```

```
Services:
Service Mgmt:
External DNS:
https://noobaa-mgmt-openshift-storage.apps.mycluster-cluster.qe.rh-ocs.com
https://a3406079515be11eaa3b70683061451e-1194613580.us-east-2.elb.amazonaws.com:443
Internal DNS:
https://noobaa-mgmt.openshift-storage.svc:443
Internal IP:
https://172.30.235.12:443
Node Ports:
https://10.0.142.103:31385
Pod Ports:
https://10.131.0.19:8443
serviceS3:
External DNS: (3)
https://s3-openshift-storage.apps.mycluster-cluster.qe.rh-ocs.com
https://a340f4e1315be11eaa3b70683061451e-943168195.us-east-2.elb.amazonaws.com:443
Internal DNS:
https://s3.openshift-storage.svc:443
Internal IP:
https://172.30.86.41:443
Node Ports:
https://10.0.142.103:31011
Pod Ports:
https://10.131.0.19:6443
```

Note: The output from the **oc describe noobaa** command lists the internal and external DNS names that are available. When using the internal DNS, the traffic is free. The external DNS uses Load Balancing to process the traffic, and therefore has a cost per hour.

Accessing the Multicloud Object Gateway from the MCG command-line interface

Use this information to access the Multicloud Object Gateway from the MCG command-line interface.

Before you begin

- A running Fusion Data Foundation Platform.
- Download the MCG command-line interface for easier management.

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-x86_64-rpms
yum install mcg
```

Note: Specify the appropriate architecture for enabling the repositories using the subscription manager.

- For IBM Power, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-ppc64le-rpms
```

- For IBM Z infrastructure, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-s390x-rpms
```

Procedure

Run the **status** command to access the endpoint, access key, and secret access key.

```
odf noobaa status -n openshift-storage
```

Example output, where **(1)** is the endpoint, **(2)** is the access key, and **(3)** is secret access key.

```

```

Results

You now have the relevant endpoint, access key, and secret access key in order to connect to your applications.

For example:

If AWS S3 CLI is the application, the following command lists the buckets in Fusion Data Foundation:

```

AWS_ACCESS_KEY_ID=<AWS_ACCESS_KEY_ID>
AWS_SECRET_ACCESS_KEY=<AWS_SECRET_ACCESS_KEY>
aws --endpoint <ENDPOINT> --no-verify-ssl s3 ls

```

Support of Multicloud Object Gateway data bucket APIs

The following table lists the Multicloud Object Gateway (MCG) data bucket APIs and their support levels.

Data buckets	Support	
List buckets	Supported	
Delete bucket	Supported	Replication configuration is part of MCG bucket class configuration
Create bucket	Supported	A different set of canned ACLs
Post bucket	Not supported	
Put bucket	Partially supported	Replication configuration is part of MCG bucket class configuration
Bucket lifecycle	Partially supported	Object expiration only
Policy (Buckets, Objects)	Partially supported	Bucket policies are supported
Bucket Website	Supported	
Bucket ACLs (Get, Put)	Supported	A different set of canned ACLs
Bucket Location	Partially	Returns a default value only
Bucket Notification	Not supported	
Bucket Object Versions	Supported	
Get Bucket Info (HEAD)	Supported	
Bucket Request Payment	Partially supported	Returns the bucket owner
Put Object	Supported	
Delete Object	Supported	
Get Object	Supported	
Object ACLs (Get, Put)	Supported	
Get Object Info (HEAD)	Supported	
POST Object	Supported	
Copy Object	Supported	
Multipart Uploads	Supported	
Object Tagging	Supported	
Storage Class	Not supported	

Adding storage resources for hybrid or Multicloud

Understand how to add and edit storage resources for hybrid or Multicloud.

- [Creating a new backing store](#)
Create a new backing store to add storage resources.
- [Overriding the default backing store](#)
Follow this procedure to override the default NooBaa backing store.
- [Adding storage resources for hybrid or Multicloud using the command line interface](#)
The Multicloud Object Gateway (MCG) simplifies the process of spanning data across the cloud provider and clusters. Add a backing storage that can be used by the MCG.
- [Creating an S3 compatible Multicloud Object Gateway backingstore](#)
Create an S3 compatible MCG backing store for IBM Storage Ceph's RGW. When the RGW is deployed, Fusion Data Foundation operator creates an S3 compatible backingstore for MCG automatically.
- [Creating a new bucket class](#)
Bucket class is a CRD representing a class of buckets that defines tiering policies and data placements for an Object Bucket Class (OBC). Use this procedure to create a bucket class in Fusion Data Foundation.
- [Editing a bucket class](#)
Use this information to edit an existing bucket class.
- [Editing backing stores for bucket class](#)
Use this procedure to edit an existing Multicloud Object Gateway (MCG) bucket class to change the underlying backing stores used in a bucket class.

Creating a new backing store

Create a new backing store to add storage resources.

Before you begin

Ensure you have Administrator access to Fusion Data Foundation.

Procedure

1. From the OpenShift® Web Console, go to Storage > Data Foundation.
2. From the Backing Store tab, click Create Backing Store.
3. From the Create New Backing Store page:
 - a. Enter a Backing Store Name.
 - b. Select a Provider.

- c. Select a Region.
- d. Optional: Enter an Endpoint..
- e. Select a Secret from the drop-down list, or create your own secret. Optionally, you can Switch to Credentials view which lets you fill in the required secrets. For more information on creating an OCP secret, see [Security, Authentication and authorization, Configuring identity providers, Creating the secret in Red Hat® OpenShift Container Platform](#) product documentation.

Each backingstore requires a different secret. For more information on creating the secret for a particular backingstore, see [Adding storage resources for hybrid or Multicloud using the MCG command line interface](#) and follow the steps to add storage resources using a YAML.

Note: This menu is relevant for all providers except Google Cloud and local PVC.

- f. Enter the Target bucket.
The target bucket is a storage that is hosted on the remote cloud service. The target bucket enables you to create a connection that tells the MCG that it can use this bucket for the system.

4. Click Create Backing Store.

What to do next

Optionally, verify the creation of the backing store:

1. From the OpenShift Web Console, go to [Storage, Data Foundation](#).
2. From the Backing Store tab to view all the backing stores.

Overriding the default backing store

Follow this procedure to override the default NooBaa backing store.

Before you begin

Download the Multicloud Object Gateway (MCG) command-line interface.

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-x86_64-rpms
yum install mcg
```

Note: Specify the appropriate architecture for enabling the repositories using the subscription manager.

- For IBM Power, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-ppc64le-rpms
```
- For IBM Z infrastructure, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-s390x-rpms
```

About this task

You can use the `manualDefaultBackingStore` flag to override the default NooBaa backing store and remove it if you do not want to use the default backing store configuration. This provides flexibility to customize your backing store configuration and tailor it to your specific needs. By leveraging this feature, you can further optimize your system and enhance its performance.

Procedure

1. Check if `noobaa-default-backing-store` is present:

```
oc get backingstore
NAME TYPE PHASE AGE
noobaa-default-backing-store pv-pool Creating 102s
```

2. Patch the NooBaa CR to enable `manualDefaultBackingStore`:

```
oc patch noobaa/noobaa --type json --patch='[{"op": "add", "path": "/spec/manualDefaultBackingStore", "value": true}]'
```

Important: Use the Multicloud Object Gateway CLI to create a new backing store and update accounts.

3. Create a new default backing store to override the default backing store.

For example:

```
odf noobaa backingstore create pv-pool _NEW-DEFAULT-BACKING-STORE_ --num-volumes 1 --pv-size-gb 16
```

- a. Replace `NEW-DEFAULT-BACKING-STORE` with the name you want for your new default backing store.

4. Update the admin account to use the new default backing store as its default resource:

```
odf noobaa account update admin@noobaa.io --new_default_resource=_NEW-DEFAULT-BACKING-STORE_
```

- a. Replace `NEW-DEFAULT-BACKING-STORE` with the name of the backing store from the previous step.

Updating the default resource for admin accounts ensures that the new configuration is used throughout your system.

5. Configure the default-bucketclass to use the new default backingstore:

```
oc patch Bucketclass noobaa-default-bucket-class -n openshift-storage --type=json --patch='[{"op": "replace", "path": "/spec/placementPolicy/tiers/0/backingStores/0", "value": "NEW-DEFAULT-BACKING-STORE"}]'
```

6. Optional: Delete the `noobaa-default-backing-store`.

- a. Delete all instances of and buckets associated with `noobaa-default-backing-store` and update the accounts using it as resource.

b. Delete the `noobaa-default-backing-store`:

```
oc delete backingstore noobaa-default-backing-store -n openshift-storage | oc patch -n openshift-storage
backingstore/noobaa-default-backing-store --type json --patch='[ { "op": "remove", "path": "/metadata/finalizers" }
]'
```

You must enable the `manualDefaultBackingStore` flag before proceeding. Additionally, it is crucial to update all accounts that use the default resource and delete all instances of and buckets associated with the default backing store to ensure a smooth transition.

Adding storage resources for hybrid or Multicloud using the command line interface

The Multicloud Object Gateway (MCG) simplifies the process of spanning data across the cloud provider and clusters. Add a backing storage that can be used by the MCG.

Depending on your deployment type, follow the appropriate procedure to add storage resources by creating a backing storage.

For VMware deployments, skip this section and go to [Creating an s3 compatible Multicloud Object Gateway backingstore](#).

- [Creating an AWS-backed backingstore](#)
Create an AWS-backed backing store using the MCG command-line interface or a YAML file to add storage resources.
- [Creating an AWS-STS-backed backingstore](#)
Creating an AWS STS-backed backingstore is supported only on clusters deployed on AWS using STS and involves creating an AWS role with temporary credentials, installing the operator, and creating the backingstore.
- [Creating an IBM COS-backed backingstore](#)
Create an IBM COS-backed backing store using the MCG command-line interface or a YAML file to add storage resources.
- [Creating an Azure-backed backingstore](#)
Create an Azure-backed backing store using the MCG command-line interface or a YAML file to add storage resources.
- [Creating an Azure STS-backed backingstore](#)
Azure Identity (also known as Azure Workload Identity) provides authentication through short-lived, temporary credentials. Creating an Azure STS-backed backingstore is supported on any OpenShift® cluster with Azure Workload Identity and OIDC provider configured.
- [Creating a GCP-backed backingstore](#)
Create a GCP-backed backing store using the MCG command-line interface or a YAML file to add storage resources.
- [Creating a local Persistent Volume-backed backingstore](#)
Create a local Persistent Volume-backed backing store using the MCG command-line interface or a YAML file to add storage resources.

Creating an AWS-backed backingstore

Create an AWS-backed backing store using the MCG command-line interface or a YAML file to add storage resources.

Before you begin, ensure the following:

- Fusion Data Foundation Platform is running.
- Download the MCG command-line interface for easier management.

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-x86_64-rpms

yum install mcg
```

Note: Specify the appropriate architecture for enabling the repositories using the subscription manager. In case of IBM Z infrastructure, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-s390x-rpms
```

- Alternatively, you can install the MCG package from the RPMs found at [Download Red Hat® OpenShift® Data Foundation page](#).

Note: Choose the correct Product Variant according to your architecture.

Create an AWS-backed backingstore using MCG command-line interface

From the MCG command-line interface, run the following command:

```
odf noobaa backingstore create aws-s3 <backingstore_name> --access-key=<AWS ACCESS KEY> --secret-key=<AWS SECRET ACCESS KEY> --
target-bucket <bucket-name> -n openshift-storage
```

backingstore_name

The name of the backingstore.

AWS ACCESS KEY and *AWS SECRET ACCESS KEY*

The AWS access key ID and secret access key you created for this purpose.

bucket-name

The existing AWS bucket name. This argument indicates to the MCG which bucket to use as a target bucket for its backing store, and subsequently, data storage and administration.

Example output:

```
INFO[0001] ✔ Exists: NooBaa "noobaa"
INFO[0002] ✔ Created: BackingStore "aws-resource"
INFO[0002] ✔ Created: Secret "backing-store-secret-aws-resource"
```

Create an AWS-backed backingstore using a YAML file

1. Create a secret with the credentials:

```
apiVersion: v1
kind: Secret
metadata:
  name: <backingstore-secret-name>
  namespace: openshift-storage
type: Opaque
data:
  AWS_ACCESS_KEY_ID: <AWS ACCESS KEY ID ENCODED IN BASE64>
  AWS_SECRET_ACCESS_KEY: <AWS SECRET ACCESS KEY ENCODED IN BASE64>
```

AWS ACCESS KEY and AWS SECRET ACCESS KEY

Supply and encode your own AWS access key ID and secret access key using Base64, and use the results for **AWS ACCESS KEY ID ENCODED IN BASE64** and **AWS SECRET ACCESS KEY ENCODED IN BASE64**.

backingstore-secret-name

The name of the backingstore secret created in [Creating a new backing store](#).

2. Apply the following YAML for a specific backing store:

```
apiVersion: noobaa.io/v1alpha1
kind: BackingStore
metadata:
  finalizers:
    - noobaa.io/finalizer
  labels:
    app: noobaa
    name: bs
    namespace: openshift-storage
spec:
  awsS3:
    secret:
      name: <backingstore-secret-name>
      namespace: openshift-storage
      targetBucket: <bucket-name>
    type: aws-s3
```

bucket-name

The existing AWS bucket name.

backingstore-secret-name

The name of the backingstore secret created in the previous step.

Creating an AWS-STS-backed backingstore

Creating an AWS STS-backed backingstore is supported only on clusters deployed on AWS using STS and involves creating an AWS role with temporary credentials, installing the operator, and creating the backingstore.

Amazon Web Services Security Token Service (AWS STS) is an AWS feature and it is a way to authenticate using short-lived credentials. Creating an AWS-STS-backed backingstore is supported only on clusters deployed on AWS using STS. The process involves the following:

- Creating an AWS role using a script, which helps to get the temporary security credentials for the role session
- Installing {product-name-short} operator in AWS STS OpenShift® cluster
- Creating backingstore in AWS STS OpenShift cluster
- [Creating an AWS role using a script](#)
You need to create a role and pass the role Amazon resource name (ARN) while installing the {product-name-short} operator.
- [Installing Red Hat OpenShift Data Foundation operator in AWS STS OpenShift cluster](#)
Install the Red Hat® OpenShift Data Foundation operator in an AWS STS OpenShift cluster by annotating the subscription with the ARN and applying the required OIDC-based credentials.
- [Creating a new AWS STS backingstore](#)
Create an AWS STS backingstore for the Multicloud Object Gateway using short-lived credentials obtained through OpenID Connect (OIDC) authentication.

Creating an AWS role using a script

You need to create a role and pass the role Amazon resource name (ARN) while installing the {product-name-short} operator.

Before you begin

Configure Red Hat® OpenShift® Container Platform cluster with AWS STS. For more information, see [Configuring an AWS cluster to use short-term credentials](#).

Procedure

Create an AWS role using a script that matches OpenID Connect (OIDC) configuration for Multicloud Object Gateway (MCG) on Red Hat OpenShift Data Foundation. The following example shows the details that are required to create the role:

```
{
  "Version": "2012-10-17",
  "Statement": [
```

```
{
  "Effect": "Allow",
  "Principal": {
    "Federated": "arn:aws:iam::123456789123:oidc-provider/mybucket-oidc.s3.us-east-2.amazonaws.com"
  },
  "Action": "sts:AssumeRoleWithWebIdentity",
  "Condition": {
    "StringEquals": {
      "mybucket-oidc.s3.us-east-2.amazonaws.com:sub": [
        "system:serviceaccount:openshift-storage:noobaa",
        "system:serviceaccount:openshift-storage:noobaa-endpoint"
      ]
    }
  }
}
```

where

123456789123

Is the AWS account ID

mybucket

Is the bucket name (using public bucket configuration)

us-east-2

Is the AWS region

openshift-storage

Is the namespace name

Sample script

```
#!/bin/bash
set -x

# This is a sample script to help you deploy MCG on AWS STS cluster.
# This script shows how to create role-policy and then create the role in AWS.
# For more information see: https://docs.openshift.com/rosa/authentication/assuming-an-aws-iam-role-for-a-service-account.html

# WARNING: This is a sample script. You need to adjust the variables based on your requirement.

# Variables :
# user variables - REPLACE these variables with your values:
ROLE_NAME="" # role name that you pick in your AWS account
NAMESPACE="" # namespace name where MCG is running. For Red Hat OpenShift Data Foundation, it is openshift-storage.

# MCG variables
SERVICE_ACCOUNT_NAME_1="" # The service account name of statefulset core and deployment operator (MCG)
SERVICE_ACCOUNT_NAME_2="" # The service account name of deployment endpoint (MCG endpoint)

# AWS variables
# Ensure these values are not empty (AWS_ACCOUNT_ID, OIDC_PROVIDER)
# AWS_ACCOUNT_ID is your AWS account number
AWS_ACCOUNT_ID=$(aws sts get-caller-identity --query "Account" --output text)
# If you want to create the role before using the cluster, replace this field too.
# The OIDC provider is in the structure:
# 1) <OIDC-bucket>.s3.<aws-region>.amazonaws.com. for OIDC bucket configurations are in an S3 public bucket
# 2) <characters>.cloudfront.net for OIDC bucket configurations in an S3 private bucket with a public CloudFront distribution
OIDC_PROVIDER=$(oc get authentication cluster -ojson | jq -r .spec.serviceAccountIssuer | sed -e "s/^https:\\/\\/\\/" )
# the permission (S3 full access)
POLICY_ARN_STRINGS="arn:aws:iam::aws:policy/AmazonS3FullAccess"

# Creating the role (with AWS command line interface)

read -r -d '' TRUST_RELATIONSHIP <<EOF
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Federated": "arn:aws:iam::${AWS_ACCOUNT_ID}:oidc-provider/${OIDC_PROVIDER}"
      },
      "Action": "sts:AssumeRoleWithWebIdentity",
      "Condition": {
        "StringEquals": {
          "${OIDC_PROVIDER}:sub": [
            "system:serviceaccount:${NAMESPACE}:${SERVICE_ACCOUNT_NAME_1}",
            "system:serviceaccount:${NAMESPACE}:${SERVICE_ACCOUNT_NAME_2}"
          ]
        }
      }
    }
  ]
}
EOF

echo "${TRUST_RELATIONSHIP}" > trust.json

aws iam create-role --role-name "${ROLE_NAME}" --assume-role-policy-document file://trust.json --description "role for demo"

while IFS= read -r POLICY_ARN; do
  echo -n "Attaching $POLICY_ARN ... "
```

```
aws iam attach-role-policy \
  --role-name "$ROLE_NAME" \
  --policy-arn "${POLICY_ARN}"
echo "ok."
done <<< "$POLICY_ARN_STRINGS"
```

Installing Red Hat OpenShift Data Foundation operator in AWS STS OpenShift cluster

Install the Red Hat® OpenShift® Data Foundation operator in an AWS STS OpenShift cluster by annotating the subscription with the ARN and applying the required OIDC-based credentials.

Before you begin

- Configure OpenShift Container Platform cluster with AWS STS. For more information, see [Configuring an AWS cluster to use short-term credentials](#).
- Create an AWS role using a script that matches OpenID Connect (OIDC) configuration. For more information, see [Creating an AWS role using a script](#).

Procedure

Install Fusion Data Foundation Operator from the Operator Hub.

- During the installation add the role ARN in the **ARN Details** field.
- Ensure that the **Update approval** field is set to **Manual**.

Creating a new AWS STS backingstore

Create an AWS STS backingstore for the Multicloud Object Gateway using short-lived credentials obtained through OpenID Connect (OIDC) authentication.

Before you begin

- Configure Red Hat® OpenShift® Container Platform cluster with AWS STS. For more information, see [Configuring an AWS cluster to use short-term credentials](#).
- Create an AWS role using a script that matches OpenID Connect (OIDC) configuration. For more information, see [Creating an AWS role using a script](#).

Procedure

1. Install Multicloud Object Gateway (MCG).
It is installed with the default backingstore by using the short-lived credentials.
2. After the MCG system is ready, you can create more backingstores of the type `aws-sts-s3` using the following MCG command line interface command:

```
odf noobaa backingstore create aws-sts-s3 <backingstore-name> --aws-sts-arn=<aws-sts-role-arn> --region=<region> --target-bucket=<target-bucket>
```

where

backingstore-name
Name of the backingstore

aws-sts-role-arn
The AWS STS role ARN which assumes role

region
The AWS bucket region

target-bucket
The target bucket name on the cloud

Creating an IBM COS-backed backingstore

Create an IBM COS-backed backing store using the MCG command-line interface or a YAML file to add storage resources.

Before you begin, ensure the following:

- Fusion Data Foundation Platform is running.
- Download the MCG command-line interface for easier management.

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-x86_64-rpms
yum install mcg
```

Note: Specify the appropriate architecture for enabling the repositories using the subscription manager.

- For IBM Power, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-ppc64le-rpms
```

- For IBM Z infrastructure, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-s390x-rpms
```

- Alternatively, you can install the MCG package from the RPMs found at [Download Red Hat® OpenShift® Data Foundation page](#).

Note: Choose the correct Product Variant according to your architecture.

Create an IBM COS-backed backingstore using MCG command-line interface

From the MCG command-line interface, run the following command:

```
odf noobaa backingstore create ibm-cos <backingstore_name> --access-key=<IBM ACCESS KEY> --secret-key=<IBM SECRET ACCESS KEY> --endpoint=<IBM COS ENDPOINT> --target-bucket <bucket-name> -n openshift-storage
```

backingstore_name

The name of the backingstore.

IBM ACCESS KEY and IBM SECRET ACCESS KEY

An IBM access key ID, secret access key and the appropriate regional endpoint that corresponds to the location of the existing IBM bucket.

To generate the preceding keys on IBM cloud, you must include HMAC credentials while creating the service credentials for your target bucket.

bucket-name

The existing IBM bucket name. This argument indicates to the MCG which bucket to use as a target bucket for its backing store, and subsequently, data storage and administration.

Example output:

```
INFO[0001] ✓ Exists: NooBaa "noobaa"
INFO[0002] ✓ Created: BackingStore "ibm-resource"
INFO[0002] ✓ Created: Secret "backing-store-secret-ibm-resource"
```

Create an IBM COS-backed backingstore using a YAML file

1. Create a secret with the credentials:

```
apiVersion: v1
kind: Secret
metadata:
  name: <backingstore-secret-name>
  namespace: openshift-storage
type: Opaque
data:
  IBM_COS_ACCESS_KEY_ID: <IBM_COS_ACCESS_KEY_ID_ENCODED_IN_BASE64>
  IBM_COS_SECRET_ACCESS_KEY: <IBM_COS_SECRET_ACCESS_KEY_ENCODED_IN_BASE64>
```

IBM ACCESS KEY and IBM SECRET ACCESS KEY

Provide and encode your own IBM COS access key ID and secret access key using Base64, and use the results in place of these attributes respectively.

backingstore-secret-name

The name of the backingstore secret created in [Creating a new backing store](#).

2. Apply the following YAML for a specific backing store:

```
apiVersion: noobaa.io/v1alpha1
kind: BackingStore
metadata:
  finalizers:
    - noobaa.io/finalizer
  labels:
    app: noobaa
  name: bs
  namespace: openshift-storage
spec:
  ibmCos:
    endpoint: <endpoint>
    secret:
      name: <backingstore-secret-name>
      namespace: openshift-storage
    targetBucket: <bucket-name>
  type: ibm-cos
```

bucket-name

An existing IBM COS bucket name.

endpoint

A regional endpoint that corresponds to the location of the existing IBM bucket name. This argument indicates to MCG about the endpoint to use for its backingstore, and subsequently, data storage and administration.

backingstore-secret-name

The name of the backingstore secret created in the previous step.

Creating an Azure-backed backingstore

Create an Azure-backed backing store using the MCG command-line interface or a YAML file to add storage resources.

Before you begin, ensure the following:

- Fusion Data Foundation Platform is running.

- Download the MCG command-line interface for easier management.

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-x86_64-rpms
```

```
yum install mcg
```

Note: Specify the appropriate architecture for enabling the repositories using the subscription manager. In case of IBM Z infrastructure, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-s390x-rpms
```

- Alternatively, you can install the MCG package from the RPMs found at [Download Red Hat® OpenShift® Data Foundation page](#).

Note: Choose the correct Product Variant according to your architecture.

Create an Azure-backed backingstore using MCG command-line interface

From the MCG command-line interface, run the following command:

```
odf noobaa backingstore create azure-blob <backingstore_name> --account-key=<AZURE ACCOUNT KEY> --account-name=<AZURE ACCOUNT NAME> --target-blob-container <blob container name> -n openshift-storage
```

backingstore_name

The name of the backingstore.

AZURE ACCOUNT KEY and *AZURE ACCOUNT NAME*

An AZURE account key and account name you created for this purpose.

blob container name

An existing Azure blob container name. This argument indicates to MCG about the bucket to use as a target bucket for its backingstore, and subsequently, data storage and administration.

Example output:

```
INFO[0001] ✔ Exists: NooBaa "noobaa"
INFO[0002] ✔ Created: BackingStore "azure-resource"
INFO[0002] ✔ Created: Secret "backing-store-secret-azure-resource"
```

Create an Azure-backed backingstore using a YAML file

1. Create a secret with the credentials:

```
apiVersion: v1
kind: Secret
metadata:
  name: <backingstore-secret-name>
type: Opaque
data:
  AccountName: <AZURE ACCOUNT NAME ENCODED IN BASE64>
  AccountKey: <AZURE ACCOUNT KEY ENCODED IN BASE64>
```

AZURE ACCOUNT NAME ENCODED IN BASE64 and *AZURE ACCOUNT KEY ENCODED IN BASE64*

Supply and encode your own Azure Account Name and Account Key using Base64, and use the results in place of these attributes respectively.

backingstore-secret-name

A unique name of backingstore secret.

2. Apply the following YAML for a specific backingstore:

```
apiVersion: noobaa.io/v1alpha1
kind: BackingStore
metadata:
  finalizers:
  - noobaa.io/finalizer
  labels:
    app: noobaa
    name: bs
    namespace: openshift-storage
spec:
  azureBlob:
    secret:
      name: <backingstore-secret-name>
      namespace: openshift-storage
      targetBlobContainer: <blob-container-name>
    type: azure-blob
```

blob-container-name

An existing Azure blob container name. This argument indicates to the MCG about the bucket to use as a target bucket for its backingstore, and subsequently, data storage and administration.

backingstore-secret-name

The name of the backingstore secret created in [Creating a new backing store](#).

Creating an Azure STS-backed backingstore

Azure Identity (also known as Azure Workload Identity) provides authentication through short-lived, temporary credentials. Creating an Azure STS-backed backingstore is supported on any OpenShift® cluster with Azure Workload Identity and OIDC provider configured.

Note: Starting with Fusion Data Foundation 4.22, you can create Azure STS-backed backingstores using Azure Workload Identity (short-lived credentials). The process of creating an Azure STS-backed backingstore involves the following steps:

- Creating an Azure managed identity for NooBaa
- Installing the Fusion Data Foundation operator in an Azure STS OpenShift cluster
- Creating a new Azure STS backingstore
- [Creating an Azure managed identity for NooBaa](#)
Create a user-assigned managed identity with federated credentials and pass the managed identity client ID when installing the Fusion Data Foundation operator.
- [Installing the Fusion Data Foundation operator in an Azure STS OpenShift cluster](#)
Install the Fusion Data Foundation operator in an Azure STS OpenShift cluster by providing the Azure managed identity credentials during installation.
- [Creating a new Azure STS backingstore](#)
Create an Azure STS backingstore for the Multicloud Object Gateway (MCG) using short-lived credentials obtained through Azure Workload Identity.

Creating an Azure managed identity for NooBaa

Create a user-assigned managed identity with federated credentials and pass the managed identity client ID when installing the Fusion Data Foundation operator.

Before you begin

- Red Hat® OpenShift® Container Platform cluster configured with Azure Workload Identity and OIDC provider. For more information, see [Install](#), [Installing on Azure](#), [Installer-provisioned infrastructure](#), [Installing a cluster on Azure with customizations](#), [Alternatives to storing administrator-level secrets in the kube-system project](#), [Configuring an Azure cluster to use short-term credentials in Red Hat OpenShift Container Platform](#) product documentation.
- Azure CLI (az) installed and authenticated.
- OpenShift CLI (oc) installed and logged in to the cluster.

Procedure

1. Set the required environment variables:

```
CLUSTER_NAME=<cluster_name>
RESOURCE_GROUP=<cluster_resource_group>
SUBSCRIPTION_ID=<azure_subscription_id>
REGION=<azure_region>
NAMESPACE=openshift-storage
MI_NAME=${CLUSTER_NAME}-noobaa-mi
```

where

cluster_name
The name of your OpenShift cluster

cluster_resource_group
The Azure resource group containing your cluster

azure_subscription_id
Your Azure subscription ID

azure_region
The Azure region where your cluster is deployed

2. Create a user-assigned managed identity:

```
az identity create \
  --name ${MI_NAME} \
  --resource-group ${RESOURCE_GROUP} \
  --location ${REGION} \
  --subscription ${SUBSCRIPTION_ID}
```

3. Retrieve the managed identity's client ID and principal ID:

```
MI_CLIENT_ID=$(az identity show --name ${MI_NAME} --resource-group ${RESOURCE_GROUP} --subscription ${SUBSCRIPTION_ID} --query clientId -o tsv)
MI_PRINCIPAL_ID=$(az identity show --name ${MI_NAME} --resource-group ${RESOURCE_GROUP} --subscription ${SUBSCRIPTION_ID} --query principalId -o tsv)
```

4. Assign the required roles to the managed identity:

```
SCOPE="/subscriptions/${SUBSCRIPTION_ID}/resourceGroups/${RESOURCE_GROUP}"
```

```
az role assignment create \
  --assignee-object-id ${MI_PRINCIPAL_ID} \
  --assignee-principal-type ServicePrincipal \
  --role "Storage Account Contributor" \
  --scope ${SCOPE} \
  --subscription ${SUBSCRIPTION_ID}
```

```
az role assignment create \
  --assignee-object-id ${MI_PRINCIPAL_ID} \
  --assignee-principal-type ServicePrincipal \
  --role "Storage Blob Data Contributor" \
  --scope ${SCOPE} \
  --subscription ${SUBSCRIPTION_ID}
```

- Retrieve the OIDC issuer URL from the cluster:

```
OIDC_ISSUER=$(oc get authentication cluster -o jsonpath='{.spec.serviceAccountIssuer}')
```

- Create federated credentials for the NooBaa service accounts (**noobaa**, **noobaa-core**, and **noobaa-endpoint**):

```
for SA in noobaa noobaa-core noobaa-endpoint; do
  az identity federated-credential create \
    --name ${MI_NAME}-${SA} \
    --identity-name ${MI_NAME} \
    --resource-group ${RESOURCE_GROUP} \
    --issuer ${OIDC_ISSUER} \
    --subject "system:serviceaccount:${NAMESPACE}:${SA}" \
    --audiences openshift \
    --subscription ${SUBSCRIPTION_ID}
done
```

- Note the managed identity client ID (**MI_CLIENT_ID**).

You need it when installing the Fusion Data Foundation operator.

```
echo "Managed Identity Client ID: ${MI_CLIENT_ID}"
```

Installing the Fusion Data Foundation operator in an Azure STS OpenShift cluster

Install the Fusion Data Foundation operator in an Azure STS OpenShift cluster by providing the Azure managed identity credentials during installation.

Before you begin

- Red Hat® OpenShift Container Platform cluster configured with Azure Workload Identity and OIDC provider. For more information, see [Install, Installing on Azure, Installer-provisioned infrastructure, Installing a cluster on Azure with customizations, Alternatives to storing administrator-level secrets in the kube-system project, Configuring an Azure cluster to use short-term credentials](#) in [Red Hat OpenShift Container Platform](#) product documentation.
- Create an Azure managed identity with federated credentials for NooBaa service accounts. For more information, see [Creating an Azure managed identity for NooBaa](#).

Procedure

Install the Fusion Data Foundation operator from the Software Catalog.

During the installation, enter the following values in their respective fields:

- Azure Client ID: The managed identity's client ID from the procedure in the prerequisites (not the service principal's client ID)
- Azure Tenant ID: Your Azure Active Directory tenant ID
- Azure Subscription ID: Your Azure subscription ID
- Azure Resource Group: The cluster's resource group name

Ensure that the Update approval field is set to Manual.

Creating a new Azure STS backingstore

Create an Azure STS backingstore for the Multicloud Object Gateway (MCG) using short-lived credentials obtained through Azure Workload Identity.

Before you begin

- Red Hat® OpenShift® Container Platform cluster configured with Azure Workload Identity and OIDC provider. For more information, see [Install, Installing on Azure, Installer-provisioned infrastructure, Installing a cluster on Azure with customizations, Alternatives to storing administrator-level secrets in the kube-system project, Configuring an Azure cluster to use short-term credentials](#) in [Red Hat OpenShift Container Platform](#) product documentation.
- Create an Azure managed identity with federated credentials for NooBaa service accounts. For more information, see [Creating an Azure managed identity for NooBaa](#).
- Install the Fusion Data Foundation operator in an Azure STS OpenShift cluster. For more information, see [Installing the Fusion Data Foundation operator in an Azure STS OpenShift cluster](#).

Procedure

- Install the MCG.

It is installed with the default backingstore by using the short-lived Azure Identity credentials.

- After the MCG system is ready, create more backingstores of the type **azure-sts-blob** using the following command:

```
odf noobaa backingstore create azure-sts-blob <backingstore-name> \
  --account-name <storage-account-name> \
  --target-blob-container <container-name> \
  --tenant-id <tenant-id> \
  --client-id <client-id>
```

where

backingstore-name

Name of the backingstore
storage-account-name
The Azure Storage Account name
container-name
The target blob container name in Azure
tenant-id
The Azure Active Directory tenant ID
client-id
The Azure managed identity client ID

Creating a GCP-backed backingstore

Create a GCP-backed backing store using the MCG command-line interface or a YAML file to add storage resources.

Before you begin, ensure the following:

- Fusion Data Foundation Platform is running.
- Download the MCG command-line interface for easier management.

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-x86_64-rpms  
yum install mcg
```

Note: Specify the appropriate architecture for enabling the repositories using the subscription manager. In case of IBM Z infrastructure, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-s390x-rpms
```

- Alternatively, you can install the MCG package from the RPMs found at [Download Red Hat® OpenShift® Data Foundation page](#).

Note: Choose the correct Product Variant according to your architecture.

Create a GCP-backed backingstore using MCG command-line interface

From the MCG command-line interface, run the following command:

```
odf noobaa backingstore create google-cloud-storage <backingstore_name> --private-key-json-file=<PATH TO GCP PRIVATE KEY JSON FILE> --target-bucket <GCP bucket name> -n openshift-storage
```

backingstore_name
Name of the backingstore.

<PATH TO GCP PRIVATE KEY JSON FILE>
A path to your GCP private key created for this purpose.

GCP bucket name
An existing GCP object storage bucket name. This argument tells the MCG which bucket to use as a target bucket for its backing store, and subsequently, data storage and administration.
The output is similar to the following:

```
INFO[0001] ✔ Exists: NooBaa "noobaa"  
INFO[0002] ✔ Created: BackingStore "google-gcp"  
INFO[0002] ✔ Created: Secret "backing-store-google-cloud-storage-gcp"
```

Create a GCP-backed backingstore using a YAML file

1. Create a secret with the credentials:

```
apiVersion: v1  
kind: Secret  
metadata:  
  name: <backingstore-secret-name>  
type: Opaque  
data:  
  GoogleServiceAccountPrivateKeyJson: <GCP PRIVATE KEY ENCODED IN BASE64>
```

GCP PRIVATE KEY ENCODED IN BASE64

Provide and encode your own GCP service account private key using Base64, and use the results for this attribute.

backingstore-secret-name
A unique name of the backingstore secret.

2. Apply the following YAML for a specific backing store:

```
apiVersion: noobaa.io/v1alpha1  
kind: BackingStore  
metadata:  
  finalizers:  
  - noobaa.io/finalizer  
  labels:  
    app: noobaa  
    name: bs  
    namespace: openshift-storage  
spec:  
  googleCloudStorage:
```

```
secret:
  name: <backingstore-secret-name>
  namespace: openshift-storage
  targetBucket: <target_bucket>
  type: google-cloud-storage
```

target bucket

An existing Google storage bucket. This argument indicates to the MCG about the bucket to use as a target bucket for its backing store, and subsequently, data storage and administration.

backingstore-secret-name

The name of the backingstore secret created in [Creating a new backing store](#).

Creating a local Persistent Volume-backed backingstore

Create a local Persistent Volume-backed backing store using the MCG command-line interface or a YAML file to add storage resources.

Before you begin, ensure the following:

- Fusion Data Foundation Platform is running.
- Download the MCG command-line interface for easier management.

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-x86_64-rpms
```

```
yum install mcg
```

Note: Specify the appropriate architecture for enabling the repositories using the subscription manager.

- For IBM Power, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-ppc64le-rpms
```

- For IBM Z infrastructure, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-s390x-rpms
```

- Alternatively, you can install the MCG package from the RPMs found at [Download Red Hat® OpenShift® Data Foundation page](#).

Note: Choose the correct Product Variant according to your architecture.

Create a local Persistent Volume-backed backingstore using MCG command-line interface

From the MCG command-line interface, run the following command:

Note: This command must be run from within the **openshift-storage** namespace.

```
odf noobaa -n openshift-storage backingstore create pv-pool <backingstore_name> --num-volumes <NUMBER OF VOLUMES> --pv-size-gb <VOLUME SIZE> --request-cpu <CPU REQUEST> --request-memory <MEMORY REQUEST> --limit-cpu <CPU LIMIT> --limit-memory <MEMORY LIMIT> --storage-class <LOCAL STORAGE CLASS>
```

backingstore_name

The name of the backingstore.

NUMBER OF VOLUMES

The number of volumes you would like to create. Increasing the number of volumes scales up the storage.

VOLUME SIZE

Required size in GB of each volume.

CPU REQUEST

Guaranteed amount of CPU requested in CPU unit **m**.

MEMORY REQUEST

Guaranteed amount of memory requested.

CPU LIMIT

Maximum amount of CPU that can be consumed in CPU unit **m**.

MEMORY LIMIT

Maximum amount of memory that can be consumed.

LOCAL STORAGE CLASS

The local storage class name, recommended to use **ocs-storagecluster-ceph-rbd**.

Create a local Persistent Volume-backed backingstore using a YAML file

Apply the following YAML for a specific backing store:

```
apiVersion: noobaa.io/v1alpha1
kind: BackingStore
metadata:
  finalizers:
  - noobaa.io/finalizer
  labels:
    app: noobaa
  name: <backingstore_name>
  namespace: openshift-storage
```

```
spec:
  pvPool:
    numVolumes: <NUMBER OF VOLUMES>
    resources:
      requests:
        storage: <VOLUME SIZE>
        cpu: <CPU REQUEST>
        memory: <MEMORY REQUEST>
      limits:
        cpu: <CPU LIMIT>
        memory: <MEMORY LIMIT>
    storageClass: <LOCAL STORAGE CLASS>
  type: pv-pool
```

backingstore_name
The name of the backingstore.

NUMBER OF VOLUMES
The number of volumes you would like to create. Increasing the number of volumes scales up the storage.

VOLUME SIZE
Required size in GB of each volume.

CPU REQUEST
Guaranteed amount of CPU requested in CPU unit *m*.

MEMORY REQUEST
Guaranteed amount of memory requested.

CPU LIMIT
Maximum amount of CPU that can be consumed in CPU unit *m*.

MEMORY LIMIT
Maximum amount of memory that can be consumed.

LOCAL STORAGE CLASS
The local storage class name, recommended to use `ocs-storagecluster-ceph-rbd`.

Example output:

```
INFO [0001] ✔ Exists: NooBaa "noobaa"
INFO [0002] ✔ Exists: BackingStore "local-mcg-storage"
```

Creating an s3 compatible Multicloud Object Gateway backingstore

Create an S3 compatible MCG backing store for IBM Storage Ceph's RGW. When the RGW is deployed, Fusion Data Foundation operator creates an S3 compatible backingstore for MCG automatically.

The Multicloud Object Gateway (MCG) can use any S3 compatible object storage as a backing store. For example, IBM Storage Ceph's RADOS Object Gateway (RGW).

Creating an s3 compatible Multicloud Object Gateway backingstore using the MCG command-line interface

- Run the following command:
Note: This command must be run from within the `openshift-storage` namespace.

```
odf noobaa backingstore create s3-compatible rgw-resource --access-key=<RGW ACCESS KEY> --secret-key=<RGW SECRET KEY> --target-bucket=<bucket-name> --endpoint=<RGW endpoint> -n openshift-storage
```

Example output:

```
INFO [0001] ✔ Exists: NooBaa "noobaa"
INFO [0002] ✔ Created: BackingStore "rgw-resource"
INFO [0002] ✔ Created: Secret "backing-store-secret-rgw-resource"
```

- To get the *RGW ACCESS KEY* and *RGW SECRET KEY*, run the following command using your RGW user secret name:

```
oc get secret <RGW USER SECRET NAME> -o yaml -n openshift-storage
```

Decode the access key ID and the access key from Base64 and keep them.

RGW ACCESS KEY

RGW SECRET KEY

Decoded data

bucket-name

An existing RGW bucket name. This argument tells the MCG which bucket to use as a target bucket for its backing store, and subsequently, data storage and administration.

RGW endpoint

To get the *RGW endpoint*, see [Accessing the RADOS Object Gateway S3 endpoint](#).

Creating an s3 compatible Multicloud Object Gateway backingstore using a YAML file

- Create a `CephObjectStore` user. This also creates a secret containing the RGW credentials:

```

apiVersion: ceph.rook.io/v1
kind: CephObjectStoreUser
metadata:
  name: <RGW-Username>
  namespace: openshift-storage
spec:
  store: ocs-storagecluster-cephobjectstore
  displayName: "<Display-name>"

```

RGW-Username

A unique RGW user name.

Display-name

A display name

2. Apply the following YAML for an S3-Compatible backing store:

```

apiVersion: noobaa.io/v1alpha1
kind: BackingStore
metadata:
  finalizers:
    - noobaa.io/finalizer
  labels:
    app: noobaa
  name: <backingstore-name>
  namespace: openshift-storage
spec:
  s3Compatible:
    endpoint: <RGW endpoint>
    secret:
      name: <backingstore-secret-name>
      namespace: openshift-storage
    signatureVersion: v4
    targetBucket: <RGW-bucket-name>

  type: s3-compatible

```

backingstore-secret-name

Name of the secret that was created with **CephObjectStore** in the previous step.

bucket-name

An existing RGW bucket name. This argument tells the MCG which bucket to use as a target bucket for its backing store, and subsequently, data storage and administration.

RGW endpoint

To get the RGW endpoint, see [Accessing the RADOS Object Gateway S3 endpoint](#).

Creating a new bucket class

Bucket class is a CRD representing a class of buckets that defines tiering policies and data placements for an Object Bucket Class (OBC). Use this procedure to create a bucket class in Fusion Data Foundation.

Procedure

1. From the OpenShift® Container Platform web console, go to **Storage > Data Foundation**.
2. From the Bucket Class tab click **Create Bucket Class**.
3. On the Create new Bucket Class page, perform the following:
 - a. Select the bucket class type by choosing one of the following options:
 - Standard: data is consumed by a Multicloud Object Gateway (MCG), deduped, compressed and encrypted.
 - Namespace: data is stored on the NamespaceStores without performing de-duplication, compression or encryption.
 - Vector: specialized bucket class for storing vector embeddings for machine learning and AI applications. Vector bucket classes require an NSFS NamespaceStore and support only the Lance vector database type.

By default, Standard is selected.

Note: If you select Vector as the bucket class type, the Placement Policy step is hidden, and you are prompted to select an NSFS NamespaceStore resource. For more information about vector bucket classes, see [Creating a vector BucketClass](#).
 - b. Enter a Bucket Class Name.
 - c. Click **Next**.
 - d. In Placement Policy, select **Tier 1 - Policy Type** and click **Next**.
You can choose one of the options as per your requirements.
 - Spread allows spreading of the data across the chosen resources.
 - Mirror allows full duplication of the data across the chosen resources.
 - e. To add another policy tier, click **Add Tier**.
 - f. Select at least one Backing Store resource from the available list if you have selected Tier 1 - Policy Type as Spread and click **Next**.
Alternatively, you can also [Creating a new backing store](#).
Note: You need to select at least two backing stores when you select Policy Type as Mirror in step [3.d](#).

What to do next

To verify the creation of the new bucket class:

1. In the OpenShift Container Platform web console, click **Storage > Data Foundation**.
2. Click the **Bucket Class** tab and search the new Bucket Class.

Editing a bucket class

Use this information to edit an existing bucket class.

Before you begin

Ensure you have Administrator access to OpenShift® Web Console.

About this task

Use the following procedure to edit the bucket class components through the YAML file by clicking the edit button on the OpenShift web console.

Procedure

1. From the OpenShift Web Console, go to [Storage](#) > [Data Foundation](#).
2. From the Bucket Class tab, next to the Bucket class you want to edit, click Action Menu > [Edit Bucket Class](#).
You are redirected to the YAML file.
3. Make the required changes in this file and click Save.

Editing backing stores for bucket class

Use this procedure to edit an existing Multicloud Object Gateway (MCG) bucket class to change the underlying backing stores used in a bucket class.

Before you begin

Ensure you have the following:

- Administrator access to OpenShift® Web Console
- A bucket class
- Backing stores

Procedure

1. From the OpenShift Web Console, go to [Storage](#) > [Data Foundation](#).
2. From the Bucket Class tab, next to the Bucket class you want to edit, click Action Menu > [Edit Bucket Class Resources](#).

Figure 1. Bucket Classes

3. On the Edit Bucket Class Resources page, edit the bucket class resources.
Edit the bucket class resources either by adding a backing store to the bucket class or by removing a backing store from the bucket class. You can also edit bucket class resources created with one or two tiers and different placement policies.
 - To add a backing store to the bucket class, select the name of the backing store.
 - To remove a backing store from the bucket class, clear the name of the backing store.

Figure 2. Editing backing stores

4. Click Save.

Creating and managing buckets using the object browser

The object browser in the OpenShift® Web Console enables you to create, view, and manage buckets and objects across different storage endpoints, including Multicloud Object Gateway (MCG) and internal mode RADOS Gateway (RGW) object storage.

A storage endpoint selector is available under **Storage > Object Storage > Buckets**, allowing you to switch between the MCG and RGW. After selecting an endpoint, the object browser presents a unified interface for creating and managing buckets, uploading and viewing objects, configuring policies, and performing related operations.

- [Accessing the object browser](#)
Access the object browser based on your user role and deployment type: provider or standalone cluster administrators and developers, and client cluster users.
- [Creating and managing buckets](#)
Create, view, and manage buckets for MCG and RGW storage endpoints using the object browser in the OpenShift Web Console.
- [Managing objects](#)
Managing objects in the Multicloud Object Gateway includes uploading, downloading, and organizing S3-compatible objects stored across backing stores.
- [Creating and managing lifecycle rules](#)
S3 bucket lifecycle rules automate object expiration and transition actions in the Multicloud Object Gateway to manage storage costs and data retention.
- [Creating and managing IAM user](#)
Use this section to create and manage IAM users for object storage access.

Accessing the object browser

Access the object browser based on your user role and deployment type: provider or standalone cluster administrators and developers, and client cluster users.

The access flow depends on your user role:

- **Administrator users**
Administrators have direct access to the object browser without additional login steps.
- **Developer users**
Developers must sign in before accessing the object browser as illustrated in [Signing in to the object browser as a developer user](#).

Note: On client (hosted) clusters, the object browser connects to the provider cluster's NooBaa endpoint through an in-cluster reverse proxy. Management operations such as listing buckets work without additional configuration. Data operations such as uploading and downloading objects require CORS enablement per bucket and browser trust of the provider's S3 certificate. For more information, see [Object browser on client clusters](#).

- [Signing in to the object browser as a developer user](#)
Sign in to the object browser with Kubernetes Secret credentials.

Signing in to the object browser as a developer user

Sign in to the object browser with Kubernetes Secret credentials.

Before you begin

- Kubernetes Secret containing S3 credentials

- Namespace and Secret name details

Procedure

1. Open the object browser in the OpenShift® Web Console.
 2. Select the storage endpoint:
 - MCG
 - RGW
- Developers must log in separately for each endpoint.
3. Select the Secret namespace and name where the S3 credentials are stored.
 4. Optional: Select Stay signed in to remain logged in across browser tabs or sessions. Click Sign in.

Note:

- The UI does not store credentials in local or session storage but only a reference to the Kubernetes Secret is stored.
- Access level depends on the credentials provided.

Creating and managing buckets

Create, view, and manage buckets for MCG and RGW storage endpoints using the object browser in the OpenShift® Web Console.

- [Creating new buckets using the object browser](#)
Create new buckets using the object browser through Object Bucket Claims or the S3 API.
- [Listing bucket details using the object browser](#)
View bucket details in the object browser for MCG or RGW storage endpoints.
- [Deleting or emptying bucket using object browser](#)
Delete or empty buckets by using the object browser in the OpenShift Web Console.

Creating new buckets using the object browser

Create new buckets using the object browser through Object Bucket Claims or the S3 API.

Before you begin

- **Administrators:** Administrator access to Fusion Data Foundation.
- **Developers:** Logged in to the object browser using secret namespace and secret name. For more information see [Accessing the object browser](#).
- Ensure that the selected storage endpoint (MCG or RGW) is deployed and its pods are healthy.

Procedure

1. In the OpenShift® Web Console, navigate to Storage > Object Storage.
2. From the Storage endpoint selector, choose MCG or RGW, then click the Buckets tab.
3. Choose one of the following options to create the buckets:
 - **Create via Object Bucket Claim**
Note: For RGW object bucket claims (OBCs), you must use the credentials associated with the OBC to access the newly created bucket. RGW administrator credentials cannot be used to access these buckets.
 - Select a namespace.
 - Enter the ObjectBucketClaim name.
 - Select the storage class.
 - Select the bucket class.
 - Select the Enable replication to obtain higher resiliency of the objects stored in the buckets.
 - Click Create using ObjectBucketClaim.
 - **Create via S3 API**
 - Enter a name for the bucket.
 - Add tags with different key and value criteria to tag your bucket.
 - Click Create.

Listing bucket details using the object browser

View bucket details in the object browser for MCG or RGW storage endpoints.

Before you begin

- **Administrators:** Administrator access to Fusion Data Foundation.
- **Developers:** Logged in to the object browser using secret namespace and secret name. For more information see [Accessing the object browser](#).
- Ensure that the selected storage endpoint (MCG or RGW) is deployed and its pods are healthy.

Procedure

1. In the OpenShift® Web Console, navigate to Storage > Object Storage.

2. From the Storage endpoint selector, choose MCG or RGW, then click the Buckets tab.
3. Select the required bucket and then click the Details tab.

Deleting or emptying bucket using object browser

Delete or empty buckets by using the object browser in the OpenShift® Web Console.

Before you begin

- **Administrators:** Administrator access to Fusion Data Foundation.
- **Developers:** Logged in to the object browser using secret namespace and secret name. For more information see [Accessing the object browser](#).
- Ensure that the selected storage endpoint (MCG or RGW) is deployed and its pods are healthy.

Procedure

1. In the OpenShift Web Console, navigate to Storage > Object Storage.
2. From the Storage endpoint selector, choose MCG or RGW and click the Buckets tab.
3. From the bucket's options menu, select Empty bucket.
4. Enter the bucket name to confirm.
5. Click Empty bucket.
6. After the bucket is empty, open the options menu again.
7. Select Delete bucket.
8. Enter the bucket name to confirm and click Delete bucket.

Managing objects

Managing objects in the Multicloud Object Gateway includes uploading, downloading, and organizing S3-compatible objects stored across backing stores.

- [Listing objects and object details using MCG object browser](#)
View objects and object details using the object browser in the OpenShift Web Console.
- [Downloading or previewing objects using the object browser](#)
Download or preview objects using the object browser in the OpenShift Web Console.
- [Generating the presigned URL to share the object](#)
Generate the presigned URL to share an object using the object browser in the OpenShift Web Console.
- [Uploading objects using the object browser](#)
Upload objects using the object browser in the OpenShift Container Platform Web Console.
- [Creating folder using the object browser](#)
Create a folder using the object browser in the OpenShift Web Console.
- [Deleting objects using the object browser](#)
Delete objects using the object browser in the OpenShift Web Console.
- [Enabling or suspending object versioning in a bucket using the object browser](#)
Enable or suspend objects versioning in a bucket using the object browser in the OpenShift Web Console.
- [Listing object versions using the object browser](#)
View object versions using the object browser in the OpenShift Web Console.

Listing objects and object details using MCG object browser

View objects and object details using the object browser in the OpenShift® Web Console.

Before you begin

- **Administrators:** Administrator access to Fusion Data Foundation.
- **Developers:** Logged in to the object browser using secret namespace and secret name. For more information see [Accessing the object browser](#).
- Ensure that the selected storage endpoint (MCG or RGW) is deployed and its pods are healthy.

Procedure

1. In the OpenShift Web Console, click Storage > Object Storage.
2. From the Storage endpoint selector, choose MCG or RGW and click the Buckets tab.
3. Select the required bucket and click the Objects tab.
4. Select the object to open the details in the sidebar.

Downloading or previewing objects using the object browser

Download or preview objects using the object browser in the OpenShift® Web Console.

Before you begin

- **Administrators:** Administrator access to Fusion Data Foundation.
- **Developers:** Logged in to the object browser using secret namespace and secret name. For more information see [Accessing the object browser](#).
- Ensure that the selected storage endpoint (MCG or RGW) is deployed and its pods are healthy.

Procedure

1. In the OpenShift Web Console, click Storage > Object Storage.
2. From the Storage endpoint selector, choose MCG or RGW, then open the required bucket.
3. Click the Objects tab.
4. From the object's options menu, select Download or Preview.
Note: Preview behavior depends on browser support. Unsupported file types that cannot be displayed in a separate tab are downloaded automatically.

Generating the presigned URL to share the object

Generate the presigned URL to share an object using the object browser in the OpenShift® Web Console.

Before you begin

- **Administrators:** Administrator access to Fusion Data Foundation.
- **Developers:** Logged in to the object browser using secret namespace and secret name. For more information see [Accessing the object browser](#).
- Ensure that the selected storage endpoint (MCG or RGW) is deployed and its pods are healthy.

Procedure

1. In the OpenShift Web Console, click Storage > Object Storage.
2. From the Storage endpoint selector, choose MCG or RGW, then open the bucket.
3. Click the Objects tab.
4. From the object's options menu, select Share with presigned URL.
5. Select the expiration time to set the validity period of the presigned URL.
6. Click Create.
7. Copy the generated URL.

Uploading objects using the object browser

Upload objects using the object browser in the OpenShift® Container Platform Web Console.

Before you begin

- **Administrators:** Administrator access to Fusion Data Foundation.
- **Developers:** Logged in to the object browser using secret namespace and secret name. For more information see [Accessing the object browser](#).
- Ensure that the selected storage endpoint (MCG or RGW) is deployed and its pods are healthy.
- **Client cluster users:** Before uploading objects from a client cluster, CORS must be enabled for the bucket and your browser must trust the provider's S3 certificate. For more information, see [Enabling data operations in the object browser on a client cluster](#).

Procedure

1. In the OpenShift Container Platform Web Console, navigate to Storage > Object Storage.
2. From the Storage endpoint selector, choose MCG or RGW, then open the bucket.
3. Click the Objects tab.
4. In the Add objects section, do one of the following:
 - Click Upload to add a folder.
 - Drag and drop individual files to upload specific files.
5. Click the uploaded object to view its Overview and Versions tab.

Creating folder using the object browser

Create a folder using the object browser in the OpenShift® Web Console.

Before you begin

- **Administrators:** Administrator access to Fusion Data Foundation.
- **Developers:** Logged in to the object browser using secret namespace and secret name. For more information see [Accessing the object browser](#).
- Ensure that the selected storage endpoint (MCG or RGW) is deployed and its pods are healthy.

Procedure

1. In the OpenShift Web Console, click Storage > Object Storage.
2. From the Storage endpoint selector, choose MCG or RGW, then open the bucket.
3. Click the Objects tab.
4. Click Create folder.
5. Enter a folder name.
6. Click Create.

Note: The folder persists only after at least one object is uploaded inside it.

Deleting objects using the object browser

Delete objects using the object browser in the OpenShift® Web Console.

Before you begin

- **Administrators:** Administrator access to Fusion Data Foundation.
- **Developers:** Logged in to the object browser using secret namespace and secret name. For more information see [Accessing the object browser](#).
- Ensure that the selected storage endpoint (MCG or RGW) is deployed and its pods are healthy.

Procedure

1. In the OpenShift Web Console, click Storage > Object Storage.
2. From the Storage endpoint selector, choose MCG or RGW, then open the bucket.
3. Click the Objects tab.
4. To delete objects, do one of the following:
 - **Multiple objects:** Select multiple objects using the checkbox and then from the Actions menu, select Delete.
 - **Single object:** Use the object's Action menu and select Delete.

Note: Folders cannot be deleted directly. Empty folders disappear automatically.

Enabling or suspending object versioning in a bucket using the object browser

Enable or suspend objects versioning in a bucket using the object browser in the OpenShift® Web Console.

Before you begin

- **Administrators:** Administrator access to Fusion Data Foundation.
- **Developers:** Logged in to the object browser using secret namespace and secret name. For more information see [Accessing the object browser](#).
- Ensure that the selected storage endpoint (MCG or RGW) is deployed and its pods are healthy.

Procedure

1. In the OpenShift Web Console, navigate to Storage > Object Storage.
2. From the Storage endpoint selector, choose MCG or RGW, then open the bucket.
3. Click the Properties tab.
4. Toggle Versioning to Enabled or Disabled.
5. Click Enable or Suspend to confirm depending on your versioning selection.
Remember: Update lifecycle rules after enabling versioning.

Listing object versions using the object browser

View object versions using the object browser in the OpenShift® Web Console.

Before you begin

- **Administrators:** Administrator access to Fusion Data Foundation.
- **Developers:** Logged in to the object browser using secret namespace and secret name. For more information see [Accessing the object browser](#).
- Ensure that the selected storage endpoint (MCG or RGW) is deployed and its pods are healthy.

Procedure

1. In the OpenShift Web Console, navigate to Storage > Object Storage.
2. From the Storage endpoint selector, choose MCG or RGW, then open the bucket.
3. Click the Objects tab.
4. Toggle List of versions.
 - When List all versions is OFF:

- The current version of the object excluding the delete markers is displayed.
- Any Action menu options apply to the current version.
- To view all versions of one object:
 - Click object and open the Versions tab from the sidebar.
- When List all versions is ON:
 - All object versions appear including deleted objects that have delete markers.
 - Deleting a version is permanent.
 - Removing a delete marker restores the most recent version. If no previous version exists, the object is permanently deleted.

Creating and managing lifecycle rules

S3 bucket lifecycle rules automate object expiration and transition actions in the Multicloud Object Gateway to manage storage costs and data retention.

- [Creating new lifecycle rules by using the object browser](#)
Create lifecycle rules using the object browser in the OpenShift Web Console.
- [Editing lifecycle rules by using the object browser](#)
Edit existing lifecycle rules using the object browser in the OpenShift Web Console.
- [Creating CORS rule](#)
Configure cross-origin resource sharing (CORS) rules using the object browser in the OpenShift Web Console.
- [Editing CORS rule](#)
Edit cross-origin resource sharing (CORS) rules using the object browser in the OpenShift Web Console.
- [Applying bucket policy to grant public or restricted access to objects](#)
Apply or edit bucket policies using the object browser to control public or restricted access to objects.
- [Setting up public access limit to S3 resources](#)
Configure public access restrictions for S3-compatible buckets by using the object browser.

Creating new lifecycle rules by using the object browser

Create lifecycle rules using the object browser in the OpenShift® Web Console.

Before you begin

- **Administrators:** Administrator access to Fusion Data Foundation.
- **Developers:** Logged in to the object browser using secret namespace and secret name. For more information see [Accessing the object browser](#).
- Ensure that the selected storage endpoint (MCG or RGW) is deployed and its pods are healthy.

Procedure

1. In the OpenShift Web Console, navigate to Storage > Object Storage.
 2. From the Storage endpoint selector, choose MCG or RGW, then open the bucket.
You can also create a new bucket using the steps from the [Creating new buckets using the object browser](#).
 3. Click the Management tab.
 4. Click Create lifecycle rule.
 5. Enter a name for the lifecycle rule.
 6. Select a Rule scope:
 - Targeted (filters: prefix, tags, size)
 - Global (Bucket-wide)
 7. Add one or more actions:
 - Delete an object after a specified time
For a versioned bucket, the current version of the object is retained as a noncurrent version. For a nonversioned object, the object is deleted permanently.
 - Noncurrent versions of the objects
This rule applies to only the versioned objects and deletes the older versions of the objects after they become noncurrent.
 - Incomplete multipart uploads
This rule cleans up the abandoned uploads that were initiated but never completed after a specified time to prevent unnecessary storage costs. The object tags and size filter that were specified for the object with the targeted rule scope are not applicable for this rule and it deletes all multipart uploads from the bucket regardless of any filter.
 - Expired object delete markers
This rule removes any unnecessary delete markers in versioned buckets that do not have any associated object versions, which might clutter bucket listings. The object tags and size filter that were specified for the object with the targeted rule scope are not applicable for this rule and it deletes all multipart uploads from the bucket regardless of any filter.
- Note:
- The object tags and object size filters are not applicable for this rule. The expired object delete markers are removed from the bucket regardless of any filters that are configured.
 - This rule is not enabled when deleting an object after a specified time rule is selected.
8. Click Save.

Editing lifecycle rules by using the object browser

Edit existing lifecycle rules using the object browser in the OpenShift® Web Console.

Before you begin

- **Administrators:** Administrator access to Fusion Data Foundation.
- **Developers:** Logged in to the object browser using secret namespace and secret name. For more information see [Accessing the object browser](#).
- Ensure that the selected storage endpoint (MCG or RGW) is deployed and its pods are healthy.

Procedure

1. In the OpenShift Web Console, navigate to Storage > Object Storage.
2. From the Storage endpoint selector, choose MCG or RGW, then open the bucket.
3. In the bucket view, click the Management tab.
4. Locate the rule, then from the Action menu select Edit lifecycle rule.
5. Edit the required fields.
6. Click Save.

Creating CORS rule

Configure cross-origin resource sharing (CORS) rules using the object browser in the OpenShift® Web Console.

Before you begin

- **Administrators:** Administrator access to Fusion Data Foundation.
- **Developers:** Logged in to the object browser using secret namespace and secret name. For more information see [Accessing the object browser](#).
- Ensure that the selected storage endpoint (MCG or RGW) is deployed and its pods are healthy.

Procedure

1. In the OpenShift Web Console, navigate to Storage > Object Storage.
2. From the Storage endpoint selector, choose MCG or RGW, then open the bucket.
3. In the bucket view, click the Permission tab and then click the CORS tab.
4. Click Create CORS rule.
5. Provide a name for the rule.
6. Configure allowed origins*.
7. Select Allowed methods.
8. Configure allowed headers.
9. Enter the maximum age of preflight request in seconds.
10. Click Create.

Editing CORS rule

Edit cross-origin resource sharing (CORS) rules using the object browser in the OpenShift® Web Console.

Before you begin

- **Administrators:** Administrator access to Fusion Data Foundation.
- **Developers:** Logged in to the object browser using secret namespace and secret name. For more information see [Accessing the object browser](#).
- Ensure that the selected storage endpoint (MCG or RGW) is deployed and its pods are healthy.

Procedure

1. In the OpenShift Web Console, navigate to Storage > Object Storage.
2. From the Storage endpoint selector, choose MCG or RGW, then open the bucket.
3. In the bucket view, click the Permission tab and then click the CORS tab.
4. Select the CORS rule that you want to edit.
5. From the Actions menu, click Edit configuration.
6. Modify the required fields.
7. Click Save.

Applying bucket policy to grant public or restricted access to objects

Apply or edit bucket policies using the object browser to control public or restricted access to objects.

Before you begin

- **Administrators:** Administrator access to Fusion Data Foundation.

- **Developers:** Logged in to the object browser using secret namespace and secret name. For more information see [Accessing the object browser](#).
- Ensure that the selected storage endpoint (MCG or RGW) is deployed and its pods are healthy.

Procedure

1. In the OpenShift® Web Console, navigate to Storage > Object Storage.
2. From the Storage endpoint selector, choose MCG or RGW, then open the bucket.
3. In the bucket view, click the Permission tab.
4. In the Bucket policy tab, you can do one of the following:
 - When no policy exists, you can do one of the following:
 - Drag a file from another location or upload a file by using the Browse button.
 - Start from scratch or use a predefined policy configuration.

Select Use a predefined policy configuration.

 - Create a new policy or choose a policy from Available policies.
 - Update the policy as required.
 - Click Apply policy.
 - Click Confirm to update the policy after reviewing the changes.
 - When a policy exists, use a predefined policy configuration by selecting the Edit bucket policy from the Action menu.
 - Select Use a predefined policy configuration.
 - Choose a policy from Available policies.
 - Update the policy as required.
 - Click Apply policy.
 - Click Confirm to update the policy after reviewing the changes.

Note: After you apply the bucket policy configuration, it can take up to 120 seconds to take effect.

Setting up public access limit to S3 resources

Configure public access restrictions for S3-compatible buckets by using the object browser.

Before you begin

- **Administrators:** Administrator access to Fusion Data Foundation.
- **Developers:** Logged in to the object browser using secret namespace and secret name. For more information see [Accessing the object browser](#).
- Ensure that the selected storage endpoint (MCG or RGW) is deployed and its pods are healthy.

Procedure

1. In the OpenShift® Web Console, navigate to Storage > Object Storage.
2. From the Storage endpoint selector, choose MCG or RGW, then open the bucket.
3. Select a bucket for which you need to set the public access limitation.
4. In the bucket view, click the Permission tab.
5. Click the Block public access tab.
6. Click Manage public access settings to set the limitations.

Select one of the following options based on your requirement:

 - Block all public access.

This blocks all forms of public access to the bucket and its objects.
 - Block public access to buckets and objects that are granted through new public bucket policies.

This prevents new policies from making your data public.
 - Block public and cross-account access to buckets and objects through any public bucket policies.

This blocks all public and cross-account access that is granted by any existing policies.
7. Click Save changes.

Creating and managing IAM user

Use this section to create and manage IAM users for object storage access.

Note the following considerations when creating and managing an IAM user:

- **Bucket policy principals and ARNs:** Bucket policies can reference either the account ID/ARN (for administrator or NooBaa CLI-created accounts) or the IAM user ARN. On upgraded clusters, bucket-policy principals previously defined using the email-based account format (account@noobaa.io) are automatically converted to the ARN format (arn:aws:iam::account_id:root).
- **S3 access requires a policy:** An IAM user's S3 requests return **AccessDenied** if no IAM policy is attached.
- **OBC account limitations:** Object Bucket Claim (OBC) accounts cannot create IAM users.
- **Default policy review:** IAM users created through the IAM console are automatically assigned a default policy that grants full access.
- **Creating an IAM user using the object browser**

Learn how to create IAM users for object storage access using the object browser.

- [Generating additional access key for an IAM user](#)
Learn how to generate an additional access key for an IAM user. You can generate one additional access key for the IAM user. IAM users can generate additional access key for themselves.
- [Activating or deactivating access key](#)
You can generate one additional access key.
- [Deleting access key for an IAM user](#)
Delete an access key for an IAM user.
- [Deleting an IAM user](#)
Delete an IAM user from the object browser.

Creating an IAM user using the object browser

Learn how to create IAM users for object storage access using the object browser.

Before you begin

- **Administrators:** Administrator access to IBM Fusion Data Foundation.
- **Developers:** Logged in to the object browser using secret namespace and secret name. For more information see [Accessing the object browser](#).
- Ensure that the selected storage endpoint (MCG or RGW) is deployed and its pods are healthy.

Procedure

1. In the OpenShift® Web Console, navigate to Storage > Object Storage.
2. From the Storage endpoint selector, choose MCG or RGW.
3. Click the IAM tab.
4. Click Create User.
5. Enter the required details in the Create User form.
After the user is created, a window appears prompting you to download the secret key.
6. Click Download secret key, or copy the key and store it securely.

Note:

- When a new IAM user is created, an inline policy permitting S3 operations is generated automatically.
- Access keys are also created automatically as part of the user creation workflow. No manual configuration is required.

Generating additional access key for an IAM user

Learn how to generate an additional access key for an IAM user. You can generate one additional access key for the IAM user. IAM users can generate additional access key for themselves.

Before you begin

- **Administrators:** Administrator access to IBM Fusion Data Foundation.
- **Developers:** Logged in to the object browser using secret namespace and secret name. For more information see [Accessing the object browser](#).
- Ensure that the selected storage endpoint (MCG or RGW) is deployed and its pods are healthy.

Procedure

1. In the OpenShift® Web Console, navigate to Storage > Object Storage.
2. From the Storage endpoint selector, choose MCG or RGW.
3. Click the IAM tab.
4. Select the IAM user for whom you want to generate access key.
5. On the user details page, click the Access keys tab.
The existing access key cards are displayed.
6. Click Generate another access key.
7. Optional: Enter a description for the new access key.
8. Click Generate.
The newly generated access key card is displayed.

Results

The additional access key is generated and displayed in the Access keys tab.

Activating or deactivating access key

You can generate one additional access key.

Before you begin

- **Administrators:** Administrator access to IBM Fusion Data Foundation.
- **Developers:** Logged in to the object browser using secret namespace and secret name. For more information see [Accessing the object browser](#).
- Ensure that the selected storage endpoint (MCG or RGW) is deployed and its pods are healthy.

Note: Object Bucket Claim (OBC) based accounts do not have permissions to manage IAM users.

Procedure

1. In the OpenShift® Web Console, navigate to Storage, Object Storage.
2. From the Storage endpoint selector, choose MCG or RGW.
3. Click the IAM tab.
4. Select the IAM user for whom you want to activate or deactivate access keys.
5. On the user details page, click the Access keys tab.
The existing access key cards are displayed.
6. Select the Actions menu corresponding to the required Access key and select Activate/Deactivate Access key.
7. Click Activate or Deactivate depending on the existing status.

Deleting access key for an IAM user

Delete an access key for an IAM user.

Before you begin

- **Administrators:** Administrator access to IBM Fusion Data Foundation.
- **Developers:** Logged in to the object browser using secret namespace and secret name. For more information see [Accessing the object browser](#).
- Ensure that the selected storage endpoint (MCG or RGW) is deployed and its pods are healthy.
- An existing IAM user with at least one access key.

Procedure

1. In the OpenShift® Web Console, navigate to Storage, Object Storage.
2. From the Storage endpoint selector, choose MCG or RGW.
3. Click the IAM tab.
4. Select the IAM user for whom you want to delete the access key.
5. On the user details page, click the Access keys tab.
The list of access key cards are displayed.
6. Locate the access key you want to delete and open the Action menu on its card.
7. Select Delete access key.
8. You must deactivate the access key before deleting it. Click Deactivate.
9. To confirm deletion, type `delete` in the confirmation field.
10. Click Delete to permanently remove the access key.

Deleting an IAM user

Delete an IAM user from the object browser.

Before you begin

- **Administrators:** Administrator access to IBM Fusion Data Foundation.
- **Developers:** Logged in to the object browser using secret namespace and secret name. For more information see [Accessing the object browser](#).
- Ensure that the selected storage endpoint (MCG or RGW) is deployed and its pods are healthy.
- All access keys and inline user policies associated with the user must be removed before deletion.

Procedure

1. In the OpenShift® Web Console, navigate to Storage, Object Storage.
2. From the Storage endpoint selector, choose MCG or RGW.
3. Click the IAM tab.
4. Select the IAM user you want to delete.
5. Click the Actions menu and select Delete user.
6. You must delete any existing access keys before deleting the user.
7. Type `delete` to confirm the user deletion.

Managing namespace buckets

Namespace buckets let you connect data repositories on different providers together, so you can interact with all of your data through a single unified view. Add the object bucket associated with each provider to the namespace bucket, and access your data through the namespace bucket to see all of your object buckets at once. This lets

you write to your preferred storage provider while reading from multiple other storage providers, greatly reducing the cost of migrating to a new storage provider. Use this information to add namespace buckets using command-line interface, YAML, and user interface and for information about sharing and accessing legacy data.

Note: A namespace bucket can only be used if its write target is available and functional.

- [Amazon S3 API endpoints for objects in namespace buckets](#)
Amazon S3 API endpoints supported for objects in namespace buckets list the operations that IBM Fusion Data Foundation supports when interacting with namespace bucket data.
- [Adding a namespace bucket using the Multicloud Object Gateway CLI and YAML](#)
A namespace bucket can be added using either Multicloud Object Gateway command-line interface or YAML files.
- [Adding a namespace bucket using the OpenShift Container Platform user interface](#)
You can add namespace buckets using the OpenShift® Container Platform user interface.
- [Sharing legacy application data with cloud native application using S3 protocol](#)
Many legacy applications use file systems to share data sets. You can access and share the legacy data in the file system by using the S3 operations.
- [Configuring or modifying the PublicAccessBlock configuration for S3 bucket](#)
Learn how to restrict public access to S3 buckets, enhancing data security by configuring or modifying the PublicAccessBlock policy through `put-bucket-policy` S3 API.

Amazon S3 API endpoints for objects in namespace buckets

Amazon S3 API endpoints supported for objects in namespace buckets list the operations that IBM Fusion Data Foundation supports when interacting with namespace bucket data.

You can interact with objects in the namespace buckets using the Amazon Simple Storage Service (S3) API.

IBM Fusion Data Foundation supports the following namespace bucket operations:

- [ListObjectVersions](#)
- [ListObjects](#)
- [PutObject](#)
- [CopyObject](#)
- [ListParts](#)
- [CreateMultipartUpload](#)
- [CompleteMultipartUpload](#)
- [UploadPart](#)
- [UploadPartCopy](#)
- [AbortMultipartUpload](#)
- [GetObjectAcl](#)
- [GetObject](#)
- [HeadObject](#)
- [DeleteObject](#)
- [DeleteObjects](#)

See the Amazon S3 API reference documentation for the most up-to-date information about these operations and how to use them.

Related information

- [Amazon S3 CLI Reference](#)

Adding a namespace bucket using the Multicloud Object Gateway CLI and YAML

A namespace bucket can be added using either Multicloud Object Gateway command-line interface or YAML files.

Depending on the type of your deployment and whether you want to use YAML or the Multicloud Object Gateway CLI, choose one of the following procedures to add a namespace bucket:

For more information about namespace buckets, see [Managing namespace buckets](#).

- [Adding an AWS S3 namespace bucket using YAML](#)
Add an AWS S3 namespace bucket using a YAML file.
- [Adding an IBM COS namespace bucket using YAML](#)
Add an IBM COS namespace bucket using a YAML file.
- [Adding an AWS S3 namespace bucket using the Multicloud Object Gateway CLI](#)
Add an AWS S3 namespace bucket using the Multicloud Object Gateway CLI.
- [Adding an IBM COS namespace bucket using the Multicloud Object Gateway CLI](#)
Add an IBM COS namespace bucket using the Multicloud Object Gateway CLI.

Adding an AWS S3 namespace bucket using YAML

Add an AWS S3 namespace bucket using a YAML file.

Before you begin

- Install OpenShift® Container Platform with Fusion Data Foundation operator.
- Ensure you have access to the Multicloud Object Gateway (MCG), see [Accessing the Multicloud Object Gateway with your applications](#).

Procedure

1. Create a secret with the credentials:

```
apiVersion: v1
kind: Secret
metadata:
  name: <namespacestore-secret-name>
  type: Opaque
data:
  AWS_ACCESS_KEY_ID: <AWS ACCESS KEY ID ENCODED IN BASE64>
  AWS_SECRET_ACCESS_KEY: <AWS SECRET ACCESS KEY ENCODED IN BASE64>
```

namespacestore-secret-name

Is a unique NamespaceStore name.

AWS ACCESS KEY ID ENCODED IN BASE64

AWS SECRET ACCESS KEY ENCODED IN BASE64

You must provide and encode your own AWS access key ID and secret access key using **Base64**, and use the results in place of *AWS ACCESS KEY ID ENCODED IN BASE64* and *AWS SECRET ACCESS KEY ENCODED IN BASE64*.

2. Create a NamespaceStore resource using OpenShift custom resource definitions (CRDs).

A NamespaceStore represents underlying storage to be used as a **read** or **write** target for the data in the MCG namespace buckets.

To create a NamespaceStore resource, apply the following YAML:

```
apiVersion: noobaa.io/v1alpha1
kind: NamespaceStore
metadata:
  finalizers:
    - noobaa.io/finalizer
  labels:
    app: noobaa
  name: <resource-name>
  namespace: openshift-storage
spec:
  awsS3:
    secret:
      name: <namespacestore-secret-name>
      namespace: <namespace-secret>
      targetBucket: <target-bucket>
    type: aws-s3
```

resource-name

The name you want to give to the resource.

namespacestore-secret-name

The secret created in the previous step.

namespace-secret

The namespace where the secret can be found.

target-bucket

The target bucket you created for the NamespaceStore.

3. Create a namespace bucket class that defines a namespace policy for the namespace buckets.

The namespace policy requires a type of either single or multi.

- A namespace policy of type single requires the following configuration:

```
apiVersion: noobaa.io/v1alpha1
kind: BucketClass
metadata:
  labels:
    app: noobaa
  name: <my-bucket-class>
  namespace: openshift-storage
spec:
  namespacePolicy:
    type: Single
    single:
      resource: <resource>
```

my-bucket-class

The unique namespace bucket class name.

resource

The name of a single NamespaceStore that defines the read and write target of the namespace bucket.

- A namespace policy of type multi requires the following configuration:

```
apiVersion: noobaa.io/v1alpha1

kind: BucketClass
metadata:
  labels:
```

```

    app: noobaa
    name: my-bucket-class
    namespace: openshift-storage
spec:
  namespacePolicy:
    type: Multi
    multi:
      writeResource: <write-resource>
      readResources:
        - <read-resources>
        - <read-resources>

```

my-bucket-class

A unique bucket class name.

write-resource

The name of a single NamespaceStore that defines the **write** target of the namespace bucket.

read-resources

A list of the names of the NamespaceStores that defines the **read** targets of the namespace bucket.

4. Create a bucket using an Object Bucket Class (OBC) resource.

Use the bucket class defined in the earlier step using the following YAML:

```

apiVersion: objectbucket.io/v1alpha1
kind: ObjectBucketClaim
metadata:
  name: <resource-name>
  namespace: openshift-storage
spec:
  generateBucketName: <my-bucket>
  storageClassName: openshift-storage.noobaa.io
  additionalConfig:
    bucketclass: <my-bucket-class>

```

resource-name

The name you want to give to the resource.

my-bucket

The name you want to give to the bucket.

my-bucket-class

The bucket class created in the previous step.

After the OBC is provisioned by the operator, a bucket is created in the MCG, and the operator creates a **Secret** and **ConfigMap** with the same name and in the same namespace as that of the OBC.

Adding an IBM COS namespace bucket using YAML

Add an IBM COS namespace bucket using a YAML file.

Before you begin

- Install OpenShift® Container Platform with Fusion Data Foundation operator.
- Access to the Multicloud Object Gateway (MCG), see [Accessing the Multicloud Object Gateway with your applications](#).

Procedure

1. Create a secret with the credentials:

```

apiVersion: v1
kind: Secret
metadata:
  name: <namespacestore-secret-name>
  type: Opaque
data:
  IBM_COS_ACCESS_KEY_ID: <IBM COS ACCESS KEY ID ENCODED IN BASE64>
  IBM_COS_SECRET_ACCESS_KEY: <IBM COS SECRET ACCESS KEY ENCODED IN BASE64>

```

namespacestore-secret-name

A unique NamespaceStore name.

IBM COS ACCESS KEY ID ENCODED IN BASE64

IBM COS SECRET ACCESS KEY ENCODED IN BASE64

You must provide and encode your own IBM COS access key ID and secret access key using **Base64**, and use the results in place of *IBM COS ACCESS KEY ID ENCODED IN BASE64* and *IBM COS SECRET ACCESS KEY ENCODED IN BASE64*

2. Create a NamespaceStore resource using OpenShift custom resource definitions (CRDs).

A NamespaceStore represents underlying storage to be used as a **read** or **write** target for the data in the MCG namespace buckets.

To create a NamespaceStore resource, apply the following YAML:

```

apiVersion: noobaa.io/v1alpha1
kind: NamespaceStore
metadata:
  finalizers:

```

```

- noobaa.io/finalizer
labels:
  app: noobaa
  name: bs
  namespace: openshift-storage
spec:
  s3Compatible:
    endpoint: <IBM COS ENDPOINT>
    secret:
      name: <namespacestore-secret-name>
      namespace: <namespace-secret>
    signatureVersion: v2
    targetBucket: <target-bucket>
    type: ibm-cos

```

IBM COS ENDPOINT

The appropriate IBM COS endpoint.

namespacestore-secret-name

The secret created in step [1](#).

namespace-secret

The namespace where the secret can be found.

target-bucket

The target bucket you created for the NamespaceStore.

3. Create a namespace bucket class that defines a namespace policy for the namespace buckets.

The namespace policy requires a type of either single or multi.

- A namespace policy of type single requires the following configuration:

```

apiVersion: noobaa.io/v1alpha1
kind: BucketClass
metadata:
  labels:
    app: noobaa
    name: <my-bucket-class>
    namespace: openshift-storage
spec:
  namespacePolicy:
    type: Single
    single:
      resource: <resource>

```

my-bucket-class

The unique namespace bucket class name.

resource

The name of a single NamespaceStore that defines the read and write target of the namespace bucket.

- A namespace policy of type multi requires the following configuration:

```

apiVersion: noobaa.io/v1alpha1

kind: BucketClass
metadata:
  labels:
    app: noobaa
    name: my-bucket-class
    namespace: openshift-storage
spec:
  namespacePolicy:
    type: Multi
    multi:
      writeResource: <write-resource>
      readResources:
        - <read-resources>
        - <read-resources>

```

my-bucket-class

A unique bucket class name.

write-resource

The name of a single NamespaceStore that defines the **w**rite target of the namespace bucket.

read-resources

A list of the names of the NamespaceStores that defines the **r**ead targets of the namespace bucket.

4. Create a bucket using an Object Bucket Class (OBC) resource.

Use the bucket class defined in the earlier step using the following YAML:

```

apiVersion: objectbucket.io/v1alpha1
kind: ObjectBucketClaim
metadata:
  name: <resource-name>
  namespace: openshift-storage
spec:
  generateBucketName: <my-bucket>
  storageClassName: openshift-storage.noobaa.io
  additionalConfig:
    bucketclass: <my-bucket-class>

```

resource-name

The name you want to give to the resource.

my-bucket

The name you want to give to the bucket.

my-bucket-class

The bucket class created in the previous step.

After the OBC is provisioned by the operator, a bucket is created in the MCG, and the operator creates a **Secret** and **ConfigMap** with the same name and in the same namespace as that of the OBC.

Adding an AWS S3 namespace bucket using the Multicloud Object Gateway CLI

Add an AWS S3 namespace bucket using the Multicloud Object Gateway CLI.

Before you begin

- Install OpenShift® Container Platform with Fusion Data Foundation operator.
- Ensure you have access to the Multicloud Object Gateway (MCG), see [Accessing the Multicloud Object Gateway with your applications](#).
- Download the MCG command-line interface for easier management.

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-x86_64-rpms
```

```
yum install mcg
```

Note: Specify the appropriate architecture for enabling the repositories using the subscription manager. In case of IBM Z infrastructure, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-s390x-rpms
```

- Alternatively, you can install the MCG package from the RPMs found at [Download Red Hat® OpenShift Data Foundation page](#).

Note: Choose the correct Product Variant according to your architecture.

Procedure

1. In the MCG command-line interface, create a NamespaceStore resource.

A NamespaceStore represents an underlying storage to be used as a **read** or **write** target for the data in MCG namespace buckets.

```
odf noobaa namespacestore create aws-s3 <namespacestore> --access-key <AWS ACCESS KEY> --secret-key <AWS SECRET ACCESS KEY> --target-bucket <bucket-name> -n openshift-storage
```

namespacestore

The name of the NamespaceStore.

AWS ACCESS KEY and *AWS SECRET ACCESS KEY*

The AWS access key ID and secret access key you created for this purpose.

bucket-name

The existing AWS bucket name. This argument tells the MCG which bucket to use as a target bucket for its backing store, and subsequently, data storage and administration.

2. Create a namespace bucket class that defines a namespace policy for the namespace buckets. The namespace policy can be either single or multi.

- To create a namespace bucket class with a namespace policy of type single:

```
odf noobaa bucketclass create namespace-bucketclass single <my-bucket-class> --resource <resource> -n openshift-storage
```

resource-name

The name you want to give the resource.

my-bucket-class

A unique bucket class name.

resource

A single namespace-store that defines the **read** and **write** target of the namespace bucket.

- To create a namespace bucket class with a namespace policy of type multi:

```
odf noobaa bucketclass create namespace-bucketclass multi <my-bucket-class> --write-resource <write-resource> --read-resources <read-resources> -n openshift-storage
```

resource-name

The name you want to give the resource.

my-bucket-class

A unique bucket class name.

write-resource

A single namespace-store that defines the **write** target of the namespace bucket.

read-resources

A list of namespace-stores separated by commas that defines the **read** targets of the namespace bucket.

3. Create a bucket using an Object Bucket Class (OBC) resource that uses the bucket class defined in the previous step.

```
odf noobaa obc create my-bucket-claim -n openshift-storage --app-namespace my-app --bucketclass <custom-bucket-class>
```

bucket-name

A bucket name of your choice.

custom-bucket-class

The name of the bucket class created in the previous step.

After the OBC is provisioned by the operator, a bucket is created in the MCG, and the operator creates a **Secret** and a **ConfigMap** with the same name and in the same namespace as that of the OBC.

Adding an IBM COS namespace bucket using the Multicloud Object Gateway CLI

Add an IBM COS namespace bucket using the Multicloud Object Gateway CLI.

Before you begin

- Ensure you have a running Fusion Data Foundation Platform.
- Download the MCG command-line interface for easier management.

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-x86_64-rpms
```

```
yum install mcg
```

Note: Specify the appropriate architecture for enabling the repositories using the subscription manager.

- For IBM Power, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-ppc64le-rpms
```

- For IBM Z infrastructure, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-s390x-rpms
```

- Alternatively, you can install the MCG package from the RPMs found at [Download Red Hat® OpenShift® Data Foundation page](#).

Note: Choose the correct Product Variant according to your architecture.

Procedure

1. In the MCG command-line interface, create a NamespaceStore resource.

A NamespaceStore represents an underlying storage to be used as a **read** or **write** target for the data in the MCG namespace buckets.

```
odf noobaa namespacestore create ibm-cos <namespacestore> --endpoint <IBM COS ENDPOINT> --access-key <IBM ACCESS KEY> --secret-key <IBM SECRET ACCESS KEY> --target-bucket <bucket-name> -n openshift-storage
```

namespacestore

The name of the NamespaceStore.

**IBM ACCESS KEY, IBM SECRET ACCESS KEY, IBM COS
ENDPOINT**

An IBM access key ID, secret access key, and the appropriate regional endpoint that corresponds to the location of the existing IBM bucket.

bucket-name

An existing IBM bucket name. This argument tells the MCG which bucket to use as a target bucket for its backing store, and subsequently, data storage and administration.

2. Create a namespace bucket class that defines a namespace policy for the namespace buckets. The namespace policy can be either single or multi.

- To create a namespace bucket class with a namespace policy of type single:

```
odf noobaa bucketclass create namespace-bucketclass single <my-bucket-class> --resource <resource> -n openshift-storage
```

resource-name

The name you want to give the resource.

my-bucket-class

A unique bucket class name.

resource

A single namespace-store that defines the **read** and **write** target of the namespace bucket.

- To create a namespace bucket class with a namespace policy of type multi:

```
odf noobaa bucketclass create namespace-bucketclass multi <my-bucket-class> --write-resource <write-resource> --read-resources <read-resources> -n openshift-storage
```

resource-name

The name you want to give the resource.

my-bucket-class

A unique bucket class name.

write-resource

A single namespace-store that defines the **write** target of the namespace bucket.

read-resources

A list of namespace-stores separated by commas that defines the **read** targets of the namespace bucket.

3. Create a bucket using an Object Bucket Class (OBC) resource that uses the bucket class defined in the previous step.

```
odf noobaa obc create my-bucket-claim -n openshift-storage --app-namespace my-app --bucketclass <custom-bucket-class>
```

bucket-name

A bucket name of your choice.

custom-bucket-class

The name of the bucket class created in the previous step.

After the OBC is provisioned by the operator, a bucket is created in the MCG, and the operator creates a **Secret** and a **ConfigMap** with the same name and in the same namespace as that of the OBC.

Adding a namespace bucket using the OpenShift Container Platform user interface

You can add namespace buckets using the OpenShift® Container Platform user interface.

Before you begin

- Install OpenShift Container Platform with Fusion Data Foundation operator.
- Access to the Multicloud Object Gateway (MCG).

About this task

For information about namespace buckets, see [Managing namespace buckets](#).

Procedure

1. Log into the OpenShift Web Console and go to Storage, Object Storage, Namespace Store.
2. Create a **namespacestore** resource to be used in the namespace bucket.
 - a. Click Create namespace store.
 - b. Enter a namespacestore name.
 - c. Choose a provider.
 - d. Choose a region.
 - e. Either select an existing secret, or click Switch to credentials to create a secret by entering a secret key and secret access key.
 - f. Choose a target bucket.
 - g. Click Create.
 - h. Verify that the namespacestore is in the *Ready* state.
 - i. Repeat these steps until you have the desired amount of resources.
3. From the Bucket Class tab, click Create a new Bucket Class.
 - a. Select the Namespace.
 - b. Enter a Bucket Class name.
 - c. Optional: Add description.
 - d. Click Next.
4. Choose a namespace policy type for your namespace bucket, and then click Next.
5. Select the target resources.
 - If your namespace policy type is Single, choose a read resource.
 - If your namespace policy type is Multi, choose read resources and a write resource.
 - If your namespace policy type is Cache, choose a Hub namespace store that defines the read and write target of the namespace bucket.
6. Click Next.
7. Review your new bucket class, and then click Create Bucketclass.
8. On the BucketClass page, verify that your newly created resource is in the *Created* phase.
9. Go to **Storage** → **Data Foundation**.
10. In the Status card, click Storage System and click the storage system link from the pop up that appears.
11. In the Object tab, go to Multicloud Object Gateway, Buckets, Namespace Buckets tab.
12. Click Create Namespace Bucket.
 - a. From the Choose Name tab, specify a name for the namespace bucket and click Next.
 - b. From the Set Placement tab:
 - i. For Read Policy, select the check box for each namespace resource created in the earlier step that the namespace bucket should read data from.
 - ii. If the namespace policy type you are using is Multi, then specify which namespace resource the namespace bucket should write data to within the Write Policy field.
 - c. Click Next.
 - d. Click Create.

What to do next

Verify that the namespace bucket is listed with a green check mark in the State column, the expected number of read resources, and the expected write resource name.

Sharing legacy application data with cloud native application using S3 protocol

Many legacy applications use file systems to share data sets. You can access and share the legacy data in the file system by using the S3 operations.

To share data:

- Export the pre-existing file system datasets, that is, RWX volume such as Ceph FileSystem (CephFS) or create a new file system datasets using the S3 protocol.
- Access file system datasets from both file system and S3 protocol.
- Configure S3 accounts and map them to the existing or a new file system unique identifiers (UIDs) and group identifiers (GIDs).
- [Creating a NamespaceStore to use a file system](#)
Create a NamespaceStore to use a file system.
- [Creating accounts with NamespaceStore file system configuration](#)
Create a Multicloud Object Gateway account with NamespaceStore file system configuration to enable file-system-backed object storage access through S3 credentials.
- [Accessing legacy application data from the openshift-storage namespace](#)
When using the Multicloud Object Gateway (MCG) NamespaceStore filesystem (NSFS) feature, you need to have the Persistent Volume Claim (PVC) where the data resides in the **openshift-storage** namespace. In almost all cases, the data you need to access is not in the **openshift-storage** namespace, but in the namespace that the legacy application uses. A PVC is used in order to access the data.

Creating a NamespaceStore to use a file system

Create a NamespaceStore to use a file system.

Before you begin

Ensure you have the following:

- OpenShift® Container Platform with Fusion Data Foundation operator installed.
- Access to the Multicloud Object Gateway (MCG).

Procedure

1. Log into the OpenShift Web Console and go to Storage > Object Storage.
2. Go to the NamespaceStore tab to create NamespaceStore resources to be used in the namespace bucket.
3. Click Create namespacestore.
4. Enter a name for the NamespaceStore.
5. Choose Filesystem as the provider.
6. Choose the Persistent volume claim.
7. Enter a folder name.
If the folder name exists, then that folder is used to create the NamespaceStore or else a folder with that name is created.
8. Click Create.
9. Verify the NamespaceStore is in the *Ready* state.

Creating accounts with NamespaceStore file system configuration

Create a Multicloud Object Gateway account with NamespaceStore file system configuration to enable file-system-backed object storage access through S3 credentials.

Before you begin

Download the Multicloud Object Gateway (MCG) command-line interface:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-x86_64-rpms
yum install mcg
```

About this task

You can either create a new account with **NamespaceStore** file system configuration or convert an existing normal account into a **NamespaceStore** file system account by editing the YAML.

Note: You cannot remove a **NamespaceStore** file system configuration from an account.

Procedure

Create a new account with **NamespaceStore** file system configuration by using the MCG command-line interface.

```
odf noobaa account create <noobaa-account-name> [flags]
```

For example:

```
odf noobaa account create testaccount --nsfs_account_config --gid 10001 --uid 10001 --default_resource fs_namespacestore
```

allow_bucket_create	Indicates whether the account is allowed to create new buckets. Supported values are true or false . Default value is true .
default_resource	The NamespaceStore resource on which the new buckets is created when using the S3 CreateBucket operation. The NamespaceStore must be backed by a rwx (ReadWriteMany) persistent volume claim (PVC).

force_md5_etag	Enables md5 etag calculation for the user account.
new_buckets_path	The file system path where directories corresponding to new buckets is created. The path is inside the file system of NamespaceStore file system PVCs where new directories are created to act as the file system mapping of newly created object bucket classes.
nsfs_account_config	A mandatory field that indicates if the account is used for NamespaceStore file system.
nsfs_only	Indicates whether the account is used only for NamespaceStore file system or not. Supported values are true or false . Default value is false . If it is set to 'true', it limits you from accessing other types of buckets.
uid	The user ID of the file system to which the MCG account is mapped and it is used to access and manage data on the file system.
gid	The group ID of the file system to which the MCG account is mapped and it is used to access and manage data on the file system.

The MCG system sends a response with the account configuration and its S3 credentials:

```
NooBaaAccount spec:
  allow_bucket_creation: true
Allowed buckets:
  full_permission: true
  permission_list: []
default_resource: noobaa-default-namespace-store
Nsfs_account_config:
  gid: 10001
  new_buckets_path: /
  nsfs_only: true
  uid: 10001
INFO[0006] ✓ Exists: Secret "noobaa-account-testaccount"
Connection info:
  AWS_ACCESS_KEY_ID      : <aws-access-key-id>
  AWS_SECRET_ACCESS_KEY  : <aws-secret-access-key>
```

What to do next

You can list all the custom resource definition (CRD) based accounts by using the following command:

```
ocf noobaa account list
```

NAME	ALLOWED_BUCKETS	DEFAULT_RESOURCE	PHASE	AGE
testaccount	[*]	noobaa-default-backing-store	Ready	1m17s

If you are interested in a particular account, you can read its custom resource definition (CRD) directly by the account name:

```
oc get noobaaaccount/testaccount -o yaml
spec:
  allow_bucket_creation: true
  allowed_buckets:
    full_permission: true
    permission_list: []
  default_resource: noobaa-default-namespace-store
  nsfs_account_config:
    gid: 10001
    new_buckets_path: /
    nsfs_only: true
    uid: 10001
```

Accessing legacy application data from the openshift-storage namespace

When using the Multicloud Object Gateway (MCG) NamespaceStore filesystem (NSFS) feature, you need to have the Persistent Volume Claim (PVC) where the data resides in the **openshift-storage** namespace. In almost all cases, the data you need to access is not in the **openshift-storage** namespace, but in the namespace that the legacy application uses. A PVC is used in order to access the data.

About this task

To access data stored in another namespace, you need to create a PVC in the **openshift-storage** namespace that points to the same CephFS volume that the legacy application uses.

Procedure

1. Display the application namespace with **scc**, where **<application_namespace>** is the name of the application namespace.

```
oc get ns <application_namespace> -o yaml | grep scc
```

For example:

```
oc get ns testnamespace -o yaml | grep scc

openshift.io/sa.scc.mcs: s0:c26,c5
openshift.io/sa.scc.supplemental-groups: 1000660000/10000
openshift.io/sa.scc.uid-range: 1000660000/10000
```

2. Navigate into the application namespace:.

```
oc project <application_namespace>
```

For example:

```
oc project testnamespace
```

3. Ensure that a ReadWriteMany (RWX) PVC is mounted on the pod that you want to consume from the noobaa S3 endpoint using the MCG NSFS feature..

```
oc get pvc
```

NAME	CAPACITY	ACCESS MODES	STORAGECLASS	STATUS	VOLUME
cephfs-write-workload-generator-no-cache-pv-claim	10Gi	RWX	ocs-storagecluster-cephfs	Bound	pvc-aa58fb91-c3d2-475b-bbee-68452a613e1a

```
oc get pod
```

NAME	READY	STATUS	RESTARTS	AGE
cephfs-write-workload-generator-no-cache-1-cv892	1/1	Running	0	11s

4. Check the mount point of the Persistent Volume (PV) inside your pod.

- a. Get the volume name of the PV from the pod, where `<pod_name>` is the name of the pod.

```
oc get pods <pod_name> -o jsonpath='{.spec.volumes[]}'
```

For example:

```
oc get pods cephfs-write-workload-generator-no-cache-1-cv892 -o jsonpath='{.spec.volumes[]}'
```

```
{ "name": "app-persistent-storage", "persistentVolumeClaim": { "claimName": "cephfs-write-workload-generator-no-cache-pv-claim" } }
```

In this example, the name of the volume for the PVC is `cephfs-write-workload-generator-no-cache-pv-claim`.

- b. List all the mounts in the pod, and check for the mount point of the volume that were identified in step [4.a](#).

```
oc get pods <pod_name> -o jsonpath='{.spec.containers[].volumeMounts}'
```

For example:

```
oc get pods cephfs-write-workload-generator-no-cache-1-cv892 -o jsonpath='{.spec.containers[].volumeMounts}'
```

```
[{"mountPath": "/mnt/pv", "name": "app-persistent-storage"}, {"mountPath": "/var/run/secrets/kubernetes.io/serviceaccount", "name": "kube-api-access-8tnc5", "readOnly": true}]
```

5. Confirm the mount point of the RWX PV in your pod, where `<mount_path>` is the path to the mount point that was identified in step [4.b](#).

```
oc exec -it <pod_name> -- df <mount_path>
```

For example:

```
oc exec -it cephfs-write-workload-generator-no-cache-1-cv892 -- df /mnt/pv
```

```
main
Filesystem
1K-blocks Used Available Use% Mounted on
172.30.202.87:6789,172.30.120.254:6789,172.30.77.247:6789:/volumes/csi/csi-vol-cc416d9e-dbf3-11ec-b286-0a580a810213/edcfe4d5-bdcb-4b8e-8824-8a03ad94d67c
10485760 0 10485760 0% /mnt/pv
```

6. Ensure that the UID and SELinux labels are the same as the ones that the legacy namespace uses.

```
oc exec -it <pod_name> -- ls -latrZ <mount_path>
```

For example:

```
oc exec -it cephfs-write-workload-generator-no-cache-1-cv892 -- ls -latrZ /mnt/pv/
```

```
total 567
drwxrwxrwx. 3 root      root system_u:object_r:container_file_t:s0:c26,c5   2 May 25 06:35 .
-rw-r--r--. 1 1000660000 root system_u:object_r:container_file_t:s0:c26,c5 580138 May 25 06:35 fs_write_cephfs-write-
workload-generator-no-cache-1-cv892-data.log
drwxrwxrwx. 3 root      root system_u:object_r:container_file_t:s0:c26,c5   30 May 25 06:35 ..
```

7. Get the information of the legacy application RWX PV that you want to make accessible from the `openshift-storage` namespace, where `<pv_name>` is the name of the PV.

```
oc get pv | grep <pv_name>
```

For example:

```
oc get pv | grep pvc-aa58fb91-c3d2-475b-bbee-68452a613e1a
```

pvc-aa58fb91-c3d2-475b-bbee-68452a613e1a	10Gi	RWX	Delete	Bound	testnamespace/cephfs-write-workload-generator-no-cache-pv-claim	ocs-storagecluster-cephfs	47s
--	------	-----	--------	-------	---	---------------------------	-----

8. Ensure that the PVC from the legacy application is accessible from the `openshift-storage` namespace so that one or more noobaa-endpoint pods can access the PVC.

- a. Find the values of the `subvolumePath` and `volumeHandle` from the `volumeAttributes`.

You can get these values from the YAML description of the legacy application PV.

```
oc get pv <pv_name> -o yaml
```

For example:

```
oc get pv pvc-aa58fb91-c3d2-475b-bbee-68452a613e1a -o yaml
```

```
apiVersion: v1
kind: PersistentVolume
```

```

```

(1)

The storage capacity of the PV that you are creating in the `openshift-storage` namespace must be the same as the original PV.

- (2) The volume handle for the target PV that you create in `openshift-storage` needs to have a different handle than the original application PV, for example, add `-clone` at the end of the volume handle.
- (3) The storage capacity of the PVC that you are creating in the `openshift-storage` namespace must be the same as the original PVC.

c. Create the PV and PVC in the `openshift-storage` namespace using the YAML file specified in step 8.b, where `YAML_file` is the name of the YAML file.

```
oc create -f <YAML_file>
```

For example:

```
oc create -f pv-openshift-storage.yaml

persistentvolume/cephfs-pv-legacy-openshift-storage created
persistentvolumeclaim/cephfs-pvc-legacy created
```

d. Ensure that the PVC is available in the `openshift-storage` namespace:

```
oc get pvc -n openshift-storage
```

NAME	STATUS	VOLUME	CAPACITY	ACCESS MODES
STORAGECLASS				
cephfs-pvc-legacy	Bound	cephfs-pv-legacy-openshift-storage	10Gi	RWX
14s				

e. Navigate into the `openshift-storage` project:

```
oc project openshift-storage
```

Now using project "openshift-storage" on server "https://api.cluster-5f6ng.5f6ng.sandbox65.opentlc.com:6443".

f. Create the NSFS namespacestore:

```
odf noobaa namespacestore create nsfs <nsfs_namespacestore> --pvc-name='<cephfs_pvc_name>' --fs-backend='CEPH_FS'
```

`nsfs_namespacestore`

A name of the NSFS namespacestore.

`cephfs_pvc_name`

A name of the CephFS PVC in the `openshift-storage` namespace.

For example:

```
odf noobaa namespacestore create nsfs legacy-namespace --pvc-name='cephfs-pvc-legacy' --fs-backend='CEPH_FS'
```

g. Ensure that the noobaa-endpoint pod restarts and that it successfully mounts the PVC at the NSFS namespacestore, for example, `/nsfs/legacy-namespace` mountpoint, where `noobaa_endpoint_pod_name` is the name of the noobaa-endpoint pod.

```
oc exec -it <noobaa_endpoint_pod_name> -- df -h /nsfs/<nsfs_namespacestore>
```

For example:

```
oc exec -it noobaa-endpoint-5875f467f5-546c6 -- df -h /nsfs/legacy-namespace
```

```
Filesystem
Size  Used Avail Use% Mounted on
172.30.202.87:6789,172.30.120.254:6789,172.30.77.247:6789:/volumes/csi/csi-vol-cc416d9e-dbf3-11ec-b286-0a580a810213/edcfe4d5-bdc6-4b8e-8824-8a03ad94d67c 10G 0 10G 0% /nsfs/legacy-namespace
```

h. Create an MCG user account:

```
odf noobaa account create <user_account> --allow_bucket_create=true --new_buckets_path="/" --nsfs_only=true --nsfs_account_config=true --gid <gid_number> --uid <uid_number> --default_resource='legacy-namespace'
```

`user_account`

Specify the name of the MCG user account.

`gid_number`

Specify the GID number.

`uid_number`

Specify the UID number.

Important: Use the same `UID` and `GID` as that of the legacy application. You can find it from the previous output.

For example:

```
odf noobaa account create leguser --allow_bucket_create=true --new_buckets_path="/" --nsfs_only=true --nsfs_account_config=true --gid 0 --uid 1000660000 --default_resource='legacy-namespace'
```

i. Create an MCG bucket.

i. Create a dedicated folder for S3 inside the NSFS share on the CephFS PV and PVC of the legacy application pod:

```
oc exec -it <pod_name> -- mkdir <mount_path>/nsfs
```

For example:

```
oc exec -it cephfs-write-workload-generator-no-cache-1-cv892 -- mkdir /mnt/pv/nsfs
```

ii. Create the MCG bucket using the `nsfs/` path:

```
odf noobaa api bucket_api create_bucket '{
  "name": "<bucket_name>",
  "namespace":{
    "write_resource": { "resource": "<nsfs_namespacestore>", "path": "nsfs/" },
    "read_resources": [ { "resource": "<nsfs_namespacestore>", "path": "nsfs/" }]
  }
},'
```

For example:

```
odf noobaa api bucket_api create_bucket '{
  "name": "legacy-bucket",
  "namespace":{
    "write_resource": { "resource": "legacy-namespace", "path": "nsfs/" },
    "read_resources": [ { "resource": "legacy-namespace", "path": "nsfs/" }]
  }
},'
```

- j. Check the SELinux labels of the folders residing in the PVCs in the legacy application and **openshift-storage** namespaces:

```
oc exec -it <noobaa_endpoint_pod_name> -n openshift-storage -- ls -ltrZ /nsfs/<nsfs_namespacestore>
```

For example:

```
oc exec -it noobaa-endpoint-5875f467f5-546c6 -n openshift-storage -- ls -ltrZ /nsfs/legacy-namespace
```

```
total 567
drwxrwxrwx. 3 root      root system_u:object_r:container_file_t:s0:c0,c26      2 May 25 06:35 .
-rw-r--r--. 1 1000660000 root system_u:object_r:container_file_t:s0:c0,c26 580138 May 25 06:35 fs_write_cephfs-write-
workload-generator-no-cache-1-cv892-data.log
drwxrwxrwx. 3 root      root system_u:object_r:container_file_t:s0:c0,c26      30 May 25 06:35 ..

oc exec -it <pod_name> -- ls -ltrZ <mount_path>
```

For example:

```
oc exec -it cephfs-write-workload-generator-no-cache-1-cv892 -- ls -ltrZ /mnt/pv/
```

```
total 567
drwxrwxrwx. 3 root      root system_u:object_r:container_file_t:s0:c26,c5      2 May 25 06:35 .
-rw-r--r--. 1 1000660000 root system_u:object_r:container_file_t:s0:c26,c5 580138 May 25 06:35 fs_write_cephfs-write-
workload-generator-no-cache-1-cv892-data.log
drwxrwxrwx. 3 root      root system_u:object_r:container_file_t:s0:c26,c5      30 May 25 06:35 ..
```

In these examples, you can see that the SELinux labels are not the same which results in permission denied or access issues.

9. Ensure that the legacy application and **openshift-storage** pods use the same SELinux labels on the files.

You can do this in one of the following ways:

- [Changing the default SELinux label on the legacy application project to match the one in the openshift-storage project](#)
- [Modifying the SELinux label only for the deployment config that has the pod which mounts the legacy application PVC](#)

10. Delete the NSFS namespacestore.

- a. Delete the MCG bucket:

```
odf noobaa bucket delete <bucket_name>
```

For example:

```
odf noobaa bucket delete legacy-bucket
```

- b. Delete the MCG user account.

```
odf noobaa account delete <user_account>
```

For example:

```
odf noobaa account delete leguser
```

- c. Delete the NSFS namespacestore.

```
odf noobaa namespacestore delete <nsfs_namespacestore>
```

For example:

```
odf noobaa namespacestore delete legacy-namespace
```

11. Delete the PV and PVC.

Important: Before you delete the PV and PVC, ensure that the PV has a retain policy configured.

```
oc delete pv <cephfs_pv_name>
```

```
oc delete pvc <cephfs_pvc_name>
```

cephfs_pv_name

Specify the CephFS PV name of the legacy application.

cephfs_pvc_name

Specify the CephFS PVC name of the legacy application.

For example:

```
oc delete pv cephfs-pv-legacy-openshift-storage
```

For example:

```
oc delete pvc cephfs-pvc-legacy
```

- [Changing the default SELinux label on the legacy application project to match the one in the openshift-storage project](#)
Ensure that the legacy application and `openshift-storage` pods use the same SELinux labels on the files, by changing the default SELinux label on the legacy application project.
- [Modifying the SELinux label only for the deployment config that has the pod which mounts the legacy application PVC](#)
Ensure that the legacy application and `openshift-storage` pods use the same SELinux labels on the files, by modifying the SELinux label on the deployment config that has the pod which mounts the legacy application.

Changing the default SELinux label on the legacy application project to match the one in the openshift-storage project

Ensure that the legacy application and `openshift-storage` pods use the same SELinux labels on the files, by changing the default SELinux label on the legacy application project.

Procedure

1. Display the current `openshift-storage` namespace with `sa.scc.mcs`:

```
oc get ns openshift-storage -o yaml | grep sa.scc.mcs
openshift.io/sa.scc.mcs: s0:c26,c0
```

2. Edit the legacy application namespace, and modify the `sa.scc.mcs`.
Use the value from the `sa.scc.mcs` of the `openshift-storage` namespace:

```
oc edit ns <application_namespace>
```

For example:

```
oc edit ns testnamespace
```

```
oc get ns <application_namespace> -o yaml | grep sa.scc.mcs
```

For example:

```
oc get ns testnamespace -o yaml | grep sa.scc.mcs
openshift.io/sa.scc.mcs: s0:c26,c0
```

3. Restart the legacy application pod.
A relabel of all the files take place and now the SELinux labels match with the `openshift-storage` deployment.

Modifying the SELinux label only for the deployment config that has the pod which mounts the legacy application PVC

Ensure that the legacy application and `openshift-storage` pods use the same SELinux labels on the files, by modifying the SELinux label on the deployment config that has the pod which mounts the legacy application.

Procedure

1. Create a new `scc` with the `MustRunAs` and `seLinuxOptions` options, with the Multi Category Security (MCS) that the `openshift-storage` project uses.
Example YAML file:

```
cat << EOF >> scc.yaml

allowHostDirVolumePlugin: false
allowHostIPC: false
allowHostNetwork: false
allowHostPID: false
allowHostPorts: false
allowPrivilegeEscalation: true
allowPrivilegedContainer: false
allowedCapabilities: null
apiVersion: security.openshift.io/v1
defaultAddCapabilities: null
fsGroup:
  type: MustRunAs
groups:
- system:authenticated
kind: SecurityContextConstraints
metadata:
  annotations:
    name: restricted-pvselinux
priority: null
readOnlyRootFilesystem: false
requiredDropCapabilities:
- KILL
- MKNOD
- SETUID
```

```

- SETGID
runAsUser:
  type: MustRunAsRange
seLinuxContext:
  selinuxOptions:
    level: s0:c26,c0
  type: MustRunAs
supplementalGroups:
  type: RunAsAny
users: []
volumes:
- configMap
- downwardAPI
- emptyDir
- persistentVolumeClaim
- projected
- secret
EOF
oc create -f scc.yaml

```

2. Create a service account for the deployment and add it to the newly created **scc**.
 - a. Create a service account, where `<service_account_name>` is the name of the service account.

```
oc create serviceaccount <service_account_name>
```

For example:

```
oc create serviceaccount testnamespacesa
```

- b. Add the service account to the newly created **scc**:

```
oc adm policy add-scc-to-user restricted-pvselinux -z <service_account_name>
```

For example:

```
oc adm policy add-scc-to-user restricted-pvselinux -z testname
```

3. Patch the legacy application deployment so that it uses the newly created service account. With this change, you can specify the SELinux label in the deployment.

```
oc patch dc/<pod_name> '{"spec":{"template":{"spec":{"serviceAccountName": "<service_account_name>"}}}}'
```

For example:

```
oc patch dc/cephfs-write-workload-generator-no-cache --patch '{"spec":{"template":{"spec":{"serviceAccountName": "testnamespacesa"}}}}'
```

4. Edit the deployment to specify the security context to use at the SELinux label in the deployment configuration:

```
oc edit dc <pod_name> -n <application_namespace>
```

Add the following lines:

```

spec:
  template:
    metadata:
      securityContext:
        selinuxOptions:
          Level: <security_context_value>

```

security_context_value

You can find this value when you run the command to create a dedicated folder for S3 inside the NSFS share on the CephFS PV and PVC of the legacy application pod.

For example:

```
oc edit dc cephfs-write-workload-generator-no-cache -n testnamespace
```

```

spec:
  template:
    metadata:
      securityContext:
        selinuxOptions:
          level: s0:c26,c0

```

5. Ensure that the security context to be used at the SELinux label in the deployment configuration is specified correctly.

```
oc get dc <pod_name> -n <application_namespace> -o yaml | grep -A 2 securityContext
```

For example:

```

oc get dc cephfs-write-workload-generator-no-cache -n testnamespace -o yaml | grep -A 2 securityContext
securityContext:
  selinuxOptions:
    level: s0:c26,c0

```

The legacy application is restarted and begins using the same SELinux labels as the **openshift-storage** namespace.

Configuring or modifying the PublicAccessBlock configuration for S3 bucket

About this task

To apply PublicAccessBlock policy to the bucket, first apply a policy that grants public access, and then apply the PublicAccessBlock policy. The policy is applied through `put-bucket-policy` S3 API, which is similar to Amazon S3. For more information, see [PutPublicAccessBlock](#) in *Amazon S3 API Reference Guide*.

Important: The Multicloud Object Gateway (MCG) checks the PublicAccessBlock policy configuration for both the bucket that contains the object and the bucket owner's account during evaluating the PublicAccessBlock policy for a bucket or an object.

Restriction: Only bucket-wide policy is supported and not account-wide policy. Also, access control lists (ACLs) are not supported within the policy.

Procedure

1. Allow a general access policy.

Command example:

```
{
  "Version": "2025-06-25",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": "*",
      "Action": "s3:*",
      "Resource": [
        "arn:aws:s3:::<bucket_name>/*",
        "arn:aws:s3:::<bucket_name>"
      ]
    }
  ]
}
```

2. Set the PublicAccessBlock policy.

The default PublicAccessBlock policy configuration is as follows:

```
{
  {
    "BlockPublicPolicy": false,
    "RestrictPublicBuckets": false
  }
}
```

To block public policies and restrict public buckets, set the value to `true` as follows:

```
{
  {
    "BlockPublicPolicy": true,
    "RestrictPublicBuckets": true
  }
}
```

The following configuration is not supported:

```
{
  {
    "BlockPublicAcls": false, <-- Not allowed even as false
    "IgnorePublicAcls": false, <-- Not allowed even as false
    "BlockPublicPolicy": true,
    "RestrictPublicBuckets": true
  }
}
```

3. Apply the PublicAccessBlock policy by using the `put-public-access-block` command.

Command example:

```
alias s3api=AWS_ACCESS_KEY_ID=<access_key> AWS_SECRET_ACCESS_KEY=<secret_key> aws s3api --no-verify-ssl --endpoint
<endpoint> --no-verify put-public-access-block --bucket <bucket_name> --public-access-block-configuration
file://<configuration_file_path>. * *
```

Securing Multicloud Object Gateway

Ensure that the Multicloud Object Gateway is secure.

- [Changing the default account credentials to ensure better security in the Multicloud Object Gateway](#)
Change and rotate your Multicloud Object Gateway (MCG) account credentials using the command-line interface to prevent issues with applications and to ensure better account security.
- [Enabling secured mode deployment for Multicloud Object Gateway](#)
You can specify a range of IP addresses that should be allowed to reach the Multicloud Object Gateway (MCG) load balancer services to enable secure mode deployment. This helps to control the IP addresses that can access the MCG services.
- [Disabling routes that enable external access to Multicloud Object Gateway](#)
Disable S3, STS, and `noobaa-mgmt` routes by updating the storagecluster CR.
- [Disabling the HTTP route for RADOS Object Gateway](#)
Disable insecure HTTP access to the RADOS Object Gateway (RGW) by configuring the `disableHTTP` option in the StorageCluster custom resource to ensure that only secure HTTPS connections are allowed to access the RGW S3 endpoint.

Changing the default account credentials to ensure better security in the Multicloud Object Gateway

Change and rotate your Multicloud Object Gateway (MCG) account credentials using the command-line interface to prevent issues with applications and to ensure better account security.

Before changing the default account credentials, ensure you have the following:

- A running Fusion Data Foundation cluster.
- Download the Multicloud Object Gateway (MCG) command-line interface for easier management. For instructions, see [Accessing the Multicloud Object Gateway with your applications](#).
- [Resetting the noobaa account password](#)
Change and rotate your Multicloud Object Gateway (MCG) account credentials by resetting the noobaa account password.
- [Setting Multicloud Object Gateway account credentials using CLI command](#)
Use this procedure to set the Multicloud Object Gateway (MCG) account credentials using the command-line interface (CLI) command. You can update and verify the MCG account credentials manually by using the MCG CLI command.
- [Regenerating the S3 credentials for the accounts](#)
Change and rotate your Multicloud Object Gateway (MCG) account credentials by regenerating the S3 credentials for the accounts.
- [Regenerating the S3 credentials for the OBC](#)
Change and rotate your Multicloud Object Gateway (MCG) account credentials by regenerating the S3 credentials for the OBC.

Resetting the noobaa account password

Change and rotate your Multicloud Object Gateway (MCG) account credentials by resetting the noobaa account password.

Procedure

To reset the noobaa account password, run the following command:

```
odf noobaa account passwd <noobaa_account_name> [options]
```

```
odf noobaa account passwd
```

```
FATA[0000] ✖ Missing expected arguments: <noobaa_account_name>
```

Options:

```
--new-password='': New Password for authentication - the best practice is to omit this flag, in that case the CLI will prompt to prompt and read it securely from the terminal to avoid leaking secrets in the shell history
--old-password='': Old Password for authentication - the best practice is to omit this flag, in that case the CLI will prompt to prompt and read it securely from the terminal to avoid leaking secrets in the shell history
--retype-new-password='': Retype new Password for authentication - the best practice is to omit this flag, in that case the CLI will prompt to prompt and read it securely from the terminal to avoid leaking secrets in the shell history
```

Usage:

```
odf noobaa account passwd <noobaa-account-name> [flags] [options]
```

Use "odf noobaa options" for a list of global command-line options (applies to all commands).

Example:

```
odf noobaa account passwd admin@noobaa.io
```

Example output:

```
Enter old-password: [got 24 characters]
Enter new-password: [got 7 characters]
Enter retype-new-password: [got 7 characters]
INFO[0017] ✔ Exists: Secret "noobaa-admin"
INFO[0017] ✔ Exists: NooBaa "noobaa"
INFO[0017] ✔ Exists: Service "noobaa-mgmt"
INFO[0017] ✔ Exists: Secret "noobaa-operator"
INFO[0017] ✔ Exists: Secret "noobaa-admin"

INFO[0020] ✔ RPC: account.reset_password() Response OK: took 2907.1ms
INFO[0020] ✔ Updated: "noobaa-admin"
INFO[0020] ✔ Successfully reset the password for the account "admin@noobaa.io"
```

Important:

To access the admin account credentials run the **noobaa status** command from the terminal:

```
----- Mgmt Credentials -----  
email    : admin@noobaa.io  
password : ***
```

Setting Multicloud Object Gateway account credentials using CLI command

Use this procedure to set the Multicloud Object Gateway (MCG) account credentials using the command-line interface (CLI) command. You can update and verify the MCG account credentials manually by using the MCG CLI command.

Before you begin

Ensure that the following prerequisites are met:

- A running Fusion Data Foundation cluster.
- Download the MCG CLI binary from the customer portal and make it executable.

Note:

- Choose the correct product variant according to your architecture.
- Available platforms are Linux (x86_64), Windows, and Mac OS.

Procedure

1. Run the following command to update the MCG account credentials:

```
odf noobaa account credentials <noobaa-account-name> [options]
```

Example:

```
odf noobaa account credentials admin@noobaa.io
```

Example output:

```
odf noobaa account credentials admin@noobaa.io  
Enter access-key: [got 20 characters]  
Enter secret-key: [got 40 characters]  
INFO[0026] ✗ Not Found: NooBaaAccount "admin@noobaa.io"  
INFO[0026] ✓ Exists: NooBaa "noobaa"  
INFO[0026] ✓ Exists: Service "noobaa-mgmt"  
INFO[0026] ✓ Exists: Secret "noobaa-operator"  
INFO[0026] ✓ Exists: Secret "noobaa-admin"  
INFO[0026] → RPC: account.update_account_keys() Request: {Email:admin@noobaa.io AccessKeys:{AccessKey:* SecretKey:}}  
WARN[0026] RPC: GetConnection creating connection to wss://localhost:33495/rpc/ 0xc000cd9980 INFO[0026] RPC: Connecting

(0xc000cd9980) &{RPC:0xc0001655e0 Address:wss://localhost:33495/rpc/ State:init WS:<nil> PendingRequests:map[]  
NextRequestID:0 Lock:{state:1 sema:0} ReconnectDelay:0s cancelPings:<nil>} INFO[0026] ✓ RPC:  
account.update_account_keys() Response OK: took 42.7ms INFO[0026] → RPC: account.read_account() Request:  
{Email:admin@noobaa.io} INFO[0026] ✓ RPC: account.read_account() Response OK: took 2.0ms INFO[0026] ✓ Updated: "noobaa-  
admin" INFO[0026] ✓ Successfully updated s3 credentials for the account "admin@noobaa.io" INFO[0026] ✓ Exists: Secret  
"noobaa-admin" Connection info: AWS_ACCESS_KEY_ID : AWS_SECRET_ACCESS_KEY : *
```

Credential complexity requirements:

Access key

The account access key must be 20 characters in length, and it must contain only alphanumeric characters.

Secret key

The secret key must be 40 characters in length, and it must contain alphanumeric characters and "+" and "/".

Example:

```
odf noobaa account credentials my-account --access-key=ABCDEF1234567890ABCD --secret-  
key=ABCDE12345+FGHIJ67890/KLMNOPQRSTUVWXYZ123456
```

2. Run the following command to verify the credentials:

```
odf noobaa account status <noobaa-account-name> --show-secrets
```

Remember: Each user must have a unique access key and secret key.

Regenerating the S3 credentials for the accounts

Change and rotate your Multicloud Object Gateway (MCG) account credentials by regenerating the S3 credentials for the accounts.

Procedure

1. Get the account name.

- For listing the accounts, run the following command:

```
odf noobaa account list
```

Example output:

NAME	ALLOWED_BUCKETS	DEFAULT_RESOURCE	PHASE	AGE
account-test	[*]	noobaa-default-backing-store	Ready	14m17s
test2	[first.bucket]	noobaa-default-backing-store	Ready	3m12s

- Alternatively, run the **oc get noobaaaccount** command from the terminal:

```
oc get noobaaaccount
```

Example output:

NAME	PHASE	AGE
account-test	Ready	15m
test2	Ready	3m59s

- To regenerate the noobaa account S3 credentials, run the following command:

```
odf noobaa account regenerate <noobaa_account_name> [options]
```

```
odf noobaa account regenerate
```

```
FATA[0000] ✖ Missing expected arguments: <noobaa-account-name>
```

Usage:

```
odf noobaa account regenerate <noobaa-account-name> [flags] [options]
```

Use "odf noobaa options" for a list of global command-line options (applies to all commands).

- After you run the **odf noobaa account regenerate** command it prompts the This will invalidate all connections between S3 clients and NooBaa which are connected using the current credentials. warning and asks for confirmation.

Example:

```
odf noobaa account regenerate account-test
```

Example output:

```
INFO[0000] You are about to regenerate an account's security credentials.
INFO[0000] This will invalidate all connections between S3 clients and NooBaa which are connected using the current
credentials.
INFO[0000] are you sure? y/n
```

After approving, the credentials are regenerated and eventually printed.

```
INFO[0015] ✔ Exists: Secret "noobaa-account-account-test"
Connection info:
AWS_ACCESS_KEY_ID      : ***
AWS_SECRET_ACCESS_KEY  : ***
```

Regenerating the S3 credentials for the OBC

Change and rotate your Multicloud Object Gateway (MCG) account credentials by regenerating the S3 credentials for the OBC.

Procedure

- Get the OBC name.

- Run the **odf noobaa obc list** command

```
odf noobaa obc list
```

Example output:

NAMESPACE	NAME	BUCKET-NAME	STORAGE-CLASS	BUCKET-CLASS
PHASE				
default	obc-test	obc-test-35800e50-8978-461f-b7e0-7793080e26ba	default.noobaa.io	noobaa-default-bucket-class
	Bound			

- Run the **oc get obc** command from the terminal.

```
oc get obc
```

Example output:

NAME	STORAGE-CLASS	PHASE	AGE
obc-test	default.noobaa.io	Bound	38s

- To regenerate the noobaa OBC S3 credentials, run the following command:

```
odf noobaa obc regenerate <bucket_claim_name> [options]
```

```
odf noobaa obc regenerate
```

```
FATA[0000] ✖ Missing expected arguments: <bucket-claim-name>
```

Usage:

```
odf noobaa obc regenerate <bucket-claim-name> [flags] [options]
```

Use "odf noobaa options" for a list of global command-line options (applies to all commands).

- After you run the `odf noobaa obc regenerate` command it prompts the This will invalidate all connections between S3 clients and NooBaa which are connected using the current credentials. warning and asks for confirmation.
Example:

```
odf noobaa obc regenerate obc-test
```

Example output:

```
INFO[0000] You are about to regenerate an OBC's security credentials.
INFO[0000] This will invalidate all connections between S3 clients and NooBaa which are connected using the current
credentials.
INFO[0000] are you sure? y/n
```

After approving, the credentials are regenerated and eventually printed.

```
INFO[0022] ✓ RPC: bucket.read_bucket() Response OK: took 95.4ms
```

ObjectBucketClaim info:

```
Phase           : Bound

```

Enabling secured mode deployment for Multicloud Object Gateway

You can specify a range of IP addresses that should be allowed to reach the Multicloud Object Gateway (MCG) load balancer services to enable secure mode deployment. This helps to control the IP addresses that can access the MCG services.

Before you begin

- A running Fusion Data Foundation cluster.
- In case of a bare metal deployment, ensure that the load balancer controller supports setting the `loadBalancerSourceRanges` attribute in the Kubernetes services.

Procedure

Edit the NooBaa custom resource (CR) to specify the range of IP addresses that can access the MCG services after deploying Fusion Data Foundation.

```
oc edit noobaa -n openshift-storage noobaa
```

noobaa

The NooBaa CR type that controls the NooBaa system deployment.

noobaa

The name of the NooBaa CR.

For example:

```
...
spec:
  ...
  loadBalancerSourceSubnets:
    s3: ["10.0.0.0/16", "192.168.10.0/32"]
  sts:
    - "10.0.0.0/16"
    - "192.168.10.0/32"
...
```

loadBalancerSourceSubnets

A new field that can be added under **spec** in the NooBaa CR to specify the IP addresses that should have access to the NooBaa services.

In this example, all the IP addresses that are in the subnet 10.0.0.0/16 or 192.168.10.0/32 be able to access MCG S3 and security token service (STS) while the other IP addresses are not allowed to access.

What to do next

To verify if the specified IP addresses are set, from the OpenShift® Web Console, run the following command and check if the output matches with the IP addresses provided to MCG:

```
oc get svc -n openshift-storage <s3 | sts> -o=go-template='{{ .spec.loadBalancerSourceRanges }}'
```

Disabling routes that enable external access to Multicloud Object Gateway

Disable **S3**, **STS**, and **noobaa-mgmt** routes by updating the storagecluster CR.

About this task

You can disable **S3**, **STS**, and **noobaa-mgmt** routes by setting the following option in the storagecluster CR:

```
spec:
  multiCloudGateway:
    disableRoutes: true
```

This stops reconciling of all the three routes so that the routes are not recreated when they are deleted.

Procedure

1. Edit the storagecluster CR in one of the following ways:

- Using the `oc patch` command:

```
oc patch storagecluster ocs-storage -n openshift-storage --type=merge -p '{"spec":{"multiCloudGateway":{"disableRoutes":true}}}'
```

- Using the interactive method:

```
oc edit storagecluster ocs-storage -n openshift-storage
```

- Add the following under **.spec**:

```
multiCloudGateway:
  disableRoutes: true
```

2. To verify, delete the existing routes and check if they are listed:

```
oc delete routes --all -n openshift-storage
oc get routes -n openshift-storage
```

The **S3**, **STS**, and **noobaa-mgmt** routes are no longer reconciled by the operator.

- [Disabling HTTP access for the NooBaa S3 route](#)

Disable insecure HTTP access to the NooBaa S3 endpoint by configuring the **denyHTTP** option in the StorageCluster custom resource to ensure that only secure HTTPS connections are allowed to access the Multicloud Object Gateway (MCG) S3 endpoint.

Disabling HTTP access for the NooBaa S3 route

Disable insecure HTTP access to the NooBaa S3 endpoint by configuring the **denyHTTP** option in the StorageCluster custom resource to ensure that only secure HTTPS connections are allowed to access the Multicloud Object Gateway (MCG) S3 endpoint.

Before you begin

- Note: Starting with Fusion Data Foundation 4.22, you can disable HTTP access for the NooBaa S3 route to enforce HTTPS-only connections to the MCG S3 endpoint.
- You have administrator access to Fusion Data Foundation.
- Fusion Data Foundation is deployed with MCG.

Procedure

1. Enable the **denyHTTP** option to disable HTTP access:

```
oc patch storagecluster ocs-storagecluster -n openshift-storage --type=merge -p '{"spec":{"multiCloudGateway":{"denyHTTP":true}}}'
```

This command patches the StorageCluster custom resource to set **spec.multiCloudGateway.denyHTTP** to **true**.

2. Wait for the S3 route to reconcile.
The operator updates the route configuration to deny HTTP traffic.

3. Verify that the S3 route's `insecureEdgeTerminationPolicy` is set to `None`:

```
oc get route s3 -n openshift-storage -o jsonpath='{.spec.tls.insecureEdgeTerminationPolicy}'
```

Example output:

None

Results

HTTP access to the NooBaa S3 endpoint is disabled. Only HTTPS connections are permitted.

What to do next

To re-enable HTTP access, set the `denyHTTP` option to `false`:

```
oc patch storagecluster ocs-storagecluster -n openshift-storage --type=merge -p '{"spec":{"multiCloudGateway":{"denyHTTP":false}}}'
```

After applying this change, the S3 route's `insecureEdgeTerminationPolicy` is set back to `Allow`, permitting both HTTP and HTTPS traffic.

Note:

- The `denyHTTP` setting affects only the S3 route. The STS and `noobaa-mgmt` routes are not affected by this configuration.
- Existing S3 client connections that use HTTPS are not interrupted when you enable or disable this feature.
- Applications that use HTTP endpoints must be reconfigured to use HTTPS endpoints when `denyHTTP` is enabled.

Disabling the HTTP route for RADOS Object Gateway

Disable insecure HTTP access to the RADOS Object Gateway (RGW) by configuring the `disableHTTP` option in the StorageCluster custom resource to ensure that only secure HTTPS connections are allowed to access the RGW S3 endpoint.

Before you begin

Note: Starting with Fusion Data Foundation 4.22, you can disable the HTTP route for the RADOS Object Gateway to enforce HTTPS-only connections to the RGW S3 endpoint.

- You have administrator access to Fusion Data Foundation.
- Fusion Data Foundation is deployed with a CephObjectStore.

Procedure

1. Edit the StorageCluster custom resource to disable the HTTP route by using the `oc patch` command:

```
oc patch storagecluster ocs-storagecluster -n openshift-storage --type=merge -p '{"spec":{"managedResources":{"cephObjectStores":{"disableHTTP":true}}}}'
```

2. Verify that the HTTP route is disabled by running the following command and confirming that only the HTTPS route is listed:

```
oc get routes -n openshift-storage | grep rgw
```

Example output:

```
rook-ceph-rgw-ocs-storagecluster-cephobjectstore-https    rook-ceph-rgw-ocs-storagecluster-cephobjectstore-https-openshift-stor
```

Results

The HTTP route for the RGW is disabled. Only HTTPS connections are permitted to access the RGW S3 endpoint.

Mirroring data for hybrid and Multicloud buckets

Create bucket classes to mirror data for hybrid and Multicloud buckets. Mirroring data can be setup by using the OpenShift® UI, YAML, or MCG command-line interface.

You can use the simplified process of the Multicloud Object Gateway (MCG) to span data across cloud providers and clusters. Before you create a bucket class that reflects the data management policy and mirroring, you must add a backing storage that can be used by the MCG. For information, see [Adding storage resources for hybrid or Multicloud](#).

- [Creating bucket classes to mirror data using the MCG command-line-interface](#)
Create bucket classes to mirror data for hybrid and Multicloud buckets using the MCG command-line interface.
- [Creating bucket classes to mirror data using a YAML](#)
Create bucket classes to mirror data for hybrid and Multicloud buckets using a YAML file.

Creating bucket classes to mirror data using the MCG command-line-interface

Create bucket classes to mirror data for hybrid and Multicloud buckets using the MCG command-line interface.

Before you begin

Ensure to download Multicloud Object Gateway (MCG) command-line interface.

Procedure

1. From the Multicloud Object Gateway (MCG) command-line interface, run the following command to create a bucket class with a mirroring policy:

```
odf noobaa bucketclass create placement-bucketclass mirror-to-aws --backingstores=azure-resource,aws-resource --placement Mirror
```

2. Set the newly created bucket class to a new bucket claim to generate a new bucket that is mirrored between two locations:

```
odf noobaa obc create mirrored-bucket --bucketclass=mirror-to-aws
```

Creating bucket classes to mirror data using a YAML

Create bucket classes to mirror data for hybrid and Multicloud buckets using a YAML file.

Procedure

1. Apply the following YAML.
This YAML is a hybrid example that mirrors data between local Ceph storage and AWS.

```
apiVersion: noobaa.io/v1alpha1
kind: BucketClass
metadata:
  labels:
    app: noobaa
    name: <bucket-class-name>
    namespace: openshift-storage
spec:
  placementPolicy:
    tiers:
      - backingStores:
          - <backing-store-1>
          - <backing-store-2>
    placement: Mirror
```

2. Add the following lines to your standard Object Bucket Claim (OBC):

```
additionalConfig:
  bucketclass: mirror-to-aws
```

For more information about OBCs, see [Object Bucket Claim](#).

Bucket policies in the Multicloud Object Gateway

Fusion Data Foundation supports AWS S3 bucket policies. Bucket policies allow you to grant users access permissions for buckets and the objects in them. Use the information in this section to understand how to use bucket policies in Multicloud Object Gateway.

- [Introduction to bucket policies](#)
Bucket policies are an access policy option available for you to grant permission to your AWS S3 buckets and objects. Bucket policies use JSON-based access policy language.
- [Using bucket policies in Multicloud Object Gateway](#)
Use these instructions to use bucket policies in Multicloud Object Gateway.
- [Creating a user in the Multicloud Object Gateway](#)
Create a user account in the Multicloud Object Gateway using the MCG command-line interface, optionally with a NamespaceStore file system configuration.

Introduction to bucket policies

Bucket policies are an access policy option available for you to grant permission to your AWS S3 buckets and objects. Bucket policies use JSON-based access policy language.

For more information about access policy language, see [AWS Access Policy Language Overview](#).

Using bucket policies in Multicloud Object Gateway

Use these instructions to use bucket policies in Multicloud Object Gateway.

Before you begin

Ensure you have the following:

- A running Fusion Data Foundation Platform.
- Access to the Multicloud Object Gateway (MCG), see [Accessing the Multicloud Object Gateway with your applications](#).

Procedure

1. Create the bucket policy in JSON format.
For example:

```
{
  "Version": "NewVersion",
  "Statement": [
    {
      "Sid": "Example",
      "Effect": "Allow",
      "Principal": [
        "john.doe@example.com"
      ],
      "Action": [
        "s3:GetObject"
      ],
      "Resource": [
        "arn:aws:s3:::john_bucket"
      ]
    }
  ]
}
```

2. Using AWS S3 client, use the **put-bucket-policy** command to apply the bucket policy to your S3 bucket:

```
aws --endpoint ENDPOINT --no-verify-ssl s3api put-bucket-policy --bucket MyBucket --policy BucketPolicy
```

ENDPOINT

An S3 endpoint.

MyBucket

A name of the bucket to set the policy on.

BucketPolicy

A bucket policy JSON file.

--no-verify-ssl

Add this if you are using the default self signed certificates.

For example:

```
aws --endpoint https://s3-openshift-storage.apps.gogo44.noobaa.org --no-verify-ssl s3api put-bucket-policy --bucket MyBucket --policy file://BucketPolicy
```

For more information on the **put-bucket-policy** command, see [AWS CLI Command Reference for put-bucket-policy](#).

Note: The principal element specifies the user that is allowed or denied access to a resource, such as a bucket. Currently, only NooBaa accounts can be used as principals. In the case of object bucket claims, NooBaa automatically creates an account .

```
obc-account.<generated bucket name>@noobaa.io
```

Note: Bucket policy conditions are not supported.

What to do next

There are many available elements for bucket policies with regard to access permissions.

- For details on these elements and examples of how they can be used to control the access permissions, see [AWS Access Policy Language Overview](#).
- For more examples of bucket policies, see [AWS Bucket Policy Examples](#).
- Fusion Data Foundation version 4.16 or higher introduces the bucket policy elements **NotPrincipal**, **NotAction**, and **NotResource**. For more information on these elements, see [IAM JSON policy elements reference](#).

Creating a user in the Multicloud Object Gateway

Create a user account in the Multicloud Object Gateway using the MCG command-line interface, optionally with a NamespaceStore file system configuration.

Before you begin

- A running Fusion Data Foundation Platform.
- Download the MCG command-line interface for easier management.

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-x86_64-rpms
```

```
yum install mcg
```

Note: Specify the appropriate architecture for enabling the repositories using the subscription manager.

- For IBM Power, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-ppc64le-rpms
```

- For IBM Z infrastructure, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-s390x-rpms
```

- Alternatively, you can install the MCG package from the RPMs found at [Download Red Hat® OpenShift® Data Foundation page](#).

Note: Choose the correct Product Variant according to your architecture.

Procedure

Run the following command to create an MCG user account:

```
odf noobaa account create <noobaa-account-name> [--allow_bucket_create=true] [--default_resource=''] [--force_md5_etag=false] [--gid=-1] [--new_buckets_path='/'] [--nsfs_account_config=false] [--nsfs_only=true] [--uid=-1]
```

<allow_bucket_create>

Specify if this account be allowed to create new buckets.

<default_resource>

Specify the default resource on which new buckets are created.

<force_md5_etag>

Specify if **md5 etag** calculation be enabled for the account.

<gid_number>

Specify the GID number.

<new_buckets_path>

Specify the path where the new buckets are created.

<nsfs_account_config>

Specify if NSFS account needs to be created.

<nsfs_only>

Set if this account is used only for NSFS.

<uid_number>

Specify the UID number.

Bucket notification in Multicloud Object Gateway

With bucket notification, you can send a notification to an external server whenever there is an event in the bucket.

Multicloud Object Gateway (MCG) supports several bucket event notification types. You can receive bucket notifications for activities such as flow creation, triggering data digestion, and so on. MCG supports the following event types that can be specified in the notification configuration:

- s3:TestEvent
- s3:ObjectCreated:*
- s3:ObjectCreated:Put
- s3:ObjectCreated:Post
- s3:ObjectCreated:Copy
- s3:ObjectCreated:CompleteMultipartUpload
- s3:ObjectRemoved:*
- s3:ObjectRemoved:Delete
- s3:ObjectRemoved:DeleteMarkerCreated
- s3:LifecycleExpiration:*
- s3:LifecycleExpiration:Delete
- s3:LifecycleExpiration:DeleteMarkerCreated
- s3:ObjectRestore:*
- s3:ObjectRestore:Post
- s3:ObjectRestore:Completed
- s3:ObjectRestore:Delete
- s3:ObjectTagging:*
- s3:ObjectTagging:Put
- s3:ObjectTagging:Delete
- [Configuring bucket notification in Multicloud Object Gateway](#)
Learn how to configure bucket notifications in Multicloud Object Gateway (MCG).

Configuring bucket notification in Multicloud Object Gateway

Learn how to configure bucket notifications in Multicloud Object Gateway (MCG).

Before you begin

- Ensure to have one of the following before configuring:

- Kafka cluster is deployed.

For example, you can deploy Kafka by using **AMQ/strimzi** by referring to [Getting Started with AMQ Streams on OpenShift®](#).

- An HTTP or HTTPS server is connected.

For example, you can set up an HTTP server to log incoming HTTP requests so that you can observe them using the **oc logs** command as follows:

```
cat http_logging_server.yaml
apiVersion: v1
kind: List
metadata: {}
items:
- apiVersion: apps/v1
  kind: Deployment
  metadata:
    name: http-logger
  spec:
    replicas: 1
    selector:
      matchLabels:
        app: http-logger
    template:
      metadata:
        labels:
          app: http-logger
      spec:
        containers:
        - name: http-logger
          image: registry.redhat.io/ubi9/python-39:latest
          command:
            - /bin/sh
            - -c
            - |
              set -e # Fail on any error
              mkdir -p /tmp/app
              pip install flask
              cat <<EOF > /tmp/app/server.py
              from flask import Flask, request
              app = Flask(__name__)
              @app.route("/", methods=["POST", "GET"])
              def log_request():
                  body = request.get_data(as_text=True)
                  print(body) # Simple one-line logging per request
                  return "", 200
              if __name__ == "__main__":
                  app.run(host="0.0.0.0", port=8676, debug=True)
              EOF
              exec python /tmp/app/server.py
          ports:
            - containerPort: 8676
              protocol: TCP
          securityContext:
            runAsNonRoot: true
            allowPrivilegeEscalation: false
- apiVersion: v1
  kind: Service
  metadata:
    name: http-logger
    labels:
      app: http-logger
  spec:
    selector:
      app: http-logger
    ports:
      - port: 8676
        targetPort: 8676
        protocol: TCP
        name: http
```

```
oc create -f http_logging_server.yaml -n <http-server-namespace>
```

- Ensure that server is accessible from the MCG core pod from which the notifications are sent.
- Ensure to fetch MCG's credentials:

```
NOOBAA_ACCESS_KEY=$(oc extract secret/noobaa-admin -n openshift-storage --keys=AWS_ACCESS_KEY_ID --to=- 2>/dev/null); \
NOOBAA_SECRET_KEY=$(oc extract secret/noobaa-admin -n openshift-storage --keys=AWS_SECRET_ACCESS_KEY --to=- 2>/dev/null); \
S3_ENDPOINT=https://$(oc get route s3 -n openshift-storage -o json | jq -r ".spec.host")
alias aws_alias='AWS_ACCESS_KEY_ID=$NOOBAA_ACCESS_KEY AWS_SECRET_ACCESS_KEY=$NOOBAA_SECRET_KEY aws --endpoint $S3_ENDPOINT'
--no-verify-
```

Procedure

1. Describe connection using a json file, for example, connection.json on your local machine.

- An example for Kafka:

```
{
  "name": "kafka_notif_conn_file" <-- any string
  "notification_protocol": "kafka",
  "metadata.broker.list": "<kafka-service-name>.<project>.svc.cluster.local:<kafka-service-port>",
  "topic": "my-topic", <-- refer to an existing KafkaTopic resource
}
```

The structure under `metadata.broker.list` must be `<service-name>.<namespace>.svc.cluster.local:9092`, topic must refer to the name of an existing `kafka` topic resource in the namespace.

- An example for HTTP or HTTPS:

```
{
  "name": "http_notif_connection_config",
  "notification_protocol": "http", <-- or "https"
  "agent_request_object": {
    "host": "<http-service>.<http-server-namespace>.svc.cluster.local",
    "port": <http-server-port>
  }
}
```

Additional options:

`request_options_object`

Value is a JSON that is passed to nodejs' http(s) request (optional).

Any field supported by nodejs' http(s) request option can be used, for example:

`path`

Used to specify the url path.

`auth`

Used for http simple auth. Syntax for the value of 'auth' is: `<name>:<password>`.

2. Create a secret from the file in the `openshift-storage` namespace.

For example:

```
oc create secret generic <connection-secret> --from-file=connect.json -n openshift-storage
```

3. Update the `NooBaa` CR in the `openshift-storage` namespace with the connection secret and an optional CephFS RWX PVC.

For example:

```
oc patch noobaa noobaa --type='merge' -n openshift-storage -p '{
  "spec": {
    "bucketNotifications": {
      "connections": [
        {
          "name": <connection-secret>,
          "namespace": "openshift-storage"
        }
      ],
      "enabled": true,
      "pvc": "bn-pvc" <-- optional
    }
  }
}'
```

Note: If PVC is not provided, MCG creates one automatically as needed.

For example:

```
oc get pvc bn-pvc -n openshift-storage
```

NAME	STATUS	VOLUME	CAPACITY	ACCESS MODES	STORAGECLASS
bn-pvc	Bound	pvc-24683f8d-48e4-4c6b-b108-d507ca2f4fd1	25Gi	RWX	ocs-storagecluster-cephfs

25h

Important: Names of the connection secret must be unique in the list even though the namespaces are different.

Wait for the `noobaa-core` and `noobaa-endpoint` pods to restart before proceeding with the next step.

4. Use `S3:PutBucketNotification` on an MCG bucket by using the `noobaa-admin` credentials and S3 endpoint under an S3 alias.

For example:

```
aws_alias s3api put-bucket-notification --bucket first.bucket --notification-configuration '{
  "TopicConfiguration": {
    "Id": "<notif_event_kafka>", <-- Unique string
    "Events": ["s3:ObjectCreated:*"], <-- a filter for events
    "Topic": "<connection-secret/connect.json>"
  }
}'
```

5. Verify that the bucket notification configuration is set on the bucket.

For example:

```
aws_alias s3api get-bucket-notification-configuration --bucket first.bucket
{
  "TopicConfigurations": [
    {
      "Id": "notif_event_kafka",
      "TopicArn": "kafka-connection-secret/connect.json",
      "Events": [
        "s3:ObjectCreated:*"
      ]
    }
  ]
}
```

6. Add some objects on the bucket.

```
echo 'a' | aws_alias s3 cp - s3://first.bucket/a
```

Wait for a while and query the topic messages to verify the expected notification has been sent and received.

An example for Kafka:

```
oc -n your-kafka-project rsh my-cluster-kafka-0 bin/kafka-console-consumer.sh \
--bootstrap-server my-cluster-kafka-bootstrap.myproject.svc.cluster.local:9092 \
--topic my-topic \
--from-beginning --timeout-ms 10000 | grep '^{.*}' | jq -c '.' | jq
```

An example for HTTP or HTTPS:

```
oc logs deployment/http-logger -n <http-server-namespace> | grep '^{.*}' | jq
```

Example output:

```
{
  "Records": [
    {
      "eventVersion": "2.3",
      "eventSource": "noobaa:s3",
      "eventTime": "2024-11-27T12:44:21.987Z",
      "s3": {
        "s3SchemaVersion": "1.0",
        "object": {
          "sequencer": 10,
          "key": "a",
          "eTag": "60b725f10c9c85c70d97880dfe8191b3"
        },
        "bucket": {
          "name": "second.bucket",
          "ownerIdentity": {
            "principalId": "admin@noobaa.io"
          },
          "arn": "arn:aws:s3:::first.bucket"
        }
      },
      "eventName": "ObjectCreated:Put",
      "userIdentity": {
        "principalId": "noobaa"
      },
      "requestParameters": {
        "sourceIPAddress": "100.64.0.3"
      },
      "responseElements": {
        "x-amz-request-id": "m3zvo0cm-5239xd-bhj",
        "x-amz-id-2": "m3zvo0cm-5239xd-bhj"
      }
    }
  ]
}
```

Multicloud Object Gateway bucket replication

Data replication from one Multicloud Object Gateway (MCG) bucket to another MCG bucket provides higher resiliency and better collaboration options. These buckets can be either data buckets or namespace buckets backed by any supported storage solution (S3, Azure, and so on). Replicate a bucket to another bucket and set replication policies using command-line interface and YAML.

A replication policy is composed of a list of replication rules. Each rule defines the destination bucket, and can specify a filter based on an object key prefix. Configuring a complementing replication policy on the second bucket results in bidirectional replication.

Replicating a bucket to another bucket

This section describes how to replicate one bucket to another using CLI and YAML.

You can set the bucket replication policy in two ways:

- [Replicating a bucket to another bucket using the MCG command-line interface.](#)
- [Replicating a bucket to another bucket using a YAML.](#)
- [Replicating a bucket to another bucket using the MCG command-line interface](#)
Provide higher resiliency and better collaboration options by replicating a bucket to another bucket using the MCG command-line interface.

- [Replicating a bucket to another bucket using a YAML](#)
Provide higher resiliency and better collaboration options by replicating a bucket to another bucket using the a YAML file.

Replicating a bucket to another bucket using the MCG command-line interface

Provide higher resiliency and better collaboration options by replicating a bucket to another bucket using the MCG command-line interface.

Before you begin

- Ensure you have a running Fusion Data Foundation Platform.
- Download the MCG command-line interface for easier management.

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-x86_64-rpms  
  
yum install mcg
```

Note: Specify the appropriate architecture for enabling the repositories using the subscription manager. In case of IBM Z infrastructure, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-s390x-rpms
```

- Alternatively, you can install the MCG package from the RPMs found at [Download Red Hat® OpenShift® Data Foundation page](#).

Note: Choose the correct Product Variant according to your architecture.

About this task

Applications that require a Multicloud Object Gateway (MCG) bucket to have a specific replication policy can create an Object Bucket Claim (OBC) and define the replication policy parameter in a JSON file.

Procedure

From the MCG command-line interface, run the following command to create an OBC with a specific replication policy:

```
odf noobaa obc create <bucket-claim-name> -n openshift-storage --replication-policy /path/to/json-file.json
```

bucket-claim-name

Specify the name of the bucket claim.

/path/to/json-file.json

Is the path to a JSON file which defines the replication policy.

Example JSON file:

```
{ "rule_id": "rule-1", "destination_bucket": "first.bucket", "filter": { "prefix": "repl" } }
```

"prefix"

(Optional:) It is the prefix of the object keys that should be replicated, and you can even leave it empty, for example, { "prefix": "" }.
For example:

```
odf noobaa obc create my-bucket-claim -n openshift-storage --replication-policy /path/to/json-file.json
```

Replicating a bucket to another bucket using a YAML

Provide higher resiliency and better collaboration options by replicating a bucket to another bucket using the a YAML file.

Before you begin

- Ensure you have a running Fusion Data Foundation Platform.
- Download the MCG command-line interface for easier management.

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-x86_64-rpms  
  
yum install mcg
```

Note: Specify the appropriate architecture for enabling the repositories using the subscription manager. In case of IBM Z infrastructure, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-s390x-rpms
```

- Alternatively, you can install the MCG package from the RPMs found at [Download Red Hat® OpenShift® Data Foundation page](#).

Note: Choose the correct Product Variant according to your architecture.

About this task

Applications that require a Multicloud Object Gateway (MCG) data bucket to have a specific replication policy can create an Object Bucket Claim (OBC) and add the spec.additionalConfig.replication-policy parameter to the OBC. For more information about OBCs, see [Object Bucket Claim](#).

Procedure

Apply the following YAML:

```
apiVersion: objectbucket.io/v1alpha1
kind: ObjectBucketClaim
metadata:
  name: <desired-bucket-claim>
  namespace: <desired-namespace>
spec:
  generateBucketName: <desired-bucket-name>
  storageClassName: openshift-storage.noobaa.io
  additionalConfig:
    replication-policy: [{ "rule_id": "<rule id>", "destination_bucket": "first.bucket", "filter": {"prefix": "<object name prefix>"} }]
```

desired-bucket-claim

Specify the name of the bucket claim.

desired-namespace

Specify the namespace.

desired-bucket-name

Specify the prefix of the bucket name.

rule_id

Specify the ID number of the rule, for example, {"rule_id": "rule-1"}.

destination_bucket

Specify the name of the destination bucket, for example, {"destination_bucket": "first.bucket"}.

object name prefix

(Optional:) It is the prefix of the object keys that should be replicated, and you can even leave it empty, for example, {"prefix": ""}.

Setting a bucket class replication policy

Set a bucket class replication policy to automatically replicate all buckets created under a bucket class using the MCG command-line interface or a YAML file.

It is possible to set up a replication policy that automatically applies to all the buckets created under a certain bucket class. You can do this in two ways:

- [Setting a bucket class replication policy using the MCG command-line interface.](#)
- [Setting a bucket class replication policy using a YAML.](#)
- [Setting a bucket class replication policy using the MCG command-line interface](#)
Provide higher resiliency and better collaboration options by setting a bucket class replication policy using the MCG command-line interface.
- [Setting a bucket class replication policy using a YAML](#)
Provide higher resiliency and better collaboration options by setting a bucket class replication policy using a YAML file.

Setting a bucket class replication policy using the MCG command-line interface

Provide higher resiliency and better collaboration options by setting a bucket class replication policy using the MCG command-line interface.

Before you begin

- Ensure you have a running Fusion Data Foundation Platform.
- Download the MCG command-line interface for easier management.

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-x86_64-rpms
```

```
yum install mcg
```

Note: Specify the appropriate architecture for enabling the repositories using the subscription manager. In case of IBM Z infrastructure, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-s390x-rpms
```

- Alternatively, you can install the MCG package from the RPMs found at [Download Red Hat® OpenShift® Data Foundation page](#).

Note: Choose the correct Product Variant according to your architecture.

About this task

Applications that require a Multicloud Object Gateway (MCG) bucket class to have a specific replication policy can create a `bucketclass` and define the replication-policy parameter in a JSON file.

It is possible to set a bucket class replication policy for two types of bucket classes:

- Placement

- Namespace

Procedure

From the MCG command-line interface, run the following command:

```
odf noobaa -n openshift-storage bucketclass create placement-bucketclass <bucketclass-name> --backingstores <backingstores> --replication-policy=/path/to/json-file.json
```

bucketclass-name

Specify the name of the bucket class.

backingstores

Specify the name of a backingstore. It is possible to pass several backingstores separated by commas.

/path/to/json-file.json

Is the path to a JSON file which defines the replication policy.

Example JSON file:

```
{ "rule_id": "rule-1", "destination_bucket": "first.bucket", "filter": { "prefix": "repl" } }
```

"prefix"

(Optional:) It is the prefix of the object keys that should be replicated, and you can even leave it empty, for example, {**"prefix": ""**}.

For example:

```
noobaa -n openshift-storage bucketclass create placement-bucketclass bc --backingstores azure-blob-ns --replication-policy=/path/to/json-file.json
```

This example creates a placement bucket class with a specific replication policy defined in the JSON file.

Setting a bucket class replication policy using a YAML

Provide higher resiliency and better collaboration options by setting a bucket class replication policy using a YAML file.

Before you begin

- Ensure you have a running Fusion Data Foundation Platform.
- Download the MCG command-line interface for easier management.

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-x86_64-rpms
```

```
yum install mcg
```

Note: Specify the appropriate architecture for enabling the repositories using the subscription manager. In case of IBM Z infrastructure, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-s390x-rpms
```

- Alternatively, you can install the MCG package from the RPMs found at [Download Red Hat® OpenShift® Data Foundation page](#).

Note: Choose the correct Product Variant according to your architecture.

About this task

Applications that require a Multicloud Object Gateway (MCG) bucket class to have a specific replication policy can create a bucket class using the spec.replicationPolicy field.

Procedure

Apply the following YAML:

```
apiVersion: noobaa.io/v1alpha1
kind: BucketClass
metadata:
  labels:
    app: <desired-app-label>
    name: <desired-bucketclass-name>
    namespace: <desired-namespace>
spec:
  placementPolicy:
    tiers:
      - backingstores:
          - <backingstore>
        placement: Spread
    replicationPolicy: [ { "rule_id": "<rule id>", "destination_bucket": "first.bucket", "filter": { "prefix": "<object name prefix>" } } ]
```

This YAML is an example that creates a placement bucket class. Each Object bucket claim (OBC) object that is uploaded to the bucket is filtered based on the prefix and is replicated to **first.bucket**.

desired-app-label

Specify a label for the app.

desired-bucketclass-name

Specify the bucket class name.

desired-namespace

Specify the namespace in which the bucket class gets created.

backingstore

Specify the name of a backingstore. It is possible to pass several backingstores.

rule_id

Specify the ID number of the rule, for example, `~{"rule_id": "rule-1"}`.

destination_bucket

Specify the name of the destination bucket, for example, `{"destination_bucket": "first.bucket"}`.

object name prefix

(Optional:) It is the prefix of the object keys that should be replicated, and you can even leave it empty, for example, `{"prefix": ""}`.

Enabling log based bucket replication

This section provides information about the log based bucket replication.

When creating a bucket replication policy, you can use logs so that recent data is replicated more quickly, while the default scan-based replication works on replicating the rest of the data.

Important:

This feature requires setting up bucket logs on AWS or Azure. For more information about setting up AWS logs, see [Enabling Amazon S3 server access logging](#). The AWS logs bucket needs to be created in the same region as the source NamespaceStore AWS bucket.

Note:

This feature is only supported in buckets that are backed by a NamespaceStore. Buckets backed by BackingStores cannot utilize log-based replication.

- [Enabling log based bucket replication for new namespace buckets using OpenShift Web Console in AWS environment](#)
You can optimize replication by using the event logs of the Amazon Web Service(AWS) cloud environment. You enable log based bucket replication for new namespace buckets using the web console during the creation of namespace buckets.
- [Enabling log based bucket replication for existing namespace buckets using YAML](#)
Enable log-based bucket replication for existing namespace buckets by editing the OBC YAML to add a replication policy with a destination bucket and a log bucket location.
- [Enabling log based bucket replication in Microsoft Azure](#)
Enable log-based bucket replication to a Microsoft Azure namespace store by registering an Azure application, creating the required NamespaceStore, and applying the replication policy.
- [Enabling log-based bucket replication deletion](#)
Enable deletion synchronization for log-based bucket replication so that objects deleted in the source bucket are also removed from the destination bucket.

Enabling log based bucket replication for new namespace buckets using OpenShift Web Console in AWS environment

You can optimize replication by using the event logs of the Amazon Web Service(AWS) cloud environment. You enable log based bucket replication for new namespace buckets using the web console during the creation of namespace buckets.

Before you begin

- Ensure that object logging is enabled in AWS. For more information, see the “Using the S3 console” section in [Enabling Amazon S3 server access logging](#).
- Administrator access to OpenShift® Web Console.

About this task

Procedure

1. In the OpenShift Web Console, navigate to **Storage → Object Storage → Object Bucket Claims**.
2. Click **Create ObjectBucketClaim**.
3. Enter the name of ObjectBucketName and select StorageClass and BucketClass.
4. Select the **Enable replication** check box to enable replication.
5. In the **Replication policy** section, select the **Optimize replication using event logs** check box.
6. Enter the name of the bucket that contains the logs under **Event log Bucket**.
If the logs are not stored in the root of the bucket, provide the full path without `s3://`
7. Enter a prefix to replicate only the objects whose name begins with the given prefix.

Enabling log based bucket replication for existing namespace buckets using YAML

Enable log-based bucket replication for existing namespace buckets by editing the OBC YAML to add a replication policy with a destination bucket and a log bucket location.

About this task

You can enable log based bucket replication for the existing buckets that are created using the command line interface or by applying an YAML, and not the buckets that are created using AWS S3 commands.

Procedure

Edit the YAML of the bucket's OBC to enable log based bucket replication. Add the following under **spec**:

```
replicationPolicy: '{"rules":[{"rule_id":"<RULE ID>", "destination_bucket":"<DEST>", "filter": {"prefix": "<PREFIX>"}]},
"log_replication_info": {"logs_location": {"logs_bucket": "<LOGS_BUCKET>"}}}'

rule_id
  Specify an ID of your choice for identifying the rule
destination_bucket
  Specify the name of the target MCG bucket that the objects are copied to
(optional) {"filter": {"prefix": "<>"}}
  Specify a prefix string that you can set to filter the objects that are replicated
log_replication_info
  Specify an object that contains data related to log-based replication optimization. {"logs_location": {"logs_bucket": "<>"}} is set to the location of the
  AWS S3 server access logs.
```

Enabling log based bucket replication in Microsoft Azure

Enable log-based bucket replication to a Microsoft Azure namespace store by registering an Azure application, creating the required NamespaceStore, and applying the replication policy.

Before you begin

- Refer to Microsoft Azure documentation and ensure that you have completed the following tasks in the Microsoft Azure portal:
 - Ensure that have created a new application and noted down the name, application (client) ID, and directory (tenant) ID.

For information, see [Register an application](#).
 - Ensure that a new client secret is created and the application secret is noted down.
 - Ensure that a new Log Analytics workspace is created and its name and workspace ID is noted down.

For information, see [Create a Log Analytics workspace](#).
 - Ensure that the **Reader** role is assigned under **Access control** and members are selected and the name of the application that you registered in the previous step is provided.

For more information, see [Assign Azure roles using the Azure portal](#).
 - Ensure that a new storage account is created and the Access keys are noted down.
 - In the **Monitoring** section of the storage account created, select a blob and in the **Diagnostic settings** screen, select only **StorageWrite** and **StorageDelete**, and in the destination details add the Log Analytics workspace that you created earlier. Ensure that a blob is selected in the **Diagnostic settings** screen of the **Monitoring** section of the storage account created. Also, ensure that only **StorageWrite** and **StorageDelete** is selected and in the destination details, the Log Analytics workspace that you created earlier is added.

For more information, see [Diagnostic settings in Azure Monitor](#).
 - Ensure that two new containers for object source and object destination are created.
- Administrator access to OpenShift® Web Console.

Procedure

- Create a secret with credentials to be used by the **namespacestores**.

```
apiVersion: v1
kind: Secret
metadata:
  name: <namespacestore-secret-name>
type: Opaque
data:
  TenantID: <AZURE TENANT ID ENCODED IN BASE64>
  ApplicationID: <AZURE APPLICATION ID ENCODED IN BASE64>
  ApplicationSecret: <AZURE APPLICATION SECRET ENCODED IN BASE64>
  LogsAnalyticsWorkspaceID: <AZURE LOG ANALYTICS WORKSPACE ID ENCODED IN BASE64>
  AccountName: <AZURE ACCOUNT NAME ENCODED IN BASE64>
  AccountKey: <AZURE ACCOUNT KEY ENCODED IN BASE64>
```

- Create a **NamespaceStore** backed by a container created in Azure.
For more information, see [Adding a namespace bucket using the OpenShift Container Platform user interface](#).
- Create a new Namespace-Bucketclass and OBC that utilizes it.
- Check the object bucket name by looking in the YAML of target OBC, or by listing all S3 buckets, for example, - **s3 ls**.

5. Use the following template to apply an Azure replication policy on your source OBC by adding the following in its YAML, under `.spec`:

```
replicationPolicy: '{"rules": [ {"rule_id": "ID goes here", "sync_deletions": "<true or false>"', "destination_bucket": object
bucket name"}
], "log_replication_info": {"endpoint_type": "AZURE"}}'
```

sync_deletion
Specify a boolean value, `true` or `false`.

destination_bucket
Ensure to use the name of the object bucket, and not the claim. The name can be retrieved using the `s3 ls` command, or by looking for the value in an OBC's YAML.

What to do next

- **Verification steps:**
 1. Write objects to the source bucket.
 2. Wait until MCG replicates them.
 3. Delete the objects from the source bucket.
 4. Verify the objects were removed from the target bucket.

Enabling log-based bucket replication deletion

Enable deletion synchronization for log-based bucket replication so that objects deleted in the source bucket are also removed from the destination bucket.

Before you begin

- Administrator access to OpenShift® Web Console.
- AWS Server Access Logging configured for the desired bucket.

Procedure

1. In the OpenShift Web Console, navigate to `Storage > Object Storage > Object Bucket Claims`.
2. Click `Create new Object bucket claim`.
3. Optional: In the `Replication rules` section, select the `Sync deletion` checkbox for each rule separately.
4. Enter the name of the bucket that contains the logs under `Event log Bucket`.
If the logs are not stored in the root of the bucket, provide the full path without `s3://`.
5. Enter a prefix to replicate only the objects whose name begins with the given prefix.

Bucket logging for Multicloud Object Gateway

Bucket logging helps in recording the S3 operations that are performed against the Multicloud Object Gateway (MCG) bucket for compliance, auditing, and optimization purposes.

Bucket logging supports the following two options:

- **Best-Effort:** Bucket logging is recorded by using the Unified Data Platform (UDP) on a best-effort basis.
- **Guaranteed:** Bucket logging with this option creates a PersistentVolumeClaim (PVC) attached to the MCG pods and saves the logs to this PVC on a guaranteed basis, and then from the PVC to the log buckets. When this option is used, logging occurs twice for each S3 operation, as follows:
 - At the start of processing the request.
 - At the end, with the result of the S3 operation.
- **[Enabling bucket logging by using the Best-Effort option](#)**
Use the NooBaa API or the S3 API to enable bucket logging for the best-effort option.
- **[Enabling bucket logging by using the Guaranteed option](#)**
Use the default CephFS storage class or ReadWriteMany PersistentVolumeClaim (RWX PVC) to enable bucket logging for the guaranteed option.

Enabling bucket logging by using the Best-Effort option

Use the NooBaa API or the S3 API to enable bucket logging for the best-effort option.

Before you begin

- Ensure that you installed the OpenShift Container Platform with the Fusion Data Foundation operator.
- Ensure that you have access to MCG.

For more information, see [Accessing the Multicloud Object Gateway with your applications](#).

Procedure

1. Create a data bucket where you can upload the objects.

```
odf nb bucket create data.bucket
```

2. Create a log bucket where you want to store the logs for bucket operations.

```
odf nb bucket create log.bucket
```

3. Configure bucket logging on data bucket with log bucket.

You can configure bucket logging by using the NooBaa API or the S3 API.

- By using the NooBaa API:

```
odf nb api bucket_api put_bucket_logging '{
  "name": "data.bucket",
  "log_bucket": "log.bucket",
  "log_prefix": "data-bucket-logs"
}'
```

- By using the S3 API:

- Define an alias for the S3 API command.

```
alias s3api_alias='AWS_ACCESS_KEY_ID=$NOOBAA_ACCESS_KEY AWS_SECRET_ACCESS_KEY=$NOOBAA_SECRET_KEY aws --endpoint
https://localhost:10443 --no-verify-ssl s3api'
```

- Create a setlogging.json file in the following format:

```
{
  "LoggingEnabled": {
    "TargetBucket": "<log-bucket-name>",
    "TargetPrefix": "<prefix/empty-string>"
  }
}
```

- Configure bucket logging based on settings defined in the setlogging.json file.

```
s3api_alias put-bucket-logging --endpoint <ep> --bucket <source-bucket> --bucket-logging-status
file://setlogging.json --no-verify-ssl
```

4. Verify whether the bucket logging is set for the data bucket in one of the following ways:

- By using the NooBaa API:

```
odf nb api bucket_api get_bucket_logging '{
  "name": "data.bucket"
}'
```

- By using the S3 API:

```
s3api_alias get-bucket-logging --no-verify-ssl --endpoint <ep> --bucket <source-bucket>
```

The S3 operations can take up to 24 hours to get recorded in the logs bucket. The following example shows the recorded logs and how to download them:

```
s3_alias cp s3://logs.bucket/data-bucket-logs/logs.bucket.bucket_data-bucket-logs_1719230150.log - | tail -n 2
```

```
Jun 24 14:00:02 10-XXX-X-XXX.sts.openshift-storage.svc.cluster.local
{"noobaa_bucket_logging": "true", "op": "GET", "bucket_owner": "operator@noobaa.io", "source_bucket": "data.bucket", "object_
key": "/data.bucket?list-type=2&prefix=data-bucket-logs&delimiter=%2F&encoding-
type=url", "log_bucket": "logs.bucket", "remote_ip": "100.XX.X.X", "request_uri": "/data.bucket?list-type=2&prefix=data-
bucket-logs&delimiter=%2F&encoding-type=url", "request_id": "luv2XXXX-ctyg2k-12gs"} Jun 24 14:00:06 10-XXX-X-
XXX.s3.openshift-storage.svc.cluster.local
{"noobaa_bucket_logging": "true", "op": "PUT", "bucket_owner": "operator@noobaa.io", "source_bucket": "data.bucket", "object_
key": "/data.bucket/B69EC83F-0177-44D8-A8D1-
4A10C5A5AB0F.file", "log_bucket": "logs.bucket", "remote_ip": "100.XX.X.X", "request_uri": "/data.bucket/B69EC83F-0177-
44D8-A8D1-4A10C5A5AB0F.file", "request_id": "luv2XXXX-9syas5-x5z"}
```

5. Optional: To disable bucket logging, run the following command:

```
odf nb api bucket_api delete_bucket_logging '{
  "name": "data.bucket"
}'
```

Enabling bucket logging by using the Guaranteed option

Use the default CephFS storage class or ReadWriteMany PersistentVolumeClaim (RWX PVC) to enable bucket logging for the guaranteed option.

Enable guaranteed bucket logging by using the NooBaa Custom Resource (CR) in one of the following ways:

- By using the default Cepheus storage class:

```
bucketLogging:
{
  loggingType: guaranteed
}
```

- By using the RWX PVC that you created:

Important: Ensure that the PVC supports RWX.

```
bucketLogging:
{
  loggingType: guaranteed
}
```

```
bucketLoggingPVC: <pvc-name>
}
```

Synchronizing versions in Multicloud Object Gateway bucket replication

Learn how to synchronize versions in Multicloud Object Gateway (MCG) bucket replication.

Before you begin

- A Multicloud Object Gateway (MCG) source bucket, which is created from an object bucket claim (OBC) and any MCG target bucket. For example, you can create the two buckets using OBCs using the MCG command line interface (CLI):

Create a source bucket using an OBC:

```
odf noobaa obc create source-bucket --exact
odf noobaa obc create target-bucket --exact
```

Where, `--exact` is optional.

- Ensure that S3 client aliases with MCG credentials and endpoint are set up.

```
NOOBAA_ACCESS_KEY=$(oc extract secret/noobaa-admin -n openshift-storage --keys=AWS_ACCESS_KEY_ID --to=- 2>/dev/null); \
NOOBAA_SECRET_KEY=$(oc extract secret/noobaa-admin -n openshift-storage --keys=AWS_SECRET_ACCESS_KEY --to=- 2>/dev/null); \
S3_ENDPOINT=https://$(oc get route s3 -n openshift-storage -o json | jq -r ".spec.host")

alias common_s3='AWS_ACCESS_KEY_ID=$NOOBAA_ACCESS_KEY AWS_SECRET_ACCESS_KEY=$NOOBAA_SECRET_KEY aws --endpoint $S3_ENDPOINT \
--no-verify-ssl'; \
alias s3_alias='common_s3 s3'; \
alias s3api_alias='common_s3 s3api'
```

- Ensure to enable versioning on both the source and target bucket by using the `put-bucket-versioning` command in the AWS S3 client:

```
s3api_alias put-bucket-versioning --bucket source-bucket --versioning-configuration Status=Enabled

s3api_alias put-bucket-versioning --bucket target-bucket --versioning-configuration Status=Enabled
```

Procedure

1. Patch or edit a replication policy with `sync_versions: true` to the source bucket's OBC:

```
oc patch obc source-bucket -n openshift-storage --type=merge -p '{"spec": {"additionalConfig": {"replicationPolicy": " \
{"rules\":[{"rule_id\":"replication-rule-a\","destination_bucket\":"target-bucket\","sync_versions\":"true"}]}}'}
```

Normal bucket replication replicates only the latest version, and the use of `sync_versions` add the functionality of replicating even the older versions, and in their original order.

Note:

- Delete markers are replicated if configured and using log base replication.
- Delete version IDs are not replicated to avoid human errors.

2. Verify the replication to the target bucket by adding a few versions under an object key and waiting for them to get replicated to the target bucket:

```
echo 'version_a' | s3_alias cp - s3://source-bucket/versioned_obj.txt
echo 'version_b' | s3_alias cp - s3://source-bucket/versioned_obj.txt
echo 'version_c' | s3_alias cp - s3://source-bucket/versioned_obj.txt
```

After a few minutes, compare the versions of the object on both the buckets:

```
s3api_alias list-object-versions --bucket source-bucket --prefix versioned_obj.txt | jq -r ".Versions[].ETag"
"aaabf266d38a8e995cef03c13ee9a7f1"
"181d8a23f59939c0cdddec1692e05cdf3"
"ebc538cc6ffa04a39263f4b1be2f832f"

s3api_alias list-object-versions --bucket target-bucket --prefix versioned_obj.txt | jq -r ".Versions[].ETag"
"aaabf266d38a8e995cef03c13ee9a7f1"
"181d8a23f59939c0cdddec1692e05cdf3"
"ebc538cc6ffa04a39263f4b1be2f832f"
```

Obtaining metrics to reflect bucket replication state

Learn how to obtain bucket-level replication metrics to evaluate replication progress.

About this task

To determine if the data is safe or available on the secondary site, the replication progress per bucket is provided using the following metrics:

- Total number of objects scanned in the last replication cycle per bucket - `bucket_last_cycle_total_objects_num{bucket="bucket-name"}`
- Number of objects successfully replicated in the last cycle per bucket - `bucket_last_cycle_replicated_objects_num{bucket="bucket-name"}`
- Number of objects that failed replication in the last cycle per bucket - `bucket_last_cycle_error_objects_num{bucket="bucket-name"}`

Procedure

1. Use the following commands to obtain the metrics:

```
JWT_TOKEN=$(oc get secret noobaa-metrics-auth-secret -n openshift-storage -o jsonpath="{.data.metrics_token}" | base64 -d)

oc -n openshift-storage exec noobaa-core-0 - curl -k -H "Authorization: Bearer ${JWT_TOKEN}" localhost:8080/metrics/bg_workers
```

For example:

```
noobaa-operator$ oc -n openshift-storage exec -it noobaa-core-0 -- curl -k -H "Authorization: Bearer ${JWT_TOKEN}" http://localhost:8080/metrics/bg_workers | grep -E "bucket_name" | grep -v "NooBaa_replication_status"
Defaulted container "core" out of: core, noobaa-log-processor

NooBaa_bucket_last_cycle_total_objects_num{bucket_name="test-buck1"} 15
NooBaa_bucket_last_cycle_total_objects_num{bucket_name="test-buck2"} 25
NooBaa_bucket_last_cycle_replicated_objects_num{bucket_name="test-buck1"} 15
NooBaa_bucket_last_cycle_replicated_objects_num{bucket_name="test-buck2"} 25
NooBaa_bucket_last_cycle_error_objects_num{bucket_name="test-buck1"} 0
NooBaa_bucket_last_cycle_error_objects_num{bucket_name="test-buck2"} 0
```

2. Use the following syntax to view the metrics in the metrics section:

```
metric_name {bucket_name='bucket_name'}
```

For example:

For NooBaa_bucket_last_cycle_total_objects_num

```
NooBaa_bucket_last_cycle_total_objects_num {bucket_name='bubck1'}
```

For NooBaa_bucket_last_cycle_replicated_objects_num

```
NooBaa_bucket_last_cycle_replicated_objects_num {bucket_name='bubck1'}
```

For NooBaa_bucket_last_cycle_error_objects_num

```
NooBaa_bucket_last_cycle_error_objects_num {bucket_name='bubck1'}
```

Managing S3 Vectors

S3 Vectors provide native vector-database storage capabilities within the Multicloud Object Gateway (MCG), enabling you to store and manage vector embeddings for machine learning and AI applications.

Note: Starting with Fusion Data Foundation 4.22, S3 Vectors are supported in the MCG.

- [S3 Vectors in Multicloud Object Gateway](#)
S3 Vectors provide native vector-database storage capabilities within the Multicloud Object Gateway (MCG). Vector buckets enable you to store and manage vector embeddings for machine learning and AI applications, backed by NSFS (NamespaceStore FileSystem) storage.
- [Creating a vector BucketClass](#)

S3 Vectors in Multicloud Object Gateway

S3 Vectors provide native vector-database storage capabilities within the Multicloud Object Gateway (MCG). Vector buckets enable you to store and manage vector embeddings for machine learning and AI applications, backed by NSFS (NamespaceStore FileSystem) storage.

Note: Starting with Fusion Data Foundation 4.22, S3 Vectors are supported in the MCG, enabling native vector-database storage for machine learning and AI applications, backed by NSFS (NamespaceStore FileSystem) storage.

Vector buckets are specialized buckets designed for storing vector data, which is commonly used in the following workloads:

- Machine learning model embeddings
- Semantic search applications
- Recommendation systems
- Natural language processing (NLP) workloads
- AI-powered applications

Vector buckets are provisioned through the standard ObjectBucketClaim (OBC) flow and are managed using the AWS S3 Vectors CLI.

Currently, MCG supports **Lance** as the vector database type. Lance is a modern columnar data format optimized for machine learning workloads.

Vector buckets integrate with MCG object storage infrastructure, with vector data stored on filesystem-based NamespaceStores for optimal performance. You can use familiar OBC workflows to create vector buckets and manage vector data using standard AWS CLI tools.

Vector buckets require the following components:

- An NSFS NamespaceStore that provides the underlying filesystem storage for vector data
- A Vector BucketClass that defines the vector policy, including the backing NamespaceStore and vector database type
- A Vector ObjectBucketClaim that provisions the vector bucket with the appropriate configuration

Limitations

- Only NSFS NamespaceStores are supported as the backing resource.
- Only **lance** is supported as the vector database type.
- Bucket tagging and quota are not yet supported for vector buckets.
- Vector BucketClass updates (spec changes) are not supported.

Creating a vector BucketClass

Create a vector BucketClass to define the storage policy for vector buckets, specifying the NSFS NamespaceStore resource and the vector database type.

Before you begin

- A running Fusion Data Foundation cluster with Multicloud Object Gateway (MCG).
- An NSFS NamespaceStore is created. For more information, see [Creating a NamespaceStore to use a file system](#).

Procedure

1. From the OpenShift® Container Platform web console, go to **Storage > Object Storage > Bucket Class**.
2. Click **Create Bucket Class**.
3. On the **Create new Bucket Class** page, complete the following steps:
 - a. Enter a Bucket Class Name.
 - b. Select **Vector** as the BucketClass type.
 - c. Click **Next**.
4. On the **Placement Policy** page, complete the following steps:
 - a. Select the NSFS NamespaceStore from the **Read and Write NamespaceStore** dropdown list.
Note: Only filesystem (NSFS) NamespaceStores are available for vector bucket classes. Other NamespaceStore types are not supported.
 - b. Click **Next**.
5. Review your configuration and click **Create Bucket Class**.
6. To verify the creation of the vector bucket class, complete the following steps:
 - a. Go to **Storage > Object Storage > Bucket Class**.
 - b. Verify that your newly created vector bucket class is in the **Ready** phase.

Results

The vector bucket class is created successfully.

For more information about creating vector buckets by using the bucket class, see [Creating vector buckets using ObjectBucketClaim](#).

Creating vector buckets using ObjectBucketClaim

Create vector buckets using ObjectBucketClaim (OBC) to provision storage for vector data in machine learning and AI applications.

Before you begin

- A running Fusion Data Foundation cluster with Multicloud Object Gateway (MCG).
- A vector BucketClass is created. For more information, see [Creating a vector BucketClass](#).
- AWS CLI v2.34.23 or later is installed (for **s3vectors** subcommand support).

Procedure

1. From the OpenShift® Container Platform web console, go to **Storage > Object Storage > ObjectBucketClaims**.
2. Click the **S3 Vector** card.
3. On the **Create ObjectBucketClaim** page, complete the following steps:
 - a. Enter an ObjectBucketClaim Name.
 - b. Select the StorageClass as **openshift-storage.noobaa.io**.
 - c. Select the vector BucketClass that you created earlier from the drop down list.
Note: Only BucketClasses that define a **vectorPolicy** are listed. BucketClasses without **vectorPolicy** are excluded.
 - d. Optional: Enter a Path in the **Additional Configuration** section to specify a subdirectory path inside the NSFS PVC where vector data is stored.
Important: If you specify a path, ensure that the directory exists on the filesystem under the PV mount path.
 - e. Click **Create**.
4. To verify the creation of the vector bucket, complete the following steps:

- a. Navigate to Storage > Object Storage > ObjectBucketClaims.
- b. Verify that your ObjectBucketClaim is in the Bound phase.
- c. Click the ObjectBucketClaim name to view details, including the bucket name and credentials.

Results

The vector bucket is created successfully.

What to do next

To manage vector indexes in your vector bucket, see [Managing vector indexes](#).

Creating vector buckets using the S3 API

Create vector buckets directly using the S3 API through the Multicloud Object Gateway (MCG) object browser interface.

Before you begin

- A running Fusion Data Foundation cluster with MCG.
- A vector BucketClass is created. For more information, see [Creating a vector BucketClass](#).
- Access to the MCG object browser. For more information, see [Accessing the object browser](#).

Procedure

1. From the OpenShift® Container Platform web console, go to Storage > Object Storage.
2. From the Object Storage page, choose the Buckets tab, then click the MultiCloud Object Gateway (MCG) tab.
3. Click the S3 Vector tab.
4. Click Create bucket.
5. Select Create via S3 API.
6. On the bucket creation form, complete the following steps:
 - a. Enter a Bucket Name.
 - b. Select the vector BucketClass from the drop down list.
Note: Only BucketClasses that define a **vectorPolicy** are listed. When you create vector buckets through the S3 API, the NamespaceStore list is restricted to filesystem (NSFS) NamespaceStores.
 - c. Optional: Configure additional settings as needed.
 - d. Click Create.
7. To verify the creation of the vector bucket, complete the following steps:
 - a. Go to Storage > Object Storage > Buckets, then click MultiCloud Object Gateway (MCG) and select the S3 Vector tab.
 - b. Verify that your newly created vector bucket is listed.
 - c. Click the bucket name to view details and access the Vector indexes tab.

Results

The vector bucket is created successfully.

What to do next

To manage vector indexes in your vector bucket, see [Managing vector indexes](#).

Managing vector indexes

Vector indexes store and organize vector embeddings within a vector bucket. You can create, list, view details, and delete vector indexes using the Multicloud Object Gateway (MCG) object browser.

The following prerequisites apply to all vector index management operations:

- A running Fusion Data Foundation cluster with MCG.
- A vector bucket is created. For more information, see [Creating vector buckets using ObjectBucketClaim](#).
- Access to the MCG object browser. For more information, see [Accessing the object browser](#).
- [Listing vector indexes](#)
View all vector indexes within a vector bucket using the Multicloud Object Gateway (MCG) object browser.
- [Creating a vector index](#)
Create a new vector index within a vector bucket using the Multicloud Object Gateway (MCG) object browser.
- [Viewing vector index details](#)
View the details of a vector index within a vector bucket using the Multicloud Object Gateway (MCG) object browser.
- [Deleting a vector index](#)
Delete a vector index from a vector bucket using the Multicloud Object Gateway (MCG) object browser.

Listing vector indexes

View all vector indexes within a vector bucket using the Multicloud Object Gateway (MCG) object browser.

Before you begin

- A running Fusion Data Foundation cluster with MCG.
- A vector bucket is created. For more information, see [Creating vector buckets using ObjectBucketClaim](#).
- Access to the MCG object browser. For more information, see [Accessing the object browser](#).

Procedure

1. From the OpenShift® Container Platform web console, go to Storage > Object Storage.
2. From the Object Storage page, choose the Buckets tab, then click the MultiCloud Object Gateway (MCG) tab.
3. Click the required vector bucket name.
4. Select the Vector indexes tab.
The page displays up to 100 vector indexes. If there are more than 100 vector indexes, use the Next and Previous buttons in the upper-right of the table to navigate between pages.

Creating a vector index

Create a new vector index within a vector bucket using the Multicloud Object Gateway (MCG) object browser.

Before you begin

- A running Fusion Data Foundation cluster with MCG.
- A vector bucket is created. For more information, see [Creating vector buckets using ObjectBucketClaim](#).
- Access to the MCG object browser. For more information, see [Accessing the object browser](#).

Procedure

1. From the OpenShift® Container Platform web console, go to Storage > Object Storage.
2. From the Object Storage page, choose the Buckets tab, then click the MultiCloud Object Gateway (MCG) tab.
3. Click the required vector bucket name.
4. Select the Vector indexes tab.
5. Click Create index.
6. On the Create index form, complete the following steps:
 - a. Enter an Index Name.
 - b. Enter the Dimension.
 - c. Enter the Distance Metric.
 - d. Provide up to 10 metadata keys.
 - e. Click Create.

Results

The newly created vector index appears in the Vector indexes tab list.

Viewing vector index details

View the details of a vector index within a vector bucket using the Multicloud Object Gateway (MCG) object browser.

Before you begin

- A running Fusion Data Foundation cluster with MCG.
- A vector bucket is created. For more information, see [Creating vector buckets using ObjectBucketClaim](#).
- Access to the MCG object browser. For more information, see [Accessing the object browser](#).

Procedure

1. From the OpenShift® Container Platform web console, go to Storage > Object Storage.
2. From the Object Storage page, choose the Buckets tab, then click the MultiCloud Object Gateway (MCG) tab.
3. Click the required vector bucket name.
4. Select the Vector indexes tab.
5. Click the row that corresponds to the vector index you want to view.
The vector index details page displays information about the index, including its name, description, creation time, and other properties.

Deleting a vector index

Delete a vector index from a vector bucket using the Multicloud Object Gateway (MCG) object browser.

Before you begin

Important: You must delete all vector indexes in a vector bucket before you can delete the bucket.

- A running Fusion Data Foundation cluster with MCG.
- A vector bucket is created. For more information, see [Creating vector buckets using ObjectBucketClaim](#).
- Access to the MCG object browser. For more information, see [Accessing the object browser](#).

Procedure

1. From the OpenShift® Container Platform web console, go to Storage > Object Storage.
2. From the Object Storage page, choose the Buckets tab, then click the MultiCloud Object Gateway (MCG) tab.
3. Click the required vector bucket name.
4. Select the Vector indexes tab.
5. Select the overflow menu corresponding to the vector index you want to delete.
6. Select Delete index.
7. In the confirmation dialog, enter the vector index name to confirm deletion.
8. Click Delete.

Results

The deleted vector index no longer appears in the Vector indexes tab list.

Deleting vector buckets

Delete vector buckets when they are no longer needed. Before deleting a vector bucket, you must first delete all vector indexes within the bucket.

Before you begin

- A running Fusion Data Foundation cluster with Multicloud Object Gateway (MCG).
- Access to the MCG object browser. For more information, see [Accessing the object browser](#).
- All vector indexes in the bucket are deleted. For more information, see [Deleting a vector index](#).

Procedure

1. From the OpenShift® Container Platform web console, go to Storage > Object Storage.
 2. From the Object Storage page, choose the Buckets tab, then click the MultiCloud Object Gateway (MCG) tab.
 3. Select the overflow menu corresponding to the vector bucket you want to delete.
 4. Select Delete bucket.
 5. In the confirmation dialog, enter the vector bucket name to confirm deletion.
 6. Click Delete bucket.
- Note: If the bucket contains vector indexes, you receive an error message. Delete all vector indexes first before you attempt to delete the bucket.

Results

The deleted vector bucket no longer appears in the S3 Vector buckets list.

Object Bucket Claim

An Object Bucket Claim can be used to request an S3 compatible bucket backend for your workloads. An object bucket claim creates a new bucket and an application account in NooBaa with permissions to the bucket, including a new access key and secret access key. The application account is allowed to access only a single bucket and can't create new buckets by default. Use this information to create, view, and delete object bucket claims.

Object Bucket Claim can be created in three ways: dynamically, using the command line interface, and using OpenShift® Web Console.

- **[Dynamic Object Bucket Claim](#)**
Similar to Persistent Volumes, you can add the details of the Object Bucket claim (OBC) to your application's YAML, and get the object service endpoint, access key, and secret access key available in a configuration map and secret. It is easy to read this information dynamically into environment variables of your application. Use this information to add the details of the Object Bucket claim (OBC) to your application's YAML.
- **[Creating an Object Bucket Claim using the command line interface](#)**
Use this information to create an Object Bucket Claim using the command line interface.
- **[Creating an Object Bucket Claim using the OpenShift Container Platform](#)**
Use this information to create an Object Bucket Claim using the OpenShift Container Platform web console.
- **[Attaching an Object Bucket Claim to a deployment](#)**
Use this information to attach an Object Bucket Claim (OBC) to a deployment. Attaching to specific deployments can only be done after the OBCs are created.

- [Viewing object buckets using the OpenShift Web Console](#)

You can view the details of object buckets created for Object Bucket Claims (OBCs) using the OpenShift Web Console.

- [Deleting Object Bucket Claims](#)

When you no longer need the Object Bucket Claims, you can delete it from the namespace using Open Shift Web Console.

Dynamic Object Bucket Claim

Similar to Persistent Volumes, you can add the details of the Object Bucket claim (OBC) to your application's YAML, and get the object service endpoint, access key, and secret access key available in a configuration map and secret. It is easy to read this information dynamically into environment variables of your application. Use this information to add the details of the Object Bucket claim (OBC) to your application's YAML.

About this task

Note: The Multicloud Object Gateway endpoints uses self-signed certificates only if OpenShift® uses self-signed certificates. Using signed certificates in OpenShift automatically replaces the Multicloud Object Gateway endpoints certificates with signed certificates. Get the certificate currently used by Multicloud Object Gateway by accessing the endpoint through the browser. For more information, see [Accessing the Multicloud Object Gateway with your applications](#).

Procedure

1. Add the following line to your application YAML:

These lines are the OBC itself.

```
apiVersion: objectbucket.io/v1alpha1
kind: ObjectBucketClaim
metadata:
  name: <obc-name>
spec:
  generateBucketName: <obc-bucket-name>
  storageClassName: openshift-storage.noobaa.io
```

<obc-name>

Use a unique OBC name.

<obc-bucket-name>

Use a unique bucket name for your OBC.

2. To automate the use of OBC, add more lines to the YAML file.

For example:

```
apiVersion: batch/v1
kind: Job
metadata:
  name: testjob
spec:
  template:
    spec:
      restartPolicy: OnFailure
      containers:
      - image: <your application image>
        name: test
        env:
        - name: BUCKET_NAME
          valueFrom:
            configMapKeyRef:
              name: <obc-name>
              key: BUCKET_NAME
        - name: BUCKET_HOST
          valueFrom:
            configMapKeyRef:
              name: <obc-name>
              key: BUCKET_HOST
        - name: BUCKET_PORT
          valueFrom:
            configMapKeyRef:
              name: <obc-name>
              key: BUCKET_PORT
        - name: AWS_ACCESS_KEY_ID
          valueFrom:
            secretKeyRef:
              name: <obc-name>
              key: AWS_ACCESS_KEY_ID
        - name: AWS_SECRET_ACCESS_KEY
          valueFrom:
            secretKeyRef:
              name: <obc-name>
              key: AWS_SECRET_ACCESS_KEY
```

The example is the mapping between the bucket claim result, which is a configuration map with data and a secret with the credentials. This specific job claims the Object Bucket from NooBaa, which creates a bucket and an account.

<obc-name>

Use your OBC name.

<your application image>

Use your application image.

3. Apply the updated YAML file, where <yaml.file> is the name of your YAML file.

```
oc apply -f <yaml.file>
```

4. To view the new configuration map, run the following command, where *<obc-name>* is the name of your OBC.

```
oc get cm <obc-name> -o yaml
```

Expect the following environment variables in the output:

BUCKET_HOST

Endpoint to use in the application.

BUCKET_HOST

The port is related to the *BUCKET_HOST*. For example, if the *BUCKET_HOST* is `https://my.example.com`, and the *BUCKET_PORT* is 443, the endpoint for the object service would be `https://my.example.com:443`.

BUCKET_NAME

Requested or generated bucket name.

AWS_ACCESS_KEY_ID

Access key that is part of the credentials.

AWS_SECRET_ACCESS_KEY

Secret access key that is part of the credentials.

Important: Retrieve the *AWS_ACCESS_KEY_ID* and *AWS_SECRET_ACCESS_KEY*. The names are used so that it is compatible with the AWS S3 API. You need to specify the keys while performing S3 operations, especially when you read, write or list from the Multicloud Object Gateway (MCG) bucket. The keys are encoded in Base64.

Decode the keys before using them, using the following command, where *<obc_name>* specifies the name of the object bucket claim:

```
oc get secret <obc_name> -o yaml
```

Creating an Object Bucket Claim using the command line interface

Use this information to create an Object Bucket Claim using the command line interface.

Before you begin

Download the Multicloud Object Gateway (MCG) command-line interface.

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-x86_64-rpms
yum install mcg
```

Note: Specify the appropriate architecture for enabling the repositories using the subscription manager.

- For IBM Power, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-ppc64le-rpms
```

- For IBM Z infrastructure, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-s390x-rpms
```

About this task

When creating an Object Bucket Claim (OBC) using the command-line interface, you get a configuration map and a Secret that together contain all the information your application needs to use the object storage service.

Procedure

1. Use the command-line interface to generate the details of a new bucket and credentials.

```
odf noobaa obc create <obc-name> -n openshift-storage
```

Replace *<obc-name>* with a unique OBC name, for example, `myappobc`.

Additionally, you can use the `--app-namespace` option to specify the namespace where the OBC configuration map and secret is created, for example, `myapp-namespace`.

For example:

```
INFO[0001] ✓ Created: ObjectBucketClaim "test2lobc"
```

2. Run the following command to view the OBC.

```
oc get obc -n openshift-storage
```

Example output:

NAME	STORAGE-CLASS	PHASE	AGE
test2lobc	openshift-storage.noobaa.io	Bound	38s

3. Run the following command to view the YAML file for the new OBC.

```
oc get obc test2lobc -o yaml -n openshift-storage
```

Example YAML output:

```

apiVersion: objectbucket.io/v1alpha1
kind: ObjectBucketClaim
metadata:
  creationTimestamp: "2019-10-24T13:30:07Z"
  finalizers:
  - objectbucket.io/finalizer
  generation: 2
  labels:
    app: noobaa
    bucket-provisioner: openshift-storage.noobaa.io-obc
    noobaa-domain: openshift-storage.noobaa.io
  name: test2lobc
  namespace: openshift-storage
  resourceVersion: "40756"
  selfLink: /apis/objectbucket.io/v1alpha1/namespaces/openshift-storage/objectbucketclaims/test2lobc
  uid: 64f04cba-f662-11e9-bc3c-0295250841af
spec:
  ObjectBucketName: obc-openshift-storage-test2lobc
  bucketName: test2lobc-933348a6-e267-4f82-82f1-e59bf4fe3bb4
  generateBucketName: test2lobc
  storageClassName: openshift-storage.noobaa.io
status:
  phase: Bound

```

4. Inside of your `openshift-storage` namespace, you can find the configuration map and the secret to use this OBC. The CM and the secret have the same name as the OBC.

```
oc get -n openshift-storage secret test2lobc -o yaml
```

For example:

```

apiVersion: v1
data:
  AWS_ACCESS_KEY_ID: c0M0R2xVanF3ODR3bHBkVW94cmY=
  AWS_SECRET_ACCESS_KEY: Wi9kcFluSWxHRzlwFlzNk1hc0xma2JXcjM1MVhqa051S1BleXpmOQ==
kind: Secret
metadata:
  creationTimestamp: "2019-10-24T13:30:07Z"
  finalizers:
  - objectbucket.io/finalizer
  labels:
    app: noobaa
    bucket-provisioner: openshift-storage.noobaa.io-obc
    noobaa-domain: openshift-storage.noobaa.io
  name: test2lobc
  namespace: openshift-storage
  ownerReferences:
  - apiVersion: objectbucket.io/v1alpha1
    blockOwnerDeletion: true
    controller: true
    kind: ObjectBucketClaim
    name: test2lobc
    uid: 64f04cba-f662-11e9-bc3c-0295250841af
  resourceVersion: "40751"
  selfLink: /api/v1/namespaces/openshift-storage/secrets/test2lobc
  uid: 65117c1c-f662-11e9-9094-0a5305de57bb
type: Opaque

```

The secret gives you S3 access credentials.

5. Run the following command to see the configuration map:

```
oc get -n openshift-storage cm test2lobc -o yaml
```

For example:

```

apiVersion: v1
data:
  BUCKET_HOST: 10.0.171.35
  BUCKET_NAME: test2lobc-933348a6-e267-4f82-82f1-e59bf4fe3bb4
  BUCKET_PORT: "31242"
  BUCKET_REGION: ""
  BUCKET_SUBREGION: ""
kind: ConfigMap
metadata:
  creationTimestamp: "2019-10-24T13:30:07Z"
  finalizers:
  - objectbucket.io/finalizer
  labels:
    app: noobaa
    bucket-provisioner: openshift-storage.noobaa.io-obc
    noobaa-domain: openshift-storage.noobaa.io
  name: test2lobc
  namespace: openshift-storage
  ownerReferences:
  - apiVersion: objectbucket.io/v1alpha1
    blockOwnerDeletion: true
    controller: true
    kind: ObjectBucketClaim
    name: test2lobc
    uid: 64f04cba-f662-11e9-bc3c-0295250841af
  resourceVersion: "40752"
  selfLink: /api/v1/namespaces/openshift-storage/configmaps/test2lobc
  uid: 651c6501-f662-11e9-9094-0a5305de57bb

```

The configuration map contains the S3 endpoint information for your application.

Creating an Object Bucket Claim using the OpenShift Container Platform

Use this information to create an Object Bucket Claim using the OpenShift Container Platform web console.

Before you begin

Ensure you have the following:

- Administrative access to the OpenShift Container Platform web console.
- In order for your applications to communicate with the OBC, you need to use the configmap and secret. For more information, see [Dynamic Object Bucket Claim](#).

Procedure

From the OpenShift Container Platform web console, go to Storage > Object Bucket Claims.

1. Choose the bucket type:
 - Click the General card to create a standard object bucket claim.
 - Click the S3 Vector card to create a vector bucket claim for storing vector embeddings. For more information, see [Creating vector buckets using ObjectBucketClaim](#).
2. Click Create Object Bucket Claim.
3. Enter a name for your object bucket claim.
4. Select the appropriate storage class based on your deployment, either internal or external, from the drop-down menu.
 - **Internal mode**
The following storage classes, which were created after deployment, are available for use:

`ocs-storagecluster-ceph-rgw`
Uses the Ceph Object Gateway (RGW).
`openshift-storage.noobaa.io`
Uses the Multicloud Object Gateway (MCG).
 - **External mode**
The following storage classes, which were created after deployment, are available for use:

`ocs-external-storagecluster-ceph-rgw`
uses the RGW.
`openshift-storage.noobaa.io`
Uses the MCG.

Note: The RGW OBC storage class is only available with fresh installations of Fusion Data Foundation. It does not apply to clusters upgraded from previous Red Hat® OpenShift Data Foundation releases.
5. Click Create.
After you create the OBC, you are redirected to its detail page.

Attaching an Object Bucket Claim to a deployment

Use this information to attach an Object Bucket Claim (OBC) to a deployment. Attaching to specific deployments can only be done after the OBCs are created.

Before you begin

Ensure you have Administrative access to the OpenShift® Web Console.

Procedure

1. Go to Storage > Object Bucket Claim.
2. Click the Action menu next to Object Bucket Claim (OBC) you want to delete.
 - a. From the drop-down menu, select Attach to deployment.
 - b. Select the desired deployment from the Deployment Name list, then click Attach.

Viewing object buckets using the OpenShift Web Console

You can view the details of object buckets created for Object Bucket Claims (OBCs) using the OpenShift® Web Console.

Before you begin

Ensure you have Administrative access to the OpenShift Web Console.

Procedure

1. Log into the Open Shift Web Console and go to Storage > Object Buckets.
Alternatively, you can also navigate to the details page of a specific OBC, and click the Resource link to view the object buckets for that OBC.

2. Select the object bucket of which you want to see the details.
After selected you are navigated to the Object Bucket Details page.

Deleting Object Bucket Claims

When you no longer need the Object Bucket Claims, you can delete it from the namespace using Open Shift Web Console.

Before you begin

Ensure you have Administrative access to the OpenShift® Web Console.

Procedure

1. Go to Storage > Object Bucket Claims.
2. From next to the Object Bucket Claim (OBC) you want to delete, click Action Menu > Delete Object Bucket Claim
3. Click Delete.

Object Bucket Claims on hosted clusters

Object Bucket Claims (OBCs) on hosted clusters enable application administrators to request S3-compatible object storage buckets directly from a client cluster that is connected to a Fusion Data Foundation 4.22 (or later) provider cluster.

In Fusion Data Foundation provider mode, a central provider cluster runs a full NooBaa installation and serves object storage to one or more client (hosted) clusters through the OCS client operator. Starting with Fusion Data Foundation 4.22, application administrators on client clusters can create and delete OBCs without requiring the storage administrator to perform those actions on the provider cluster.

When an application administrator creates an OBC on a client cluster, the OCS client operator sends a gRPC notification to the OCS provider server on the provider cluster. The provider server creates the OBC on the provider cluster with an obscured name and adds labels that link it to the originating client cluster and storage consumer. NooBaa provisions the bucket on the provider cluster and the resulting resources (the Object Bucket (OB), a Secret, and a ConfigMap) are copied back to the client cluster. The OBC on the client cluster transitions to **Bound** status when all resources are in place.

Supported operations

The following OBC operations are supported on client clusters:

- Create an OBC (greenfield: new bucket only)
- Delete an OBC

Limitations

The following limitations apply to OBC support on hosted clusters:

- Only NooBaa OBCs backed by a backingstore and data buckets are supported. Namespace stores and namespace buckets are not supported.
- Only new buckets (greenfield) are supported. Existing buckets (brownfield) cannot be attached to an OBC on a client cluster.
- Updating an existing OBC is not supported.
- The MCG command-line interface (CLI) is not available on client clusters.
- OBC credential regeneration from the client cluster is not supported. A storage administrator can regenerate OBC credentials from the provider cluster using the MCG CLI. For more information, see [Regenerating OBC credentials for a client cluster OBC](#).
- Migration from a provider cluster OBC to a client cluster OBC is not supported.
- An application cluster must have a single storage client.
- Object storage consumption is not included in the storage quota enforced for block and file storage on the storage consumer.

Alerts

OBC-related alerts, including `ObcQuotaBytesAlert`, `ObcQuotaBytesExhaustedAlert`, `ObcQuotaObjectsAlert`, and `ObcQuotaObjectsExhaustedAlert`, fire on the provider cluster. They are not visible on the client cluster. The provider cluster administrator monitors these alerts on behalf of all client clusters.

Storage class distribution

The NooBaa storage class (`openshift-storage.noobaa.io`) must be distributed to each storage consumer. The provider cluster administrator can distribute the default NooBaa storage class or additional NooBaa storage classes to specific storage consumers. For more information, see [Distributing the NooBaa storage class to a client cluster](#).

Client cluster offboarding

A client cluster that has active OBCs cannot be offboarded. You must delete all OBCs on the client cluster before the storage client can be removed. If the provider cluster administrator force-deletes a storage consumer, all associated OBCs on the provider cluster are deleted as part of that operation.

Object browser

Starting with Fusion Data Foundation 4.22, users on client clusters can also use the object browser in the OpenShift® Container Platform Web Console to browse and manage buckets and objects on the provider's NooBaa endpoint. Data operations such as uploading and downloading objects require additional one-time configuration. For more information, see [Object browser on client clusters](#).

- [Enabling Object Bucket Claim support on a client cluster](#)
Install the Object Bucket (OB) and Object Bucket Claim (OBC) custom resource definitions (CRDs) on a client cluster so that application administrators can create OBCs. This procedure applies to Fusion Data Foundation 4.22 and later.
- [Distributing the NooBaa storage class to a client cluster](#)
Distribute the NooBaa storage class from the provider cluster to a client cluster so that application administrators on the client cluster can create Object Bucket Claims (OBCs). This procedure applies to Fusion Data Foundation 4.22 and later.
- [Creating an Object Bucket Claim on a client cluster](#)
Create an Object Bucket Claim (OBC) on a client cluster to provision an S3-compatible object storage bucket backed by the NooBaa installation on the provider cluster. This procedure applies to Fusion Data Foundation 4.22 and later.
- [Deleting an Object Bucket Claim on a client cluster](#)
Delete an Object Bucket Claim (OBC) on a client cluster to remove the associated bucket and S3 credentials from both the client cluster and the provider cluster. This procedure applies to Fusion Data Foundation 4.22 and later.
- [Regenerating OBC credentials for a client cluster OBC](#)
Regenerate the S3 credentials for an Object Bucket Claim (OBC) that was created on a client cluster by running the MCG CLI on the provider cluster. This procedure applies to Fusion Data Foundation 4.22 and later.
- [Object browser on client clusters](#)
Client clusters in Fusion Data Foundation 4.22 (or later) provider mode can use the object browser in the OpenShift Container Platform Web Console to browse and manage buckets and objects served by the provider cluster's NooBaa endpoint.

Enabling Object Bucket Claim support on a client cluster

Install the Object Bucket (OB) and Object Bucket Claim (OBC) custom resource definitions (CRDs) on a client cluster so that application administrators can create OBCs. This procedure applies to Fusion Data Foundation 4.22 and later.

Before you begin

- The client cluster is onboarded and connected to the provider cluster. Verify the connection by running the following command on the client cluster:

```
oc get storageclient
```

The output must show a storage client with a **Connected** phase before you proceed.
- The Red Hat® OpenShift® Data Foundation CLI tool is installed on the client cluster. To download the Red Hat OpenShift Data Foundation CLI tool, see the [Red Hat Customer Portal](#).

Note: Download the latest Red Hat OpenShift Data Foundation CLI package from the Red Hat Customer Portal. No additional license is required to use the CLI tool. The latest CLI package works with earlier and later versions of Fusion Data Foundation, though newer CLI versions can include additional capabilities.
- You have administrator access to the client cluster.

About this task

Because NooBaa is not installed on client clusters, the OB and OBC CRDs are not present by default. You must install these CRDs using the Red Hat OpenShift Data Foundation CLI tool before application administrators can create OBCs on the client cluster.

Important: This step is required only once per client cluster. After the CRDs are installed, they persist across restarts and upgrades.

Procedure

1. On the client cluster, run the following Red Hat OpenShift Data Foundation CLI command to install the OB and OBC CRDs:

```
odf object enable remote-obc
```

The CLI confirms successful installation with the following output:

```
Info: CRD "objectbuckets.objectbucket.io" installed successfully
Info: CRD "objectbucketclaims.objectbucket.io" installed successfully
```

2. Verify that both CRDs are installed on the client cluster:

```
oc get crd | grep objectbucket.io
```

The output lists both CRDs:

```
objectbucketclaims.objectbucket.io    <timestamp>
objectbuckets.objectbucket.io          <timestamp>
```

What to do next

After the CRDs are installed, the provider cluster administrator must distribute the NooBaa storage class to the client cluster before application administrators can create OBCs. For instructions, see [Distributing the NooBaa storage class to a client cluster](#).

Distributing the NooBaa storage class to a client cluster

Distribute the NooBaa storage class from the provider cluster to a client cluster so that application administrators on the client cluster can create Object Bucket Claims (OBCs). This procedure applies to Fusion Data Foundation 4.22 and later.

Before you begin

- You have administrator access to the provider cluster.
- The OB and OBC CRDs are installed on the client cluster. For instructions, see [Enabling Object Bucket Claim support on a client cluster](#).
- A storage consumer exists on the provider cluster for the client cluster to be configured.

About this task

The NooBaa storage class (`openshift-storage.noobaa.io`) must be distributed to each storage consumer before application administrators on the client cluster can create OBCs. Use either of the following methods to distribute the default NooBaa storage class or any additional NooBaa storage classes to a storage consumer.

Procedure

1. Distribute the NooBaa storage class using one of the following methods:

- **OpenShift® Container Platform Web Console (UI method):**

- On the provider cluster, go to Storage > Storage Clients.
- Click the overflow menu (⋮) next to the storage consumer that corresponds to the target client cluster, and click Distribute resources.
- Click the Storage classes tab.
- Select the check box next to `openshift-storage.noobaa.io`, or next to any additional NooBaa storage class you want to distribute.
Note: The checkbox next to `openshift-storage.noobaa.io` may appear preselected in the UI, but the storage class is not distributed until you save the changes.
- Click Save.

- **Command line (CR edit method):**

- On the provider cluster, edit the storage consumer CR, replacing `<storage-consumer-name>` with the name of the storage consumer:

```
oc edit storageconsumer -n openshift-storage <storage-consumer-name>
```

- In the `storageClasses` list, add the NooBaa storage class entry. For example:

```
storageClasses:
- name: ocs-storagecluster-ceph-rbd
- name: ocs-storagecluster-cephfs
- name: openshift-storage.noobaa.io
```

- Save and close the editor.

2. On the client cluster, verify that the NooBaa storage class was distributed successfully:

```
oc get storageclass | grep noobaa
```

The output lists the NooBaa storage class:

```
openshift-storage.noobaa.io  openshift-storage.noobaa.io/obc  Delete  Immediate  false  <age>
```

What to do next

After the NooBaa storage class is distributed to the client cluster, application administrators can create OBCs on the client cluster. For instructions, see [Creating an Object Bucket Claim on a client cluster](#).

Creating an Object Bucket Claim on a client cluster

Create an Object Bucket Claim (OBC) on a client cluster to provision an S3-compatible object storage bucket backed by the NooBaa installation on the provider cluster. This procedure applies to Fusion Data Foundation 4.22 and later.

Before you begin

- The OB and OBC CRDs are installed on the client cluster. For instructions, see [Enabling Object Bucket Claim support on a client cluster](#).
- The NooBaa storage class is distributed to the client cluster. For instructions, see [Distributing the NooBaa storage class to a client cluster](#).
- You have administrator access to the client cluster.
- The namespace in which you want to create the OBC exists on the client cluster. If it does not exist, create it:

```
oc create ns <namespace-name>
```

About this task

When you create an OBC on the client cluster, the OCS client operator communicates with the provider cluster to provision the bucket. The resulting Secret and ConfigMap, which contain the S3 credentials and endpoint information, are automatically copied to the client cluster in the same namespace as the OBC.

Note: Only new buckets (greenfield) are supported. You cannot attach an existing bucket to an OBC on a client cluster.

Procedure

1. Create the OBC using one of the following methods:

- **Command line:**

Apply an OBC manifest, replacing the placeholder values with your own:

```
oc apply -f <path-to-obc-yaml>
```

Example OBC manifest:

```
apiVersion: objectbucket.io/v1alpha1
kind: ObjectBucketClaim
metadata:
  name: <obc-name>
  namespace: <namespace-name>
spec:
  generateBucketName: <bucket-name-prefix>
  storageClassName: openshift-storage.noobaa.io
```

<obc-name>

A unique name for the OBC.

<namespace-name>

The namespace in which to create the OBC.

<bucket-name-prefix>

A prefix used when generating the bucket name.

- **OpenShift® Container Platform Web Console:**

- On the client cluster, go to Storage > Object Storage > Object Bucket Claims.
- Click Create ObjectBucketClaim.
- Select the project in which you want to create the OBC.
- Enter a name for the OBC.
- Select **openshift-storage.noobaa.io**, or the applicable NooBaa storage class, from the storage class list.
- Click Create.

2. Verify that the OBC is in **Bound** status:

```
oc get obc -n <namespace-name>
```

The output shows the OBC with a **Bound** phase:

NAMESPACE	NAME	STORAGE-CLASS	PHASE	AGE
<namespace>	<obc-name>	openshift-storage.noobaa.io	Bound	<age>

3. Verify that the Secret and ConfigMap with the same name as the OBC are present in the namespace:

```
oc get secret <obc-name> -n <namespace-name>
oc get configmap <obc-name> -n <namespace-name>
```

Both resources are listed. The Secret contains the **AWS_ACCESS_KEY_ID** and **AWS_SECRET_ACCESS_KEY** credentials. The ConfigMap contains the S3 endpoint information, including **BUCKET_HOST**, **BUCKET_NAME**, and **BUCKET_PORT**.

4. Verify that the Object Bucket (OB) is in **Bound** status. The OB name follows the pattern **obc-<namespace-name>-<obc-name>**:

```
oc get ob obc-<namespace-name>-<obc-name>
```

The output shows the OB with a **Bound** phase:

NAME	STORAGE-CLASS	RECLAIM-POLICY	PHASE	AGE
obc-<namespace-name>-<obc-name>	openshift-storage.noobaa.io	Delete	Bound	<age>

Deleting an Object Bucket Claim on a client cluster

Delete an Object Bucket Claim (OBC) on a client cluster to remove the associated bucket and S3 credentials from both the client cluster and the provider cluster. This procedure applies to Fusion Data Foundation 4.22 and later.

Before you begin

- You have administrator access to the client cluster.
- The OBC you want to delete is in the **Bound** state.

About this task

When you delete an OBC on the client cluster, the OCS client operator notifies the provider cluster to delete the corresponding OBC, OB, Secret, and ConfigMap on the provider cluster. After deletion is complete, the OBC, OB, Secret, and ConfigMap are also removed from the client cluster.

Important: You must delete all OBCs on a client cluster before the storage client can be offboarded. Offboarding a client cluster that still has active OBCs is blocked until all OBCs are removed.

Procedure

1. Delete the OBC using one of the following methods:

- **Command line:**

```
oc delete obc <obc-name> -n <namespace-name>
```

- **OpenShift® Container Platform Web Console:**

- On the client cluster, go to Storage > Object Storage > Object Bucket Claims.
- Click the overflow menu (⋮) next to the OBC you want to delete, and click Delete Object Bucket Claim.
- In the confirmation dialog, click Delete.

2. Verify that the OBC no longer exists on the client cluster:

Note: Deletion may take a few minutes to complete. When an OBC is deleted, all objects in the bucket are also deleted on the provider cluster. The bucket, OBC account, and credentials are then removed on the provider cluster, and those changes are propagated back to the client cluster. Wait until this process completes before you verify the deletion.

```
oc get obc <obc-name> -n <namespace-name>
```

The command returns a **NotFound** error, confirming the OBC was deleted.

3. Verify that the Secret and ConfigMap with the same name as the OBC are also removed:

```
oc get secret <obc-name> -n <namespace-name>
oc get configmap <obc-name> -n <namespace-name>
```

Both commands return a **NotFound** error.

4. Verify that the Object Bucket (OB) is also removed:

```
oc get ob obc- <namespace-name>-<obc-name>
```

The command returns a **NotFound** error.

Regenerating OBC credentials for a client cluster OBC

Regenerate the S3 credentials for an Object Bucket Claim (OBC) that was created on a client cluster by running the MCG CLI on the provider cluster. This procedure applies to Fusion Data Foundation 4.22 and later.

Before you begin

- You have administrator access to the provider cluster.
- The MCG CLI (**noobaa**) is installed on the provider cluster.
- The OBC for which you want to regenerate credentials was created on a client cluster and is in the **Bound** state.

About this task

OBCs that are created on a client cluster are represented on the provider cluster with an obscured name and carry labels that identify the originating client cluster. Because the MCG CLI is not available on client clusters, credential regeneration must be performed from the provider cluster using the **--remote-obc** flag. After regeneration, the updated Secret is automatically propagated back to the client cluster.

Important: Regenerating credentials invalidates all existing S3 connections that use the current credentials. Plan this operation during a maintenance window or when the affected application can tolerate a brief interruption.

Procedure

1. On the provider cluster, list the OBCs to find the provider-side OBC name that corresponds to the client cluster OBC. Each client-side OBC has three labels on the provider cluster: **remote-obc-name**, **remote-obc-namespace**, and **remote-obc-uid**. Run the following command:

```
oc get obc -A --show-labels
```

The output lists all OBCs on the provider cluster with their labels. Identify the OBC whose **remote-obc-name** label matches the OBC name on the client cluster.

2. Regenerate the S3 credentials for the client cluster OBC by running the following command on the provider cluster, replacing **<provider-obc-name>** and **<provider-obc-namespace>** with the values identified in the previous step:

```
noobaa obc regenerate <provider-obc-name> -n <provider-obc-namespace> --remote-obc
```

The MCG CLI prompts you to confirm the operation before regenerating the credentials.

3. Enter **y** to confirm.

The MCG CLI regenerates the credentials and prints the updated connection information.

4. On the client cluster, verify that the Secret for the OBC contains the updated credentials. The Secret name matches the OBC name on the client cluster:

```
oc get secret <obc-name> -n <namespace-name> -o yaml
```

The **AWS_ACCESS_KEY_ID** and **AWS_SECRET_ACCESS_KEY** values in the Secret are updated with the new credentials.

Object browser on client clusters

Client clusters in Fusion Data Foundation 4.22 (or later) provider mode can use the object browser in the OpenShift® Container Platform Web Console to browse and manage buckets and objects served by the provider cluster's NooBaa endpoint.

Starting with Fusion Data Foundation 4.22, the object browser is available on client (hosted) clusters that are connected to a provider cluster running NooBaa.

Operation types

The object browser on a client cluster uses two communication paths, depending on the operation type:

Management operations

Operations such as listing buckets, configuring CORS rules, and managing bucket policies are forwarded from the browser through the OpenShift Container Platform Web Console proxy to the in-cluster Nginx reverse proxy, which is deployed as part of the `odf-client-console` pod on the client cluster. The reverse proxy then forwards the requests to the provider's S3 endpoint. These operations do not require direct browser-to-S3 connectivity.

Data operations

Operations such as uploading objects, downloading objects, previewing objects, and generating presigned URLs connect directly from the browser to the provider's S3 Route. Before you perform data operations, you must enable CORS for each bucket and ensure that your browser trusts the provider's S3 certificate. For more information, see [Enabling data operations in the object browser on a client cluster](#).

Prerequisites

Ensure that the following conditions are met before you use the object browser on a client cluster:

Client cluster connectivity

The client cluster must be connected to a Fusion Data Foundation 4.22 (or later) provider cluster that is running NooBaa.

Object browser access

You must have administrator or developer access to the OpenShift Container Platform Web Console on the client cluster. Developers must sign in to the object browser before performing any operation. For more information, see [Signing in to the object browser as a developer user](#).

Prerequisites for management operations

Management operations use the in-cluster Nginx reverse proxy and do not require CORS configuration or browser-level TLS trust. Ensure that the following additional condition is met before you perform management operations:

Proxy TLS trust (private or custom CA only)

If the provider S3 Route certificate is signed by a publicly trusted certificate authority (CA), no additional configuration is required. If the certificate uses a private or custom CA, the in-cluster Nginx reverse proxy cannot verify the S3 endpoint certificate and management operations fail. To resolve this, manually configure CA trust for the proxy by creating or updating the following Kubernetes `Secret` in the client operator namespace:

- **Secret name:** `ocs-client-operator-console-s3-endpoint-ca-certs`
- **Key:** `ocs-s3-endpoints-list-STORAGECLIENT_UID-noobaaS3.crt`
- **Value:** The root or intermediate CA certificate chain used to sign the provider S3 endpoint certificate.

Prerequisites for data operations

Complete the following prerequisites before you perform data operations from the client cluster object browser:

CORS enablement

Because the client console origin differs from the provider's S3 Route origin, the browser blocks direct data requests unless cross-origin resource sharing (CORS) is configured for the bucket. The object browser displays an Enable CORS alert when CORS is not yet configured. You can enable CORS directly from the bucket view in the object browser. CORS enablement is a one-time operation per bucket.

For instructions, see [Creating CORS rule](#).

Browser TLS trust

If the provider S3 Route certificate is signed by a publicly trusted certificate authority (CA), no additional configuration is required. If the certificate uses a private or custom CA, the browser blocks the connection until that CA is trusted. To resolve a certificate trust issue, use one of the following approaches:

- Configure the provider cluster ingress to use a certificate signed by a publicly trusted CA. For more information about replacing the default ingress certificate, see [Security, Security and compliance, Configuring certificates in Red Hat® OpenShift Container Platform](#) product documentation.
- Add the custom CA certificate chain to your operating system trust store. The exact steps depend on your operating system and browser.
- As a temporary workaround, open the S3 Route URL directly in your browser and accept the security warning. After the certificate is accepted, return to the client console tab and refresh the page.

Important: The TLS trust requirement applies per browser and operating system combination. This is a standard browser security requirement and is not specific to Fusion Data Foundation.

Limitations

The following limitations apply to the object browser on client clusters:

- Only the NooBaa endpoint on the provider cluster is accessible from the client object browser. RGW endpoints are not supported on client clusters.
- CORS must be enabled separately for each bucket on which you want to perform data operations.
- Browser trust of the provider S3 certificate is required for data operations when a private or custom CA is in use. This configuration is not automated.

- [Enabling data operations in the object browser on a client cluster](#)

Enable CORS and verify browser TLS trust so that you can upload, download, preview, and share objects using the object browser on a Fusion Data Foundation 4.22 and later client cluster.

Enabling data operations in the object browser on a client cluster

Enable CORS and verify browser TLS trust so that you can upload, download, preview, and share objects using the object browser on a Fusion Data Foundation 4.22 and later client cluster.

Before you begin

- The client cluster is connected to a Fusion Data Foundation 4.22 (or later) provider cluster running NooBaa.
- An Object Bucket Claim (OBC) exists on the client cluster and is in **Bound** status. For more information, see [Creating an Object Bucket Claim on a client cluster](#).
- Administrator or developer access to the client cluster OpenShift® Container Platform Web Console.

About this task

Data operations in the object browser connect the browser directly to the provider cluster's S3 Route. Two one-time configuration steps are required before data operations work: enabling CORS for each bucket and ensuring that the browser trusts the provider's S3 certificate. Management operations such as listing buckets and configuring policies are unaffected and work without these steps.

Procedure

1. In the OpenShift Container Platform Web Console on the client cluster, navigate to **Storage > Object Storage**.
2. Select the bucket on which you want to perform data operations.
3. If the object browser displays an Enable CORS alert, click **Enable CORS** to configure CORS for the bucket.
CORS enablement is a one-time operation per bucket. After CORS is enabled, the alert no longer appears for that bucket. For detailed CORS configuration options, see [Creating CORS rule](#).
4. Attempt a data operation such as uploading an object to verify that the browser can connect directly to the provider S3 endpoint.
If the browser displays a certificate error, the provider's S3 certificate is signed by a private or custom CA that your browser does not trust. Resolve the certificate trust issue by using one of the following methods:
 - Configure the provider cluster ingress to use a certificate signed by a publicly trusted CA. For more information, see the OpenShift Container Platform documentation on replacing the default ingress certificate.
 - Add the custom CA certificate chain to your operating system trust store. The exact steps depend on your operating system and browser.
 - As a temporary workaround, open the provider S3 Route URL directly in your browser and accept the security warning. After the certificate is accepted, return to the client console tab and refresh the page.**Important:** The TLS trust configuration is not automated. You must repeat this configuration for each browser and operating system combination from which you access the client object browser.
5. Verify that the data operation completes successfully.
After CORS is enabled and the provider certificate is trusted in your browser, data operations including uploading, downloading, previewing, and sharing objects work from the client cluster object browser.

Managing bucket quota

Bucket quota allows you to set limits on the number of objects and total storage size for buckets in the Multicloud Object Gateway (MCG), helping prevent resource starvation and enabling better capacity planning and cost control.

Note: Starting with Fusion Data Foundation 4.22, bucket quota is supported in MCG.

- [Bucket quota in Multicloud Object Gateway](#)
Multicloud Object Gateway (MCG) supports quota configuration for Object Bucket Claims (OBCs) and buckets to prevent resource starvation and optimize storage usage.
- [Setting quota on a BucketClass](#)
Set a default quota on a BucketClass so that every new bucket created under it inherits an individual quota limit.
- [Setting quota on an Object Bucket Claim using YAML](#)
Set quota limits on an Object Bucket Claim (OBC) to control the maximum number of objects and total storage size for a bucket.
- [Setting quota on an Object Bucket Claim using the CLI](#)
Create an Object Bucket Claim (OBC) with quota limits by using the Multicloud Object Gateway (MCG) command-line interface.
- [Setting quota on buckets](#)
Set quota limits directly on buckets by using the Multicloud Object Gateway (MCG) command-line interface.

Bucket quota in Multicloud Object Gateway

Multicloud Object Gateway (MCG) supports quota configuration for Object Bucket Claims (OBCs) and buckets to prevent resource starvation and optimize storage usage.

Note: Starting with Fusion Data Foundation 4.22, bucket quota is supported in MCG.

Quota configuration provides the following benefits:

- **Resource management:** Prevents individual buckets from consuming excessive storage resources.
- **Cost control:** Limits storage usage to control costs in cloud environments.
- **Multi-tenancy:** Ensures fair resource allocation across multiple applications and teams.
- **Capacity planning:** Enables better prediction and management of storage requirements.

Quota types

MCG supports two types of quota limits:

- **maxObjects:** Maximum number of objects allowed in a bucket.
- **maxSize:** Maximum total size of all objects in a bucket. You can specify the size using standard units such as **Gi** (gibibytes) or **Mi** (mebibytes).

Important:

MCG uses a non-strict quota mechanism:

- Quota calculations are based on statistics aggregation.

- Statistics calculation cycle runs every 2 minutes.
- Quota enforcement occurs after the next statistics calculation cycle completes.
- Clients may temporarily exceed quota limits until the next cycle runs.

Quota configuration levels

MCG supports quota configuration at three different levels:

BucketClass level

Applies to all OBCs and buckets created from that BucketClass. This is useful for setting default quotas for a category of buckets.

Object Bucket Claim (OBC) level

Applies to a specific OBC and its associated bucket. This provides fine-grained control for individual bucket claims.

Bucket level (Direct)

Applies directly to a specific bucket. This provides the highest level of control.

Quota precedence rules

When quotas are configured at both the OBC and BucketClass levels, the most restrictive (minimum) value is applied per dimension. For example, if a BucketClass sets `maxObjects: 1000` and the OBC sets `maxObjects: 2000`, the resulting bucket has a quota of 1000 objects.

Quotas set directly on a bucket through the CLI take effect immediately, but might be overwritten on the next OBC reconciliation (for example, OBC edit, operator restart). For OBC-managed buckets, always set quotas through the OBC or BucketClass rather than directly on the bucket.

Supported bucket types

Quota is only supported on regular (placement-based) buckets. Quota configuration is not supported on the following bucket types:

- Namespace buckets
- Cache buckets

Setting quota on a BucketClass

Set a default quota on a BucketClass so that every new bucket created under it inherits an individual quota limit.

You can set a default quota on a BucketClass so that every new bucket created under it inherits an individual quota limit. This is not a shared quota across buckets. Each bucket gets its own copy of the configured limits.

- [Creating a BucketClass with quota using YAML](#)
Create a BucketClass with quota limits by applying a YAML definition to your cluster.
- [Creating a BucketClass with quota using the CLI](#)
Create a BucketClass with quota limits by using the command-line interface.

Creating a BucketClass with quota using YAML

Create a BucketClass with quota limits by applying a YAML definition to your cluster.

Before you begin

- Download the Red Hat® OpenShift® Data Foundation CLI tool from the [Red Hat Customer Portal](#) and make it executable.
Note: Download the latest Red Hat OpenShift Data Foundation CLI package from the Red Hat Customer Portal. No additional license is required to use the CLI tool. The latest CLI package works with earlier and later versions of Fusion Data Foundation, though newer CLI versions can include additional capabilities.
- An existing backstore or the ability to create one.

Procedure

1. Create a YAML file with the BucketClass definition:

```
apiVersion: noobaa.io/v1alpha1
kind: BucketClass
metadata:
  name: <bucketclass-name>
  namespace: openshift-storage
spec:
  placementPolicy:
    tiers:
      - backingStores:
          - <backingstore-name>
  quota:
    maxSize: "<max-size>" # for example, "10Gi"
    maxObjects: "<max-objects>" # for example, "1000"
```

2. Apply the YAML file:

```
oc apply -f <bucketclass-file>.yaml
```

3. Check the BucketClass status to verify the quota configuration:

```
odf noobaa bucketclass status <bucketclass-name> -n openshift-storage
```

The output shows the quota values in the BucketClass configuration.

Results

The BucketClass is created with the specified quota limits.

Creating a BucketClass with quota using the CLI

Create a BucketClass with quota limits by using the command-line interface.

Before you begin

- Download the Red Hat® OpenShift® Data Foundation CLI tool from the [Red Hat Customer Portal](#) and make it executable.
Note: Download the latest Red Hat OpenShift Data Foundation CLI package from the Red Hat Customer Portal. No additional license is required to use the CLI tool. The latest CLI package works with earlier and later versions of Fusion Data Foundation, though newer CLI versions can include additional capabilities.
- An existing backingstore or the ability to create one.

Procedure

1. Create a BucketClass with quota limits:

```
odf noobaa bucketclass create placement-bucketclass <bucketclass-name> \
--backingstores <backingstore-name> \
--max-size <max-size> --max-objects <max-objects> \
-n openshift-storage
```

For example, to create a BucketClass with both object and size limits:

```
odf noobaa bucketclass create placement-bucketclass limited-bucketclass \
--backingstores noobaa-default-backing-store \
--max-size 10Gi --max-objects 1000 \
-n openshift-storage
```

2. Check the BucketClass status to verify the quota configuration:

```
odf noobaa bucketclass status <bucketclass-name> -n openshift-storage
```

The quota values appear in the BucketClass status output.

Note: If both the BucketClass and the OBC define quota, the most restrictive (minimum) value is applied per dimension.

Results

The BucketClass is created with the specified quota limits.

Setting quota on an Object Bucket Claim using YAML

Set quota limits on an Object Bucket Claim (OBC) to control the maximum number of objects and total storage size for a bucket.

Before you begin

- Access to the OpenShift® Container Platform cluster.
- An existing BucketClass or the default storage class.

About this task

Quotas set at the OBC level override any quotas defined at the BucketClass level.

Procedure

1. Create a YAML file for the OBC with quota configuration in the `spec.additionalConfig` section:

```
apiVersion: objectbucket.io/v1alpha1
kind: ObjectBucketClaim
metadata:
  name: my-limited-bucket
  namespace: my-app
spec:
  generateBucketName: my-bucket
  storageClassName: openshift-storage.noobaa.io
  additionalConfig:
    maxObjects: '20000'
    maxSize: 1Gi
```

The following parameters define the quota limits:

maxObjects
Maximum number of objects allowed in the bucket. Specify as a string value.

maxSize
Maximum total size of all objects in the bucket.

2. Apply the YAML file:

```
oc apply -f <obc-quota-file>.yaml
```

3. Verify that the OBC was created successfully:

```
oc get obc -n <namespace>
```

- [Updating quota on an existing Object Bucket Claim](#)
Update the quota limits on an existing Object Bucket Claim (OBC) by using the **oc patch** command.

Updating quota on an existing Object Bucket Claim

Update the quota limits on an existing Object Bucket Claim (OBC) by using the **oc patch** command.

Before you begin

- Access to the OpenShift® Container Platform cluster.
- An existing OBC with quota configured.

Procedure

1. To update the **maxObjects** quota, run the following command:

```
oc patch objectbucketclaim <obc-name> -n <namespace> \
--type merge \
-p '{"spec":{"additionalConfig": {"maxObjects":"50000"}}}'
```

2. To update the **maxSize** quota, run the following command:

```
oc patch objectbucketclaim <obc-name> -n <namespace> \
--type merge \
-p '{"spec":{"additionalConfig": {"maxSize":"10Gi"}}}'
```

3. To update both quota parameters, run the following command:

```
oc patch objectbucketclaim <obc-name> -n <namespace> \
--type merge \
-p '{"spec":{"additionalConfig": {"maxObjects":"30000", "maxSize":"5Gi"}}}'
```

4. Verify the quota configuration by viewing the OBC details:

```
oc get obc <obc-name> -n <namespace> -o yaml
```

The output shows the quota values in the **spec.additionalConfig** section.

Results

The quota limits on the OBC are updated.

Setting quota on an Object Bucket Claim using the CLI

Create an Object Bucket Claim (OBC) with quota limits by using the Multicloud Object Gateway (MCG) command-line interface.

Before you begin

Download the Red Hat® OpenShift® Data Foundation CLI tool from the [Red Hat Customer Portal](#) and make it executable.

Note: Download the latest Red Hat OpenShift Data Foundation CLI package from the Red Hat Customer Portal. No additional license is required to use the CLI tool. The latest CLI package works with earlier and later versions of Fusion Data Foundation, though newer CLI versions can include additional capabilities.

About this task

You can set the maximum number of objects and total storage size for a bucket at the time of creation.

Procedure

1. Create an OBC with quota limits by using the MCG CLI:

```
odf noobaa obc create <obc-name> \
--max-objects=<number> \
```

```
--max-size=<size> \  
-n openshift-storage
```

The following options define the quota limits:

```
--max-objects  
    Maximum number of objects allowed in the bucket (optional).  
--max-size  
    Maximum total size of all objects in the bucket.
```

For example, to create an OBC with both object and size limits:

```
odf noobaa obc create my-limited-bucket \  
--max-objects=20000 \  
--max-size=1Gi \  
-n openshift-storage
```

Example output:

```
INFO[0001] ✓ Created: ObjectBucketClaim "my-limited-bucket"
```

2. View the OBC details to confirm the quota configuration:

```
oc get obc <obc-name> -n openshift-storage -o yaml
```

The output shows the quota values in the `spec.additionalConfig` section:

```
spec:  
  additionalConfig:  
    maxObjects: "20000"  
    maxSize: 1Gi
```

Results

The OBC is created with the specified quota limits.

Setting quota on buckets

Set quota limits directly on buckets by using the Multicloud Object Gateway (MCG) command-line interface.

You can set quota limits directly on buckets by using the MCG CLI. This provides the highest level of control and overrides any quotas set at the Object Bucket Claim (OBC) level.

- [Creating a bucket with quota](#)
Create a new bucket with quota limits by using the **odf noobaa bucket create** command.
- [Updating quota on an existing bucket](#)
Update the quota limits on an existing bucket by using the **odf noobaa bucket update** command.

Creating a bucket with quota

Create a new bucket with quota limits by using the **odf noobaa bucket create** command.

Before you begin

- Download the Red Hat® OpenShift® Data Foundation CLI tool from the [Red Hat Customer Portal](#) and make it executable.
Note: Download the latest Red Hat OpenShift Data Foundation CLI package from the Red Hat Customer Portal. No additional license is required to use the CLI tool. The latest CLI package works with earlier and later versions of Fusion Data Foundation, though newer CLI versions can include additional capabilities.
- An existing bucket or the ability to create one.

Procedure

1. Create a bucket with quota limits:

```
odf noobaa bucket create <bucket-name> \  
--max-objects=<number> \  
--max-size=<size>
```

The following options define the quota limits:

- **--max-objects**: Maximum number of objects allowed in the bucket (optional).
- **--max-size**: Maximum total size of all objects in the bucket (optional).

For example, to create a bucket with both object and size limits:

```
odf noobaa bucket create production-data \  
--max-objects=50000 \  
--max-size=20Gi
```

For example, to create a bucket with a size limit only:

```
odf noobaa bucket create media-storage \  
--max-size=100Gi
```

For example, to create a bucket with an object limit only:

```
odf noobaa bucket create log-archive \
--max-objects=1000000
```

2. Check the bucket status to verify the quota configuration:

```
odf noobaa bucket status <bucket-name>
```

Results

The bucket is created with the specified quota limits.

Updating quota on an existing bucket

Update the quota limits on an existing bucket by using the **odf noobaa bucket update** command.

Before you begin

- Download the Red Hat® OpenShift® Data Foundation CLI tool from the [Red Hat Customer Portal](#) and make it executable.
Note: Download the latest Red Hat OpenShift Data Foundation CLI package from the Red Hat Customer Portal. No additional license is required to use the CLI tool. The latest CLI package works with earlier and later versions of Fusion Data Foundation, though newer CLI versions can include additional capabilities.
- An existing bucket with or without quota configured.

Procedure

1. Update the quota limits on an existing bucket:

```
odf noobaa bucket update <bucket-name> \
--max-objects=<number> \
--max-size=<size>
```

For example, to update both quota parameters:

```
odf noobaa bucket update production-data \
--max-objects=100000 \
--max-size=50Gi
```

2. Check the bucket status to verify the updated quota configuration:

```
odf noobaa bucket status <bucket-name>
```

Results

The quota limits on the bucket are updated.

Caching policy for object buckets

A cache bucket is a namespace bucket with a hub target and a cache target. The hub target is an S3 compatible large object storage bucket. The cache bucket is the local Multicloud Object Gateway bucket. You can create a cache bucket that caches an AWS bucket or an IBM COS bucket.

- [Creating an AWS cache bucket](#)
Create an AWS cache bucket.
- [Creating an IBM COS cache bucket](#)
Create an IBM COS cache bucket.

Creating an AWS cache bucket

Create an AWS cache bucket.

Before you begin

- A running Fusion Data Foundation Platform.
- Download the MCG command-line interface for easier management.

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-x86_64-rpms
yum install mcg
```

Note: Specify the appropriate architecture for enabling the repositories using the subscription manager. In case of IBM Z infrastructure, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-s390x-rpms
```

- Alternatively, you can install the MCG package from the RPMs found at [Download Red Hat® OpenShift® Data Foundation page](#).

Note: Choose the correct Product Variant according to your architecture.

About this task

This procedure describes creating a NamespaceStore. A NamespaceStore represents an underlying storage to be used as a read or write target for the data in the MCG namespace buckets.

Procedure

1. Create NamespaceStore in one of the following ways:

- From the MCG command-line interface, run the following command:

```
odf noobaa namespacestore create aws-s3 <namespacestore> --access-key <AWS ACCESS KEY> --secret-key <AWS SECRET ACCESS KEY> --target-bucket <bucket-name>
```

namespacestore

Name of the namespacestore

AWS ACCESS KEY and *AWS SECRET ACCESS KEY*

AWS access key ID and secret access key you created for this purpose.

bucket-name

An existing AWS bucket name. This argument tells the MCG which bucket to use as a target bucket for its backing store, and subsequently, data storage and administration.

- Add storage resources by applying a YAML.

- Create a secret with credentials, where *<namespacestore-secret-name>* is a unique name for the NamespaceStore secret.

```
apiVersion: v1
kind: Secret
metadata:
  name: <namespacestore-secret-name>
type: Opaque
data:
  AWS_ACCESS_KEY_ID: <AWS ACCESS KEY ID ENCODED IN BASE64>
  AWS_SECRET_ACCESS_KEY: <AWS SECRET ACCESS KEY ENCODED IN BASE64>
```

You must supply and encode your own AWS access key ID and secret access key using Base64, and use the results in place of *<AWS ACCESS KEY ID ENCODED IN BASE64>* and *<AWS SECRET ACCESS KEY ENCODED IN BASE64>*.

- Apply the following YAML:

```
apiVersion: noobaa.io/v1alpha1
kind: NamespaceStore
metadata:
  finalizers:
    - noobaa.io/finalizer
  labels:
    app: noobaa
    name: <namespacestore>
    namespace: openshift-storage
spec:
  awsS3:
    secret:
      name: <namespacestore-secret-name>
      namespace: <namespace-secret>
      targetBucket: <target-bucket>
    type: aws-s3
```

namespacestore

A unique name for the NamespaceStore secret.

namespacestore-secret-name

A name for the NamespaceStore secret created in the previous step.

namespace-secret

Namespace used to create the secret in the previous step.

target-bucket

the AWS S3 bucket you created for the NamespaceStore.

2. Run the following command to create a bucket class:

```
odf noobaa bucketclass create namespace-bucketclass cache <my-cache-bucket-class> --backingstores <backing-store> --hub-resource <namespacestore>
```

my-cache-bucket-class

A unique bucket class name.

backing-store

Name of the relevant backing store. You can also list more than one backing stores separated by commas.

namespacestore

Name of the NamespaceStore created in the previous step.

3. Run the following command to create a bucket using an Object Bucket Claim (OBC) resource that uses the bucket class defined in the previous step.

```
odf noobaa obc create <my-bucket-claim> my-app --bucketclass <custom-bucket-class>
```

my-bucket-claim

A unique object bucket claim name.

custom-bucket-class

Name of the bucket class created in the previous step.

Creating an IBM COS cache bucket

Create an IBM COS cache bucket.

Before you begin

- A running Fusion Data Foundation Platform.
- Download the MCG command-line interface for easier management.

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-x86_64-rpms
yum install mcg
```

Note: Specify the appropriate architecture for enabling the repositories using the subscription manager.

- For IBM Power, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-ppc64le-rpms
```

- For IBM Z infrastructure, use the following command:

```
subscription-manager repos --enable=rh-odf-4-for-rhel-8-s390x-rpms
```

- Alternatively, you can install the MCG package from the RPMs found at [Download Red Hat® OpenShift® Data Foundation page](#).

Note: Choose the correct Product Variant according to your architecture.

About this task

This procedure describes creating a NamespaceStore. A NamespaceStore represents an underlying storage to be used as a read or write target for the data in the MCG namespace buckets.

Procedure

1. Create NamespaceStore in one of the following ways:

- From the MCG command-line interface, run the following command:

```
odf noobaa namespacestore create ibm-cos <namespacestore> --endpoint <IBM COS ENDPOINT> --access-key <IBM ACCESS KEY> --
namespacestore
    Name of the NamespaceStore
IBM COS ENDPOINT
    An appropriate regional endpoint that corresponds to the location of the existing IBM bucket.
IBM ACCESS KEY and IBM SECRET ACCESS KEY
    IBM access key ID and secret access key you created for this purpose.
bucket-name
    An existing IBM bucket name. This argument tells the MCG which bucket to use as a target bucket for its backing store, and subsequently, data storage
    and administration.
```

- Add storage resources by applying a YAML.

- Create a secret with credentials, where <namespacestore-secret-name> is a unique name for the NamespaceStore secret.

```
apiVersion: v1
kind: Secret
metadata:
  name: <namespacestore-secret-name>
type: Opaque
data:
  IBM_COS_ACCESS_KEY_ID: <IBM COS ACCESS KEY ID ENCODED IN BASE64>
  IBM_COS_SECRET_ACCESS_KEY: <IBM COS SECRET ACCESS KEY ENCODED IN BASE64>
```

You must supply and encode your own IBM COS access key ID and secret access key using Base64, and use the results in place of <IBM COS ACCESS KEY ID ENCODED IN BASE64> and <IBM COS SECRET ACCESS KEY ENCODED IN BASE64>.

- Apply the following YAML:

```
apiVersion: noobaa.io/v1alpha1
kind: NamespaceStore
metadata:
  finalizers:
  - noobaa.io/finalizer
  labels:
    app: noobaa
    name: <namespacestore>
    namespace: openshift-storage
spec:
  s3Compatible:
    endpoint: <IBM COS ENDPOINT>
  secret:
    name: <backingstore-secret-name>
    namespace: <namespace-secret>
  signatureVersion: v2
```

```
targetBucket: <target-bucket>
type: ibm-cos
```

namespacestore

A unique name for the NamespaceStore secret.

IBM COS ENDPOINT

An appropriate regional endpoint that corresponds to the location of the existing IBM bucket.

backingstore-secret-name

A name for the backing store secret created in the previous step.

namespace-secret

Namespace used to create the secret in the previous step.

target-bucket

the IBM COS bucket you created for the NamespaceStore.

2. Run the following command to create a bucket class:

```
odf noobaa bucketclass create namespace-bucketclass cache <my-bucket-class> --backingstores <backing-store> --hub-resource <namespacestore>
```

my-bucket-class

A unique bucket class name.

backing-store

Name of the relevant backing store. You can also list more than one backing stores separated by commas.

namespacestore

Name of the NamespaceStore created in the previous step.

3. Run the following command to create a bucket using an Object Bucket Claim (OBC) resource that uses the bucket class defined in the previous step.

```
odf noobaa obc create <my-bucket-claim> my-app --bucketclass <custom-bucket-class>
```

my-bucket-claim

A unique object bucket claim name.

custom-bucket-class

Name of the bucket class created in the previous step.

Lifecycle bucket configuration in Multicloud Object Gateway

Multicloud Object Gateway (MCG) lifecycle provides a way to reduce storage costs due to accumulated data objects.

Deletion of expired objects is a simplified way that enables handling of unused data. Data expiration is a part of Amazon Web Services (AWS) lifecycle management and sets an expiration date for automatic deletion. The minimal time resolution of the lifecycle expiration is one day. For more information, see [Expiring objects](#).

AWS S3 API is used to configure lifecycle bucket in MCG. For information about the data bucket APIs and their support level, see [Support of Multicloud Object Gateway data bucket APIs](#).

There are a few limitations with the expiratation rule API for MCG in comparison with AWS:

- **ExpiredObjectDeleteMarker** is accepted but it is not processed.
- No option to define specific non-current version's expiration conditions

The expiration rule API for MCG doesn't support transition rules like AWS does for both current and noncurrent objects.

You can configure the bucket lifecycle by using the MCG object browser. For more information, see [Creating new lifecycle rules by using the object browser](#).

Scaling Multicloud Object Gateway performance

The Multicloud Object Gateway (MCG) performance may vary from one environment to another. In some cases, specific applications require faster performance which can be addressed by scaling S3 endpoints.

The MCG resource pool is a group of NooBaa daemon containers that provide two types of services enabled by default:

- Storage service
- S3 endpoint service

S3 endpoint service

The S3 endpoint is a service that every Multicloud Object Gateway (MCG) provides by default that handles the heavy lifting data digestion in the MCG. The endpoint service handles the inline data chunking, deduplication, compression, and encryption, and it accepts data placement instructions from the MCG.

- [Automatic scaling of MultiCloud Object Gateway endpoints](#)

The number of MultiCloud Object Gateway (MCG) endpoints scale automatically when the load on the MCG S3 service increases or decreases.

- [Autoscaling RGW in Fusion Data Foundation using HPA and KEDA](#)

Enable autoscaling for RGW (RADOS Gateway) in Fusion Data Foundation by integrating with OpenShift® Horizontal Pod Autoscaler (HPA) with KEDA (Kubernetes Event-Driven Autoscaling).

- [Scaling the Multicloud Object Gateway with storage nodes](#)

A storage node in the MCG is a NooBaa daemon container attached to one or more Persistent Volumes (PVs) and used for local object service data storage. NooBaa daemons can be deployed on Kubernetes nodes. This can be done by creating a Kubernetes pool consisting of `StatefulSet` pods.

- [Increasing CPU and memory for PV pool resources](#)

Multicloud Object Gateway (MCG) default configuration supports low resource consumption. However, when you need to increase CPU and memory to

accommodate specific workloads and to increase MCG performance for the workloads, it is possible to configure the required values for CPU and memory in the OpenShift Web Console.

Automatic scaling of MultiCloud Object Gateway endpoints

The number of MultiCloud Object Gateway (MCG) endpoints scale automatically when the load on the MCG S3 service increases or decreases.

Fusion Data Foundation clusters are deployed with one active MCG endpoint. Each MCG endpoint pod is configured by default with 1 CPU and 2Gi memory request, with limits matching the request. When the CPU load on the endpoint crosses over an 80% usage threshold for a consistent period of time, a second endpoint is deployed lowering the load on the first endpoint. When the average CPU load on both endpoints falls below the 80% threshold for a consistent period of time, one of the endpoints is deleted. This feature improves performance and serviceability of the MCG.

Autoscaling RGW in Fusion Data Foundation using HPA and KEDA

Enable autoscaling for RGW (RADOS Gateway) in Fusion Data Foundation by integrating with OpenShift® Horizontal Pod Autoscaler (HPA) with KEDA (Kubernetes Event-Driven Autoscaling).

Before you begin

- All resources described in this procedure (Roles, RoleBindings, TriggerAuthentication, ScaledObject, and so on) must be created in the **openshift-storage** namespace.
- Custom Metrics Autoscaler Operator version must be 2.6 or later.

Procedure

1. Install the Custom Metrics Autoscaler Operator.
 - a. Log in to the Red Hat® OpenShift Container Platform web console.
 - b. Click Ecosystem > Software Catalog.
 - c. Scroll or type Custom Metrics Autoscaler into the Filter by keyword box to find the Custom Metrics Autoscaler Operator.
 - d. Click Install.
2. Create a Custom Metrics Autoscaler controller and verify whether the following pods are running in the **openshift-keda** namespace:

```
oc get pods -n openshift-keda
```

NAME	READY	STATUS	RESTARTS	AGE
custom-metrics-autoscaler-operator-6cb698bb4d-nnpmj	1/1	Running	0	103m
keda-admission-c6d879546-twprp	1/1	Running	0	103m
keda-metrics-apiserver-68788fbd9b-h715n	1/1	Running	0	103m
keda-operator-664dc57859-mb49f	1/1	Running	0	20m

3. Configure Custom Metrics Autoscaler with the Thanos Query Service.

Prometheus scaler that is supported by Custom Metrics Autoscaler collects metrics through the Thanos Query service provided by OpenShift Monitoring. Because Thanos Query requires authentication, a ServiceAccount token must be used for bearer authentication.

- a. Create a service account.

Command example:

```
oc create serviceaccount thanos -n openshift-storage
```

- b. Create a secret to generate the token.

```
apiVersion: v1
kind: Secret
metadata:
  name: thanos-token-secret
  namespace: openshift-storage
  annotations:
    kubernetes.io/service-account.name: "thanos"
type: kubernetes.io/service-account-token
```

Command example:

```
oc apply -f secret.yaml
```

- c. Add the **cluster-monitoring-view** cluster role to the created Service Account in the **openshift-storage** namespace.

Command example:

```
oc adm policy add-cluster-role-to-user cluster-monitoring-view -z thanos
```

- d. Create a **triggerAuthentication** CRD for the bearer authentication using the secret name.

```
apiVersion: keda.sh/v1alpha1
kind: TriggerAuthentication
metadata:
  name: keda-trigger-auth-prometheus
  namespace: openshift-storage
spec:
  secretTargetRef:
    - parameter: bearerToken
      name: thanos-token-secret
      key: token
    - parameter: ca
```

```
name: thanos-token-secret
key: ca.crt
```

4. Enable RGW autoscaling.

Command example:

```
oc annotate storagecluster ocs-storagecluster ocs.openshift.io/enable-rgw-autoscale="true" -n openshift-storage
```

This behavior takes precedence over manual scaling. You can revert this change by performing the following command:

```
oc annotate storagecluster ocs-storagecluster ocs.openshift.io/enable-rgw-autoscale- -n openshift-storage
```

5. Create ScaledObject for autoscaling RGW.

Autoscaling using the HPA feature of OpenShift triggers scaling based on custom metrics. The Prometheus metrics related to RGW exported by the Ceph manager is used. The following example uses `ceph_rgw_put_obj_ops` metrics and scale up to five pods.

```
apiVersion: keda.sh/v1alpha1
kind: ScaledObject
metadata:
  name: rgw-scale-namespace
  namespace: openshift-storage
spec:
  scaleTargetRef:
    apiVersion: ceph.rook.io/v1
    kind: CephObjectStore
    name: ocs-storagecluster-cephobjectstore
    namespace: openshift-storage
  minReplicaCount: 1
  maxReplicaCount: 5
  triggers:
    - type: prometheus
      metadata:
        serverAddress: https://thanos-querier.openshift-monitoring.svc.cluster.local:9091
        metricName: ceph_rgw_put_obj_ops
        query: |
          sum(rate(ceph_rgw_op_put_obj_ops[2m]))
        threshold: "1"
        authModes: "bearer"
        namespace: openshift-storage
        authenticationRef:
          name: keda-trigger-auth-prometheus
```

Scaling the Multicloud Object Gateway with storage nodes

A storage node in the MCG is a NooBaa daemon container attached to one or more Persistent Volumes (PVs) and used for local object service data storage. NooBaa daemons can be deployed on Kubernetes nodes. This can be done by creating a Kubernetes pool consisting of `StatefulSet` pods.

Before you begin

Ensure you have a running Fusion Data Foundation cluster on OpenShift® Container Platform with access to the Multicloud Object Gateway (MCG).

Procedure

1. Log in to the OpenShift Web Console.
2. From the MCG user interface, go to Overview > Add Storage Resources.
3. Click **Deploy Kubernetes Pool**.
4. In the Create Pool step, create the target pool for the future installed nodes.
5. In the Configure step, configure the number of requested pods and the size of each PV.
For each new pod, one PV is to be created
6. In the Review step, you can find the details of the new pool and select the deployment method you wish to use: local or external deployment.
If local deployment is selected, the Kubernetes nodes deploys within the cluster. If external deployment is selected, you is provided with a YAML file to run externally.

What to do next

All nodes is assigned to the pool you chose in the first step. To verify, go to Resources > Storage resources > Resource name.

Increasing CPU and memory for PV pool resources

Multicloud Object Gateway (MCG) default configuration supports low resource consumption. However, when you need to increase CPU and memory to accommodate specific workloads and to increase MCG performance for the workloads, it is possible to configure the required values for CPU and memory in the OpenShift® Web Console.

Procedure

1. From the OpenShift Web Console, go to Storage > Object storage > Backingstore tab.
2. Select the new backingstore.
3. Click Edit PV pool resources.
4. From the edit window, edit the following values, based on your requirements: based on the requirement.

- Mem, CPU, and Vol size
- 5. Click **Save**.

What to do next

To verify, check the resource values of the PV pool pods.

Accessing the RADOS Object Gateway S3 endpoint

Users can access the RADOS Object Gateway (RGW) endpoint directly. The RGW route is created by default and is named `rook-ceph-rgw-ocs-storagecluster-cephobjectstore`.

For information about the S3 application programming interface (API) verbs that the RADOS Object Gateway (RGW) supports and does not support, see [S3 supported and unsupported verbs](#) in the *Red Hat® Ceph Storage developer guide*.

Using TLS certificates for applications accessing RGW

Fetch TLS certificates stored as Kubernetes secrets and configure applications to use them when accessing the RADOS Object Gateway (RGW) over a secure connection.

Before you begin

A running Fusion Data Foundation cluster.

About this task

Most of the S3 applications require TLS certificate in the forms such as an option included in the Deployment configuration file, passed as a file in the request, or stored in `/etc/pki` paths.

TLS certificates for RADOS Object Gateway (RGW) are stored as Kubernetes secret and you need to fetch the details from the secret.

Procedure

- For internal RGW server
Get the TLS certificate and key from the kubernetes secret:

```
oc get secrets/<secret_name> --template={{.data.tls.crt}} | base64 -d
oc get secrets/<secret_name> --template={{.data.tls.key}} | base64 -d
<secret_name>
```

The default kubernetes secret name is `<objectstore_name>-cos-ceph-rgw-tls-cert`. Specify the name of the object store.

- For external RGW server
Get the TLS certificate from the kubernetes secret:

```
oc get secrets/<secret_name> --template={{.data.cert}} | base64 -d
<secret_name>
```

The default kubernetes secret name is `ceph-rgw-tls-cert` and it is an opaque type of secret. The key value for storing the TLS certificates is `cert`.

- [Accessing external RGW server](#)
This section describes the two ways of accessing external RGW server

Accessing external RGW server

This section describes the two ways of accessing external RGW server

The S3 credentials such as **AccessKey** or **Secret Key** is stored in the secret generated by the Object Bucket Claim (OBC) creation and you can fetch the same by using the following commands:

Accessing External RGW server using Object Bucket Claims

```
oc get secret <object bucket claim name> -o jsonpath='{.data.AWS_SECRET_ACCESS_KEY}' | base64 --decode
oc get secret <object bucket claim name> -o jsonpath='{.data.AWS_ACCESS_KEY_ID}' | base64 --decode
```

Similarly, you can fetch the endpoint details from the `configmap` of OBC:

```
oc get cm <object bucket claim name> -o jsonpath='{.data.BUCKET_HOST}'
oc get cm <object bucket claim name> -o jsonpath='{.data.BUCKET_PORT}'
oc get cm <object bucket claim name> -o jsonpath='{.data.BUCKET_NAME}'
```

Accessing External RGW server using the Ceph Object Store User CR

You can fetch the S3 Credentials and endpoint details from the secret generated as part of the `Ceph Object Store User` CR:

```
oc get secret rook-ceph-object-user-<object-store-cr-name>-<object-user-cr-name> -o jsonpath='{.data.AccessKey}' | base64 --decode
oc get secret rook-ceph-object-user-<object-store-cr-name>-<object-user-cr-name> -o jsonpath='{.data.SecretKey}' | base64 --decode
oc get secret rook-ceph-object-user-<object-store-cr-name>-<object-user-cr-name> -o jsonpath='{.data.Endpoint}' | base64 --decode
```

Important:

For both the access mechanisms, you can either request for new certificates from the administrator or reuse the certificates from the Kubernetes secret, `ceph-rgw-tls-cert`.

Using the security token service of Multicloud Object Gateway to assume the role of another user

Multicloud Object Gateway (MCG) supports for a security token service (STS) similar to the one provided by Amazon Web Services. This STS of the MCG authorizes a user to assume the role of another user.

About this task

To authorize other users to assume the role of a certain user, you need to assign a role configuration to the user. You can manage the configuration of roles that use the MCG command-line interface (CLI) tool.

The following example shows the role configuration that allows two MCG users (*assumer@mcg.test* and *assumer2@mcg.test*) to assume a certain user's role:

```
'{"role_name": "AllowTwoAssumers", "assume_role_policy": {"version": "2012-10-17", "statement": [ {"action": ["sts:AssumeRole"], "effect": "allow", "principal": ["assumer@mcg.test", "assumer2@mcg.test"]} ]}'
```

Procedure

1. Assign the role configuration by using the MCG CLI tool.

```
mcg sts assign-role --email <assumed user's username> --role_config '{"role_name": "AllowTwoAssumers", "assume_role_policy": {"version": "2012-10-17", "statement": [ {"action": ["sts:AssumeRole"], "effect": "allow", "principal": ["assumer@mcg.test", "assumer2@mcg.test"]} ]}'
```

2. Collect the following information:

- The access key ID and secret access key of the assumer (the user who assumes the role).
- The MCG STS endpoint, which can be retrieved by using the command:

```
oc -n openshift-storage get route
```

- The access key ID of the assumed user.
- The value of the *role_name* in your role configuration.
- A name of your choice for the role session.

3. Assign the configuration role to the appropriate user.

```
AWS_ACCESS_KEY_ID=<aws-access-key-id> AWS_SECRET_ACCESS_KEY=<aws-secret-access-key> aws --endpoint-url <mcg-sts-endpoint> sts assume-role --role-arn arn:aws:sts::<assumed-user-access-key-id>:role/<role-name> --role-session-name <role-session-name>
```

Note: Adding `--no-verify-ssl` might be necessary depending on the configuration of the cluster.

The output contains the access key ID, secret access key, and session token that can be used for running actions while assuming the other user's role.

You can use the credentials generated after the assume role steps, as shown in the following example:

```
AWS_ACCESS_KEY_ID=<aws-access-key-id> AWS_SECRET_ACCESS_KEY=<aws-secret-access-key> AWS_SESSION_TOKEN=<session token> aws --endpoint-url <mcg-s3-endpoint> s3 ls
```

Replacing nodes and devices

Explains how to safely replace a node and storage devices in a Fusion Data Foundation cluster.

Fusion Data Foundation node replacement can be performed proactively for an operational node and reactively for a failed node. See [Fusion Data Foundation storage node failure](#) to replace storage nodes on Fusion Data Foundation using local storage devices.

See [Disk replacement and OpenShift dedicated OSD failure recovery](#) to replace storage devices on Fusion Data Foundation using local storage devices.

- [Fusion Data Foundation storage node failure](#)

You can do a node replacement proactively for an operational node and reactively for a failed node. For a failed node backed by local storage devices, you must replace the Fusion Data Foundation storage node.

- [Disk replacement and OpenShift dedicated OSD failure recovery](#)

Learn how to replace a faulty disk in a Red Hat OpenShift dedicated Object Storage Device (OSD) cluster.

Fusion Data Foundation storage node failure

You can do a node replacement proactively for an operational node and reactively for a failed node. For a failed node backed by local storage devices, you must replace the Fusion Data Foundation storage node.

Before you begin

IBM recommends that replacement nodes be configured with similar infrastructure, resources, and disks as the node planned for replacement.

Note: [Contact IBM Support](#) before you proceed with any of these fixes.

Procedure

Do the following steps to check for the occurrence of Fusion Data Foundation storage node failure and identify the failed node:

1. Set the Fusion Data Foundation cluster to maintenance mode:

```
oc label odclusters.odf.isf.ibm.com -n ibm-spectrum-fusion-ns odcluster "odf.isf.ibm.com/maintenanceMode=true"
```

Example output:

```
[root@fu40 ~]# oc label odclusters.odf.isf.ibm.com -n ibm-spectrum-fusion-ns odcluster "odf.isf.ibm.com/maintenanceMode=true"
odcluster.odf.isf.ibm.com/odcluster labeled
```

2. Identify the failed node:
 - a. Log in to IBM Fusion user interface.
 - b. Go to Data foundation page and check for warning in the Health section for storage cluster.Alternatively, you can use the `oc` command to identify the node:

```
oc get node -l cluster.ocs.openshift.io/openshift-storage=
```

Sample output:

```
[root@fu71-f09-vm3 ~]# oc get node -l cluster.ocs.openshift.io/openshift-storage=
NAME                                STATUS    ROLES    AGE    VERSION
f09-prc4m-worker-cluster-b-9chb5    NotReady worker   27d    v1.24.0+4f0dd4d
f09-prc4m-worker-cluster-c-mfb77    Ready    worker   31d    v1.24.0+4f0dd4d
f09-prc4m-worker-cluster-d-r5bxx    Ready    worker   27d    v1.24.0+4f0dd4d
```

3. Identify the failed mon (if any) and Red Hat OpenShift Dedicated pods that are running in the node, which is planned for replacement:
In an operational storage node environment:

```
oc get pods -n openshift-storage -o wide | grep -i <node_name>
```

4. If the storage node failed in a failed storage node, there is no `node_name` for the failed pods. Filter the `pending` pods instead.

```
oc get pods -n openshift-storage -o wide | grep -i pending
```

Example output: The mon deployment is `rook-ceph-mon-d`, and the Red Hat OpenShift Dedicated deployment is `ook-ceph-osd-0`.

```
[root@fu71-f09-vm3 ~]# oc get pods -n openshift-storage -o wide | grep -i pending
rook-ceph-mon-d-67686857d7-zv62c    0/2    Pending    0            8m50s    <none>
<none>                                <none>    <none>
rook-ceph-osd-0-75b954c9bf-62xm4    0/2    Pending    0            8m50s    <none>
<none>                                <none>    <none>
```

5. Remove the failed objects.

Remove the failed node from `odcluster` CR

```
spec:
  autoScaleUp: false
  creator: CreatedByFusion
  deviceSets:
  - capacity: "0"
    count: 3
    name: ocs-deviceset-ibm-spectrum-fusion-local
    storageClass: ibm-spectrum-fusion-local
  encryption:
    keyManagementService: {}
  localVolumeSetSpec:
    deviceTypes:
    - disk
    - part
    size: 2Ti
  storageNodes:
  - f09-prc4m-worker-cluster-d-r5bxx
  - f09-prc4m-worker-cluster-c-mfb77
  - f09-prc4m-worker-cluster-b-9chb5 <-- this one, remove this line.
```

Remove the mon and Red Hat OpenShift Dedicated pods

Scale down the deployments of the identified pods. The mon deployment is `rook-ceph-mon-d` and the Red Hat OpenShift Dedicated deployment is `rook-ceph-osd-0`.

```
oc scale deployment rook-ceph-mon-d --replicas=0 -n openshift-storage
oc scale deployment rook-ceph-osd-0 --replicas=0 -n openshift-storage
```

Ensure that you confirm the values of `mon_id` and `osd_id`.

Remove the crashcollector pods

Remove the crashcollector pods (if any). You must put scale replica to 0.

```
oc scale deployment --selector=app=rook-ceph-crashcollector,node_name=<node_name> --replicas=0 -n openshift-storage
```

Mark the failed node as unschedulable

Mark the node as `SchedulingDisabled`.

```
oc adm cordon <node_name>
```

Example command and output:

```
oc adm cordon f09-prc4m-worker-cluster-b-9chb5
node/f09-prc4m-worker-cluster-b-9chb5 cordoned
```

```
oc get node -l cluster.ocs.openshift.io/openshift-storage=
```

NAME	STATUS	ROLES	AGE	VERSION
f09-prc4m-worker-cluster-b-9chb5	NotReady, SchedulingDisabled	worker	28d	v1.24.0+4f0dd4d
f09-prc4m-worker-cluster-c-mfb77	Ready	worker	31d	v1.24.0+4f0dd4d
f09-prc4m-worker-cluster-d-r5bxx	Ready	worker	27d	v1.24.0+4f0dd4d

Remove the pods which are in Terminating state

This step is for the failed storage node. You can ignore this step if you are removing an operational node.

```
oc get pods -A -o wide | grep -i <node_name> | awk '{if ($4 == "Terminating") system ("oc -n " $1 " delete pods " $2 " --grace-period=0 " " --force ")}'
```

Example command and output:

```
oc get pods -A -o wide | grep -i f09-prc4m-worker-cluster-b-9chb5 | awk '{if ($4 == "Terminating") system ("oc -n " $1 " delete pods " $2 " --grace-period=0 " " --force ")}'
```

warning: Immediate deletion does not wait for confirmation that the running resource has been terminated. The resource pod "isf-data-protection-operator-controller-manager-5c7cf574d5ms4xx" force deleted

Drain the node

```
oc adm drain <node_name> --force --delete-emptydir-data=true --ignore-daemonsets
```

Example command and output:

```
oc adm drain f09-prc4m-worker-cluster-b-9chb5 --force --delete-emptydir-data=true --ignore-daemonsets
node/f09-prc4m-worker-cluster-b-9chb5 already cordoned
```

WARNING: ignoring DaemonSet-managed Pods: openshift-cluster-csi-drivers/vmware-vsphere-csi-driver-node-7696f, openshift-node/f09-prc4m-worker-cluster-b-9chb5 drained

Delete the node

Delete the failed node:

```
oc delete node <node_name>
```

If you do not want to destroy this node for test purpose, you can remove the storage label `cluster.ocs.openshift.io/openshift-storage=`.

```
oc label nodes/f09-prc4m-worker-cluster-b-9chb5 cluster.ocs.openshift.io/openshift-storage-
```

6. Add new OpenShift® compute nodes.

- Create a new compute node and ensure that the new node is in ready state.
- Update new node info in `odfcluster` CR.

Edit the `odfcluster` cr and add new node name in `StorageNodes`

```
oc edit odfclusters.odf.isf.ibm.com -n ibm-spectrum-fusion-ns odfcluster
```

```
storageNodes:
- f09-prc4m-worker-cluster-b-djplp <---- new node
- f09-prc4m-worker-cluster-d-r5bxx
- f09-prc4m-worker-cluster-c-mfb77
```

Verify whether the new nodes are labeled successfully as storage node.

```
oc get node -l cluster.ocs.openshift.io/openshift-storage=
```

NAME	STATUS	ROLES	AGE	VERSION
f09-prc4m-worker-cluster-b-djplp	Ready	worker	27d	v1.24.0+4f0dd4d <-- this node
f09-prc4m-worker-cluster-c-mfb77	Ready	worker	31d	v1.24.0+4f0dd4d
f09-prc4m-worker-cluster-d-r5bxx	Ready	worker	27d	v1.24.0+4f0dd4d

Verify whether the new PVs are created automatically. The local PV gets created automatically in a short time.

```
oc get pv | grep Available
```

local-pv-e97b23d7	2Ti	RWO	Delete	Available
-------------------	-----	-----	--------	-----------

c. Replace the failed Red Hat OpenShift Dedicated disks.

Remove the failed Red Hat OpenShift Dedicated from the cluster. You can also specify multiple failed ODs. Use the correct `failed_osd_id`.

The `failed_osd_id` is the integer in the pod name immediately after the `rook-ceph-osd` prefix. You can add comma separated Red Hat OpenShift Dedicated IDs in the command to remove more than one Red Hat OpenShift Dedicated, for example, `FAILED_OSD_IDS=0,1,2`.

Remove the failed Red Hat OpenShift Dedicated:

```
oc process -n openshift-storage ocs-osd-removal \
-p FAILED_OSD_IDS=<failed_osd_id> FORCE_OSD_REMOVAL=true | oc create -n openshift-storage -f -
```

Example output:

```
[root@fu71-f09-vm3 ~]# oc process -n openshift-storage ocs-osd-removal -p FAILED_OSD_IDS=0
FORCE_OSD_REMOVAL=true | oc create -n openshift-storage -f -
Warning: would violate PodSecurity "restricted:latest": allowPrivilegeEscalation != false (container "operator"
```

```
must set securityContext.allowPrivilegeEscalation=false), unrestricted capabilities (container "operator" must
set securityContext.capabilities.drop=["ALL"]), runAsNonRoot != true (pod or container "operator" must set
securityContext.runAsNonRoot=true), seccompProfile (pod or container "operator" must set
securityContext.seccompProfile.type to "RuntimeDefault" or "Localhost")
job.batch/ocs-osd-removal-job created
```

Check the status of the `ocs-osd-removal-job` pod to verify whether the Red Hat OpenShift Dedicated got removed successfully. A status of Completed confirms that the Red Hat OpenShift Dedicated removal job succeeded.

```
oc get pod -l job-name=ocs-osd-removal-job -n openshift-storage
```

Example output:

```
[root@fu71-f09-vm3 ~]# oc get pod -n openshift-storage | grep ocs-osd-removal
ocs-osd-removal-job-1s651 0/1 Completed 0 23s
```

Ensure that the Red Hat OpenShift Dedicated removal is completed:

```
oc logs -l job-name=ocs-osd-removal-job -n openshift-storage --tail=-1 | egrep -i 'completed removal'
```

Example output:

```
[root@fu71-f09-vm3 ~]# oc logs -l job-name=ocs-osd-removal-job -n openshift-storage --tail=-1 | egrep -i
'completed removal'
2022-11-24 15:19:28.750910 I | cephosd: completed removal of OSD 0
```

Delete the `ocs-osd-removal-job`:

```
oc delete -n openshift-storage job ocs-osd-removal-job
```

Delete the Released PV which is attached to the previous node.

```
oc get pv | grep -i released
```

```
local-pv-e4a12175 2Ti RWO Delete Released openshift-
storage/ocs-deviceset-ibm-spectrum-fusion-local-0-data-1m6gnz ibm-spectrum-fusion-local 3h34m
[root@fu71-f09-vm3 ~]# oc delete pv local-pv-e4a12175
persistentvolume "local-pv-e4a12175" deleted
```

7. Recover the failed objects.

a. Restart the mon deployment/pod:

i. Update the nodeSelector in deployment with new node.

```
oc edit deployment -n openshift-storage rook-ceph-mon-d
nodeSelector:
  kubernetes.io/hostname: f09-prc4m-worker-cluster-b-djplp <--new node
```

ii. Scale the replica to 1 and wait till the mon pods are in running state.

```
oc scale deployment rook-ceph-mon-d --replicas=1 -n openshift-storage
```

Example:

```
oc scale deployment rook-ceph-mon-d --replicas=1 -n openshift-storage
deployment.apps/rook-ceph-mon-d scaled
```

```
[root@fu71-f09-vm3 ~]# oc get pod -n openshift-storage | grep mon
rook-ceph-mon-a-5bbb9dd98b-z54fx 2/2 Running 0 4m45s
rook-ceph-mon-b-7fdd8f958b-lk9g2 2/2 Running 0 5m18s
rook-ceph-mon-d-6945fbbfc5-nhhw8 2/2 Running 0 5m41s
```

b. Verify the Red Hat OpenShift Dedicated pods.

Wait till all the pods are in running state.

```
oc get pods -o wide -n openshift-storage | grep osd
```

```
[root@fu71-f09-vm3 ~]# oc get pods -o wide -n openshift-storage | grep osd
rook-ceph-osd-0-d559cc4fb-xspr8 2/2 Running 0 4m58s
10.129.6.49 f09-prc4m-worker-cluster-b-djplp <none> <none>
rook-ceph-osd-1-6df7f9c669-n94md 2/2 Running 0 5m20s
10.128.6.95 f09-prc4m-worker-cluster-d-r5bxx <none> <none>
rook-ceph-osd-2-5c5d48ff7c-sdd71 2/2 Running 0 5m17s
10.129.4.125 f09-prc4m-worker-cluster-c-mfb77 <none> <none>
rook-ceph-osd-prepare-1bf7dd3d71fe899383e625dd0c27ea37-x9v7k 0/1 Completed 0 4h8m
10.128.6.79 f09-prc4m-worker-cluster-d-r5bxx <none> <none>
rook-ceph-osd-prepare-24272b5641dc95baffc7932d78894e3c-zhz8m 0/1 Completed 0 5m24s
10.129.6.48 f09-prc4m-worker-cluster-b-djplp <none> <none>
rook-ceph-osd-prepare-6f3c3b4626ec9888b6f5597afd55ea-zh7cp 0/1 Completed 0 4h8m
10.129.4.113 f09-prc4m-worker-cluster-c-mfb77 <none> <none>
```

c. Verify the Red Hat OpenShift Dedicated encryption settings. If cluster wide encryption is enabled, make sure the "crypt" keyword beside the ocs-deviceset name(s)

```
oc debug node/<new-node-name> -- chroot /host dmsetup ls
```

Example output:

```
# oc debug node/fu47 -- chroot /host dmsetup ls
Starting pod/fu47-debug ...
To use host binaries, run `chroot /host`
ocs-deviceset-sc-lvs-0-data-0clwxf-block-dmccrypt (253:0)
```

If verification fails, contact [IBM support](#).

- Exit maintenance mode after all steps are completed.

```
oc label odfclusters.odf.isf.ibm.com -n ibm-spectrum-fusion-ns odfcluster "odf.isf.ibm.com/maintenanceMode-"
```

Example output:

```
[root@fu40 ~]# oc label odfclusters.odf.isf.ibm.com -n ibm-spectrum-fusion-ns odfcluster "odf.isf.ibm.com/maintenanceMode-"  
odfcluster.odf.isf.ibm.com/odfcluster unlabeled
```

- Go to Data foundation page in IBM Fusion user interface and check the health of the Storage cluster in the Health section.

Disk replacement and OpenShift dedicated OSD failure recovery

Learn how to replace a faulty disk in a Red Hat® OpenShift® dedicated Object Storage Device (OSD) cluster.

Procedure

- Identify the failed OSD.

Command example:

```
oc get -n openshift-storage pods -l app=rook-ceph-osd -o wide
```

An example output where osd-19 is failed and the status is **CrashLoopBackOff**:

NAME	READY	STATUS	RESTARTS	AGE	IP	NODE
rook-ceph-osd-0-85fcb5fd9-5cvws	2/2	Running	0	9d	9.42.107.150	compute-1-ru7.<domainnam
rook-ceph-osd-1-5dd8bc8d9d-cbz7g	2/2	Running	0	37d	9.42.107.149	compute-1-ru6.<domainnam

- Scale down **ocs-operator** first, then **rook-ceph-operator**.

- Scale down **ocs-operator**.

- Log in to the Red Hat OpenShift Container Platform web console and select your project.
- Go to Workloads, > Pods page and verify that **ocs-operator** is in the **Running** status in the Pods list.
- Go to Workloads, > Deployments page.
- Click **ocs-operator** and check the Deployment details tab.

For example, the Deployment details tab displays that **ocs-operator** has 1 Pod.

- Scale down the Pod number to 0.
- Go back to the Pods tab and check for the **ocs-operator**.

The **ocs-operator** does not appear or is no longer available in the Pods list.

- Scale down **rook-ceph-operator**.

- Go to Workloads, > Pods page and verify that **rook-ceph-operator** is in the **Running** status in the Pods list.
- Go to Workloads, > Deployments page.
- Click **rook-ceph-operator** and check the Deployment details tab.

For example, the Deployment details tab displays that **rook-ceph-operator** has 1 Pod.

- Scale down the Pod number to 0.
- Go back to the Pods tab and check for the **rook-ceph-operator**.

The **rook-ceph-operator** does not appear or is no longer available in the Pods list.

- Optional: Verify whether Pods for **ocs-operator** and **rook-ceph-operator** are removed as expected.

Command example:

```
oc get pods |grep operator
```

Example output:

noobaa-operator-79446cc789-gj66l	1/1	Running	0	38d
ocs-client-operator-console-7d85dc6bf9-vdbhn	1/1	Running	0	9d
ocs-client-operator-controller-manager-85bbcc7bfd-znvx4	2/2	Running	1 (6d1h ago)	37d
odf-operator-controller-manager-59465654c-jmj5z	2/2	Running	0	38d

- Clean up failed OSD.

- a. Scale down the **rook-ceph-osd** deployment.

Command example:

```
osd_id_to_remove=<replace-it-with-osd-id>
oc scale -n openshift-storage deployment rook-ceph-osd- $\{osd\_id\_to\_remove\}$  --replicas=0
```

Example output:

```
deployment.apps/rook-ceph-osd-19 scaled
```

- b. Verify that the **rook-ceph-osd** Pod for the faulty OSD is deleted.

Command example:

```
oc get -n openshift-storage pods -l app=rook-ceph-osd -o wide
```

Example output:

NAME	READY	STATUS	RESTARTS	AGE	IP	NODE	
rook-ceph-osd-0-85fcb5fd9-5cvws	2/2	Running	0	9d	9.42.107.150	compute-1-ru7.<domainname>	<non
rook-ceph-osd-1-5dd8bc8d9d-cbz7g	2/2	Running	0	37d	9.42.107.149	compute-1-ru6.<domainname>	<non

5. Remove the old OSD from the cluster.

- a. Delete any existing **ocs-osd-removal** jobs, if present.

Command example:

```
oc delete -n openshift-storage job ocs-osd-removal-job
```

Example output:

```
job.batch "ocs-osd-removal-job" deleted
```

- b. Remove the old OSD from the cluster

Command example:

```
oc process -n openshift-storage ocs-osd-removal -p FAILED_OSD_IDS= $\{osd\_id\_to\_remove\}$  FORCE_OSD_REMOVAL=true | oc create -n openshift-storage -f -
```

Important: Ensure that you set the correct **osd_id_to_remove**.

Example output:

```
job.batch/ocs-osd-removal-job created
```

- c. Verify that the **ocs-osd-removal-job** has completed.

Command example:

```
oc get pod -l job-name=ocs-osd-removal-job -n openshift-storage
```

Example output:

NAME	READY	STATUS	RESTARTS	AGE
ocs-osd-removal-job-rh72h	0/1	Completed	0	39s

After the **ocs-osd-removal-job** completes, the associated Persistent Volumes (PVs) are released, and the Persistent Volume Claims (PVCs) are either deleted or move to the **Pending** state.

- d. Check the PV state.

Command example:

```
oc get pv |grep Released
```

Example output:

NAME	STATUS	RECLAIMPOLICY	STORAGECLASS	LOCAL	FILESYSTEM	ACCESSMODES	SIZE	AGE
local-pv-141605d2	Released	Retain	openshift-storage/ocs-de		ext4	RWO	7153Gi	37d

- e. If encryption is enabled, remove the associated configuration.

Do the following steps:

- i. Retrieve PVC and node details.

Command example:

```
oc describe pv local-pv-141605d2
```

Example output:

```

Name: local-pv-141605d2
Labels:
  kubernetes.io/hostname=control-1-ru2.<domainname>
  storage.openshift.com/owner-kind=LocalVolumeSet
  storage.openshift.com/owner-name=ibm-spectrum-fusion-local

```

- ii. Remove the **dm-crypt**-managed device-mapper mapping from the OSD devices.

Command example:

```

oc debug node/<node name>
chroot /host
dmsetup ls | grep <pvc name>

```

Example output:

```

ocs-deviceset-ibm-spectrum-fusion-local-0-data-32b6465-block-dmccrypt    (253:3)

```

- iii. Remove the mapped device.

Command example:

```

cryptsetup luksClose --debug --verbose ocs-deviceset-ibm-spectrum-fusion-local-0-data-32b6465-block-dmccrypt

```

Example output:

```

# cryptsetup 2.6.0 processing "cryptsetup luksClose --debug --verbose ocs-deviceset-ibm-spectrum-fusion-local-0-data-32b6465-block-dmccrypt"
# Verifying parameters for command close.

# Releasing crypt device empty context.
# Releasing device-mapper backend.
Command successful.

```

- f. Identify and delete the failed PV.
Do the following steps:

i. Identify the failed PV.

Command example:

```
oc get pv -l kubernetes.io/hostname=control-1-ru2.<domainname>
```

The status of the failed PV shows as **Released**.

Example output:

NAME	CAPACITY	ACCESS MODES	RECLAIM POLICY	STATUS	CLAIM
local-pv-141605d2	7153Gi	RWO	Delete	Released	openshift-storage/ocs-deviceset-ibm-spectr
local-pv-4ce100b9	7153Gi	RWO	Delete	Bound	openshift-storage/ocs-deviceset-ibm-spectr
local-pv-5b320962	7153Gi	RWO	Delete	Bound	openshift-storage/ocs-deviceset-ibm-spectr
local-pv-6ba1664e	7153Gi	RWO	Delete	Bound	openshift-storage/ocs-deviceset-ibm-spectr
local-pv-89429641	7153Gi	RWO	Delete	Bound	openshift-storage/ocs-deviceset-ibm-spectr
local-pv-a3bb3040	7153Gi	RWO	Delete	Bound	openshift-storage/ocs-deviceset-ibm-spectr
local-pv-e9ed407b	7153Gi	RWO	Delete	Bound	openshift-storage/ocs-deviceset-ibm-spectr

ii. Delete the failed PV.

Command example:

```
oc delete pv local-pv-141605d2
```

Example output:

```
persistentvolume "local-pv-141605d2" deleted
```

iii. Verify that the failed PV is deleted.

Command example:

```
oc get pv -l kubernetes.io/hostname=control-1-ru2.<domainname>
```

Example output:

NAME	CAPACITY	ACCESS MODES	RECLAIM POLICY	STATUS	CLAIM
local-pv-4ce100b9	7153Gi	RWO	Delete	Bound	openshift-storage/ocs-deviceset-ibm-spectrum
local-pv-5b320962	7153Gi	RWO	Delete	Bound	openshift-storage/ocs-deviceset-ibm-spectrum
local-pv-6ba1664e	7153Gi	RWO	Delete	Bound	openshift-storage/ocs-deviceset-ibm-spectrum
local-pv-89429641	7153Gi	RWO	Delete	Bound	openshift-storage/ocs-deviceset-ibm-spectrum
local-pv-a3bb3040	7153Gi	RWO	Delete	Bound	openshift-storage/ocs-deviceset-ibm-spectrum
local-pv-e9ed407b	7153Gi	RWO	Delete	Bound	openshift-storage/ocs-deviceset-ibm-spectrum

6. Verify that the stale OSD entry is removed.

Command example:

```
oc get pods
```

Example output:

7. Add a new disk to the node.

Important:

- If a fresh or unused disk is inserted, a new PV is created in the **Available** state.
- If a used disk is inserted as a replacement, it must be formatted for the corresponding PV to become available.

After adding the new disk, verify the status of the new PV.

Command example:

```
oc get pv | grep local
```

Example output:

local-pv-159elb8e	7153Gi	RWO	Delete	Bound	openshift-storage/ocs-device
local-pv-2ac8a85b	7153Gi	RWO	Delete	Bound	openshift-storage/ocs-device
local-pv-406f1af8	7153Gi	RWO	Delete	Bound	openshift-storage/ocs-device

local-pv-4da6a449	7153Gi	RWO	Delete	Available	
local-pv-521ee04f	7153Gi	RWO	Delete	Bound	openshift-storage/ocs-device
.					
.					
.					
.					
local-pv-b7c4932c	7153Gi	RWO	Delete	Bound	openshift-storage/ocs-device

8. Scale up **ocs-operator** first, then **rook-ceph-operator**.

a. Scale up **ocs-operator**.

- Go to Workloads > Deployments page.
- Click **ocs-operator** and check the Deployment details tab.

For example, the Deployment details tab displays that **ocs-operator** has 0 Pod.

- Scale up the Pod number to 1.
- Go to Workloads > Pods page and verify that **ocs-operator** is in the **Running** status in the Pods list.

b. Scale up **rook-ceph-operator**.

- Go to Workloads > Deployments page.
- Click **rook-ceph-operator** and check the Deployment details tab.

For example, the Deployment details tab displays that **rook-ceph-operator** has 0 Pod.

- Scale up the Pod number to 1.
- Go to Workloads > Pods page and verify that **rook-ceph-operator** is in the **Running** status in the Pods list.

9. Verify that the new OSD Pod is running.

Command example:

```
oc get -n openshift-storage pods -l app=rook-ceph-osd -o wide
```

Example output:

NAME	READY	STATUS	RESTARTS	AGE	IP	NODE	
rook-ceph-osd-0-85fcb5fd9-5cvws	2/2	Running	0	9d	9.42.107.150	compute-1-ru7.<domainname>	<none>

10. Verify that the PV and PVC are successfully created.
Command example for PVC:

```
oc get pvc -n openshift-storage |grep local-pv-4da6a449
```

Command example for PV:

```
oc get pv -n openshift-storage |grep local-pv-4da6a449
```

Example output for PVC:

```
ocs-deviceset-ibm-spectrum-fusion-local-0-data-35tw7jf    Bound    local-pv-4da6a449    7153Gi    RWO
```

Example output for PV:

```
local-pv-4da6a449    7153Gi    RWO    Delete    Bound    openshift-storage/ocs-deviceset
```

Results

Faulty disk or failed OSD replacement is complete.

What to do next

Wait for the storage cluster to reconcile its health status. If it remains in the **Warning** state despite all Fusion Data Foundation Pods running, check for and resolve any previous crashes.

To verify the health status, do as follows:

- Log in to the IBM Fusion web console and go to **Storage > Local storage** to check the health of the local storage.
- In the Red Hat OpenShift Container Platform web console, go to **Storage > Data Foundation** and check the health of the storage.

Troubleshooting Fusion Data Foundation service issues

Use this troubleshooting information to diagnose and resolve install, upgrade, and operational problems that are related to the Fusion Data Foundation service.

Review the following troubleshooting information to diagnose and resolve Fusion Data Foundation service issues:

- [Known issues in upgrade](#)
- [ceph-csi-controller-manager pod in Crashloopbackoff state](#)
- [Fusion Data Foundation operator upgrade is not initiated](#)
- [Fusion Data Foundation ocs-client-operator-console-xxx pod is stuck while upgrade](#)
-
- [Admission webhook warning](#)
- [Local storage operator unable to find candidate storage nodes](#)
- [Fusion Data Foundation capacity cannot be loaded](#)
- [Fusion Data Foundation cluster fails due to pending StorageClusterPreparing stage](#)
- [Deletion of StorageCluster does not delete connected StorageClient](#)
- [The StorageClient pod is in ContainerStatusUnknown and CrashLoopBackOff state](#)
- [Storage client status reporter pod is stuck in terminating state](#)
- [Fusion Data Foundation storage node failure](#)
- [Disk replacement and OpenShift dedicated OSD failure recovery](#)

Known issues in upgrade

- You cannot upgrade Fusion Data Foundation from 4.14 or 4.15 to 4.16. Instead, do a fresh installation of Fusion Data Foundation 4.16.

ceph-csi-controller-manager pod in Crashloopbackoff state

Problem statement

After the upgrade of OpenShift Container Platform 4.16 and Fusion Data Foundation 4.16 to 4.17, the Fusion Data Foundation goes into a degraded state.

Cause

The error occurs because of the `Crashloopbackoff` state of the `ceph-csi-controller-manager` pod.

Resolution

To resolve and validate this error, complete the following steps:

1. Run the following example command to remove the limit from the CSV:

```
oc patch csv cephcsi-operator.v4.17.1 --type json -p '[{"op": "remove", "path": "/spec/install/spec/deployments/0/spec/template/spec/containers/1/resources/limits"}]' clusterserviceversion.operators.coreos.com/cephcsi-operator.v4.17.1 patched
```

2. Run the following command to verify the pod status:

```
oc get pods
```

Example output:

NAME	READY	STATUS	RESTARTS	AGE
ceph-csi-controller-manager-675dc67f7b-f64pb	2/2	Running	0	3h39m
ceph-csi-controller-manager-8854c7f5-xdrv	1/2	Running	0	6s

Fusion Data Foundation operator upgrade is not initiated

Problem statement

Fusion Data Foundation operator upgrade is not initiated even though the service is installed successfully. If auto-upgrade is not enabled for Fusion Data Foundation during the upgrade to version 4.17 or later, some components might not upgrade automatically.

Resolution

To ensure that all components are upgraded successfully, verify that all `InstallPlans` in the `openshift-storage` namespace are approved. Complete the following steps to verify and manually approve any pending `InstallPlans`:

1. Run the following command to retrieve the list of `InstallPlans` in the `openshift-storage` namespace:

```
oc get installplan -n openshift-storage
```

2. Check the `APPROVED` column in the output and verify that all listed `InstallPlans` are set to `true`.
3. If any `InstallPlan` in the `APPROVED` column is set to `false`, manually approve it by running the following command:

```
for ip in $(oc get installplan --no-headers -n openshift-storage | grep false | awk '{print $1}'); do
  oc patch installplan $ip -n openshift-storage --type merge --patch '{"spec":{"approved":true}}'
done
```

4. After approving all pending `InstallPlans`, repeat steps 1 and 2 to confirm that all `InstallPlans` are set to `true`.

Fusion Data Foundation ocs-client-operator-console-xxx pod is stuck while upgrade

Problem statement

During the Fusion Data Foundation service upgrade from version 4.18.2 to 4.18.3, the `odf-operator` CSV `ocs-operator.v4.18.3` is unavailable because the `ocs-client-operator-console-xxx` pod is stuck in `ContainerCreating` state.

Resolution

Delete the pod to resolve the issue:

```
oc delete pod <name> -n openshift-storage
```

Admission webhook warning

Problem statement

After you create an Object Bucket Claim, the following error occurs:

```
Admission webhook warning :- ObjectBucketClaim my-obj-bucket violates policy 299 - "unknown field "spec.ss||" after object bu
```

Resolution

For more information about this known issue, see [Red Hat Known issues](#).

Local storage operator unable to find candidate storage nodes

Problem statement

When you configure a Fusion Data Foundation cluster, no candidate storage nodes are found.

Cause

When you configure a Fusion Data Foundation cluster, only compute nodes with available disks (SSD/NVMe or HDD) are displayed on the Data Foundation page of the IBM Fusion HCI user interface. The following nodes are filtered out and do not appear:

- Nodes that have SSD/NVMe or HDD disks but those disks are not in an available state.
- Nodes where the selected disk properties are not present. For example, the disk size or disk type does not match.
- Nodes where the total disk count (with the same disk size and disk type) is fewer than 3.

Steps to verify whether you have the correct storage node candidates

1. In the Red Hat OpenShift Container Platform web console, go to Operators > Installed Operators.
2. Verify that the `LocalStorage` operator is installed successfully.
3. Run the following command to list all worker nodes:

```
oc get node -l node-role.kubernetes.io/worker=
```

4. Run the following command to check whether discovery results are created for all worker nodes:

```
oc get localvolumediscoveryresult -n openshift-local-storage
```

5. Run the following command to confirm that none of the nodes have a Fusion Data Foundation storage label:

```
oc get node -l cluster.ocs.openshift.io/openshift-storage=
```

Note: On the Linux on IBM Z platform, disks might need to be formatted and partitioned first. For more information, see section 4.1.1 and 4.1.2 of the [Red Hat OpenShift Data Foundation on IBM Z and IBM LinuxONE - Reference Architecture](#).

If all the preceding checks pass but the node is still not visible in the IBM Fusion user interface, contact [IBM support](#).

Fusion Data Foundation capacity cannot be loaded

If you encounter this issue on the Data Foundation page of the IBM Fusion user interface, contact [IBM support](#).

Fusion Data Foundation cluster fails due to pending StorageClusterPreparing stage

Problem statement

The PVC is not created, and the `odfcluster` status shows the following condition:

```
conditions:
- lastTransitionTime: "2022-12-01T15:09:47Z"
  message: storagecluster is not ready, install pending
  reason: StorageClusterPreparing
  status: "False"
  type: Ready
phase: InProgress
replica: 1
```

Diagnosis and resolution

To diagnose and fix the problem, complete the following steps:

1. Run the following command to open the `storagecluster` CR:

```
oc get storageclusters.ocs.openshift.io -n openshift-storage ocs-storagecluster -o yaml
```

2. Check whether the output shows the following error message in the status:

```
ConfigMap "ocs-kms-connection-details" not found'
```

Example output:

```
status:
conditions:
- lastHeartbeatTime: "2023-03-29T08:01:10Z"
  lastTransitionTime: "2023-03-29T07:49:47Z"
  message: 'Error while reconciling: some StorageClasses were skipped while waiting
for pre-requisites to be met: [ocs-storagecluster-cephfs,ocs-storagecluster-ceph-rbd]'
  reason: ReconcileFailed
  status: "False"
  type: ReconcileComplete
```

3. If you see the error message, check the root-operator logs with the following command:

```
oc logs -n openshift-storage $(oc get pod -n openshift-storage -l app=rook-ceph-operator -o name)
```

Example output:

```
2023-03-29 07:55:41.297073 E | ceph-cluster-controller: failed to reconcile CephCluster "openshift-storage/ocs-storagecluster"
cluster "ocs-storagecluster-cephcluster": failed to configure local ceph cluster: failed to perform validation before clu
URL: GET https://9.9.9.75:8200/v1/sys/mounts
Code: 403. Errors: * permission denied
```

Deletion of StorageCluster does not delete connected StorageClient

Workaround

Remove the finalizer from the `StorageClient` and verify that the `StorageClient` instance is not present on the cleaned-up cluster.

Note: This issue occurs on a reinstalled or re-provisioned cluster.

The StorageClient pod is in ContainerStatusUnknown and CrashLoopBackOff state

Diagnosis

When Fusion Data Foundation is reinstalled and reconfigured, the `StorageClient` continues pointing to the old instance. As a result, no storage classes or few storage classes are created, and NooBaa DB PVCs remain in the pending state.

Workaround

Check the metadata of the `StorageClient` CR. The metadata contains details from the last connection. Force delete the old `StorageClient` instance and wait for it to be recreated.

Note: This issue occurs on a reinstalled or re-provisioned cluster.

Storage client status reporter pod is stuck in terminating state

Problem statement

The `storageclient-status-reporter` pod gets stuck during termination. In this state, the following options do not work:

- Force deletion of the pod.
- Patching of the finalizer.

Resolution

Remove the finalizer by running the following command:

```
for pod in $(oc get pod --field-selector=status.phase=Failed -oname -n openshift-storage | grep storageclient)
do
    oc patch $pod -n openshift-storage --type merge -p '{"status":{"qosClass":"BestEffort"}}' --subresource status
    oc patch $pod -n openshift-storage --type merge -p '{"metadata":{"finalizers": []}}'
done
```

Global Data Platform

Learn how to install and configure Global Data Platform service.

- [Installing Global Data Platform](#)
From the Services page, enable the IBM Fusion Global data platform service.
- [Configuring Global Data Platform local storage](#)
Configure Global Data Platform as your storage, then configure storage nodes, and finally set its encryption.
- [Setting up encryption for storage](#)
Setting encryption for the different storage types in IBM Fusion HCI .
- [Configuring storage](#)
You can configure Global Data Platform as your storage.
- [Sharing data](#)
Active file management (AFM) is a scalable, high-performance, file system caching layer, and enables sharing of data across clusters, even if the networks are unreliable or have high latency.
- [Global Data Platform service install and upgrade issues](#)
Use this troubleshooting information to resolve install and upgrade problems that are related to Global Data Platform service.
- [Global Data Platform service issues](#)
This section lists the troubleshooting tips and tricks when you use IBM Fusion storage.

Installing Global Data Platform

From the Services page, enable the IBM Fusion Global data platform service.

About this task

Ensure that you are aware of the following points before you install Global Data Platform:

- For more information about the compatibility of services on the different supported versions of OpenShift® Container Platform, see [Support matrix](#).
- The IBM Fusion supports Global Data Platform version 5.2.3.4 and Global Data Platform Remote Mount version 6.0.0.1.
- Do NOT delete IBM Storage Scale pods. In many circumstances, the deletion of Scale pods has implications on the availability and data integrity.
- If Global Data Platform service is installed on a OpenShift Container Platform cluster, check whether the nodes are running with secure boot:

```
mokutil --sb-state
```

As a root user, disable secure boot with the following command:

```
mokutil --disable-validation
```

Procedure

1. Go to the Services page in the IBM Fusion user interface.
2. In the Available section, click Global data platform tile to install and configure storage service.
Note: You cannot install other dependent services until you install and configure a storage service.
3. In the Global Data Platform page, go through the details and click Install.
If you have less than six storage nodes, then the Install is disabled. Go to the Nodes page > Discovered tab and add nodes to the cluster so that it has enough storage for Global Data Platform. After you add a minimum of six nodes, the Install is enabled and you continue with the installation.
After you enable the Global Data Platform, you can view the service version and health status. In the Services page, you can see Global data platform tile under Installed section.

Table 1. Health states Global Data Platform service

State	Description
Healthy	The Running and Ready states for the following items indicate that the service is healthy: • All the pods in <code>ibm-spectrum-scale</code> namespace are running. • Scale operator pod in <code>ibm-spectrum-scale-operator</code> namespace. • <code>ScaleManager</code> CR in the Fusion namespace. • All the pods in <code>ibm-spectrum-scale-csi</code> namespace are running. • GPFS Scale service is active on all the pods. • The filesystem is mounted on all the nodes.

State	Description
Degraded	If any of the following conditions are not met, then the service goes to a degraded state. - Any one of the scale core pod statuses is not running per Recovery Group (RG) - GPFS service is not active on any one of the pods per RG. - If one of the PM collector pods is not running or all containers are not in the ready state. - If one of the GUI pods is not running or all containers are not in the ready state.
Critical	2 scale core pods are not running per RG with erasure code parity 4+2P 2 or 3 scale core pods are not running per RG with erasure code parity 4+3P 2 or 3 scale core pods are not running per RG with erasure code parity 8+3P - GPFS service is not active on 2 scale core pods per RG (4+2P per RG) - GPFS service is not active on 2 or 3 scale core pods per RG (4+3P per RG) - GPFS service is not active on 2 or 3 scale core pods per RG (8+3P per RG) - If both the PM collector pods are not running or all containers are not in the ready state. - If any of the CSI pods are not running or all containers are not in the ready state. - If both the GUI pods are not running or all containers are not in the ready state. - Add Filesystem is not mounted on more than the tolerable number of nodes.
Down	- More than 2 scale core pods are not running (4+2P per RG) - More than 3 scale core pods are not running (4+3P Per RG) - More than 3 scale core pods are not running (8+3P Per RG) - GPFS service not Active on more than 2 scale core pods per RG (4+2P per RG) - GPFS service not Active on more than 3 scale core pods per RG (4+3P Per RG) - GPFS service not Active on more than 3 scale core pods per RG (8+3P Per RG)

From the ellipsis menu, you can download logs and view documentation. After you successfully collect the logs, a success notification gets displayed. The notification disappears automatically after some time.

For more information about Global data platform service issues during IBM Fusion HCI installation, see [Installation issues](#).

4. Verify Global Data Platform installation.

Validate Global Data Platform operators, deployments, and pods from the OpenShift management console

- Log in to the OpenShift web console.
 - From the menu navigation, click Operators, Installed Operators.
 - From the Installed Operators list, click IBM Storage Fusion operator. The Details tab is open by default.
 - Open Scale tab, and check whether the storagemanager is in the Scales list and is healthy.
- Note: For Global Data Platform Remote Mount version 6.0.0.1, the **storage-manager** is not created.
- From the menu navigation, click Workloads, Deployments.
 - Check whether the following namespaces and their deployments are available:

```
ibm-spectrum-fusion-ns project
  • isf-storage-service-dep
  • isf-storage-operator-controller-manager
```

```
ibm-spectrum-scale-operator project
  ibm-spectrum-scale-controller-manager
```

```
ibm-spectrum-scale-csi project
  ibm-spectrum-scale-csi-operator
```

Note: For Global Data Platform Remote Mount version 6.0.0.1, the **ibm-spectrum-scale-csi-operator** pod is no longer available.

- From the menu navigation, click Workloads, Pods.
- Check whether you can see the following pods:

```
ibm-spectrum-fusion-ns project
  isf-storage-operator-controller-manager
  isf-storage-service-dep
ibm-spectrum-scale-csi project
  ibm-spectrum-scale-csi-operator
  ibm-spectrum-scale-csi-provisioner
  ibm-spectrum-scale-csi-attacher
  ibm-spectrum-scale-csi
```

Note: For Global Data Platform Remote Mount version 6.0.0.1, the **ibm-spectrum-scale-csi-operator** pod is no longer available.

```
ibm-spectrum-scale project
  compute-1-ruX
  ibm-spectrum-scale-gui-0
  ibm-spectrum-scale-gui-1
  ibm-spectrum-scale-pmcollector-0
  ibm-spectrum-scale-pmcollector-1
ibm-spectrum-scale-operator
  ibm-spectrum-scale-controller-manager
```

Validate other pods from the CLI

- To list all DNS pods, run the OC command:

```
./oc get pods -n ibm-spectrum-scale-dns
```

For example, see the following result:

```
oc get po -n ibm-spectrum-scale-dns
NAME          READY   STATUS    RESTARTS   AGE
coredns-4gmrq 1/1     Running   3           7d16h
coredns-bjpv7 1/1     Running   5           7d16h
coredns-hnrph 1/1     Running   3           7d16h
coredns-j4dxq 1/1     Running   3           7d16h
coredns-ln6gj 1/1     Running   3           7d16h
coredns-rtfdg 1/1     Running   3           7d16h
```

Ensure all the pods are up and running.

Verify the storage class.

Note: Ensure that the following storage classes are created.

```
oc get sc
```

What to do next

1. Configure storage to work with other dependent services. For the procedure to configure, see [Configuring Global Data Platform local storage](#).
 2. In the Hosted Control Plane cluster, go to Remote file systems page of the user interface and connect to remote file systems. For the procedure to connect to remote file systems, see [Connecting to remote IBM Storage Scale file systems](#).
 3. In a Hosted Control Plane cluster, to consume the remote file system by using Global Data Platform, see [Static provisioning of Persistent Volume in filesystem](#) and [Dynamic provisioning of Persistent Volume in filesystem](#).
 4. You can now install other available IBM Fusion services.
- [Global Data Platform storage support for multi rack](#)
Compatibility of Global Data Platform storage service with IBM Fusion HCI multi-rack and expansion rack.

Global Data Platform storage support for multi rack

Compatibility of Global Data Platform storage service with IBM Fusion HCI multi-rack and expansion rack.

Table 1. Global Data Platform support on IBM Fusion HCI multi rack deployment topologies

Deployment topology	Fresh installation	Node upsize	Disk upsize	Remote mount
Expansion rack	Require a minimum of 6 storage nodes on the base rack	Any number of Compute-only, Compute-Storage, and GPU nodes can be added	Even number of disks with the same capacity can only be up sized	Supported

Configuring Global Data Platform local storage

Configure Global Data Platform as your storage, then configure storage nodes, and finally set its encryption.

Before you begin

- Install a local storage provider from the Services page. For the procedure to install, see [Installing Global Data Platform](#).
- Plan whether you want to configure storage and set it for disaster recovery. If you choose the disaster recovery option, select whether you want to do a Metro-DR configuration or a Regional DR configuration.

About this task

The configuration of the local storage can take up to several hours depending on your cluster size or the amount of nodes you have in your cluster.

Important:

- If Global Data Platform is not configured or is configured but are not in a healthy state, then a few pods, like logcollector, might remain in a pending state. The pods come into a running state automatically once storage is configured and in a healthy state.
- Both Global Data Platform and Fusion Data Foundation cannot coexist as your storage.

Procedure

1. Go to Storage > Local storage.
2. Wait for the discovery of compute nodes to complete.
After the discovery process completes, the Configure storage button is enabled.
3. Click Configure.
4. Optional: In the Configure local storage page, you can decide to select Set up Disaster Recovery or not.
A disaster recovery configuration provides data replication between two HCI clusters by connecting the storage networks used by the clusters. The default is always disabled.
If you selected the Set up Disaster Recovery option in the previous step, then the configuration section is displayed with Metro and Regional options. If you did not select the Set up Disaster Recovery option, then skip step 5 and 6.
5. Select Metro or Regional tile.

Option	Description
--------	-------------

Option	Description
Metro	Select whether you want this rack to be your First site or Second site of the disaster recovery pair. First site - Select First site tile. - Go to step 6. Second site - Select Second site tile. - In the Connect to the first site section, paste the connection snippet of the first site. For the procedure to get the snippet, see Upgrade and upsize considerations in Metro-DR. - Select whether you want to enable Jumbo frames or not. Jumbo frames improve the performance of the storage network between the two IBM Fusion HCI clusters in a disaster recovery pair. To know more about Jumbo frames and its prerequisites, see the <i>Jumbo frames</i> section of General Metro-DR prerequisites topic. - Click Configure. The storage configuration of site 2 is same as the site 1 so the wizard closes after you click Configure, and the configuration of Global Data Platform service starts for the second site. - Go to step 10 to view the details of the configured Global Data Platform.
Regional	Proceed with step 6. For asynchronous disaster recovery set up, go to Disaster recovery page after you install the Global Data Platform service.

6. Click Next.

7. In the Storage option wizard page, click Stronger data resiliency tile or Better storage efficiency tile.

The Storage option wizard page provides storage capabilities of IBM Fusion with two storage configurations, Stronger data resiliency and Better storage efficiency. If there are eleven or more storage nodes in the appliance, you can choose between Stronger data resiliency and Better storage efficiency building block configurations. If there are less than eleven storage nodes in the appliance, the Stronger data resiliency building block configuration is only available.

Note: The storage setting is predetermined to 4+3P erasure coding for a high availability cluster.

A Stronger data resiliency option is an optimal set of (4+2P) building blocks based on the number of nodes in the rack. If enough nodes exist for the two building blocks, then IBM Fusion creates a two-building block configuration. This configuration increases the number of simultaneous node failures, which the appliance can withstand. For example, if you set up a rack and choose a (4+2P) building block configuration, then for every six nodes, you get two nodes or disk failure tolerance. If the number of nodes are less for two building block configuration, a Strong data resiliency option appears with one (4+2P) building block configuration. For example, if you set up a rack and choose a (4+2P) building block configuration, then for every six nodes, you get one node or disk failure tolerance.

The Better storage efficiency option uses a single building block configuration, consisting of a minimum of eleven storage nodes. The building block resiliency is achieved by using (8+3p) erasure coding. It means that the cluster can withstand a maximum of three storage node failures, with the data recovered from other nodes in the building block.

Note:

- The building block configuration that you choose applies to all storage nodes that you add in the future when you expand the rack. For example, if you start with a single (4+2p) Stronger data resiliency building block and later add six additional storage nodes, then those new nodes are used to create a second (4+2p) Stronger data resiliency building block.
- You do not have to configure the Global data platform for site 2 in a Metro-DR setup because IBM Fusion HCI automatically applies the configuration of the primary rack or site 1 to site 2.

Important: You cannot change the building block configuration post the installation.

8. Expand Advanced and select Block size.

An advanced setting is available that you can use to customize the Block size for IBM Fusion HCI's Global data platform. As OpenShift clusters run a mix of workloads with different I/O characteristics, it is recommended that you use the default 4 MiB block size that is optimized for mixed workloads.

If the applications that get deployed to the OpenShift cluster are specifically workloads that drive large or small IOs, you can customize the block size for better performance.

For single rack, the available block sizes for Stronger data resiliency or (4+2p) erasure code are 1 MiB and 4 MiB.

For high-availability cluster, the available block sizes for Stronger data resiliency or (4+3p) erasure code are 1 MiB and 4 MiB.

The available block sizes for Better storage efficiency or (8+3p) erasure code are 1 MiB, 4 MiB, and 16 MiB.

Note: Considerations before you choose a block size:

- For general workloads, it is recommended to choose 4 MiB block size.
- If the cluster primarily deals with many small files, it is recommended to choose a small block size such as 1 MiB.
- For large files or streaming workloads, it is recommended to choose 16 MiB block size.

For more information about block size, see [Block size](#).

9. Click Configure.

10. Go to the Global Data Platform page in the IBM Fusion user interface.

The Local storage page now includes Usable capacity, Health, and Nodes sections. Here, the Usable capacity is configuring storage and the Health is initializing. Note: Sometimes, it can take up to five minutes to show the summary of Usable capacity and Health sections.

Usable capacity

The amount of capacity that is available for storing data on a system after the RAID or mirroring technology is applied. Usable capacity is represented in a line graph.

Health

It includes the health of the following:

- Storage cluster
- Global Data Platform service

The status gets displayed only after the provisioning is complete.

Nodes

It includes a list of all nodes that you used in your local storage configuration. The node details listed in the table are Name, Storage status, Type, Disk count, Disk size (TiB), CPU core, and Memory (GiB).

In the Nodes section, the initial Storage status is Installing storage software. After the initial status, it can have the following statuses:

Normal

The component or the service that is hosted on the node is working as expected, and no active error events exist.

Critical

The component or the service that is hosted on the node failed because of the failure of some of its critical components.

Degraded

The node or the service that is hosted on the node is not working as expected. A problem occurred with the component, but it is not a complete failure.

Unknown

The status of the component or the service that is hosted on the node is not known.

You can use the search option to filter and search for nodes. You can add nodes to scale up.

11. To enable encryption, click Configure encryption.

If the encryption is already set up, then the Connection settings is displayed.

For the procedure to configure encryption, see [Configuring encryption for Global Data Platform storage](#).

What to do next

You can now add disks.

Setting up encryption for storage

Setting encryption for the different storage types in IBM Fusion HCI .

Global Data Platform

You can connect to an encrypted remote IBM Storage Scale file system.

- The encryption server is configured after the configuration of encryption workflow. After the encryption settings are added, you cannot disable the local storage encryption.
- In Global Data Platform storage, you can connect to an encrypted remote IBM Storage Scale file system.
- The local storage can have non-encrypted data and encrypted data after you add the encryption settings on the Configure encryption page.
- The local storage gets automatically encrypted from the point a key management server is added to .
- Remote filesystem encryption is configured on remote Scale before you add it to the user interface.
- To secure or encrypt your etcd data, follow the steps that are mentioned in the OpenShift® Container Platform documentation. See [Enabling etcd encryption](#).
- [Configuring encryption for Global Data Platform storage](#)
You can set the encryption for the IBM Fusion local storage.

Configuring encryption for Global Data Platform storage

You can set the encryption for the IBM Fusion local storage.

Before you begin

Prepare IBM® Security Guardium® Key Lifecycle Manager (GKLM) server for IBM Fusion. To establish an encryption-enabled environment, see part 1 of [Simplified setup: Using GKLM with a self-signed certificate](#).

Ensure that you go through the firewall recommendations for GKLM. See [Firewall recommendations for IBM GKLM](#)

About this task

The IBM Storage Scale admin encrypts the remote file system. As a IBM Fusion user, you must connect to the same key management server so that encrypted data can be accessed.

Procedure

1. Go to the Storage > Remote file systems page in IBM Fusion user interface to configure encryption for remote IBM Storage Scale filesystem.
For Global Data Platform local storage, go to Storage > Local storage
2. Click Connect in the Encryption tile.
3. Enter the following connection details:

Hostname

For local storage, enter the Security Key Lifecycle Manager host name to connect.

Backup host name

Optionally, enter secondary GKLM server host name.

Port number (optional)

The REST port number connects IBM Fusion to Security Key Lifecycle Manager REST admin interface. The default port number is 9443.

Note: It can depend on Security Key Lifecycle Manager version. See [Firewall recommendations for IBM GKLM](#).

User name

The administrator user name to connect to the GKLM Server is **GKLMAdmin**.

Password

The administrator password for the GKLMAdmin of the GKLM Server.

4. Enter the following Certificate details.

Note: TLS/KMIP Certificates for secure communication on the KMIP port, only require when the key server is running with a certificate chain from a Certificate Authority (CA) rather than with a self-signed server certificate. The certificates must be formatted as PEM-encoded X.509 certificates.

Root certificate

The root CA certificate from the Certificate Authority.

Endpoint certificate

The server certificate that is signed by a CA.

Intermediate certificate (optional)

The intermediate CA certificates are required only when the server certificate is signed by one of them. If you have more intermediate certificates, then click Add intermediate certificate to add them.

5. For the local storage, to encrypt data, select NIST SP 800-131A or NIST SP 800-131AFAST for the Encryption algorithm.

6. For the remote file systems, enter the following values for File system tenants.

Encryption tenant ID

Represents the keyspace configured on the GKLM server. All IBM Fusion systems that want to share or use encryption keys must use the same tenant ID.

Remote key management ID

It is the remote key management ID. All nodes in the IBM Fusion system must use the same RKMID, which describes a combination of keyserver, tenant, and client on the remote scale cluster.

Important: The DNS name for the key server or tenant must start with a letter or number. Special characters at the beginning of the DNS name are not supported and can result in an invalid RKMID.

You can add more such Encryption tenant ID and Remote key management ID pairs.

Run the following commands on the remote scale cluster to retrieve the values:

```
mmkeyserv client show
```

This command gives the tenant name. If the tenant name is displayed as (none), then first register client using `mmkeyserv client register` command. For more information about this command, see [mmkeyserv command](#).

To get Remote key management ID, run the following command on the remote scale cluster:

```
mmkeyserv tenant show
```

7. Click Configure.

Configuring storage

You can configure Global Data Platform as your storage.

Important:

- If either Global Data Platform or Fusion Data Foundation are not configured or are configured but are not in a healthy state, then a few pods, like logcollector, might remain in a pending state. The pods come into a running state automatically once storage is configured and in a healthy state.
- Both Global Data Platform and Fusion Data Foundation cannot coexist as your storage.

Sharing data

Active file management (AFM) is a scalable, high-performance, file system caching layer, and enables sharing of data across clusters, even if the networks are unreliable or have high latency.

Use IBM Fusion HCI as a cache cluster. For AFM, you also need a home cluster. To set up a home cluster, see [Setting up the home cluster](#).

The subsections provide insights on how you can work with Active file management (AFM) volume management in IBM Fusion HCI.

- [Retrieving credentials](#)
As a user, you must authenticate the REST APIs for Active file management (AFM).
- [Active file management \(AFM\) fileset creation](#)
Create an Active file management (AFM) fileset according to this procedure.
- [Create Persistent Volume and Persistent Volume Claim](#)
Create a Persistent Volume and Persistent Volume Claim.

Retrieving credentials

As a user, you must authenticate the REST APIs for Active file management (AFM).

To retrieve the credentials (username and password) and use it for authentication, run the following `OC` command in the `ibm-spectrum-scale` namespace:

```
oc get secret/ibm-spectrum-scale-gui-secret -n ibm-spectrum-scale -o go-template --template="{{.data.username|base64decode}}"
oc get secret/ibm-spectrum-scale-gui-secret -n ibm-spectrum-scale -o go-template --template="{{.data.password|base64decode}}"
```

Active file management (AFM) fileset creation

Create an Active file management (AFM) fileset according to this procedure.

1. Create Active file management (AFM) fileset with IBM Storage Scale server and NFS or with any other NFS server

Prerequisite

- An NFS export is available from the home cluster with `no_root_squash`. The NFS export must have read/write permissions. See the following snippet:

```
/test *(rw,nohide,insecure,no_subtree_check,sync,no_root_squash,fsid=101)
```

- To retrieve the route, run the following `OC` command:

```
oc get route -n ibm-spectrum-scale
```

Example output:

NAME	HOST/PORT	PATH
ibm-spectrum-scale-gui	ibm-spectrum-scale-gui-ibm-spectrum-scale.apps.isf.ibm.com	ibm-spectrum-scale

- To retrieve the authorization token, run the following `curl` command:

```
curl -X POST --header 'Content-Type: application/json' --header 'Accept: application/json' -u '<userName>:<password>' -d '{"type": "USER", "clusterName": "<clusterName>", "requestingUser": "<userName>", "accessToken": "access-token-1", "authData": { "userName": "<userName>", "roles": { "<userName>": "PENDING", "status": "PENDING" } }' https://<Scale Route URL>/scalemgmt/v2/access -k
```

Where, `<"userName">:<"password">` or `<"userName">` are the username and password that is retrieved from the *Retrieving credentials* topic.

`"clusterName"` is the OpenShift® cluster name.

Example command:

```
curl -X POST --header 'Content-Type: application/json' --header 'Accept: application/json' -u 'admin:passw0rd' -d '{"type": "USER", "clusterName": "fus0.sdi.dmz", "requestingUser": "admin", "accessToken": "access-token-1", "authData": { "userName": "admin", "roles": { "admin": "PENDING", "status": "PENDING" } }' https://ibm-spectrum-scale-gui-ibm-spectrum-scale.apps.fus0.sdi.dmz/scalemgmt/v2/access -k
```

Example output:

```
{ "clusterName" : "ibm-spectrum-scale.fus0.sdi.dmz", "status" : { "code" : 200, "message" : "The request finished successfully." }, "token" : "0ccfb637-d46c-dead-beef-f8438c2842d5" }
```

- Retrieve the filesystem name (`filesystem_name`) that is mounted on the OpenShift Container Platform cluster. Example command:

```
curl -k -H "Authorization:Token <token retrieved from the previous command>" -X GET --header 'content-type:application/json' https://<spectrum_scale_gui_route>/scalemgmt/v2/filesystems
```

Example output:

```
{ "filesystems" : [ { "name" : "ibmspectrum-fs" } ], "status" : { "code" : 200, "message" : "The request finished successfully." } }
```

For more information about the REST API, see [Filesystems: GET](#).

Procedure

Run the REST API to create the Active file management (AFM) fileset in IBM Fusion as follows:

```
curl -k -H "Authorization:Token <token retrieved from the previous command>" -X POST --header 'content-type:application/json' --header 'accept:application/json' -d '{
  "filesetName": "<afm_fileset_name>",
  "path": "/mnt/<filesystem_name>/<afm_fileset_name>",
  "afmTarget": "nfs://<nfs_home_ip>/<export_path_on_home>",
  "afmMode": "independent-writer"
}' https://<spectrum_scale_gui_route>/scalemgmt/v2/filesystems/<filesystem_name>/filesets
```

An example is as follows:

```
curl -k -H "Authorization:Token <token retrieved from the previous command>" -X POST --header 'content-type:application/json' --header 'accept:application/json' -d '{
  > "filesetName": "afmfsetnfs",
  > "path": "/mnt/ibmspectrum-fs/afmfsetnfs",
  > "afmTarget": "nfs://9.9.9.9/mnt/fs1/fset1",
  > "afmMode": "independent-writer"
  > }' https://ibm-spectrum-scale-gui-ibm-spectrum-scale.apps.isf.ibm.com/scalemgmt/v2/filesystems/ibmspectrum-fs/filesets
```

2. Create AFM fileset with Object store as home

Prerequisite

- A bucket is available on an S3 compliant object store.
- Access key and secret key are available to access the bucket.
- Configure the AFM to Cloud Object Storage by using the keys that are created or generated on the Cloud Object Storage.

For more information, see [Configuring AFM to cloud object storage](#).

Procedure

- Run the REST API to create Active file management (AFM) fileset in IBM Fusion as follows:

```
curl -k -H "Authorization:Token <token retrieved from the previous command>" -X POST --header 'content-type:application/json' --header 'accept:application/json' -d '{
  "filesetName": "<afm_fileset_name>",
  "endpoint": "<s3_endpoint>",
  "useObjectFs": true,
  "bucket": "<bucket_name>",
  "mode": "<iw/ro>",
  "accessKey": "<access_key>",
  "secretKey": "<secret_key>"
}' 'https://<spectrum_scale_gui_route>/scalemgmt/v2/filesystems/<filesystem_name>/filesets/cos'
```

An example is as follows:

```
curl -k -H "Authorization:Token <token retrieved from the previous command>" -X POST --header 'content-type:application/json' --header 'accept:application/json' -d '{
  "filesetName": "cosfset1",
  "endpoint": "http://us-east-2@s3.us-east-2.amazonaws.com",
  "useObjectFs": true,
  "bucket": "mybucket",
  "mode": "iw",
  "accessKey": "xxxxxxx",
  "secretKey": "xxxxxxxxxxxxxx"
}' 'https://ibm-spectrum-scale-gui-ibm-spectrum-scale.apps.fusion.cp.fyre.ibm.com/scalemgmt/v2/filesystems/ibmspectrum-fs/filesets/cos'
```

- Make note of the job ID. See the following sample text:

```
{
  "jobs" : [ {
    "jobId" : 50000000000543,
    "status" : "RUNNING",
    "submitted" : "2021-11-08 05:57:02,375",
    "completed" : "N/A",
    "runtime" : 2,
    "request" : {
      "data" : {
        "afmMode" : "read-only",
        "afmTarget" : "nfs://<ip_address>/gpfs/fs1/tgt1",
        "filesetName" : "roCacheFileset",
        "path" : "/mnt/rackhscale/roCacheFileset"
      },
      "type" : "POST",
      "url" : "/scalemgmt/v2/filesystems/rackhscale/filesets"
    },
    "result" : { },
    "pids" : [ ]
  } ],
  "status" : {
    "code" : 202,
    "message" : "The request was accepted for processing."
  }
}
```

3. Verification of Active file management (AFM) fileset creation configuration

Procedure

- Check that the fileset creation job is successful as follows:

```
curl -k -H "Authorization:Token <token retrieved from the previous command>" -X GET --header 'content-type:application/json' https://<spectrum_scale_gui_route>/scalemgmt/v2/jobs/<job_id>
```

- Verify that Active file management (AFM) cache fileset is created and cache is active as follows:

```
curl -k -H "Authorization:Token <token retrieved from the previous command>" -X GET --header 'content-type:application/json' https://<spectrum_scale_gui_route>/scalemgmt/v2/filesystems/<filesystem_name>/afm/state
```

An example is as follows:

```
curl -k -H "Authorization:Token <token retrieved from the previous command>" -X GET --header 'content-type:application/json' https://ibm-spectrum-scale-gui-ibm-spectrum-scale.apps.fusion.cp.fyre.ibm.com/scalemgmt/v2/filesystems/ibmspectrum-fs/afm/state
{
  "filesetAfmStateList" : [ {
    "cacheState" : "Active",
    "filesetName" : "afmfsetnfs",
    "filesystemName" : "ibmspectrum-fs"
  }, {
    "cacheState" : "Active",
    "filesetName" : "afmpall",
    "filesystemName" : "ibmspectrum-fs"
  }, {
    "cacheState" : "Active",
    "filesetName" : "afms",
    "filesystemName" : "ibmspectrum-fs"
  } ],
  "status" : {
    "code" : 200,
    "message" : "The request finished successfully."
  }
}
```

```
}  
}
```

Note: For the container logs, go to /var/log/cnlog/mgtsrv. To view the last few lines of the container log file, run the following tail command:

```
tail -f mgtsrv-trace-log in ibm-spectrum-scale-gui-0 pod
```

If you face errors, then it can be in the container log file of any of the two GUI pods. Check the log of `ibm-spectrum-scale-gui-1` as well.

Create Persistent Volume and Persistent Volume Claim

Create a Persistent Volume and Persistent Volume Claim.

You must create a persistent volume and a persistent volume claim. For more information, see [Generating static provisioning manifests](#).

Global Data Platform service install and upgrade issues

Use this troubleshooting information to resolve install and upgrade problems that are related to Global Data Platform service.

Warning: Do NOT delete IBM Storage Scale pods. Deletion of Scale pods in many circumstances has implications on availability and data integrity.

IBM Storage Scale stuck with error

Problem statement

If IBM Storage Scale installation stuck with the error ERROR Failed to define vdiskset {"controller": "filesystem", "controllerGroup": "scale.spectrum.ibm.com", "controllerKind": "Filesystem", "Filesystem": {"name": "ibmspectrum-fs", "namespace": "ibm-spectrum-scale"}, "namespace": "ibm-spectrum-scale", "name": "ibmspectrum-fs", "reconcileID": "5fcf21a4-b488-44db-8db5-0f3c1ab695cd", "cmd": "/usr/lpp/mmfs/bin/mmvdisk vs define --vs ibmspectrum-fs-0 --rg rg1 --code 4+2P --bs 4M -

Resolution

As a resolution, run the following command to manually create a recovery group.

```
mmvdisk recoverygroup create --recovery-group <RG name> --node-class <Node class name>
```

Upgrade does not complete as node pod is in ContainerStatusUnknown state

Problem statement

Global data platform upgrade does not complete because a compute node pod is in `ContainerStatusUnknown` state.

Workaround

Delete the pod in `ContainerStatusUnknown` state and restart the compute node.

Pod drain issues in Global data platform upgrade

Diagnosis and resolution

If the upgrade of Global data platform gets struck, then do the following diagnose and resolve:

1. Go through the logs from the scale operator.
2. Check whether you observe the following error:
ERROR Drain error when evicting pods
3. If it is a drain error, then check whether the virtual machine's PVC were created ReadWriteOnce.
The PVCs created by using ReadWriteAfter are not shareable or moveable and can cause the draining of the node.

For example:

```
oc get pods
```

NAME	READY	STATUS	RESTARTS	AGE
compute-0	2/2	Running	0	20h
compute-1	2/2	Running	0	24h
compute-13	2/2	Running	0	21h
compute-14	2/2	Running	3	21h
compute-2	2/2	Running	0	21h
compute-3	2/2	Running	0	21h
control-0	2/2	Running	0	23h
control-1	2/2	Running	0	23h
control-1-1	2/2	Running	0	23h
control1-1-reboot	0/1	ContainerStatusUnknown	1	23h
control-2	2/2	Running	0	23h
ibm-spectrum-scale-gui-0	4/4	Running	0	20h
ibm-spectrum-scale-gui-1	4/4	Running	0	23h
ibm-spectrum-scale-pmcollector-0	2/2	Running	0	23h
ibm-spectrum-scale-pmcollector-1	2/2	Running	0	20h

4. If virtual machine's PVC got created ReadWriteOnce, then stop the virtual machine to continue the upgrade of scale pods.
5. If the upgrade fails further, then check whether the reason can be due to an orphaned `control-1-reboot` container left in the `ibm-spectrum-scale` namespace. Delete the container to resume and complete the installation.

IBM Storage Scale might get stuck during upgrade

Resolution

Do the following steps:

1. Shut down all applications that use storage.
2. Scale down the IBM Storage Scale operator. Make the replica as 0 for deployment **ibm-spectrum-scale-controller-manager**.
 - a. Use **ibm-spectrum-scale-operator** project:

```
oc project ibm-spectrum-scale-operator
```

- b. Scale down the IBM Storage Scale operator.

```
oc scale --replicas=0 deployment ibm-spectrum-scale-controller-manager -n ibm-spectrum-scale-operator
```

- c. Run the following command to confirm resources are not found in **ibm-spectrum-scale-operator** namespace.

```
oc get po
```

3. Log in to the one of the IBM Storage Scale core pods and shut down the server.

- a. Log in to the server:

```
oc rsh compute-0
```

- b. Shut down the server:

```
mmshutdown -a
```

Example output:

```
Thu May 19 07:46:47 UTC 2022: mmshutdown: Starting force unmount of GPFS file systems
Thu May 19 07:46:52 UTC 2022: mmshutdown: Shutting down GPFS daemons
compute-13.ibm-spectrum-scale-core.ibm-spectrum-scale.svc.cluster.local: Shutting down!
compute-14.ibm-spectrum-scale-core.ibm-spectrum-scale.svc.cluster.local: Shutting down!
compute-0.ibm-spectrum-scale-core.ibm-spectrum-scale.svc.cluster.local: Shutting down!
control-1.ibm-spectrum-scale-core.ibm-spectrum-scale.svc.cluster.local: Shutting down!
control-0.ibm-spectrum-scale-core.ibm-spectrum-scale.svc.cluster.local: Shutting down!

compute-14.ibm-spectrum-scale-core.ibm-spectrum-scale.svc.cluster.local: 'shutdown' command about to kill process 1
compute-14.ibm-spectrum-scale-core.ibm-spectrum-scale.svc.cluster.local: Unloading modules from /lib/modules/4.18.0
compute-14.ibm-spectrum-scale-core.ibm-spectrum-scale.svc.cluster.local: mmfsenv: Module mmfslinux is still in use.
compute-13.ibm-spectrum-scale-core.ibm-spectrum-scale.svc.cluster.local: mmfsenv: Module mmfslinux is still in use.
compute-14.ibm-spectrum-scale-core.ibm-spectrum-scale.svc.cluster.local: Unloading module mmfs26
compute-13.ibm-spectrum-scale-core.ibm-spectrum-scale.svc.cluster.local: Unloading module mmfs26
compute-14.ibm-spectrum-scale-core.ibm-spectrum-scale.svc.cluster.local: Unmount all GPFS file system
..
compute-2.ibm-spectrum-scale-core.ibm-spectrum-scale.svc.cluster.local: Unloading module mmfs26
control-2.ibm-spectrum-scale-core.ibm-spectrum-scale.svc.cluster.local: Unloading module mmfs26
control-2.ibm-spectrum-scale-core.ibm-spectrum-scale.svc.cluster.local: Unloading module mmfslinux
compute-0.ibm-spectrum-scale-core.ibm-spectrum-scale.svc.cluster.local: Unloading module mmfslinux
compute-2.ibm-spectrum-scale-core.ibm-spectrum-scale.svc.cluster.local: Unloading module mmfslinux
Thu May 19 07:47:03 UTC 2022: mmshutdown: Finished
```

4. Check whether the states are down:

```
mmgetstate -a
```

Sample output:

Node number	Node name	GPFS state
1	control-0-daemon	down
2	control-1-daemon	down
3	control-2-daemon	down
4	compute-14-daemon	down
5	compute-13-daemon	down
6	compute-0-daemon	down
7	compute-1-daemon	down
8	compute-2-daemon	down

5. Delete all the pods in **ibm-spectrum-scale** namespace:

```
oc delete pods --all -n ibm-spectrum-scale
```

6. To verify, get the list of pods:

```
oc get po -n ibm-spectrum-scale
```

Sample output:

NAME	READY	STATUS	RESTARTS	AGE
ibm-spectrum-scale-gui-0	0/4	Pending	0	7s
ibm-spectrum-scale-pmcollector-0	0/2	Pending	0	7s

Note: Only IBM Storage Scale pods get deleted and not GUI and **pmcollector**.

IBM Storage Scale upgrade gets stuck

Cause

The IBM Storage Scale upgrade gets stuck because of `isf-storage-service`. It happens whenever the `scaleoutstatus` or `scaleupStatus` is **In Progress** in the Scale CR.

Important: Do not update the latest image for the `isf-storage-service` when a IBM Storage Scale operation is in progress.

Workaround

Steps to upgrade the IBM Storage Scale on the rack:

1. Go to the `isf-storage-service` in `ibm-spectrum-fusion-ns` project and change the image to `cp.icr.io/cp/isf/isf-storage-services:2.2.0-latest` or run the following OC command.

```
oc patch deploy isf-storage-service-dep -n ibm-spectrum-fusion-ns --patch='{ "spec": { "template": { "spec": { "containers": [ { "name": "app", "image": "cp.icr.io/cp/isf/isf-storage-services:2.2.0-latest" } ] } } } }
```

2. After the `isf-storage-service` pod goes to running state and points to the `cp.icr.io/cp/isf/isf-storage-services:2.2.0-latest` version, run the following API endpoint command in the `isf-storage-service` pod's terminal:

```
curl -k https://isf-scale-svc/api/v1/upgradeExcludingOperator
```

You can observe the new logs for `isf-storage-service` as well.

3. Set the Edition to `erasure-code` in the `Daemon` CR:

```
oc patch daemon ibm-spectrum-scale \
--type='json' -n ibm-spectrum-scale \
-p='[{"op": "replace", "path": "/spec/edition", "value": "erasure-code"}]'
```

4. Run the following curl command to deploy the operator on the Red Hat® OpenShift® Container Platform cluster:

```
curl -k https://isf-scale-svc/api/v1/upgradeWithOperator
```

You can observe new logs for `isf-storage-service`.

5. Wait for sometime and check whether the status of IBM Storage Scale core pod is in restart or running state in `ibm-spectrum-scale`.

CSI Pods experience scheduling problems post node drain

Problem statement

Whenever a compute node is drained, an eviction of CSI PODs or sidecar PODs occur. The remaining available set of compute nodes cannot host the CSI PODs or sidecar PODs because of resource constraints at that point in time.

Resolution

Ensure that a functional system exists with available compute nodes, having sufficient resources to accommodate evicted CSI PODs or sidecar PODs.

Global Data Platform upgrade progress

Problem statement

During Global Data Platform upgrade, the progress percentage can go beyond 100% in a few cases. You can ignore this issue, as the percentage comes down to 100 % after the successful completion of the upgrade.

Scale installation might get stuck with ECE pods in `init` state

Problem statement

The Scale installation might get stuck with ECE pods in `init` state with the following error:

```
The node already belongs to a GPFS cluster.
```

Resolution

1. Check whether the daemon-network IP of the pod is pingable.
2. If it is not pingable, then restart all available TORs.
3. After you restart TORs, check whether daemon-network IP is pingable.
4. Run the following command to manually clean up the nodes:
For the given worker node, run the following `oc` command:

```
oc debug node/<openshift_worker_node> -T -- chroot /host sh -c "rm -rf /var/mmfs"
```
5. Kill the pod and wait for it to come up again. The Scale installation resumes after all the ECE pods goes to running state.

Expansion rack fails for 4+2p setup

Problem statement

Sometimes, in a high-availability cluster, the expansion rack fails for 4+2p setup.

Resolution

- Do the following workaround steps to resolve the issue:
 1. In the OpenShift Container Platform user interface, go to Administration > CustomResourceDefinitions > Scale > Instances > storagemanager > Yaml and check whether the `scaleoutStatus`: **IN-PROGRESS**
 2. If `scaleoutStatus`: **IN-PROGRESS**, go to Administration > CustomResourceDefinitions > RecoveryGroup > Instances and check for the created RecoveryGroups.
 3. If more than two recovery groups are created, do the following actions:
 - a. Go to Administration > CustomResourceDefinitions > RecoveryGroup > Instances > ..
 - b. Find **RecoveryGroup** instance with suffix `rg2`.

- c. Click the ellipsis menu for that instance and select the Delete RecoveryGroup option.
4. Do the following checks to validate whether the node upsize completed successfully:
 - In the IBM Fusion user interface, go to the IBM Storage Scale user interface by using the app switcher.
 - Click Recovery groups on the IBM Spectrum Scale RAID tile.
 - Click the entry of Recovery group server nodes.
 - Check whether all the newly added nodes for expansion rack are listed and is in Healthy state.
 - Create a sample PVC to check whether the storage can be provisioned.
5. Check for the labels on each recovery group.
 - a. In the OpenShift Container Platform console, go to Administration > CustomResourceDefinitions > RecoveryGroup > Instances > Yaml.
 - b. Check whether the YAML contains either of these two labels:
 - `scale.spectrum.ibm.com/scale: up`
 - `scale.spectrum.ibm.com/scale: out`
 - c. If it is yes for the previous step, remove those labels from each recovery group and click Save.

Known issues in installation

- The display unit of filesystem block size in `storagesetupcr` is MiB and that of `ibmspectrum-fs` is M. As IBM Storage Scale also uses MiB format internally, you can ignore this inconsistency.

Known issues in upgrade

- During upgrade, the IBM Fusion rack user interface, IBM Storage Scale user interface, Grafana endpoint, and Applications are not reachable for sometime.
- During the upgrade, an intermittent error `-1 node updated successfully out of 5 nodes` shows on the IBM Fusion user interface in the upgrade details page.
- During the upgrade, an intermittent error shows on the IBM Fusion user interface that the progress percentage for the Global Data Platform decreased. It occurs, especially when the upgrade for one node is completed.
- During the upgrade, an intermittent error `Global Data Platform upgrade failed` shows on the IBM Fusion user interface in the upgrade details page. Ignore the error because it might recover during the next reconciliation.

Global Data Platform service issues

This section lists the troubleshooting tips and tricks when you use IBM Fusion storage.

Warning: Do NOT delete IBM Storage Scale pods. Deletion of Scale pods in many circumstances has implications on availability and data integrity.

Filesystem status from Remote file systems is stuck in Connecting state

Cause

The secure boot is not supported by Scale and CNSA.

Resolution

1. Check whether the nodes are running with secure boot:

```
mokutil --sb-state
SecureBoot enabled
```

2. As a root password, you can disable the secure boot with the following command:

```
mokutil --disable-validation
password length: 8~16
input password:
input password again:
```

Increased CPU usage on Scale pods after upgrading to Cloud Pak for Integration (CP4I)

Problem statement

Scale pod CPU usage has increased due to changes in MQ streams application. It is because of IBM MQ's liveness and readiness probes.

Resolution

The file handle reservation can be turned off by setting the environment variable `AMQ_NO_RESERVE_FD=1`. It fixes the high CPU usage.

Scale operator failed to add quorum label

Problem statement

During Storage configuration, the recovery group status can be `"Waiting on some daemons in the recovery group to be restarted"`.

Resolution

1. Run the following command to check the count of the quorum node:

```
oc get nodes -l scale.spectrum.ibm.com/designation=quorum
```

2. Check the number of quorum nodes. Whenever the node count is less than 10, there must 3 quorum nodes. If not, apply the following quorum label for the missing nodes:

Remote filesystem connection goes to a Disconnected state

Problem statement

If even one scale core pod is not ready due to node restart or other issues, then a problem occurs on the filesystem mount of that node and the filesystem CR reports errors. As a result, the filesystem goes to a Disconnected and the same is displayed on the IBM Fusion user interface.

Resolution

Wait for the scale core pod to go to Ready state, and the filesystem automatically changes to Connected state.

PVCs stuck in pending state

Resolution

If PVCs are stuck in a pending state for a long time, restart Scale GUI pods.

Nodes with pods scheduled for storage results in a `crashloopbackoff` or container creating errors

Problem statement

When install, upgrade, or upsize operations are in progress and the storage configuration is not yet done, the nodes with pods scheduled for storage results in a `crashloopbackoff` or container creating errors.

Resolution

To resolve this issue, disable schedule on these nodes before you begin these operations, and schedule the pods on nodes that are configured for storage.

File system is not mounted on some nodes

Problem statement

After IBM Storage Scale upgrade, the file system is not mounted on some nodes.

Resolution

Do the following workaround steps:

1. Delete the problematic pod where the file system is not mounted. Delete one pod at a time.
2. Refresh the pod overview page until the pod appears. Run `watch oc get pods`.
3. When the problematic pod comes up, set the replicas to 0 in the `Spec` section in the `ibm-spectrum-scale-operator` namespace. You must stop the operator deployment immediately. Ensure that no operator pod is running in `ibm-spectrum-scale-operator` namespace. Command for setting the operator replica to 0:

```
oc patch deploy ibm-spectrum-scale-controller-manager \
--type='json' -n ibm-spectrum-scale-operator \
-p='[{"op": "replace", "path": "/spec/replicas", "value": 0}]'
```

```
oc get deployment -n ibm-spectrum-scale-operator
```

Sample output:

```
I0420 16:56:23.579340 4184 request.go:645] Throttling request took 1.192496025s, request: GET:https://api.
<domainname>:6443/apis/nmstate.io/v1beta1?timeout=32s
NAME READY UP-TO-DATE AVAILABLE AGE
ibm-spectrum-scale-controller-manager 0/0 0 0 28h
```

4. Wait till the problematic pod is in `init` container state and run the following command:

```
oc exec podname -- mmsdrrestore -p <any working core ip/name[Specify pod IP where FS is mounted]>
```

5. After the previous step is successful, set the replicas to 1 again in the `ibm-spectrum-scale-operator` deployment. Ensure that the operator pod is running in `ibm-spectrum-scale-operator` namespace.

Run the following command for setting the operator replica to 1:

```
oc patch deploy ibm-spectrum-scale-controller-manager \
--type='json' -n ibm-spectrum-scale-operator \
-p='[{"op": "replace", "path": "/spec/replicas", "value": 1}]'
```

```
oc get deployment -n ibm-spectrum-scale-operator
```

Sample output:

```
I0420 16:56:23.579340 4184 request.go:645] Throttling request took 1.192496025s, request: GET:https://api.
<domainname>:6443/apis/nmstate.io/v1beta1?timeout=32s
NAME READY UP-TO-DATE AVAILABLE AGE
ibm-spectrum-scale-controller-manager 1/1 0 0 28h
```

6. Wait for some time for the problematic pod to come in running state and file system gets mounted on this problematic node.

IBM Storage Scale user interface does not load properly or IBM Storage Scale CSI pods are in `CrashLoopBack` state

Problem statement

Sometimes, IBM Storage Scale user interface might not load properly or IBM Storage Scale CSI pods are in **CrashLoopBack** state.

Resolution

As a workaround, do the following steps:

1. Restart the GUI pods and check whether it is working properly.
2. If GUI pod restart does not open the IBM Storage Scale console, then restart the **ibm-spectrum-scale-controller-manager** pod and then restart GUI pod.

Not able to log in to IBM Storage Scale user interface

Cause

The secret that is mounted in GUI pods /etc/gui-oauth/oauth.properties file and secret present in the **ibm-spectrum-scale-gui-oauthclient** are different.

```
gui-1
sh-4.4$ cd /etc/gui-oauth/
sh-4.4$ cat oauth.properties
secret=tjCK6kE0pmCe2d8b7azw
oauthServer=https://oauth.openshift.apps.<domainname>
redirectURI=https://ibm-spectrum-scale-gui-ibm-spectrum-scale.apps.<domainname>/auth/redirect
clientID=ibm-spectrum-scale-gui-oauthclient

```

Resolution

As a resolution, do the following steps:

1. As a resolution, restart the GUI pods.
2. If the previous step (step 1) does not resolve the issue, then restart IBM Storage Scale Operator pod and then restart the GUI pods.

Download log files of all deployments

If you cannot download log files of all deployments, individually download the log files.

Issues in node drain and node restart

Resolution

To resolve such node related issues, see [Issues related to IBM Fusion HCI node drains](#).

IBM Storage Scale cluster failed to recover after powering off and on the compute nodes

Diagnosis

Identify if the nodes joining the cluster are in an out-of-tolerance situation.

1. mmhealth reported UNKNOWN RG status on some nodes.
2. mmrepquota commands have been generated repeatedly, likely by the GUI, which has caused many long waits.
3. Due to the large number of long waits, the cluster manager node was not responding to any **ts cmd** other than **tsctl nqStatus**.
As a resolution, follow the steps defined in the [Recover storage cluster from an unplanned multi-node restart or failure](#).

MCO rollout is not progressing for more than 5 hours during the scale upgrade

Cause

Whenever the nodes are over committed and no pod limit is available, you might see delays in the policy rollout, ICSP, pull secret, and MCO rollout changes.

Resolution

As a resolution, do the following step:

- IBM Fusion HCI nodes allow the maximum number of pods on a node as defined by OpenShift® Container Platform default and ensure to keep that count within the limit. Otherwise, you might see this issue.

IBM Storage Scale cluster status is in a critical state after power on/off the rack

Cause

IBM Storage Scale cluster status is in critical state due to **unmounted_fs_check** is present on the **filesystem** CR.

Resolution

As a resolution, wait until this **filesystem** CR status gets cleared; after that, the IBM Storage Scale cluster status automatically returns to a healthy state. If the issue persists for a long time, then contact [IBM support](#).

Disk upsize issues

- Manual steps to test the **/dev** mount:
After you add a new NVMe disk to the server, the new disk cannot be discovered in the IBM Storage Scale pod. The disks do not show up with **/dev/nvme*** device names in the POD, IBM Storage Scale need the device name **/dev/nvme*** to access the disks. Without the **/dev/nvme*** device name, the new disks cannot be added into recovery group.

Resolution

Do the following manual steps to mount disks to **/dev** in the pod.

1. Log in to each IBM Storage Scale storage pods.

```
oc exec -it <pod name> -c <container> /bin/sh
```

2. Stop the GPFS daemons on one or more nodes:

```
mmshutdown
```

3. Mount **/dev** from the host running the following command:

```
mount -t devtmpfs none /dev
```

4. Validate that the content of **/dev** is from host and you can see sub directories like block, bus, char.

```
mmstartup
```

- [Recover storage cluster from an unplanned multi-node restart or failure](#)
The service of IBM Storage Scale file system might hang if the storage nodes are restarted.
- [IBM Storage Scale file system not showing newly added file system size](#)
The IBM Storage Scale file system is not showing the newly added file system size after adding six nodes as upsize.

Recover storage cluster from an unplanned multi-node restart or failure

The service of IBM Storage Scale file system might hang if the storage nodes are restarted.

The storage nodes might get restarted unexpectedly and might cause the disk to miss in the storage cluster. If the missing disks exceed the fault tolerance RAID code used that is used in the storage cluster, the file system might stop to provide service. It cannot finish the log recovery process for the lost nodes. It might also block the restarting nodes to join the cluster again.

Follow these steps to recover IBM Spectrum® Storage Scale Erasure Code Edition (ECE) from the out of fault tolerance.

Note: Out of fault tolerance in the IBM Storage Scale Erasure Code Edition (ECE) environment can be caused due to different reasons.

1. Identify the problem.
 - a. Run the **mmfsadm dump waiters** command on the running node of the application. It displays the long waiters of I/O threads.

- b. Run the **mmgetstate** command. It displays the restart nodes in arbitrating state and others in active state.
- c. Run the **tslsrecgroup rg_1 --server --v2** command several times. It displays that Log Groups jumps between nodes.
- d. Check the **mmfs.log** file on all storage nodes. The log message shows up in loop on different nodes. See the message as follows:

```
[E] Beginning to resign log group LG002 in recovery group rg1 ....
```

It means that the user log group continues to resign.

2. Start the recovery process.
 - a. Run the **mmlscluster** command to find all the quorum nodes.
 - b. Run the **mmshutdown** command on all quorum nodes. This action causes all nodes to unmount from the file system.
 - c. Run the **mmstartup** command on all quorum nodes.
 - d. Run the **mmlsrecoverygroup rg1 -l --pdisk** to check whether the recovery group is active again and that no missing **pdisk** exists.
 - e. Mount the file system again on all the client nodes and restart the application.

IBM Storage Scale file system not showing newly added file system size

The IBM Storage Scale file system is not showing the newly added file system size after adding six nodes as upsize.

About this task

A system with a single recovery group (setup with 4+2p erasure code) needs to do node upscaling with six nodes all together.

Procedure

1. Follow the steps to upsize nodes:
 - a. Follow the standard node upsize process. For more information, see [Configuring nodes for management](#).
 - b. IBM Fusion HCI user interface shows the Running state for the newly added nodes.
 - c. In the IBM Fusion HCI user interface, use the app switcher to go to the IBM Storage Scale user interface.
 - d. Click Recovery groups on the IBM Storage Scale RAID tile.
The entry for the recovery group server nodes column shows up empty. If true, perform the following steps. Otherwise, contact the [IBM support](#).
 - e. Edit the labels of newly added nodes, change the label **scale.spectrum.ibm.com/rg: rg1** to **scale.spectrum.ibm.com/rg: rg2**.
 - f. Repeat the following process for each newly added node.
 - i. Open the OpenShift Container Platform user interface.
 - ii. Go to Compute > Nodes > Details > Actions > Edit labels.
 - iii. Remove the label **scale.spectrum.ibm.com/rg: rg1** and add the label **scale.spectrum.ibm.com/rg: rg2**.
 - iv. Click Save.
2. Follow the steps to validate the upsized nodes:
 - a. In the IBM Fusion HCI user interface, use the app switcher to go to the IBM Storage Scale user interface.
 - b. Click Recovery groups on the IBM Storage Scale RAID tile.
 - c. Click the entry of the recovery group server nodes column for rg2.
 - d. Check all the newly added nodes are listed and in healthy state.
 - e. Create a sample PVC to check that storage can be provisioned.

Remote IBM Storage Scale storage cluster in IBM Fusion

IBM Storage Scale remote mount feature enables you to connect to a remote IBM Storage Scale cluster as though it is a part of your local cluster.

About this task

- The Global Data Platform remote mount capability is available only for the following deployment modes:
 - Standalone rack with Global Data Platform (newly installed IBM Fusion versions 2.10.0 or later, that is compliant with network requirements with OpenShift® Container Platform 4.16 or later. For more information about the network requirements, see [Planning and prerequisites for remote mount support](#).
 - Standalone rack with Fusion Data Foundation (newly installed with IBM Fusion versions 2.9.0 or later).
 - Expansion multirack with Global Data Platform storage (newly installed with IBM Fusion versions 2.9.0 or later).
- Important:
 - On Red Hat® OpenShift Container Platform 4.20 or earlier and Fusion Data Foundation 4.20 or earlier, Fusion Data Foundation and the Global Data Platform remote mount service can be installed independently.
 - Starting with Red Hat OpenShift Container Platform 4.21 and Fusion Data Foundation 4.21 or later, install Fusion Data Foundation first. After installation, the Global Data Platform remote mount tile becomes available for configuration.
 - If you install Fusion Data Foundation as local storage, you must explicitly install and configure the remote mount service by using the Global Data Platform remote mount service tile. If you install Global Data Platform as local storage, the remote mount capability is available by default.
 - On a FIPS-enabled cluster, the Global Data Platform remote mount service tile is not displayed and is unavailable for installation.
- You can run a container workload against an existing data set that is stored on an IBM Storage Scale file system. For example, an IBM Storage Scale file system contains lot of images and you want to run a container workload that specializes in image processing.
- The remote file system mount must be configured. For more information, see [Connecting to remote IBM Storage Scale file systems](#).
- When the remote file system mount is created, the IBM Fusion automatically creates a statically provisioned volume that points to the file system. You must know how to identify this Persistent Volume.
- Optionally, modify the file system path that is specified in the Persistent Volume so that it points to a specific directory in the file system, rather than the root.
- Now a Persistent Volume Claim (PVC) can be made against the Persistent Volume. It can be accomplished by matching the **accessMode** and storage request against the specified in the Persistent Volume.
- A workload that uses the Persistent Volume Claim can view the contents of the file system.

- Configure the UID/GID to match the one that is used to write the data set on the IBM Storage Scale file system. If you do not configure, then the container workload cannot access the files, because it does not have the permission.

Procedure

1. Click **Storage > Remote file systems** menu in the IBM Fusion user interface.
It lists all existing connections to file systems with their details in a table format. The details include File System, FS status, Cluster, Cluster status, and Storage class. You can enter keywords in Search to search for a connection. You can also filter records based on the status.
2. Click ellipsis of a remote file system record to do the following actions:
 - Details- Click to view details about the remote file system connection.
 - Edit cluster- Click to change the cluster of a file system connection.
 - Remove- Click to delete a file system record.

Connecting to remote IBM Storage Scale file systems

In IBM Fusion, from a containerized workload, you can access and store data from existing IBM Storage Scale clusters.

Before you begin

On Red Hat® OpenShift® Container Platform 4.20 or earlier and Fusion Data Foundation 4.20 or earlier, Fusion Data Foundation and the Global Data Platform remote mount service can be installed independently.

Starting with Red Hat OpenShift Container Platform 4.21 and Fusion Data Foundation 4.21 or later, install Fusion Data Foundation first. After installation, the Global Data Platform remote mount tile becomes available for configuration.

If you install Fusion Data Foundation as local storage, you must explicitly install and configure the remote mount service by using the Global Data Platform remote mount service tile. If you install Global Data Platform as local storage, the remote mount capability is available by default.

Firewall requirements

Important: For details of IBM Storage Scale container native storage access firewall requirements, see [Network and firewall requirements](#).

Network planning and prerequisites

For network planning and prerequisites for remote mount support, see [Network planning](#).

- The IBM Fusion admin must exchange information with the IBM Storage Scale admin, and provide instructions on how the IBM Storage Scale admin must configure the file system sharing on the IBM Storage Scale side.
 - As a OpenShift Container Platform administrator, confirm whether you configured IBM Storage Scale remote file system mounts during the installation of IBM Fusion. You can check whether the IBM Fusion user interface displays a Remote file systems menu option in the left-navigation. To determine whether the appropriate remote mount service is installed, check the Services page.
 - **Important:** The IBM Storage Scale administrator must do a remote filesystem configuration on the IBM Storage Scale Container Storage Interface Driver storage cluster by following **steps 1 to 6** of [Storage cluster configuration for Container Storage Interface \(CSI\)](#) on non-AWS environment (like on-premises).
 - The IBM Storage Scale administrator in turn provides you the necessary information about cluster, file system, encryption algorithms. For instructions to share, click Instructions link in the Add IBM Storage Scale file system slide out pane. For the Instructions link, see [Storage cluster](#).
Note: The details include host name, port, Cluster ID, IBM Storage Scale certificate, user name, and password.
 - You can enter cluster access credentials information that is provided by the IBM Storage Scale admin into the IBM Fusion user interface, or place it into a CR by using YAML.
 - Run the following precheck commands on the IBM Storage Scale GUI node:
 - Check whether the user that does the remote mount configuration has correct access rights:

```
/usr/lpp/mmfs/gui/cli/luser | grep ContainerOperator | grep CsiAdmin
```

By default, the user passwords expire after 90 days. If the security policy of your organization permits it, use the `-e 1` option on the `mkuser` command to create a user with a password that does not expire. Also, create a unique GUI user for each OpenShift Container Platform cluster on the same remote Scale cluster.

If not present, create the user with both ContainerOperator and CsiAdmin roles.

```
/usr/lpp/mmfs/gui/cli/mkuser csi-storage-gui-user -p passwd0rd -g CsiAdmin,ContainerOperator
```

- Run the following command to ensure all the nodes of your cluster are active:

```
/usr/lpp/mmfs/bin/mmgetstate -a
```

Sample output:

Node number	Node name	GPFS state
1	host1	active
2	host2	active
3	host3	active

If any of the node is down, analysis the issue and start the node.

- Run the following command to validate whether the gpfsGui service is running:

```
systemctl status gpfsGui
```

If gui service has issues, stop and start the service:

```
systemctl stop gpfsui.service
systemctl start gpfsui.service
```

Log in to the GUI of **scalectruster** by using the validated username and password.

- To get more information about the cluster, run **/usr/lpp/mmfs/bin/mmcluster** command.

About this task

All the IBM Storage Scale commands are run by the IBM Storage Scale administrator on the remote IBM Storage Scale cluster.

/usr/lpp/mmfs/bin/xxx

Procedure

1. Click **Storage > Remote file systems** menu in the IBM Fusion user interface.

2. Click **Add file system**.

The **Add IBM Spectrum Scale** file system slide out pane gets displayed.

3. Enter the following details to add one or more file systems.

You can add one or more file systems of the existing cluster or choose to connect to a new cluster.

Note: The OpenShift Container Platform admin needs the IBM Storage Scale admin to provide all of this information. The CLI commands referenced in this topic are run by the IBM Storage Scale admin on the remote IBM Storage Scale cluster.

- Connect to a new cluster option:
 - Enter the following cluster access credentials for IBM Storage Scale:

Host name

The host name is the GUI REST API endpoint. It needs to have a user with ContainerOperator and CsiAdmin roles. You can enter up to a maximum of three hosts.

Port

The port is the GUI port, that is, the REST API endpoint port. By default, the port is 443. If the remote cluster uses other ports, you can provide it.

Cluster ID

Enter the ID of the cluster. Contact your IBM Storage Scale administrator to get the cluster ID.

IBM Spectrum Scale certificate

Enter the IBM Storage Scale root CA. If you provide the root CA value, the IBM Fusion verifies the certificate chain and hostname of the IBM Storage Scale cluster. If you do not provide the root CA value, the IBM Fusion skips the verification step.

User name

Enter the GUI user name of the cluster.

Note: Ensure that this user has both container operator permissions and IBM Storage Scale Container Storage Interface Driver administrator permissions.

Password

Enter the password for the GUI user name.

- Define up to three nodes on the IBM Storage Scale cluster to establish connection. These nodes are contact nodes, which is used to communicate with remote storage cluster. The projects and data get distributed between these nodes.

Run the following command to get node details:

```
/usr/lpp/mmfs/bin/mmcluster
```

- Enter the name and IP address for node 1, node 2, and node 3.
Note: The name value must consist of lower case alphanumeric characters, '-' or '.', and must start and end with an alphanumeric character.
- Enter a Subnet value. It is mandatory for remote file systems whenever Global Data Platform is the local storage. This field takes IP address in CIDR notation. For example, 100.8.9.10/32.
Note: You cannot edit the Subnet value after you add.
- Enter the following details to identify the file system or system:
 - File system name - The name helps to identify the file system or systems that can be accessed through IBM Fusion. Run the following command to get the file system name:

```
/usr/lpp/mmfs/bin/mmcluster
```

The file system name must be an existing file system on the IBM Storage Scale cluster that you want to remote mount.

- Storage class name - Enter a unique storage class name to add to this file system. The Storage class must not exist in the Red Hat OpenShift cluster.

Note: Click **Add** to add more than one file system from this cluster. You can click the remove icon to delete a file system.

- If you choose **Select an existing connect cluster**, then select the host name from the **Select a cluster drop-down** list. The cluster details are displayed, such as host name and name of the connected file system. Enter the following details to identify the file system:

- File system name - The name helps to identify the file system or systems that can be accessed through IBM Fusion. Run the following command to get the file system name:

```
/usr/lpp/mmfs/bin/mmcluster
```

The file system name must be an existing file system on the IBM Storage Scale cluster that you want to remote mount.

- Storage class name - Enter a unique storage class name to add to this file system. The Storage class must not exist in the Red Hat OpenShift cluster. Click **Add** to include more than one file system from this cluster. You can click the remove icon to delete a file system.

4. Click **Add file system**.

An information message informs you that the file system is connecting. After the connection is complete, a success message appears to confirm that the file system is connected. The new connection gets added to the Remote file system list.

Backup & Restore

The Backup & Restore service protects your workloads with tailored backups by using a hub and spoke model. You can restore your data rapidly from local snapshots without having to rely on external storage. Backups can be transferred to external object storage solutions like IBM Cloud, Microsoft Azure, Amazon Web Services, and any S3-compliant object storage. It allows the protection of the IBM Fusion Backup & Restore service itself to a S3 bucket.

- [Backup & Restore overview](#)
You can protect your container workloads and virtual machines by using the IBM Fusion Backup & Restore service.
- [Install Backup & Restore](#)
Protect your data with application-centric backups. Use local snapshots for quick recovery or transfer backups to external object storage for safe keeping. The IBM Fusion Backup & Restore service installation include backup hub and backup spoke.
- [Uninstalling Backup & Restore](#)
Steps to uninstall IBM Fusion Backup & Restore by using command-line or command prompt interface.
- [Getting started](#)
To quick start the service, define the StorageClass and make sure the VolumeSnapshotClass matches the StorageClass provisioner. Next, connect your clusters and set up the backup locations. Create and assign backup policies to the relevant applications, and regularly back up for continuity. This section also introduces you to the protection of the Backup & Restore service itself from data corruption and loss.
- [Backup & Restore of your workloads](#)
The Backup & Restore service is designed to protect a wide range of workloads, including virtual machines, Kubernetes applications, AI workloads, and various IBM Cloud Paks. Additionally, it can also back up the Backup & Restore data management service to an S3 bucket.
- [Managing backup for multi-cluster environment](#)
You can connect and manage cluster connections in IBM Fusion. It includes steps to establish connections and manage existing connections. You can also reconnect an OpenShift Container Platform cluster either after a disaster recovery event or a temporary unavailability.
- [Backup consistencies](#)
- [Performance and scaling](#)
Backup and restore performance depends on agent concurrency, data mover pod counts, and storage throughput. Tuning these parameters helps IBM Fusion meet capacity and latency requirements for large workloads.
- [FIPS-140-2](#)
The Federal Information Processing Standard Publication 140-2 (FIPS-140-2) is a standard that defines a set of security requirements for the use of cryptographic modules. Law mandates this standard for the US government agencies and contractors and is also referenced in other international and industry specific standards.
- [Backup & Restore service installation and upgrade issues](#)
Use this troubleshooting information to resolve install and upgrade problems that are related to Backup & Restore service.
- [Troubleshooting Backup & Restore service issues](#)
List of known Backup & Restore issues in IBM Fusion.

Backup & Restore overview

You can protect your container workloads and virtual machines by using the IBM Fusion Backup & Restore service.

In the event of data loss or corruption, such as accidental deletion or malicious ransomware attacks, a backup and restore system is needed to ensure data integrity and availability. By taking periodic backups of applications and storing them safely, you can restore your workloads during disasters, thereby minimizing downtime and data loss. Whenever disaster occurs, you can restore the workloads in place or to an alternate cluster.

Backup & Restore service protects both containerized and virtual machine (VM) workloads, going beyond data protection to include the application's state and essential etcd resources. This capability is not only for stateful applications but also for stateless ones, ensuring complete restoration of functionality and configuration.

Backup and restore works by first choosing a secure backup location and then defining backup policies tailored to your application needs with frequency and retention parameters. You can then associate the workloads with defined backup policies to automate and streamline the backup process. Finally, you can recover the backed up workloads either in their original location or to an alternate cluster based on the requirements.

For more complex scenarios or whenever you need to run tailored and repeatable workflows, you can make use of the advanced recipes provided by Backup & Restore service.

Backup & Restore supports both single-cluster mode and hub and spoke model. In a single cluster mode, all backup and restore operations are managed within a single cluster. In case of hub and spoke model, the hub acts as a central management point and spokes are individual clusters that run backup and restore tasks locally. You can choose this mode to manage backups across multiple clusters, and it is useful for large-scale environments where multiple clusters need to be managed with resilience in case of failures.

The IBM Fusion Backup & Restore service protection involves the backup of the Backup & Restore data management service itself to a S3 bucket.

- [Backup and restore planning](#)
Plan resource requirements for backups.
- [How Backup & Restore service backs up application data](#)
Backup & Restore service includes support for block volume mode PVs along with the backup of applications with filesystem volume mode PVs. It also supports incremental backups for stateful data (PVC) using Fusion Backup & Restore.
- [Backup & Restore service architecture](#)
This topic explains the high-level workings of the Backup & Restore service to replicate data. It provides an overall idea of the internal components and their roles in the backup and restore operation, resulting in the final transfer of data to designated storage.
- [Hub and spoke model overview](#)
Hub and spoke model allows a single administrator to manage backups for multiple applications that exist on the different clusters.

Backup and restore planning

Plan resource requirements for backups.

The first backup is a full backup. All subsequent backups are incremental.

The capacity required for a backup repository on a remote S3 object store depends on the initial size of all application PVCs and resources, the application data change rate, the backup frequency, and the retention settings. Because the repository is remote, the network must support transferring data volumes equivalent to the S3 object store size.

For example, consider an application that uses 2 TB of data and generates 300 MB of changed data per day. With a daily backup policy and 7-day retention, the initial backup transfers and stores 2 TB of data. Each subsequent daily incremental backup transfers and stores 300 MB.

IBM Fusion HCI supports backup and recovery operations on Red Hat® OpenShift® Container Platform environment with any storage provider that implemented the Container Storage Interface driver and meets the following prerequisites:

- The Container Storage Interface driver must be v1 or higher (no support for *alpha* or *beta* versions)
- The Container Storage Interface driver must support [Volume Snapshot and Restore](#).

Note: It is also recommended that the `VolumeSnapshotClass` deletion policy is configured to delete snapshots after the corresponding `VolumeSnapshotContent` is deleted (`deletionPolicy: Delete`).

How Backup & Restore service backups up application data

Backup & Restore service includes support for block volume mode PVs along with the backup of applications with filesystem volume mode PVs. It also supports incremental backups for stateful data (PVC) using Fusion Backup & Restore.

You can backup an application data, and it consists of PVC data and resources. For the PVC data, you can use online backups or snapshots. You mount the snapshot as a separate PVC for independent processing of the backup without impacting the application. The first back is a full backup and all subsequent backups are incremental. The backups are store in a S3 repository or locally on the system using snapshots (not recommended). The detection and processing of Block volume mode PVs is automatic with no user configuration or changes to the input.

Backup and restore of PV

The Backup & Restore service can backup data hosted on both `volumeMode`:

Block and **Filesystem persistent volumes (PV)**. The detection and processing of the `volumeMode` is automatic and does not need any user configuration or changes.

PV with volumeMode: Filesystem

The pod mounts it as a filesystem directory.

PV with volumeMode: Block

The pod mounts it as a raw block device without any filesystem on it. This mode provides the best performance as it eliminates the filesystem layer between the pod and the PV. A common application for block PVs is database and virtual machines, that is, Red Hat® Red Hat OpenShift Virtualization.

Example Block volume mode PersistentVolume definition.

```
kind: PersistentVolume
apiVersion: v1
metadata:
  name: local-pv-76dela29
  uid: 42643cc7-ac33-4536-b31b-6774524ee590
spec:
  capacity:
    storage: 3576Gi
  local:
    path: /mnt/local-storage/mylocalvs/nvme-Dell_Ent_NVMe_CM6_RI_3.84TB_Y2B0A01HTCE8
  accessModes:
    - ReadWriteOnce
  claimRef:
    kind: PersistentVolumeClaim
    namespace: openshift-storage
    name: ocs-deviceset-mylocalvs-0-data-4xh44d
    uid: 9abbala3-6cd9-4d61-9f3e-95b29dab2094
    apiVersion: v1
    resourceVersion: '71161'
  persistentVolumeReclaimPolicy: Delete
  storageClassName: mylocalvs
  volumeMode: Block
```

Backup and restore of PVC data

Stateful data (PVC) backups with Fusion Backup & Restore are incremental, meaning that only new or changed data since the previous backup is sent to the backup storage location. After the initial backup, which copies all stateful data on the PVCs, subsequent backups only transfer new or modified data. After the first backup, the entire data is never copied again; instead, backups continue to send only new or changed data.

RADOS Block Device (RBD) storage class based volumes

In RBD storage class based volumes, change block detection capability speeds up processing time of the backup.

Resources

Kubernetes resource data is always copied in its entirety on each backup operation. Comparatively, the Kubernetes resource data represents a very small percentage of the total amount of data that gets transferred for the backup operation.

Backup & Restore service architecture

This topic explains the high-level workings of the Backup & Restore service to replicate data. It provides an overall idea of the internal components and their roles in the backup and restore operation, resulting in the final transfer of data to designated storage.

The following diagram depicts the workflow of a Backup & Restore hub and local agent.

The IBM Fusion CRs (Application and Data Protections CRs) and operators (Application and Fusion DP operator) interact with the Backup & Restore service. The Backup & Restore service includes Agent and Server components.

Agents handle specific tasks to perform up to ten backup or restore jobs at once:

- The Transaction Manager facilitates the backup or restore job requests from the server. These actions include request for PVC snapshots, recipe processing, and status updates to the server.
- To process the backup, the Data Mover mounts the PVC snapshot to read the data, determines any deduplication, and then transfers the data to the designated S3 bucket.

The server includes components like Backup Policy, Backup Location, Job Manager, Application Service, Backup Service, Redis, and MongoDB.

- The Backup Policy manages scheduling and cleanup tasks through Policy CRs.
- the Backup Location validates BSL CRs without performing extensive validations as it directly communicates with the S3 bucket to verify connectivity and existence.
- The Job Manager distributes jobs to agents and monitors job progress to detect and cancel hung jobs. It also prevents duplicate jobs for the same application or policy combination from running at the same time.
- Applications Service maintains records of all existing applications across clusters.
- The Backup Service updates backup and restore Custom Resource with their respective statuses.
- Redis is employed to manage lock contentions; for instance, during scheduled backups involving replica instances, after one acquires a Redis lock, it initiates the task while others are dormant.
- MongoDB functions as the central repository for backup and metadata details.

Backup & Restore service uses Kafka as the primary communication medium among services, providing scalability and resilience. It also allows multiple replicas to process distinct messages concurrently.

The following diagram depicts the workflow of a Backup & Restore hub with multiple spokes.

In case of hub and spoke, it is similar but the agents are on different clusters. The Fusion UI, CRs, Backup & Restore server and local agent are the same except that it needs additional cross cluster communication.

When you attach a spoke cluster to the hub, install the Backup & Restore Agent service on the spoke. The installation of the Backup & Restore Agent service requires a temporary token provided by the Hub for initial setup of the secure cross-cluster communication between the hub and spoke.

Hub and spoke model overview

Hub and spoke model allows a single administrator to manage backups for multiple applications that exist on the different clusters.

The Hub is the single location from where the administrator can login and manage all the applications on all the spoke and hub clusters. The hub location hosts the server and facilitates the Backup & restore administrator to run backup and restore jobs across all clusters.

The hub includes all the Backup & restore server components and agent components for backing up components on its own cluster. The spoke has only the Backup & restore agent installed in it. The Backup & restore hub maintains all scheduling, retention, policy handling, location management, and everything else from a management point of view. The agent or spoke takes care of requests to facilitate Backup & restore jobs on that cluster.

Whenever you want to manage applications on a spoke cluster, you must install IBM Fusion and the Backup & restore Agent Service on that cluster. As part of the spoke agent installation process, a communication is established between the hub and spoke cluster. The spoke Agent installation requests for a connection snippet to be generated on the hub and you must provide it within an hour to the Agent installation. This temporary connection snippet generates a permanent communication between the hub and spoke by generating a certificate from the Certificate Authority (CA) of the hub. By default, this certificate expires after 90 days. IBM Fusion takes care of the needed steps to auto-renew a certificate before it expires.

IBM Fusion is also resilient to unreliable network connections and can recover with network disconnections between the hub and spoke clusters up to an hour.

In the Jobs page of the hub cluster, you can view all the backup and restore jobs across all clusters. You can filter jobs of a specific cluster. When a backup or restore job gets initiated, it gets remotely deployed to the cluster where the agent picks up the job to run it locally on that cluster.

The Service Protection feature provides the ability to restore applications from remote S3 backups (local snapshot only backups not supported) across all hub and spoke clusters. While the Service Protection backup is configured on the hub cluster, all backup information for spoke clusters is automatically included and no configuration on the spoke clusters are required.

In the event of a cluster crash, you can restore application backups on the replacement cluster.

Note: Service protection is just for backup restore on the hub cluster and not for other configurations that exist in IBM Fusion. For example, Red Hat® OpenShift® Container Platform cluster, disaster recovery, Red Hat OpenShift Data Foundation.

In the Topology page, you can see the hub cluster in the first row followed by all connected spoke clusters. The details of the connected clusters, such as health, status, success rate are available in this view.

The two available backup storage locations are the in place local snapshots and S3 remote object store locations. If you want to restore applications on another cluster, configure a S3 remote object store for the backup storage locations. The S3 remote object store is to store data on an external location. During instances wherein the cluster crashes, the backups that are stored in the local snapshots are lost along with it. Hence, it is important to offload your backups to an external storage location, and later restore the application on a replacement cluster.

You can share the locations and policies for applications that are backed up across the cluster. From the hub cluster, you can apply policies to any number of applications across any number of clusters. All applications get backed up at the same time as they share policies and the schedules. However, it can cause resource contention in the network cluster. For example, all backups need network connection to a S3 location at the same time. Though it gives the advantage of maintaining limited number of policies, it might place a strain on the network. Similar to the policies, you can use one location to store every backup of all clusters. It can cause contention of network requests on the same backup location.

The Applications page shows only applications on that cluster and not any applications on the spoke cluster. The Backedup application page shows all applications that are protected across the cluster. To protect new applications in the cluster, click Protect apps in the Backedup application page, and select applications from a specific cluster.

Install Backup & Restore

Protect your data with application-centric backups. Use local snapshots for quick recovery or transfer backups to external object storage for safe keeping. The IBM Fusion Backup & Restore service installation include backup hub and backup spoke.

About this task

To know more about the hub and spoke architecture of Backup & Restore service, see [Hub and spoke model overview](#).

- [Prerequisites](#)
Ensure that you meet the prerequisites before you work with Backup & Restore service.
- [Backup & Restore hub](#)
Protect your data with application-centric backups. Use local snapshots for quick recovery or transfer backups to external object storage for safe keeping.
- [Backup & Restore spoke](#)
Protect your data with application-centric backups. Use local snapshots for quick recovery or transfer backups to external object storage for safe keeping.
- [Establishing connection between hub and spoke](#)
Generate YAML from the hub cluster to establish mutual authentication between the hub and spoke clusters.
- [Reduce and restore operator cluster-admin privileges](#)
Download and run the `updateFusionAuthority.sh` script to reduce cluster-admin level permissions for IBM Fusion operators after installation, and to restore those permissions before an upgrade or patch.

Prerequisites

Ensure that you meet the prerequisites before you work with Backup & Restore service.

1. Install either the Backup & Restore or Backup & Restore Agent service. For the procedure to install, see [Install Backup & Restore](#).
2. Ensure that you define a StorageClass that is provisioned by a supported CSI driver. Check the `provisioner` in the `Spec` to make sure that it is backed by CSI.
Sample Storage Class for Fusion Data Foundation:

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
  name: ocs-storagecluster-cephfs
provisioner: openshift-storage.cephfs.csi.ceph.com
reclaimPolicy: Delete
allowVolumeExpansion: true
volumeBindingMode: Immediate
```

Note: The Storage Class must have the CSI Snapshot capability (`VolumeSnapshotClass`).

3. For backups and restores to run successfully, ensure that CSI compliant storage classes have `volumeBindingMode: Immediate` or `volumeBindingMode: WaitForFirstConsumer` and `allowVolumeExpansion: true`.
4. Ensure that the VolumeSnapshotClass has a `driver` that matches the `provisioner` in the StorageClass.
Sample YAML for Red Hat® OpenShift® Data Foundation RBD storage:

```
apiVersion: snapshot.storage.k8s.io/v1
kind: VolumeSnapshotClass
driver: openshift-storage.cephfs.csi.ceph.com
metadata:
  name: ocs-storagecluster-cephfsplugin-snapclass
deletionPolicy: Delete
parameters:
  clusterID: openshift-storage
  csi.storage.k8s.io/snapshotter-secret-name: rook-csi-cephfs-provisioner
  csi.storage.k8s.io/snapshotter-secret-namespace: openshift-storage
```

Note: If you plan to create and use your own storage classes in IBM Fusion HCI, ensure that you have the VolumeSnapshotClass.

Backup & Restore hub

Protect your data with application-centric backups. Use local snapshots for quick recovery or transfer backups to external object storage for safe keeping.

Before you begin

Consider the following points before you begin installation:

- Firewall ports required for Hub and Spoke architecture:
 - Hub
Must be able to make a TCP connection to the Spoke cluster API address

- Spoke

- Must be able to make a TCP connection to the Hub cluster API address
- Must be able to make a TCP connection address :443, where **<kafka-route>:443** can be found by running the following command on the hub:

```
oc get route -n ibm-bnr -l app=kafka-bridge-rbac-proxy
```

Example output:

NAME	HOST/PORT
kafka-bridge	kafka-bridge-ibm-bnr.bnr-98b7318c91b01bd72490e80cc2328915-0000.ca-tor.containers.app
kafka-bridge-rbac-proxy	kafka-bridge-ibm-bnr.bnr-98b7318c91b01bd72490e80cc2328915-0000.ca-tor.containers.app
kafka-bridge-rbac-proxy1	kafka-bridge-ibm-bnr.bnr-98b7318c91b01bd72490e80cc2328915-0000.ca-tor.containers.app
kafka-bridge-rbac-proxy2	kafka-bridge-ibm-bnr.bnr-98b7318c91b01bd72490e80cc2328915-0000.ca-tor.containers.app
kafka-bridge-rbac-proxy3	kafka-bridge-ibm-bnr.bnr-98b7318c91b01bd72490e80cc2328915-0000.ca-tor.containers.app

- A route on the host that creates a DNS address exists for the Kubernetes API, which is enabled by default during the installation of Red Hat® OpenShift®. Check whether it is available and is resolvable from the spoke containers. Format of the URL is **api.<cluster-name>.<domain>** but is changeable. This is port 443 on all control plane nodes.
- A route to the Kafka Bridge creates a DNS address. Check whether it is available and is resolvable from the spoke containers. Uses port 443 on compute nodes. Run the following command and check the role in the output to know which nodes are compute nodes (needed for Kafka Bridge) and control plane nodes (for Kubernetes API connection):

```
oc get nodes
```

Example output:

```
NAME STATUS ROLES AGE VERSION
bootstrap.ocpfsn.pok.stglabs.ibm.com Ready worker 3d18h v1.25.14+20cda61
master0.ocpfsn.pok.stglabs.ibm.com Ready control-plane,master 3d19h v1.25.14+20cda61
master1.ocpfsn.pok.stglabs.ibm.com Ready control-plane,master 3d19h v1.25.14+20cda61
master2.ocpfsn.pok.stglabs.ibm.com Ready control-plane,master 3d19h v1.25.14+20cda61
worker0.ocpfsn.pok.stglabs.ibm.com Ready worker 3d18h v1.25.14+20cda61
worker1.ocpfsn.pok.stglabs.ibm.com Ready worker 3d18h v1.25.14+20cda61
worker3.ocpfsn.pok.stglabs.ibm.com Ready worker 2d2h v1.25.14+20cda61
```

Alternatively, to check the roles from OpenShift console, do the following steps:

1. Log in to the OpenShift console.
 2. Click Compute, > Nodes menu.
 3. Check the role of the nodes.
- The following command can be used to get the cluster API address of a cluster:

```
oc cluster-info
```

For example:

```
Kubernetes control plane is running at https://c109-e.us-east.containers.cloud.ibm.com:30363
```

Procedure

1. Go to Services page in IBM Fusion user interface.
2. In the Available section, click the Backup & Restore tile.
3. In the Backup & Restore page, go through the features and capabilities of the service and click Install.
In the Install service window, the **ocs-storagecluster-ceph-rbd** class is set by default for the Backup & Restore service. The internal data catalog requires a minimum of 200 GB for ReadWriteAfter storage.
4. Click Install.
The installation starts and a notification appears on the Services page. You can see the progress of the installation in the Services > Installed section. After the installation completes successfully, you can see the status as normal and a Get started link.
After you enable the Backup & Restore, you can view the service version and health status. From the ellipsis menu, you can download logs and view documentation. After you successfully collect the logs, a success notification gets displayed. The notification disappears automatically after some time.

The Backup & Restore menu in the spoke cluster includes the following sub-menus:

- Topology
- Backed up applications
- Policies
- Locations
- Jobs
- Service protection

In the Backup & restore > Overview page, you have quick links to generate YAML, Connect locations, Create backup policies, and protect your applications.

In case of other failures, go through the downloaded logs to understand the cause of the failure and fix the issue. For more information about service issues in IBM Fusion, see [Backup & Restore service installation and upgrade issues](#).

5. Validate the installation:
Note: Ensure that the Backup & Restore IBM Fusion service is enabled before validation.

Verify that the Backup & Restore IBM Fusion service operators from the OpenShift Container Platform web console:

- a. Go to Installed operators from OpenShift Container Platform web console.
- b. Select the project as **ibm-backup-restore**.
- c. Verify that the following operators show the status as **succeeded**.
 - Red Hat Integration - AMQ Streams
 - IBM Fusion Backup & Restore Hub
 - IBM Fusion Backup & Restore Spoke
 - OADP Operator
- d. Alternatively, you can verify the status of operators by running the following oc command:
Note: More operators appear in the command line output than in the web console.

```
oc get csv -n ibm-backup-restore
```

A sample result of the oc command is as follows:

NAME	DISPLAY	VERSION	REPLACES	PHASE
amqstreams.v2.3.0-1	Red Hat Integration - AMQ Streams		2.3.0-1	amqstreams.v2.3.0-0
Succeeded				
guardian-dm-operator.v2.5.0	IBM Fusion Backup and Restore Data Mover		2.5.0	
Succeeded				
guardian-dp-operator.v2.5.0	IBM Fusion Backup and Restore Data Protection		2.5.0	
Succeeded				
guardian-mongo-operator.v2.5.0	IBM Fusion Backup and Restore Mongo		2.5.0	
Succeeded				
ibm-dataprotectionagent.v2.5.0	IBM Fusion Backup and Restore Agent		2.5.0	
Succeeded				
ibm-dataprotectionserver.v2.5.0	IBM Fusion Backup and Restore Server		2.5.0	
Succeeded				
oadp-operator.v1.1.2	OADP Operator		1.1.2	oadp-operator.v1.1.1
Succeeded				
redis-operator.v2.5.0	IBM Fusion Backup and Restore Redis		2.5.0	
Succeeded				

.Ensure that the status shows **Succeeded**.

Verify the Backup & Restore pods from the OpenShift Container Platform console:

- Go to Workloads, > Pods.
- Select the namespace, where you installed IBM Fusion Backup & Restore. In this case, select **ibm-backup-restore** namespace. It lists all the pods. Ensure that all pods are running.
- Verify whether the following pods are running successfully:

```
amq-streams-cluster-operator
applicationsvc
backup-location-deployment
backup-service
backuppolicy-deployment
guardian-dm-controller-manager
guardian-dp-operator-controller-manager
guardian-kafka-cluster-entity-operator
guardian-kafka-cluster-kafka-0
guardian-kafka-cluster-kafka-1
guardian-kafka-cluster-kafka-2
guardian-kafka-cluster-zookeeper-0
guardian-kafka-cluster-zookeeper-1
guardian-kafka-cluster-zookeeper-2
guardian-minio-0
guardian-mongo-operator-controller-manager
ibm-dataprotectionagent-controller-manager
ibm-dataprotectionserver-catalog-ibm-backup-restore
ibm-dataprotectionserver-controller-manager
ibm-backup-restoreagent-controller-manager
ibm-backup-restoreserver-controller-manager
job-manager
mongodb-0
mongodb-1
mongodb-2
mongodb-ab-0
openshift-adp-controller-manager
redis-master-0
redis-operator-controller-manager
redis-replicas-0
redis-replicas-1
redis-replicas-2
transaction-manager
velero
```

- Alternatively, you can verify the installation by running the following oc command:

```
oc get pods -n ibm-backup-restore
```

A sample result of the oc command is as follows:

NAME	READY	STATUS	R
amq-streams-cluster-operator-v2.3.0-1-7d6fb79d84-jdkfh	1/1	Running	0

Verify the Backup & Restore IBM Fusion service installation status from the OpenShift Container Platform web console:

- Go to Installed operators from OpenShift Container Platform web console.
- Select the namespace as **ibm-backup-restore**.
- Select IBM Fusion Backup & Restore server.
- Click the Data Protection server tab and select Data Protection server.
- Select the YAML tab.
- In the status section, make sure the following:
 - HealthStatuses** Shows the health status of all components listed. It may take 5 minutes or more for all components to show up as healthy.
 - Ensure the install status shows Complete and **progressPercentage** as 100.
- Alternatively, you can verify the installation status by running the following oc command:

```
oc describe dataprotectionserver dataprotectionserver -n ibm-backup-restore
```

A sample result of the oc command is as follows:

```
Status:
Health Statuses:
  Service Name:  applicationservice
  Status:        Healthy
  Service Name:  backuplocation
  Status:        Healthy
  Service Name:  backuppolicy
  Status:        Healthy
  Service Name:  backupservice
  Status:        Healthy
  Service Name:  jobmanager
  Status:        Healthy
  Service Name:  backupagent
  Status:        Healthy
  Service Name:  mongo
  Status:        Healthy
  Service Name:  redis
  Status:        Healthy
  Service Name:  kafka
  Status:        Healthy
Install Status:
  Progress Percentage: 100
  Retry On Failure:    false
  Status:              Completed
  Installed Version:   2.5.0
  Upgrade In Progress: false
  Upgrade Status:
    Retry On Failure: false
```

- Check the status section at the end of the CR and make sure the following:
 - The Install Status section shows the status of the install along with the percentage complete.
 - The install status shows the install status as Completed when the installation is successfully completed.
 - The health status section lists and shows components health status as healthy.
 - Note: Individual component health statuses may show **Unknown** or **Degraded** for up to five minutes, and show a healthy status when installation is complete.

What to do next

- Generate a connection snippet or YAML. For the procedure to generate, see [Establishing connection between hub and spoke](#).
- You can now begin to protect your IBM Fusion applications.
 - Add location to determine whether the network verification is needed. For the procedure to add a location, see [Adding backup storage location](#).
 - [Creating backup policy](#).
 - [Assigning backup policy](#).

Backup & Restore spoke

Protect your data with application-centric backups. Use local snapshots for quick recovery or transfer backups to external object storage for safe keeping.

Before you begin

- Install backup hub. For the procedure to install, see [Backup & Restore hub](#).
- Generate the YAML. This YAML is required to establish mutual authentication between the two clusters. For the procedure to generate, see [Establishing connection between hub and spoke](#).

- When you add a Spoke to a Hub, the version of the Spoke must be the same version as the Hub.
- Consider the following points before you begin installation:
 - Firewall ports required for Hub and Spoke architecture:
 - Hub
 - Must be able to make a TCP connection to the Spoke cluster API address
 - Spoke
 - Must be able to make a TCP connection to the Hub cluster API address
 - Must be able to make a TCP connection address :443, where `<kafka-route>:443` can be found by running the following command on the hub:

```
oc get route -n ibm-bnr -l app=kafka-bridge-rbac-proxy
```

Example output:

NAME	HOST/PORT
kafka-bridge	kafka-bridge-ibm-bnr.bnr-98b7318c91b01bd72490e80cc2328915-0000.ca-tor.container
kafka-bridge-rbac-proxy	kafka-bridge-ibm-bnr.bnr-98b7318c91b01bd72490e80cc2328915-0000.ca-tor.container
kafka-bridge-rbac-proxy1	kafka-bridge-ibm-bnr.bnr-98b7318c91b01bd72490e80cc2328915-0000.ca-tor.container
kafka-bridge-rbac-proxy2	kafka-bridge-ibm-bnr.bnr-98b7318c91b01bd72490e80cc2328915-0000.ca-tor.container
kafka-bridge-rbac-proxy3	kafka-bridge-ibm-bnr.bnr-98b7318c91b01bd72490e80cc2328915-0000.ca-tor.container

- A route on the host that creates a DNS address exists for the Kubernetes API, which is enabled by default during the installation of Red Hat® OpenShift®. Check whether it is available and is resolvable from the spoke containers. Format of the URL is `api.<cluster-name>.<domain>` but is changeable. This is port 443 on all control plane nodes.
- A route to the Kafka Bridge creates a DNS address. Check whether it is available and is resolvable from the spoke containers. Uses port 443 on compute nodes. Run the following command and check the role in the output to know which nodes are compute nodes (needed for Kafka Bridge) and control plane nodes (for Kubernetes API connection):

```
oc get nodes
```

Example output:

```
NAME STATUS ROLES AGE VERSION
bootstrap.ocpfsn.pok.stglabs.ibm.com Ready worker 3d18h v1.25.14+20cda61
master0.ocpfsn.pok.stglabs.ibm.com Ready control-plane,master 3d19h v1.25.14+20cda61
master1.ocpfsn.pok.stglabs.ibm.com Ready control-plane,master 3d19h v1.25.14+20cda61
master2.ocpfsn.pok.stglabs.ibm.com Ready control-plane,master 3d19h v1.25.14+20cda61
worker0.ocpfsn.pok.stglabs.ibm.com Ready worker 3d18h v1.25.14+20cda61
worker1.ocpfsn.pok.stglabs.ibm.com Ready worker 3d18h v1.25.14+20cda61
worker3.ocpfsn.pok.stglabs.ibm.com Ready worker 2d2h v1.25.14+20cda61
```

Alternatively, to check the roles from OpenShift console, do the following steps:

1. Log in to the OpenShift console.
 2. Click Compute > Nodes menu.
 3. Check the role of the nodes.
- The following command can be used to get the cluster API address of a cluster:

```
oc cluster-info
```

For example:

```
Kubernetes control plane is running at https://c109-e.us-east.containers.cloud.ibm.com:30363
```

Procedure

1. Go to Services page in IBM Fusion user interface.
2. In the Available section, click the Backup & Restore Agent tile.
3. In the Backup & Restore page, go through the features and capabilities of the service and click Install.
In the Install service window, the `ocs-storagecluster-ceph-rbd` class is set by default for the Backup & Restore service. The internal data catalog requires a minimum of 200 GB for ReadWriteAfter storage.
4. In the Install service window, select a Storage class that is used for the service.
so select a storage class that supports this criteria.
5. Enter a connection snippet that is generated from the backup hub cluster.
Important: When you install Spoke from the user interface, use the snippet. Use YAML option only when you do an automated deployment outside the IBM Fusion user interface.
For more information about establishing connection between the Hub and Spoke, see [Establishing connection between hub and spoke](#).
6. Click Install.
A validation is done to check whether the connection is possible. If connection failed message appears, check the message and take corrective action. The installation starts and a notification appears on the Services page. You can see the progress of the installation in the Services > Installed section. After the installation completes successfully, you can see the status as normal and a Get started link.
After you enable the Backup & Restore, you can view the service version and health status. From the ellipsis menu, you can download logs and view documentation. After you successfully collect the logs, a success notification gets displayed. The notification disappears automatically after some time.

The Backup & Restore menu in the spoke cluster includes the following sub-menus:

- Topology
- Backed up applications

In case of other failures, go through the downloaded logs to understand the cause of the failure and fix the issue. For more information about service issues in IBM Fusion, see [Backup & Restore service installation and upgrade issues](#).

7. Validate the installation:

Note: Ensure that the Backup & Restore IBM Fusion service is enabled before validation.

Verify that the Backup & Restore IBM Fusion service operators from the OpenShift Container Platform web console:

- a. Go to Installed operators from OpenShift Container Platform web console.

- b. Select the project as **ibm-backup-restore**.
- c. Verify that the following operators show the status as **succeeded**.
 - Red Hat Integration - AMQ Streams
 - IBM Fusion Backup & Restore Hub
 - IBM Fusion Backup & Restore Spoke
 - OADP Operator

- d. Alternatively, you can verify the status of operators by running the following oc command:
Note: More operators appear in the command line output than in the web console.

```
oc get csv -n ibm-backup-restore
```

A sample result of the oc command is as follows:

NAME	DISPLAY	VERSION	REPLACES	PHASE
amqstreams.v2.3.0-1 Succeeded	Red Hat Integration - AMQ Streams		2.3.0-1	amqstreams.v2.3.0-0
guardian-dm-operator.v2.5.0 Succeeded	IBM Fusion Backup and Restore Data Mover		2.5.0	
guardian-dp-operator.v2.5.0 Succeeded	IBM Fusion Backup and Restore Data Protection		2.5.0	
guardian-mongo-operator.v2.5.0 Succeeded	IBM Fusion Backup and Restore Mongo		2.5.0	
ibm-dataprotectionagent.v2.5.0 Succeeded	IBM Fusion Backup and Restore Agent		2.5.0	
ibm-dataprotectionserver.v2.5.0 Succeeded	IBM Fusion Backup and Restore Server		2.5.0	
oadp-operator.v1.1.2 Succeeded	OADP Operator		1.1.2	oadp-operator.v1.1.1
redis-operator.v2.5.0 Succeeded	IBM Fusion Backup and Restore Redis		2.5.0	

.Ensure that the status shows **Succeeded**.

Verify the Backup & Restore pods from the OpenShift Container Platform console:

- a. Go to Workloads, > Pods.
- b. Select the namespace, where you installed IBM Fusion Backup & Restore. In this case, select **ibm-backup-restore** namespace.
It lists all the pods. Ensure that all pods are running.
- c. Verify whether the following pods are running successfully:

```
amq-streams-cluster-operator
applicationsvc
backup-location-deployment
backup-service
backuppolicy-deployment
guardian-dm-controller-manager
guardian-dp-operator-controller-manager
guardian-kafka-cluster-entity-operator
guardian-kafka-cluster-kafka-0
guardian-kafka-cluster-kafka-1
guardian-kafka-cluster-kafka-2
guardian-kafka-cluster-zookeeper-0
guardian-kafka-cluster-zookeeper-1
guardian-kafka-cluster-zookeeper-2
guardian-minio-0
guardian-mongo-operator-controller-manager
ibm-dataprotectionagent-controller-manager
ibm-dataprotectionserver-catalog-ibm-backup-restore
ibm-dataprotectionserver-controller-manager
ibm-backup-restoreagent-controller-manager
ibm-backup-restoreserver-controller-manager
job-manager
mongodb-0
mongodb-1
mongodb-2
mongodb-ab-0
openshift-adp-controller-manager
redis-master-0
redis-operator-controller-manager
redis-replicas-0
redis-replicas-1
redis-replicas-2
transaction-manager
velero
```

- d. Alternatively, you can verify the installation by running the following oc command:

```
oc get pods -n ibm-backup-restore
```

A sample result of the oc command is as follows:

NAME	READY	STATUS	R
amq-streams-cluster-operator-v2.3.0-1-7d6fb79d84-jdkfh	1/1	Running	0

Verify the Backup & Restore IBM Fusion service installation status from the OpenShift Container Platform web console:

- Go to Installed operators from OpenShift Container Platform web console.
- Select the namespace as **ibm-backup-restore**.
- Select IBM Fusion Backup & Restore server.
- Click the Data Protection server tab and select Data Protection server.
- Select the YAML tab.
- In the status section, make sure the following:
 - HealthStatuses** Shows the health status of all components listed. It may take 5 minutes or more for all components to show up as healthy.
 - Ensure the install status shows Complete and **progressPercentage** as 100.
- Alternatively, you can verify the installation status by running the following oc command:

```
oc describe dataprotectionserver dataprotectionserver -n ibm-backup-restore
```

A sample result of the oc command is as follows:

```
Status:
Health Statuses:
  Service Name:  application-service
  Status:        Healthy
  Service Name:  backup-location
  Status:        Healthy
  Service Name:  backup-policy
  Status:        Healthy
  Service Name:  backup-service
  Status:        Healthy
  Service Name:  job-manager
  Status:        Healthy
  Service Name:  backup-agent
  Status:        Healthy
  Service Name:  mongo
  Status:        Healthy
  Service Name:  redis
  Status:        Healthy
  Service Name:  kafka
  Status:        Healthy
Install Status:
  Progress Percentage: 100
  Retry On Failure:    false
  Status:              Completed
  Installed Version:   2.5.0
  Upgrade In Progress: false
  Upgrade Status:
    Retry On Failure:  false
```

- Check the status section at the end of the CR and make sure the following:
 - The Install Status section shows the status of the install along with the percentage complete.
 - The install status shows the install status as Completed when the installation is successfully completed.
 - The health status section lists and shows components health status as healthy.
 - Note: Individual component health statuses may show **Unknown** or **Degraded** for up to five minutes, and show a healthy status when installation is complete.

What to do next

- You can set the configuration parameters in ConfigMap guardian-configmap to change defaults for IBM Fusion Backup & restore agent. For more information about the parameters, see [Backup & restore configuration parameters](#).
- Go to the Backup spoke cluster user interface > Overview page and click Launch Backup Hub to open the Backup hub. In the Backup & restore > Overview page, you have quick links to generate YAML, connect locations, create backup policies, and protect your applications.
- You can now begin to protect your IBM Fusion applications.
 - Add location to determine whether the network verification is needed. For the procedure to add a location, see [Adding backup storage location](#).
 - [Creating backup policy](#).
 - [Assigning backup policy](#).

Establishing connection between hub and spoke

Generate YAML from the hub cluster to establish mutual authentication between the hub and spoke clusters.

Procedure

1. Log in to the user interface of the hub cluster.
2. Click Backup & Restore > Overview.
3. Use any of the following methods to generate the YAML.

Option	Description
Use the Fusion UI	a. In the step 1: Connect your clusters (optional) section, click Connect clusters. b. From the drop-down list, select Use the Fusion UI. The connect your cluster > Use the Fusion UI window appears. The snippet starts to generate. c. After the snippet is generated successfully, click Copy snippet. d. Enter the copied connection snippet when prompted during the spoke installation. For the step in Spoke installation, see Enter connection snippet.
Automate deployment	a. In the step 1: Connect your clusters (optional) section, click Connect clusters. b. From the drop-down list, select Automate deployment. The connect your cluster > Automate deployment window appears. c. Select the storage class to use on the spoke where you want to run the YAML. d. Click Generate. The YAML starts to generate. e. In the Deploy using YAML section, click copy icon in Deployment YAML or click Download YAML. Alternatively, in the Or deploy using oc command section, click Copy command. Important: If you use a custom namespace, then do not use the Copy command because the encoded command is not editable and is of no value with a custom namespace. f. Apply the downloaded YAML or the copied oc command on the Spoke cluster.

4. To validate the connection, do the following steps:
 - a. Click Backup & Restore > Topology.
In the Topology page, you can see the hub cluster. In the Cluster table, you can see a list of spokes connected.
 - b. In the Topology page > Cluster table, check whether there is an entry for the spoke and the Connection status column is Connected for it. The Service status is Normal.

Reduce and restore operator cluster-admin privileges

Download and run the **updateFusionAuthority.sh** script to reduce cluster-admin level permissions for IBM Fusion operators after installation, and to restore those permissions before an upgrade or patch.

Before you begin

Before you run the script, ensure the following tools are installed and available in your **PATH**:

- **oc**: OpenShift® CLI, used to interact with the OpenShift Container Platform cluster.
- **yq** v4.x or later: command-line YAML processor. Verify the version with **yq --version**. The output must show **version v4..**. For installation instructions, see <https://github.com/mikefarah/yq/>.
- **jq**: command-line JSON processor, used to parse JSON output from **oc** commands.

After installing the tools, log in to the cluster:

```
oc login
```

About this task

By default, IBM Fusion operators are installed with cluster-admin level permissions that are required for initial deployment and lifecycle operations. Organizations that require a least-privilege security posture can use the **updateFusionAuthority.sh** script to reduce these permissions after installation.

The script modifies ClusterRole and ClusterRoleBinding definitions for the following operators:

- Prerequisites operator (**isf-prereq-operator-controller-manager**)
- Application operator (**isf-application-operator-controller-manager**)
- Platform operator (**isf-platform-operator-controller-manager**)
- Serviceability operator (**isf-serviceability-operator-controller-manager**)
- Data Mover operator (**guardian-dm-controller-manager**)
- Server Install operator
- Agent Install operator

Important:

- This utility is supported for IBM Fusion version 2.14.0 only.
- You must restore operator authority before every upgrade or patch. Failure to restore authority before upgrading causes the upgrade to fail. After the upgrade or patch completes, you can reapply the authority reduction.

Procedure

1. Download `updateFusionAuthority.sh` from the IBM Storage Fusion GitHub repository: <https://github.com/IBM/storage-fusion/tree/master/backup-restore/cluster-admin-privileges/updateFusionAuthority.sh>.
2. Make the script executable:

```
chmod +x updateFusionAuthority.sh
```

3. Run the script with the `reduce-authority` option after installation, an upgrade, or a patch:

```
./updateFusionAuthority.sh reduce-authority
```

The script reduces RBAC write verbs to `get`, `list`, and `watch` for all affected operators.

4. Run the script with the `restore-authority` option before every upgrade or patch:

```
./updateFusionAuthority.sh restore-authority
```

The script restores the full set of RBAC verbs required for upgrade and patch operations.

Results

The script prints a status line for each operator as it runs. A check mark (✓) indicates success; a cross (✗) indicates failure. A successful run ends with the following footer:

```
Completed authority change IBM Fusion cluster at <date and time>
```

If any step fails, the script exits with a non-zero exit code and prints an `ERROR:` message that identifies the failing operator and the reason for the failure. Resolve the reported issue and rerun the script.

Uninstalling Backup & Restore

Steps to uninstall IBM Fusion Backup & Restore by using command-line or command prompt interface.

Before you begin

- Ensure you have the following installed:
 - Bash 5.0 or higher
 - OpenShift® Container Platform command line 4.14 or higher
 - `jq` 1.6 or higher version.

About this task

The `uninstall-backup-restore.sh` script has two optional arguments `-u` and `-d`. Use the `-u` argument to uninstall agent when the hub still exists.

Procedure

1. Log in to your cluster.
2. From your browser, go to this URL- <https://github.com/IBM/storage-fusion/blob/master/backup-restore/uninstall/uninstall-backup-restore.sh>.
3. Download `uninstall-backup-restore.sh` and run the script.

What to do next

Note: On the Topology page, it can take 10 minutes for the Connection Status of the spoke cluster to change from **Connected** to **Unknown**. Though in the Backedup applications page, you can see the previous application backups from the spoke cluster, no new backups are possible.

After uninstall of agent or server, you may want to delete the connection from the system. You can remove the connection for a spoke from the hub user interface, but the agent user interface does not have this capability. When you try to remove a connection from a hub, check your firewall. For more information, see [Remove connections](#).

Getting started

To quick start the service, define the `StorageClass` and make sure the `VolumeSnapshotClass` matches the `StorageClass` provisioner. Next, connect your clusters and set up the backup locations. Create and assign backup policies to the relevant applications, and regularly back up for continuity. This section also introduces you to the protection of the Backup & Restore service itself from data corruption and loss.

- [Quick start Backup & Restore service](#)
The Overview page provides quick access to essential Backup & Restore service tasks, which enables you to quickly set up and use the service.
- [Service protection](#)
The IBM Fusion Backup & Restore service protection involves the backup of the Backup & Restore data management service to a S3 bucket.

Quick start Backup & Restore service

The Overview page provides quick access to essential Backup & Restore service tasks, which enables you to quickly set up and use the service.

Get started

From the Get started pane, you can quickly add locations, create policies, and assign a policy to your applications.

Step 1: Connect your cluster

Create connections to the clusters that you provide backup services for. If you are only backing up applications in this cluster, you can skip this step. Use any of the following methods to generate the YAML. For more information about the options, see [Connect clusters](#).

Step 2: Connect backup locations

Connect S3 compatible object storage locations that stores the backups.

Step 3: Create backup policies

Define backup frequency, storage location, and how long they are retained.

Step 4: Protect your applications

Assign backup policies to your applications.

Step 5: Protect your Backup & Restore service

Protect the backup service by backing up the control plane to an S3 bucket. You can restore the backup service in another cluster in the event that this cluster fails.

Explore capabilities

Application resiliency

Backup applications so they can be recovered in the event of cluster loss, data loss, or corruption. See [Backup & Restore overview](#).

Application mobility

Move applications between different clusters by using Hub & Spoke cluster configurations. Application backups taken in one cluster can be restored to a separate cluster. See [Restoring an application](#).

Isolate your systems

Remote S3 backup location separates access between backups and applications. Your backups are not compromised even when a workload cluster is compromised. See [Install Backup & Restore](#).

Orchestrate a backup or restore

Use a custom, application-specific recipe to consistently automate and control the required backup or restore sequence of an application. See [Orchestrate a backup or restore](#).

Service protection

The IBM Fusion Backup & Restore service protection involves the backup of the Backup & Restore data management service to a S3 bucket.

If the cluster or the storage containing metadata becomes unavailable, you can recover the Backup & Restore metadata required to restore application backups.

You can configure service backups by specifying locations, setting schedules, and managing credentials. Additionally, you can restore a service configuration from a backup, connect to various backup locations (such as Azure, IBM Cloud, and Amazon Web Services), enter credentials, and initiate the restore process.

For more information about how to configure and restore, see [Configuring service backups](#) and [Recovering service backups](#).

Backup & Restore of your workloads

The Backup & Restore service is designed to protect a wide range of workloads, including virtual machines, Kubernetes applications, AI workloads, and various IBM Cloud Paks. Additionally, it can also back up the Backup & Restore data management service to an S3 bucket.

Backup of application and VMs: The workload includes the following data:

- PVs of the deployed workloads
- Namespace and cluster scope resources for deployed workloads
- Application VMs that use filesystem based PVCs are backed up and restored.

Important: To backup application VMs, ensure that the following prerequisites are met:

- Bare Metal cluster is available
- Red Hat OpenShift Virtualization feature is installed from the Operator Hub of OpenShift® Container Platform console.

Support is available for VMs based on Filesystem PVCs (PersistentVolume has the `volumeMode: Filesystem` defined). The Block mode volumes (`volumeMode: Block`) support is also available.

Note: The Backup & Restore uses Velero hooks that are present on an application or resource. This means that if your application has hooks, then they are automatically run by Velero at the time of backup or restore.

For Software Hub, watsonx Orchestrate, and watsonx.ai backup and restore using IBM Fusion, see [Backup and restore of IBM Software Hub to the same or different cluster](#).

For more information about OpenShift Container Platform applications, see <https://docs.openshift.com/>.

- [Backup & Restore of your applications and virtual machines](#)

To protect your applications, create storage location, storage policy, and then enroll your applications for backup and restore.

- [Service protection](#)

The IBM Fusion Backup & Restore service protection involves the backup of the Backup & Restore data management service to a S3 bucket.

- [Self-service Backup & Restore](#)

You can protect your namespace application with IBM Fusion Backup & Restore even as an application user without cluster rights or a user without IBM Fusion administration rights. Application owners can create IBM Fusion Backup & Restore Custom Resource (CRs) within the application's namespace to self-manage their application's backup and restore needs without the involvement of a cluster or IBM Fusion Backup & Restore administrator.

Backup & Restore of your applications and virtual machines

To protect your applications, create storage location, storage policy, and then enroll your applications for backup and restore.

You create backup storage locations and policies as a prerequisite to backup. Assign the policies to applications such that backups run based on the defined policy schedule. Only one backup per policy or application combination allowed at a time. Redundant backups are canceled. IBM Fusion Backup & Restore supports block level incremental backups, which detect change blocks and processes only the changes since the last snapshot. It is also applicable for backups of OpenShift® Container Platform virtualization VMs using block volumes.

- [Backup storage locations](#)
You can create backups by assigning a backup policy to an application. The policy specifies how frequently to backup the application, and where to store the backup. The location where the backup is stored is called a backup location and it is a prerequisite to create a policy.
- [Backup policies](#)
A backup policy is a set of rules and schedules that define how and when data is backed up. It outlines the frequency of backups, the type of data to be backed up, the retention period, and the storage location. The Backup & Restore service you can create and manage backup policies to ensure your data is protected according to your specific needs.
- [Running on demand backups](#)
Backup policies are applied to applications to ensure scheduled backups occur at the specified frequency. However, there are instances where you may want to run a backup outside of the predefined schedule. The Backup & Restore provides you the option to initiate backups on demand.
- [Jobs](#)
A job in the Backup & Restore service represents the process of data backup and recovery. You can monitor jobs, manage jobs, and troubleshooting any issues that may arise during the backup and recovery process.
- [Restoring an application](#)
You can restore backed-up data to the same project, a different project, or even a different cluster, while specifying the desired target storage classes.
- [Backup and restore as code](#)
Make use of the backup and restore services through custom resources (CRs) and integrate these functionalities with the application code. It manages application backups by using a declarative state and maintains your backup posture for an application alongside the application in Git.
- [Reducing elevated privileges for Fusion Backup and Restore service](#)
After you deploy the Fusion Backup and Restore service, you can reduce its elevated cluster administrator privileges if your organization's security policies require it. [Contact IBM Support](#) to obtain the utility script for your release.
- [Backup & restore service from OpenShift Container Platform](#)
You can monitor and manage Backup & restore service related operations from the OpenShift Container Platform console.

Backup storage locations

You can create backups by assigning a backup policy to an application. The policy specifies how frequently to backup the application, and where to store the backup. The location where the backup is stored is called a backup location and it is a prerequisite to create a policy.

Local snapshots store the backup on the local cluster, but it is a good practice to specify an external object store as a backup location so that you do not lose backups upon local storage failures. IBM Fusion uses a secure connection to transfer the backups to the object storage provider of your choice.

Supports multiple backup storage locations:

You can backup your Red Hat® OpenShift® applications to local and object storage target locations, such as IBM Cloud®, Microsoft Azure, Amazon Web Services, and any S3 Compliant object storage.

For S3 compliant object storage, ensure that the ACL (access control list) is enabled, and that read permission is granted. Also, ensure that S3 is not in the same cluster or namespace as IBM Fusion Backup & Restore service. You can plan to use cluster services like MinIO or NooBaa but ensure to host them on different clusters. If your backups are in the same place as your primary data, then the data is not protected.

Important: Backup & Restore does not support OpenStack Swift of ANY version.

On the Locations page of the IBM Fusion user interface, you can configure at least one location to store your backed-up data. It supports a variety of object storage types and includes details such as name, status, type, used capacity, associated policies, and applications. You can perform actions like viewing details, editing credentials, and removing locations using the ellipsis menu.

To manage the backup location by using CRs, see [Backup and restore as code](#).

- [Creating a secret](#)
You must create a secret for S3 targets that use a self signed certificate before you create a backup storage location.
- [Adding a backup storage location](#)
You can add new location from the Backup & restore page of the IBM Fusion or IBM Fusion HCI user interface.
- [Managing backup storage location details](#)
You can view location details, update credentials (like access key and secret key for AWS, or account name and account key for Azure), access the YAML configuration, and remove the location record.

Creating a secret

You must create a secret for S3 targets that use a self signed certificate before you create a backup storage location.

Whenever you create a backup storage location for S3 compliant storage, you have the option to specify a certificate to authenticate the connection.

1. Extract the certificate from an S3 compliant service to a file. Use the `openssl` command to extract the certificate into the file `tls.crt`.
Note: Ensure that the file name must be `tls.crt`.

```
openssl s_client -connect <s3-service-name>:<s3-service-namespace>.apps.<fusion-hostname>.<domainname>:443 -showcerts \
| sed -n '/BEGIN CERTIFICATE/,/END CERTIFICATE/p' > tls.crt
```

For example, use the `openssl` command to extract the certificate from the `minio` service in the `minio-ns` namespace on a IBM Fusion cluster.

```
echo | openssl s_client -connect minio-minio-ns.apps.myfusionhostname.mydomain:443 2>&1 | sed -ne '/-BEGIN CERTIFICATE-/,/-END CERTIFICATE-/p' > tls.crt
```

2. Run the `OC` command to create a generic secret in the IBM Fusion namespace using the `tls.crt` file.

```
oc create secret generic <secret-name> --type=opaque --from-file=tls.crt -n <fusion-namespace>
```

For example, in the default IBM Fusion namespace `ibm-spectrum-fusion-ns`.

```
oc create secret generic minio-cert-secret --type=opaque --from-file=tls.crt -n ibm-spectrum-fusion-ns
```

Note: Make a note of this secret name. You need it to create a backup storage location.

Adding a backup storage location

You can add new location from the Backup & restore page of the IBM Fusion or IBM Fusion HCI user interface.

Before you begin

If you plan to use a certificate for a S3 compliant backup storage location, then create a secret with the certificate as a prerequisite. For the procedure to create a secret, see [Creating a secret](#).

About this task

Create the backup storage location in the specified sequence. High-level steps to add a backup storage location:

1. Go to Backup & restore > Locations, and click Add location.
2. Enter Location name, type of object storage, and credentials for the storage.
3. If applicable, enter the certificate's secret name for S3 compliant storage locations.
4. Click Add.

Note: IBM does not support the creation of two backup storage locations that have both identical endpoint and bucket names.

Procedure

1. Log in to IBM Fusion user interface.
2. From the menu, click Backup & restore > Locations.
3. In the Locations page, click Add location.
The Add backup location wizard page is displayed.
4. In the Add backup location, enter the Location name.
5. Select the type of object storage backup location. The different location types are Azure (Microsoft Object Storage), IBM Cloud (IBM Object Storage), AWS (Amazon Object Storage), MCG/NooBaa (Red Hat Object Storage), S3Compliant (Any Object Storage), and Storage Protect.
For the procedure to add MCG/NooBaa location, see [Using MCG or Noobaa as a backup storage location](#). For the procedure to add Storage Protect location, see [Using IBM Storage Protect as a backup storage location](#).
Note: S3 buckets must not enable expiration policies. For more information about this known issue, see [S3 buckets must not enable expiration policies](#). Also, the bucket must not have an archive rule set.
6. Click Next.
7. In the Login credentials section, enter the following credentials to connect IBM Fusion to your backup location: Endpoint, Bucket, Access key, Secret key. If the location is Azure (Microsoft Object Storage), then enter the Account name and Account key instead of Access key and Secret key. If the location is Amazon AWS, then you must also enter the Region.
Example for AWS endpoint:

```
https://s3.us-west-1.amazonaws.com
```

8. In the Certificate settings (optional) section, enter the Secret name for the certificate.

Note:

- This setting is applicable only when you create an S3 compliant backup storage location type.
- The endpoint URL must be an HTTPS protocol with a trusted connection. If the endpoint URL contains the HTTPS protocol, then you need to enter the name of the secret that contains the SSL certificate.
- If you did not create a secret before you create the backup storage location, then you cannot complete further steps. Ensure that you cancel the operation and go back to the create secret step. For the procedure to create a secret, see [Creating a secret](#).
- If you plan to use a S3 location, check whether your permissions are valid with the cloud provider for that particular endpoint and bucket or equivalent. For certificates, run the following `openssl` command to check whether a Subject Alternative Name (SAN) exists:

```
openssl x509 -in <filepath> -text
```

The output displays a SAN field. This SAN field must match the endpoint host of the S3 bucket.

- Do not use "wildcard + self-signed certificate" as it is a major security risk. If installed system-wide, then on exposure, all encrypted communication can be decrypted.

Warning: For security reasons, HTTP connections to S3 backup storage locations are disabled by default. Enable HTTP access only in non-production environments. IBM strongly recommends avoiding this option whenever possible. To allow insecure connections, set the `allowInsecureS3` property to `true` in the `DataProtectionAgent` custom resource.

For example:

```
apiVersion: dataprotectionagent.idp.ibm.com/v1
kind: DataProtectionAgent
metadata:
  name: dpagent
```

```
namespace: ibm-backup-restore
spec:
  transactionManager:
    allowInsecureS3: 'true'
```

9. Click Add.

A success message gets displayed after adding the location.

- [Using MCG or Noobaa as a backup storage location](#)
Create an MCG or Noobaa S3 target backup storage location.
- [Using IBM Storage Protect as a backup storage location](#)
Backup OpenShift Container Platform applications to an IBM Storage Protect server and optionally make a copy of the data on tape.

Using MCG or Noobaa as a backup storage location

Create an MCG or Noobaa S3 target backup storage location.

Procedure

1. Log in to Red Hat® OpenShift® Container Platform.
2. Go to Storage > Object Bucket Claims.
3. In the Create ObjectBucketClaim page, create an Object Bucket claim with the following details: capture credential details.

ObjectBucketClaim Name

Enter the name of the Object Bucket Claim. If you do not enter a value, a generic name gets generated.

StorageClass

Select `openshift-storage.noobaa.io` class. It defines the object storage service and the bucket provision.

BucketClass

Select `noobaa-default-bucket-class`.

4. Click Create.
5. Note down the Object Bucket Claim credentials like Endpoint, Bucket Name, Access Key, Secret key.
6. Extract the certificate from an S3 compliant service to a file. Use the `openssl` command to extract the certificate into the file `tls.crt`.
Note: Ensure that the file name must be `tls.crt`.

```
openssl s_client -connect <s3-service-name>-<s3-service-namespace>.apps.<fusion-hostname>.<domainname>:443 -showcerts \
sed -n '/BEGIN CERTIFICATE/,/END CERTIFICATE/p' > tls.crt
```

For example, use the `openssl` command to extract the certificate from the `MCG/Noobaa` service.

```
export s3_url=$(oc get routes.route.openshift.io -n openshift-storage s3 -o jsonpath='{.spec.host}'):443
echo $s3_url
openssl s_client -connect $s3_url -showcerts \ | sed -n '/BEGIN CERTIFICATE/,/END CERTIFICATE/p' > tls.crt
```

7. Run the `OC` command to create a generic secret in the IBM Fusion namespace by using the `tls.crt` file.

```
oc create secret generic <secret-name> --type=opaque --from-file=tls.crt -n <fusion-namespace>
```

For example, in the default IBM Fusion namespace `ibm-spectrum-fusion-ns`:

```
oc create secret generic bsl-cert --type=opaque --from-file=tls.crt -n ibm-spectrum-fusion-ns
```

8. Log in to IBM Fusion user interface.
9. From the menu, click Backup & restore > Locations.
10. In the Locations page, click Add location.
The Add a backup location wizard page is displayed.
11. Enter the Login credentials and Certificate settings to create a backup storage location.
In the Secret Name for Certificate field, enter the secret name created in step 7.
12. After the backup storage location is created, go to the Locations page and check whether the status is Connected.
13. If you want to create a S3 of NooBaa type, do the following steps:
You can add the location as a separate NooBaa type instead of the S3, but you cannot do it from the UI.

It requires additional steps to create the credentials secret and BSL YAML.

- a. Create a secret using the `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY` from NooBaa.

```
kind: Secret
apiVersion: v1
metadata:
  name: <noobaa bsl secret>
  namespace: <fusion namespace>
  labels:
    dp.isf.ibm.com/ownedBy: fbsl
    dp.isf.ibm.com/provider-name: isf-backup-restore
data:
  access-key-id: <base64-encoded AWS_ACCESS_KEY_ID>
  secret-access-key: <base64-encoded AWS_SECRET_ACCESS_KEY>
type: Opaque
```

If a YAML is used, encode the values using base64.

- b. Copy the location of the S3 route to use as the endpoint for the BSL CR. Use noobaa CLI to get the list of buckets to choose from:

```
noobaa bucket list
```

c. Create the BSL CR with type `noobaa`:

```
apiVersion: data-protection.isf.ibm.com/v1alpha1
kind: BackupStorageLocation
metadata:
  name: <noobaa bsl>
  namespace: <fusion namespace>
  labels:
    dp.isf.ibm.com/provider-name: isf-backup-restore
spec:
  credentialName: <noobaa bsl secret>
  params:
    bucket: <bucket name>
    endpoint: '<noobaa s3 route>'
  privateCertificateName: <optional noobaa certificate secret>
  provider: isf-backup-restore
  type: noobaa
```

Using IBM Storage Protect as a backup storage location

Backup OpenShift® Container Platform applications to an IBM Storage Protect server and optionally make a copy of the data on tape.

Before you begin

Ensure that you have IBM Storage Protect 8.1.18 server or higher.

Before you implement this solution, see [IBM Storage Protect documentation](#) to understand expected recovery time of data from tape based on the total amount of managed data on the tape.

About this task

If the IBM Storage Protect server already has an object agent defined, you must recreate the object agent to ensure that the public certificate is generated correctly. To recreate the object agent, you must do the following steps to remove the current object agent:

1. From the IBM Storage Protect server, issue the command `delete server <object_agent_name>`.
2. Uninstall the IBM Storage Protect object agent on the system by using the `ibmspecified` command from the `delete server` output.
3. Delete the object agent directory under the server instance directory on the machine that hosts the IBM Storage Protect installation.
4. Proceed with the steps in the procedure to define the IBM Storage Protect object agent.

Procedure

1. Configure the object agent service on the IBM Storage Protect server.
 - a. Run the following command on IBM Storage Protect server:

```
setopt objectagentsancertificate yes
```

Note:

- If you are using a self-signed certificate, then you need this step to allow the object agent to create a self-signed certificate with the Subject Alternate Name (SAN).
- If you are using a CA-signed certificate, then this step is not required.

- b. Create the object agent service by using the `DEFINE SERVER` command.

For details about the command, see [IBM Storage Protect 8.1.18 documentation](#).

Note: If you are using a self-signed certificate, then you must `ibmspecify` the `HLAddress` in dotted decimal format.

- c. Configure an object client as documented in IBM Storage Protect documentation.
- d. Create an object storage bucket. You can create a bucket either by using the S3 API or by using the following MinIO client command:

```
mc mb
```

2. Configure a backup location from the IBM Fusion interface.
 - a. Location name is any name of your choice.
 - b. Location type is S3 Compliant.
 - c. Endpoint is the URL using the dotted IP address of the object agent client, which was configured on the IBM Storage Protect server.
 - d. Bucket is the bucket that was configured on the IBM Storage Protect server.
 - e. Access key and Secret key are the keys that were generated when the object client was created on the IBM Storage Protect server.
 - f. Secret name for certificate to create a secret to store the IBM Storage Protect public certificate as documented in the [Adding a location](#) or [Adding a backup storage location](#).

After the backup location is created, create a backup policy using the new backup location and assign one or more applications to the backup policy.

3. Copy data to and from tape:
 - a. Optionally, copy IBM ibmspectrum Protect data to tape:

```
PROTECT STGPOOL
      Type=Local
```

You can schedule this command to run periodically.

- b. To recover data that is no longer available in the primary storage pool, use the `REPAIR STGPOOL` command to recover the data from tape to the primary storage pool. For more information about the command, see [IBM Storage Protect documentation](#).
- c. Initiate the restore request from IBM Fusion.

Managing backup storage location details

You can view location details, update credentials (like access key and secret key for AWS, or account name and account key for Azure), access the YAML configuration, and remove the location record.

View location details

From the ellipsis overflow menu of the location record, click Details to open the <Location name> slide out pane.

- Expand the Policies and Applications to see a list of associated policies and applications. The number that is mentioned within parenthesis for Policies and Applications indicate the total number of associated policies and applications respectively.
- Click the edit icon to update Access key and Secret key. For Azure, the values are Account name and Account key.
- Click the launch YAML icon to view the YAML.

The details about the location vary based on the type. For example, Amazon AWS includes the following details: Type, Status, Used capacity, Endpoint, Bucket, Region, and associated Policies and Applications. The Region is only applicable for AWS locations.

Add location

Click Add Location to add a new location. For more information about the procedure, see [Adding a backup storage location](#).

Edit location details

From the ellipsis overflow menu, click Edit to update the values of Access key and Secret key. For Azure, the values are Account name and Account key.

Alternatively, you can also select the location that you want to edit and click the edit icon in the side pane to modify the location details.

Note: You cannot update bucket details except credentials because two backup storage locations with different names can share the same credentials and endpoint.

Remove a location

From the ellipsis overflow menu of a location record, click Remove to delete the location record. Click Remove in the Confirm remove window. This action removes the location as an available backup location from IBM Fusion. However, you can still access this backup location through your storage service provider.

Backup policies

A backup policy is a set of rules and schedules that define how and when data is backed up. It outlines the frequency of backups, the type of data to be backed up, the retention period, and the storage location. The Backup & Restore service you can create and manage backup policies to ensure your data is protected according to your specific needs.

The Policies page lists all policies. You can search for policy records based on the backup location or other keywords, configure the table display, and perform actions like viewing, editing, or deleting policies from the ellipsis overflow menu.

- [Creating backup policy](#)
You can add new backup policies from the Backup page of the user interface.
- [Managing backup policy](#)
Click Manage policies to manage policies for an application and initiate backup now.

Creating backup policy

You can add new backup policies from the Backup page of the user interface.

Before you begin

As a prerequisite to create a backup policy with object storage, you must first add a backup storage location.

To know more about configuring the target backup storage Location, see [Backup storage locations](#).

About this task

To manage the backup policies and backup location by using CRs, see [Backup and restore as code](#).

High-level steps to create a policy:

1. In the Policies page, click Add policy to open the Create a backup policy panel.
2. Enter the policy name and select the desired frequency (Hourly, Daily, Weekly, Monthly, or Custom) with specific times and days.
3. Select between In place snapshot or Object storage for the backup location.
4. Enter the retention period.
5. Click Create policy.

Procedure

1. Log in to IBM Fusion user interface.
2. From the menu, click Backup & Restore > Policies.
3. Click Add policy.
The Create a backup policy slide out pane displays on the screen.
4. In the Create a backup policy pane, enter the following details to create a new backup policy that meets your business needs:
 - a. Enter the Policy name.
 - b. Enter the Frequency details:
 - i. Enter whether the frequency is Hourly, Daily, Weekly, Monthly, or Custom:

Hourly

Choose a time.

Daily

Choose a time.

Weekly

Select a day for Schedule and Choose a time.

Monthly

Choose a day from calendar and time.

Custom

Choose a specific day and time.
 - ii. If you select frequency intervals of 1 day or more, the Time window section is visible on the screen for you to select a start time, end time, and time zone.
Note: Consider the following points when you enter details in the Time Window:
 - The minimum time window is 4 hours from start to end time. An error message gets displayed whenever the time window is less than 4 hours.
 - When you change the start time, the end time is automatically adjusted to reflect the new start time plus the current time window duration.
 - When you change the end time, the duration between the start and end time is adjusted automatically, while the start time remains unchanged.
 - If the start and end times are identical, the duration is considered a 24-hour time window.
 - c. Select either In place snapshot or Object storage from Backup Locations.

In place snapshot

For In place snapshot policies, the resource backup information is kept locally on the cluster in the backup and restore install namespace of the MinIO storage. The VolumeSnapshots and VolumeSnapshotContent objects are kept in the application namespace. The VolumeSnapshotContent objects that are not namespaced get stored at cluster scope. The restore job fails whenever you delete the VolumeSnapshots or VolumeSnapshotContent objects. At expiration time, the resource backup in MinIO, VolumeSnapshots, and VolumeSnapshotContents get deleted. The deletion of the used StorageClasses or VolumeSnapshotClass objects, which are used in backup and restore also causes the expiration to fail.
Note: Capacity for in place snapshots is not available.

Object storage

Using the Object Storage option, you to choose from a list of available object storage. You can also use the Search option to filter the location records.
 - d. Enter the retention period. It is the duration in which the backup copies exist in the storage location. Choose a value for its unit that can be days, weeks, months, or years.
For example, 30 Days.
5. Click Create policy.
A message gets displayed informing you about the successful creation of a new backup policy along with the policy name.

Managing backup policy

Click Manage policies to manage policies for an application and initiate backup now.

Procedure

1. Go to Backup & Restore > Backedup applications page.
2. Select one or more applications from the list.

Option	Description
Single application	a. Select an application. b. From the ellipsis overflow menu, select Manage policies. A Manage policies page is displayed with a list of all policies in the local cluster.
Multiple applications	a. Select multiple applications. b. Click Manage policies. A Manage policies page is displayed with a list of all policies in the local cluster. The following notification message is displayed: Mixed policies the application selected do not share the same set of policies.

3. To remove all policies, do the following steps:
 - a. In the Manage policies page, click the Remove all policies toggle button.
 - b. If you set the Remove all policies toggle button to on, then the policies table is disabled.
 - c. In the Remove all assigned policies confirmation window, click OK to proceed.
4. Click Backup now to initiate an immediate backup of one or more applications.
5. Select one or more policies and click Save.

Setting up backup policies

After you create a policy, you can assign them to applications so that application data is backed up in the specified frequency and stored in the defined storage, such as object storage or in place snapshot. You can set up backups for applications of the local cluster from the Applications page. To setup backup for applications of both hub and spoke clusters, go to Backed up applications page.

Set up policies from the Applications page

Before you begin

For backup and restore to work, you must create volume snapshot class.

About this task

The high-level steps to set policies for applications are as follows:

1. Go to the Applications page.
2. Select one or more applications for which you want to assign a backup policy.
3. Assign one or more policies for the selected applications, and click Assign. You can also initiate an immediate backup.

Procedure

1. Go to Applications from the menu.
For applications that do not have backup policy set, the Backup status columns of these records show No policy. If a policy is assigned, the name of the policy is displayed in the Policies column. If more than one backup policy is assigned to the application, the number of policies is displayed.
2. Select the check box from the Name column or click ellipsis menu and select Assign backup policy in the Policies column to assign a backup policy to a single application with no policy assigned.
Note: If there are no policies assigned before, select the policy provider either Backup & Restore or Backup & Restore (legacy).
To assign a policy to multiple applications, select the checkboxes in the Name column for the applications to which you want to assign the policy, and click Assign policy. The Assign policies window gets displayed and click Continue.
The Assign backup policy slide out pane gets displayed.
3. In the Assign backup policy slide out pane, the Backup & Restore is selected by default as a policy provider and you can assign one or more backup policies to the selected application.
The details of all available backup policies are displayed, such as location, locationtype, frequency, retention, and time.
4. Select Run backup now check box.
5. Click Assign to assign a backup policy.
In the Applications page, you can observe that the Backup status of the selected application shows as Not backed up for applications that have not got backed up yet. After the backup set up is done, the Backup status of the selected application changes to Completed with a green check mark. Also, the Last backup time shows the backup time.
Now you can check the status of your job from the Jobs tab.

Set up policies from Backed up applications page

Before you begin

As a prerequisite, you must have created policies.

- Ensure one or more policies exist.
- If you want the application VMs to be backed up and restored, then you need to ensure that the following prerequisites are met:
 - Bare Metal cluster is available
 - Red Hat OpenShift Virtualization feature is installed from the Operator Hub of OpenShift® Container Platform console.

Note: Support is available VMs based on Filesystem PVCs (PersistentVolume has the `volumeMode: Filesystem` defined). From 2.8 release, the Block mode volumes (`volumeMode: Block`) support is available as a technical preview.

Recipes for VMs are not supported.

Ensure you are aware of the Backup & Restore service related issues before you protect your applications. For more information about issues and how to resolve them, see [Troubleshooting Backup & Restore service issues](#).

Procedure

1. Go to Backup & Restore > Backed up applications.
2. Click Protect apps.
The Protect applications wizard page gets displayed.
3. In the Select applications page, select a Hub or Spoke cluster on which you want to backup your applications.
After you select the cluster, the number of unprotected applications on the cluster gets displayed. The applications table populates only unprotected applications and does not display applications that are already protected.
4. Select your application record(s). You can also select the entire list all together.
5. Click Next.
The Assign policies wizard page gets displayed. The table includes Name, Location, Type, Frequency, Time, Retention, and Backup now column headings. The Type indicates the supported providers, such as Microsoft Azure, IBM Cloud®, S3 compliant object storage, Amazon Web Services, and Storage protect.
6. Select policies to assign to the applications. You can select a single to all policies for assignment.
7. Optionally, you can turn on the Backup now toggle for a record to immediately start the backup.
8. Click Assign.
After the validation is successful, a success notification message is displayed. You can go to the Backed up applications page and search the applications table for the newly selected applications.

Managing your application workloads

Applications contain resources, such as microservices, databases, and other stateful data distributed across projects. IBM Fusion provides ways to do application-centric backup, which provides data loss protection for your applications.

Note: If IBM Storage Scale is used for storage, it must have a minimum of 5G PVC size to perform backup and restore operations.

Note: The Applications page shows only local cluster applications or remote DR applications. Remote Backup & Restore Spoke applications do not show up on the Hub cluster. To view Spoke applications, go to Backup & Restore > Backed up applications > Protect apps view.

Application list

The Applications page lists all your OpenShift® applications with their backup details, such as Name, Used, Capacity, DR status, Backup status, Last backup on, Success rate, and Policies.

Table 1. Application list

Application list	The Applications page lists all your OpenShift applications with their backup details, such as Name, Used, Capacity, Backup status, Last backup on, and Policies. Note: In the Applications page, if you continue to see applications that got deleted from OpenShift, check whether associated backups are available. If you no longer need to restore those backups, delete the Application CR instance of that application from the CRD.
Actions	View details Use the Search field to filter and find your record from the list. You can use the settings icon to customize the headings. To view the application details, click the Name link of the record or click View details in the ellipsis menu. Assign backup policy To assign backup policy, see Assign backup policy. Backup now To start the backup of an application right away, click Backup now in the ellipsis menu of the application record. Restore Restore the application backup. For the steps to restore an application resource, see Restoring an application.

Assign backup policy

Select applications with no policy assigned:

1. Select one or more application(s) and click Assign backup policy. Alternatively, for an application, click Assign backup policy from the ellipsis menu. The Assign a backup policy slide out pane gets displayed.
2. Select one or more backup policies. You can select Run backup now to initiate a backup. If you do not see any policy that suits your requirement, create a new policy. For the procedure to, create a new policy, see [Managing backup policies for application workloads](#).
3. Click Assign .

Select multiple applications having a mix of policies:

1. Select one or more application(s) and click Assign backup policy. Alternatively, for an application, click Assign backup policy from the ellipsis menu. The Assign a backup policy slide out pane gets displayed.
2. In the Policy provider section, select which service you want to use as a policy provider.
3. Select one or more backup policies. You can select Run backup now to initiate a backup. If you do not see any policy that suits your requirement, create a new policy. For the procedure to, create a new policy, see [Managing backup policies for application workloads](#).
4. Click Assign .
5. In the Confirm assignment confirmation page, go through the information about the number of applications that cannot be assigned as they use policies that are provided by another backup service.
6. Click OK.

Managing the application details

The application details are classified into Overview, Storage, Backups, and Resources tabs.

You can click the Assign a policy to open the Assign a backup policy page. For more information about Assign a backup policy page, see [Setting up backup policies](#).

In addition, you can also click Assign policy to open the Assign a backup policy page. For more information about Assign a backup policy page, see [Setting up backup policies](#).

Overview tab

The Overview tab includes the following details:

Table 1. Overview tab details

Element	Description
Storage	The Storage section provides a summary of how this application is using storage resources. It represents overall capacity and usage of the PVCs in a line chart. The capacity usage of storage classes is represented as a pie chart. For example, 1200 GiB is the overall capacity and 300 GiB is the used capacity.

Element	Description
Events	The Events section includes critical and recent events that occurred on the application. Click View all to see all the events that are associated to this application.
Backups	The Backups section provides a summary of backup jobs. The percentage of successful backups, timestamp of the recent successful backup, and total number of available backups and backup policies. The storage capacity usage from a policy perspective is represented as a pie chart. For example, there are 3 policies and 600 GiB overall capacity. The "check_app" policy usage is 400 GiB, the "object_policy" usage is 150 GiB, and the "client26" usage is 50 GiB.
Inventory	The Inventory section displays a clickable list of storage and resources. The number within parenthesis for Storage and Resources headings indicate the total number of available storage and resources respectively.

Storage tab

The Storage tab includes the following details:

Table 2. Storage tab details

Element	Description
Capacity usage by PVCs	Capacity usage by PVCs section displays the current application capacity usage by PVCs.
Capacity by storage class	Capacity by storage class section represents in a pie chart the total capacity of the storage class and the amount of used storage in GiB.
Storage classes	Storage classes section individually lists all the storage classes along with the total number of PVCs, total capacity of the PVC, and the total used capacity in GiB. The number that is specified within parentheses is the total number of storage classes. Note: A Persistent Volume (PV) storage is dynamically provisioned by using the storage classes. For more information about how to create storage classes, see Dynamic provisioning of Persistent Volume in filesystem .
Persistent Volume Claims	The Persistent Volume Claims section lists PVCs distributed across the associated storage classes along with their used and total capacities. Note: The PVC is a storage request and it uses the PV resources. It also does claim checks to these resources. The following details of the PVCs are available in the list: - The Name of the storage class. - The PVC status of the storage class. The values are Bound and Unbound. - The Used and Capacity indicates the used storage and the total capacity in GiB. - The Storage class and PV indicates the associated storage class and PV. Use the Search text box to filter the records in the list. You can filter based on PVC status and storage class parameters. You can further refine your search based on the different values of these parameters. For example, you can filter PVC status based on Bound, unbound, or All. You can also use the settings icon to choose the columns to display. Click Reset to default if you want the original system settings.

Backups tab

The Backups tab includes the following details:

Note: If a backup is in progress for the application, then a message is displayed with details about the percentage completion of the backup job.

Table 3. Backups tab details

Element	Description
Backups list	The Backups section lists all backup jobs. By default, the following details about a backup are available in the list: - The Time of backup. Click the Time link of a record to view details. You can sort records based on Time. The most recent - The Status of the backup. The various statuses are namely, Snapshot in progress, In progress, Completed, Failed, PartiallyFailed, Failed Validation. - The Policy used. - The Location where it is backed up. - The Size (GiB). Additionally, you can select following details available under Edit columns section by clicking the setting icon. - The Location. - The Duration. - The End time.
Search	Use the Search text box to filter the records in the list. You can also use the settings icon to customize the column display. Click Reset to default if you want the original system settings. For advanced search on the records, click the filter icon and select values for Policy, Status, or Location from the drop-down lists. After selecting the values, click Done. Click Clear filters to clear the selection made in these drop-down lists.
Usage section	The Usage section provides total number of available backups and used capacity.
Backup policies section	For individual associated policies, it provides Retention, Used Capacity, Last backup, and Location. You can use the ellipsis overflow menu to view details, edit, or remove a policy association from the application. If you want to assign policies from this section, click Assign. For the procedure to assign, see Setting up backup policies .

Element	Description
Actions from the ellipsis overflow menu of a backed up record	The ellipsis menu of your backed up record includes the following options: View details and Delete backup. View details The details slide out pane is displayed: - The Backup details section contains the time, status, policy, location, and name of the application. If the backup is available, then the status is Available. The Size and Expiration information is added to the Backup details section. Click  (Launch YAML icon) to open and view the YAML. Click  (Restore icon) to restore the backed up data. If the restore is in progress, then the Restore icon is disabled. - The Job details section contains the Job ID and Elapsed time. - The Inventory, Backup sequence, and Data transfer phases are displayed for monitoring. The backup's inline notification is displayed. If an error occurs in another of the statuses, then click View job details to know more information about the job. Delete backup Click Delete backup to delete the backup record.

Resources tab

The Resources tab lists all the included resources of the selected application in a table format with Name, Type, and Label headers.

Use the Search text box to filter the records in the list. For advanced search, click the filter icon and select a value from the Type drop down to list all resources that belong only to a selected type.

You can also use the settings icon to choose the columns to display. Click Reset to default if you want the original system settings.

Actions that you can perform on an application details page

Click Actions and select any of the following operations:

Table 4. Actions available in a application details page

Manage backup policies	Click Manage backup policies to select one or more backup policies for data protection. In the Assign policy slide out pane, click the Frequency and select run backup now to do an immediate backup. It overrides the frequency set in the policy and starts the on-demand backup job immediately. However, the scheduled backups continue to run as set in the associated policy. After you select, click Done to complete the operation. If the listed policies do not match your requirement, then create a new policy from the Backup Policies page. A message is displayed to inform the success of the policy assignment operation. Note: If you have not assigned a policy to this application, the Actions and Restore buttons are not visible. Instead Assign policy button is available.
Backup now	Click Backup now to backup the application data. In the Backup now slide out pane, verify the application, policy, backed up data location, and retention period. If there is more than one policy associated to the application, then select one or more policies and click Run <n> backup policies. Here, n indicates the number of policies that are selected to run backup. In the confirmation window, click Run backup policy to initiate the backup job.
Restore	Click Restore to restore the application backup. A Restore Application <application name> slide out pane gets displayed. For more information about how to work with the slide out pane, see Restoring an application .
Failover This action is available only in a Metro-DR setup.	Click Failover to register this application for disaster recovery. For more information about failover steps, see <i>Failover</i> section in Managing your application workloads . For more information about disaster recovery, see Upgrade and upsize considerations in Metro-DR . A message gets displayed confirming that the application is enabled for disaster recovery. Note: If the two sites of the Metro sync DR setup are in network disconnected state, then before you start the failover or fallback operation on the surviving site, scale down the Ramen DR. To get the name of surviving site, run mmlsmgr command. After network issues are resolved, scale up the Ramen DR.
Remove disaster recovery This action is available only in a Metro-DR setup.	After an application is enabled for disaster recovery, the Actions shows Remove disaster recovery option. If you no longer need disaster recovery (fail back) for an application, click Remove disaster recovery to disable the protection for the application. In the confirmation message box, click Disable to proceed with the disable operation. In the Remove disaster recovery window, click Remove.

Note: The Application CR remains as long as there are PolicyAssignments or Backups associated with the application. The system checks for both, and the Application CR is retained until neither exists. To completely remove the application, you must delete all existing Backups and PolicyAssignments, and then delete the namespace.

Running on demand backups

Backup policies are applied to applications to ensure scheduled backups occur at the specified frequency. However, there are instances where you may want to run a backup outside of the predefined schedule. The Backup & Restore provides you the option to initiate backups on demand.

Before you begin

- When you restore an application from Hub to Spoke or Spoke to Hub cluster, ensure that the same StorageClass exists in both Hub and Spoke.
- In Backup & Restore, one hub cluster and more than one spoke clusters may be connected to manage application backups in multi-clusters. For various reasons, the OpenShift® Container Platform cluster may have problems and become unusable. If the cluster recovers after the expiry of the client cert, you must clean and setup to rejoin the recovered cluster to the Hub or Spoke. For the procedure to rejoin, see [Reconnecting OpenShift Container Platform cluster](#).

About this task

- You can backup one policy or more policies.
- The label `velero.io/exclude-from-backup=true` is not supported by the Backup & Restore service.

Procedure

1. Go to Backup & Restore > Backedup applications page.
2. Select one or more applications from the list.

Note: Applications using remote Global Data Platform storage are not supported for Backup & Restore.

Option	Description
Single application	a. Click the Backup now option from the ellipsis overflow menu of an application record. b. Click Backup in the Backup now confirmation window to start the backup operation of the application immediately. The <code>Initiating backup Starting backup on [app name]</code> notification is displayed.
Multiple applications	a. Select multiple applications and then click the global Backup now. When different policies are assigned for multiple records, then the Backup now window is displayed. b. Select the backup policies that are used to backup the selected applications. c. Click Backup. The Backup now confirmation window appears with a notification about the availability of multiple policies. d. In the Backup now confirmation window, you can optionally select Exclude applications with multiple policies. e. Click Backup in the Backup now confirmation window to start the backup operation of the application immediately. The <code>Initiating backup on [n] applications</code> notification is displayed. In the Backedup applications page, you can observe that the Backup status of the selected applications are in progress.

Jobs

A job in the Backup & Restore service represents the process of data backup and recovery. You can monitor jobs, manage jobs, and troubleshooting any issues that may arise during the backup and recovery process.

View backup and restore jobs

The Jobs page of the IBM Fusion user interface the backup and restore jobs are segregated in their respective tab pages.

In the Backups tab page, you can monitor the statuses of all backup jobs, which can be categorized as failed, pending, in-progress, canceled, or completed. You can sort these jobs based on the Started field. The Backups table provides a comprehensive overview of each job, including its name, associated cluster, application, status, time, policies, and recipes used. By clicking on the job name, you can access detailed information about each backup job. Similarly, you can view the list of all restore jobs in the Restore tab page.

In the job details, you can manage and track your backup and restore jobs, cancel ongoing jobs, rerun jobs, adjust job resources, and collect logs. It also enables you to quickly access detailed information about any specific job to investigate further or troubleshoot any issues.

In the Summary section, you can view the start time and duration of the job. You can toggle between the List view or Log view.

Within the Summary section, the backup jobs follow the Inventory, Backup sequence, and Data transfer order. The restore jobs follows the Inventory, Data transfer, and Restore sequence order.

Inventory

In the Workloads section, you can see the number of deployments, deploymentConfigs, stateful sets, and pods.

In the Storage section, you can see the number of PVCs attached.

In the Resources section, you can see the number of routes, secrets, services, and configMaps.

You can also download the resource list to your local.

Backup sequence

You can see the status of pre-hook, backing up PVCs, post-hook, and backing up etcd resources.

Data transfer

You can view the backup location, backup size, upload speed, upload status, and the upload progress percentage.

Note: You can view the data transfer details only for the jobs such as backups to S3 object and restore from S3 object.

From the Actions menu, you can click View YAML to view the CR's YAML in the OpenShift® console.

Cancel jobs

In the Jobs page, click Cancel jobs to cancel an ongoing job or a job in the queue. Alternatively, you can cancel jobs by using the Backup or Restore CR. Add the following line to the CR specification to cancel jobs that are in queue or running state.

```
spec:
  jobControl: cancel
```

If you cancel during backup, the volume snapshots get removed as a part of cleanup.

If you issue a cancel during restore, the cleanup happens only when you choose a new or an existing namespace.

Note: When you cancel a restore job to the original namespace, cleanup does not happen and can result in a corrupt application after the cancellation completes.

Scale jobs

You can scale out the number of transaction manager pods to process more jobs at the same time. For example, run the following command to increase the number of agent pods to two:

```
oc scale deployments/transaction-manager --replicas=2 -n ibm-backup-restore
```

To the scale out from the OpenShift Container Platform console, do the following steps:

1. Change the project to the Backup & Restore install namespace. The default is **ibm-backup-restore**.
2. Search and select the **transaction-manager** deployment.
3. Click the scale up or down to increase or decrease the scale. It takes about 30 seconds for a replica to start in optimal conditions. Do not click multiple times instead wait for each pod to get to ready status.

Re-run jobs

From the Actions menu, select Run job again to restart a previously completed or failed job.

Download logs

Download the log package for the current cluster and optionally any spoke clusters. Select the Collect service logs option in the Actions menu and choose your spoke clusters and click Create. The logs provide a high-level overview of the status of the job, including start and end times, success or failure, and any error messages. They are useful for quickly checking the overall status of a job and identifying any immediate issues.

Restoring an application

You can restore backed-up data to the same project, a different project, or even a different cluster, while specifying the desired target storage classes.

Before you begin

- When you restore an application from the Hub cluster to a Spoke cluster, manually check whether the same storageclass that is used to define the PVCs on the Hub exists on the Spoke cluster.
- By default, if PVCs with the same name exist in the namespace, they get restored with a new name (original name + “-n” suffix with n=1,2,3). If you want to skip the restore of existing PVCs, manually create a Restore CR from the command line and set an optional **spec** field **skipExistingPVC** to true.
- You must have OpenShift® APIs for Data Protection (OADP) version 1.3.1.
- For the Datamover operator to restore CephFS and Global Data Platform 5.2.0+ snapshots by using the ReadOnlyMany access mode, ensure that the value of backingSnapshot is **true** in the storageclass.
- Manually modify the restore when the original application already exists on the cluster and creates conflicts with each other.

About this task

- You can use the following restore options for your applications:
 - From S3 to the same cluster and project
 - From S3 to the same cluster and existing project
 - From S3 to the same cluster and new project
 - From S3 to a different cluster
 - From S3 to IBM Software Hub.
 - Restore from snapshot
- Backups that are taken using an In place snapshot can be restored only to the same project, and not to any new or a different project that exists. If you try to restore a project that is deleted from Red Hat® OpenShift, then the restore to the same project with In place snapshot does not include PVCs.
- After you remove an Agent or Spoke connection from the Hub cluster, it does not show up in the Topology page. Also, you can restore the available (not expired) successful application backups with an object storage location from that cluster to a different cluster.
- When you do a restore operation, the restored files, directories, and mount points can have different permissions, group, and owner from the source that was backed up; it is an expected behavior of Red Hat OpenShift design. For more information, see [OpenShift documentation](https://access.redhat.com/solutions/7007252) and <https://access.redhat.com/solutions/7007252>. You can modify this behavior by using security context constraints (SCCs), parameters such as fsGroup, or a custom script or command such as **chmod** or **chown**.
- IBM Cloud Paks instance backups cannot be created when continuous backup is enabled on the MongoDB service.
- You can restore backup data to a different StorageClass provisioner on an alternate cluster, for example, restore data that was originally backed-up from a CephFS provisioned StorageClass to a Scale provisioned StorageClass.

Procedure

1. In the menu, click Applications.
2. In the Applications page, search and open your application that you want to restore.
3. In the application details page, go to the Backups tab and from the ellipsis overflow menu of the backup record, click Restore option. Alternatively, go to the Backed up applications page and select Restore option from the ellipsis overflow menu of an application record. A Restore Application <application name> slide out window gets displayed.
4. In the Restore Application <application name>, select a Cluster destination where you want the application to be restored.
5. Select a Project destination for the application data.

Single namespace to the same or new cluster

For a single namespace, you can choose from any of the following options:

Note: For the single namespace to same or new cluster, the option Choose existing project is only available for same cluster restores.

- If you select the Use same project option, then click Next and proceed.
- If you select Choose existing project option, then select a Project from the list and click Next to proceed.
- If you select Create a new project option, then enter the name of the project and click Next to proceed.

Multi-namespace to the same or new cluster

For multiple namespaces, you can choose from any of the following options:

- If you select the Use same project option, then click Next and proceed.
- If you select Create a new project option, then select Project suffix and click Next to proceed.
The Project suffix is used to avoid name conflicts by associating it with a specific namespace. For example, if you select enter 123 for Project suffix, then in the preview you can see <Project name>-one-123. You can also choose different combinations of available suffixes in the Suffix preview.

The details in the Summary section vary based on your selections.

6. If you have not selected the backups, then select the backups that you want to restore and click Next.
7. If you do not want to use the existing Target storage class in your cluster to restore the PVCs, then select Change target storage class and enter a storage class of the same type to change it.
By default, restore occurs on a matching storage class name. If **target storage class** is specified, then restore happens on PVCs from this class. If the original storage class is non-existent or **target storage class** is not provided, the default storage class of the cluster is used.
Example scenarios where there may be a need to change the Target storage class are as follows:
 - If there is a requirement for a filesystem PVC with RWX access mode that a particular storage class (such as RBD) does not support, consider using an alternative storage class that meets the requirement.
 - An application may require a storage class with specific attributes, such as a particular compression or encryption setting.
 The restore does not overwrite existing PVCs instead new PVCs are created with an annotated name. Modify your application deployment to use the new PVCs.
8. In the Missing etcd resources section, select Include missing etcd resources to restore non-PVC application resources that are included in this backup but do not exist in this Red Hat OpenShift project.
Note: If you do not select the Missing etcd resources, the application-specific pods that need deployment resources or jobs may not start.
9. If you select Only restore a subset of selected PVCs, then select all PVCs or choose individual PVCs from the selected backup to restore.
10. Check the Summary and confirm the changes after restore.
11. Click Restore.
A message appears informing that the restore of the application from its backup is in progress. The status of the backup record in the Backups tab is initially set to Restoring and then it changes to Completed.
12. Go to the application to confirm the success of the restore operation.

What to do next

Storage classes that are used by applications on the source cluster must exist or be created on the target cluster before you attempt to restore the applications that use those classes.

Backup and restore as code

Make use of the backup and restore services through custom resources (CRs) and integrate these functionalities with the application code. It manages application backups by using a declarative state and maintains your backup posture for an application alongside the application in Git.

You can use CRs to deploy backup storage locations, establish backup policies to each cluster, assign policies to applications, and perform backup and restore operations for applications and their resources.

Note: If you are not currently in the same namespace, then include **-n** <namespace> in all commands. If you are already in the IBM Fusion namespace (**ibm-spectrum-fusion-ns**), then **-n <namespace>** is not necessary.

Backup storage location

If you want to create a backup storage location, then define the type of the S3 endpoint, the name of the target S3 bucket, credentials to connect to the endpoint, and some optional parameters based on the type.

Create a backup storage location

```
oc create -f <storagelocation.yaml>
```

Sample storage location YAML file:

```
apiVersion: v1
data:
  access-key-id: AMIATNJ3JEMKR6GAUOLN
  secret-access-key: vgm9AJPztPkOygBFpBp2UzEErLBelTc3JPdPn9c
kind: Secret
metadata:
  name: backup-storage-location-example-secret-0
  namespace: ibm-spectrum-fusion-ns
---
apiVersion: data-protection.isf.ibm.com/v1alpha1
kind: BackupStorageLocation
metadata:
  name: backup-storage-location-example
  namespace: ibm-spectrum-fusion-ns
spec:
  type: aws
  credentialName: backup-storage-location-example-secret-0
  provider: isf-backup-restore
  params:
    region: us-west-2
    bucket: bucket-name
    endpoint: https://s3.us-west-2.amazonaws.com
```

In this sample, a secret and backup storage locations are created.

Note: The secret is created before the triple dashes, and the backup storage location is created after the triple dashes in the YAML file.
Run the following command to generate the cloud data:

```
printf "[default]\naws_access_key_id=minio\naws_secret_access_key=minio123\n" | base64 -w 0
```

Replace the value of `aws_access_key_id` and `aws_secret_access_key` with your value.

Modify backup storage location

```
oc edit fbsl backup-storage-location-example
```

You can modify the backup storage location details.

Modify secret

```
oc edit secret backup-storage-location-example-secret-0
```

You can modify the secret details.

Delete backup storage location

```
oc delete fbsl backup-storage-location-example
```

Note: You cannot delete a backup storage location if there are any existing backup policies or backups associated with it. For successful backups, they must surpass their retention period before IBM Fusion can automatically remove them. However, failed backups can be manually removed through the IBM Fusion web console.

Delete secret

```
oc delete secret backup-storage-location-example-secret-0
```

Get all backup storage locations

```
oc get fbsl
```

Backup policy

Create a backup policy

```
oc create -f <backuppolicy.yaml>
```

or

```
oc apply -f <backuppolicy.yaml>
```

Sample backup policy YAML files:

- Backup policy to take backups daily:

```
apiVersion: data-protection.isf.ibm.com/v1alpha1
kind: BackupPolicy
metadata:
  name: daily-policy
  namespace: ibm-spectrum-fusion-ns
spec:
  provider: isf-backup-restore
  backupStorageLocation: backup-storage-location-example
  retention:
    number: 10
    unit: days
  schedule:
    cron: "30 10 * * *"
    timezone: America/Los_Angeles
```

- Backup policy to take backups weekly from Monday through Friday:

```
apiVersion: data-protection.isf.ibm.com/v1alpha1
kind: BackupPolicy
metadata:
  name: backup-policy-weekdays
  namespace: ibm-spectrum-fusion-ns
spec:
  provider: isf-backup-restore
  backupStorageLocation: backup-storage-location-example
  retention:
    number: 4
    unit: weeks
  schedule:
    cron: "30 20 * * 1,2,3,4,5"
    timezone: America/Los_Angeles
```

Edit a backup policy

```
oc edit backuppolicy <backuppolicy name>
```

You cannot modify the policy name and CR name.

Delete a backup policy

```
oc delete backuppolicy <backuppolicy name>
```

Example:

```
oc delete backuppolicy daily-policy
```

If at least one reference exists a **backupObject** or **PolicyAssignment** Object, then you cannot delete the policy.

Get the basic information about a backup policy

```
oc get backuppolicy <backuppolicy name>
```

Get all the information about a backup policy

```
oc describe backuppolicy daily-policy
```

Alternatively, you can use the following sample OC command:

```
oc describe backuppolicy/daily-policy
```

Get all backup policies

```
oc get backuppolicies
```

Assign a policy to an application

BackupPolicyAssignment is a call to create backups by associating a backup policy with an application. You must assign a policy to an application to schedule backups.

```
oc create -f <policyassignment.yaml>
```

Note: The appCluster is the name of the cluster where this application resides. It is optional and only required for remote Spoke applications to designate which Spoke cluster to run the job against. If it is not provided, the assumption is that the jobs are for an application on the Hub cluster.

Sample assignment YAML file for daily backup:

```
apiVersion: data-protection.isf.ibm.com/v1alpha1
kind: PolicyAssignment
metadata:
  name: backup-policy-assignment-example
  namespace: ibm-spectrum-fusion-ns
spec:
  application: application-sample
  backupPolicy: daily-policy
  appCluster: fusion-cluster
```

Run the following command to get the name:

```
oc get cluster
```

Example:

```
apiVersion: data-protection.isf.ibm.com/v1alpha1
kind: PolicyAssignment
metadata:
  name: filebrowser-20220919-1834111-isf-auto-ibmcos-backuppolicy-20220919-183411
  namespace: ibm-spectrum-fusion-ns
spec:
  application: filebrowser-20220919-1834111
  backupPolicy: isf-auto-ibmcos-backuppolicy-20220919-183411
  appCluster: fusion-cluster
  runNow: true
```

The corresponding backup CRD file is as follows:

```
apiVersion: data-protection.isf.ibm.com/v1alpha1
kind: BackupPolicy
metadata:
  name: isf-auto-ibmcos-backuppolicy-20220919-183411
  namespace: ibm-spectrum-fusion-ns
spec:
  backupStorageLocation: isf-ibm-location-20220919-183411
  provider: isf-backup-restore
  retention:
    number: 1
    unit: days
  schedule:
    cron: 51 18 1 * *
    timezone: America/Los_Angeles
```

Edit policy assignment

```
oc edit policyassignment <policyassignment-name>
```

Delete policy assignment

```
oc delete policyassignment <policyassignment-name>
```

Backup and restore

Create backup CR for on-demand backup

Here, one time application backup is taken by using an on-demand backup policy.

```
oc create -f <CR_Ondemand_backup.yaml>
```

Sample YAML file:

```

apiVersion: data-protection.isf.ibm.com/v1alpha1
kind: Backup
metadata:
  name: auto-fb-spoke1-20230702-1122581-azure-dpcos1-daily-202307102004
  namespace: ibm-spectrum-fusion-ns
spec:
  appCluster: apps.bnr-sno-sunshine.fusion-sno-ibm.com
  application: auto-fb-spoke1-20230702-1122581
  backupPolicy: azure-dpcos1-daily

```

Note: The `appCluster` is the name of the cluster where this application resides. It is optional and only required for remote Spoke applications to designate which Spoke cluster to run the job against. If it is not provided, the assumption is that the jobs are for an application on the Hub cluster. Run the following command to get the name of the cluster where this application resides and add it as a value for `appCluster`:

```
oc get cluster
```

Delete backup request CR

A `DeleteBackupRequest` can be used to delete a backup CR and all the related resources (backup data, snapshot, and so on) of a backup CR.

```
oc create -f <delete_CR_Name.yaml>
```

Sample YAML file:

```

apiVersion: data-protection.isf.ibm.com/v1alpha1
kind: DeleteBackupRequest
metadata:
  name: backup-example-delete-request
  namespace: ibm-spectrum-fusion-ns
spec:
  backup: backup-example

```

Restore an application

```
oc create -f <backup-restore.yaml>
```

Sample of YAML restore file:

The following sample restores the `backup-wordpress` backup.

For cross cluster restore, the `targetCluster` is provided. If `targetCluster` is not available, then default to the same cluster where the backup got originated from:

```

apiVersion: data-protection.isf.ibm.com/v1alpha1
kind: Restore
metadata:
  dp.isf.ibm.com/provider-name: isf-backup-restore
  name: restore-complete-wordpress-1689030046
  namespace: ibm-spectrum-fusion-ns
spec:
  backup: complete-wordpress-ibm-do-not-use-202307102253
  objectsToRestore:
    RESOURCES:
      - ALL
      v1/persistentvolumeclaim:
        - complete-wordpress/mysql-pv-claim
        - complete-wordpress/wp-pv-claim
  targetCluster: guard-vpc-dog-98b7318c91b01bd72490e80cc2328915-0000.us-south.containers.appdomain.cloud

```

Restore an application to alternate namespaces

You can restore application to alternate namespaces on same cluster or another cluster.

For example, application A comprising of three namespaces namely `ns1`, `ns2`, and `ns3` are backed up, then you need to specify the `namespaceMapping` field in Restore CR to restore this application to alternate namespace.

```

apiVersion: data-protection.isf.ibm.com/v1alpha1
kind: Restore
metadata:
  name: <custom-restore-name>
  namespace: ibm-spectrum-fusion-ns
spec:
  backup: <your-backup-job-name>
  namespaceMapping:
    ns1: ns1-new
    ns2: ns2-new
    ns3: ns3-new

```

Namespace variables automatically point to the correct namespaces during backup and restore. And it would be useful in scenarios, where you want to refer current namespace like exec hooks, mainly in restore cases.

Note: If a namespace or namespace field is missing in the `namespaceMapping`, then it restores to the original namespace.

An example of application that is backed up with three variables in Application CR.

```

apiVersion: application.isf.ibm.com/v1alpha1
kind: Application
...
spec:
  includedNamespaces:
    - ns1
    - ns2
    - ns3
  variables:
    - name: PARENT_NAMESPACE
      value: ns1

```

```
- name: CHILD1_NAMESPACE
  value: ns2
- name: CHILD2_NAMESPACE
  value: ns3
```

There are two methods to access these variables:

- The first method is using `${PARENT_NAMESPACE}`. It is valid only in backup scenario, and becomes invalid during restore as still referring to `ns1`.
- The second method is using new construct `${APP}.${PARENT_NAMESPACE}.name`, which substitutes namespace variables correctly. This refers to `ns1` in case of backup and `ns1-new` when restoring to alternate namespace.

In a restore scenario within the same namespace, it refers to `ns1` only. This new construct can be used while specifying hook `namespace` field and exec commands.

List backups

```
oc get backups.data-protection.isf.ibm.com
```

List restores

```
oc get restores.data-protection.isf.ibm.com
```

List policy assignments

```
oc get policyassignments.data-protection.isf.ibm.com
```

Self-service Backup & Restore

Create a `RecoverBackup` CR

To create a `RecoverBackup` CR, see [Self-service Backup & Restore](#).

Service protection

Note: The service protection is supported only through the user interface and not from the command line.

Retrieve a backup logs and resources information

The following commands use `jq` to process the JSON output.

Get the Backup & Restore namespaces with the following commands using the former to retrieve the latter. Skip this step if you know the namespace used in the environment.

Note: You can run these commands only from the hub cluster, even when the Backup CR is created in a spoke cluster.

```
oc get spectrumfusion -A --no-headers | cut -d" " -f1
```

```
oc -n <fusion namespace> get fusionserviceinstance ibm-backup-restore-service-instance -o json | jq -rc
'[(.spec.parameters[] | "\n",.name,.value)] | @csv' | tr -d '"' | grep ",namespace," | cut -d"," -f3
```

Port forward to the backup service, then use curl or a web browser with either URL.

```
oc port-forward svc/backup-service 9443:9443 -n <backup and restore namespace> &
```

```
curl -k <logURL or resourcesURL> | jq -r ' [.logs] | @sh'
```

Alternatively, the following steps may be used to run curl from the backup service pod:

1. Get the backup service's pod on the Backup & Restore namespace.

```
oc get pod -n <backup and restore namespace> --field-selector=status.phase=Running --selector=app=backup-service | grep
backup-service | head -n 1 | cut -d ' ' -f1
```

2. Run the curl command on the backup service pod.

```
oc exec -it <backup-service-pod ID> -n <backup and restore namespace> -- curl -k <logURL or resourceURL> | jq -r ' [.logs]
| @sh'
```

Example:

```
: oc get spectrumfusion -A --no-headers | cut -d" " -f1
> ibm-spectrum-fusion-ns
```

```
: oc -n ibm-spectrum-fusion-ns get fusionserviceinstance ibm-backup-restore-service-instance -o json | jq -rc
'[(.spec.parameters[] | "\n",.name,.value)] | @csv' | tr -d '"' | grep ",namespace," | cut -d"," -f3

```

Reducing elevated privileges for Fusion Backup and Restore service

After you deploy the Fusion Backup and Restore service, you can reduce its elevated cluster administrator privileges if your organization's security policies require it. [Contact IBM Support](#) to obtain the utility script for your release.

Before you begin

Before you reduce the elevated privileges, ensure that you have the following prerequisites:

- **oc** (OpenShift CLI) installed on your system
- **yq** (command-line YAML processor, version 4.x or later) installed
- **jq** (command-line JSON processor) installed
- Cluster administrator access to your OpenShift® cluster
- The **updateFusionAuthority.sh** script obtained from [IBM Support](#) for your Fusion release

About this task

The Fusion Backup and Restore service needs elevated privileges to access other application namespaces and perform backup and restore operations. After the initial deployment, you can reduce these privileges to a minimal level if your organization's security policies require it.

Attention:

- The Fusion Backup and Restore service requires elevated privileges during the initial deployment.
- You must restore elevated privileges before any upgrade or patch operation. See the prerequisites for instructions.

Procedure

1. [Contact IBM Support](#) to obtain the **updateFusionAuthority.sh** script for your Fusion release.
2. Make the script executable:

```
chmod +x updateFusionAuthority.sh
```

3. Verify that you are logged into your OpenShift cluster:

```
oc whoami
```

4. Run the script to reduce the elevated privileges:

```
./updateFusionAuthority.sh reduce-authority
```

The script modifies the role-based access control (RBAC) configuration for Fusion operators by removing cluster administrator privileges while maintaining the minimum permissions that are required for backup and restore operations.

5. Verify that the privilege reduction was successful by reviewing the output from the script.

Results

The Fusion Backup and Restore service now runs with reduced privileges. The service continues to function with the minimum permissions that are required for backup and restore operations within authorized namespaces.

What to do next

After reducing privileges, be aware of the following requirements:

Restoring elevated privileges before upgrades or patches

Before you upgrade or apply a patch, you must restore elevated privileges by running the following command:

```
./updateFusionAuthority.sh restore-authority
```

After the upgrade or patch is complete, you can rerun the script with the **reduce-authority** option to reduce privileges again.

Backup & restore service from OpenShift Container Platform

You can monitor and manage Backup & restore service related operations from the OpenShift® Container Platform console.

In the OpenShift Container Platform console, go to **Storage > Backup & Restore**. The Backup & Restore page includes the following tabs:

- [Overview tab](#)
From this tab page, you can monitor storage consumption, backup storage activity, backup coverage, and backup and restore jobs.
- [Policies tab](#)
From this tab page, you can do the following operations:
 - Create a backup policy
 - Edit an existing policy
 - Delete an existing policy
- [Locations tab](#)
From this tab page, you can do the following operations:
 - Create a new backup storage location
 - Edit credentials of a backup location
 - Remove an existing backup location

- [Applications tab](#)
From this tab page, you can do the following operations:
 - Assign backup policy to applications
 - Restore backups of applications
- [Jobs tab](#)
From this tab page, you can do the following operations:
 - Delete backup jobs
 - Collect logs
 - View job summary

At any point in time, you can click Go to Fusion Backup & Restore to go to the Backup & restore page of the IBM Fusion user interface.

Prerequisites

- Enable Backup & restore service in IBM Fusion.
For the steps to enable Backup & restore service from IBM Fusion user interface, see [Install Backup & Restore](#).
- If for some reason, you can access OpenShift Container Platform console prior to or during ongoing IBM Fusion HCI installation, then wait for 10-20 seconds after installation to see the following notification in the OpenShift Container Platform console:

Web console update is available

Click Refresh web console link to refresh and view the Backup & restore service.
- The user interface works only for the supported OpenShift Container Platform 4.16. Do not try to access that user interface on any older OpenShift Container Platform versions.

Overview tab

The Overview tab page is a dashboard view to monitor Backup & restore service details.

Section	Description
Status	The Status section includes Statuses of Backup location and Applications. The Backup locations are either Active or inactive. The Active refers to the connected location status and inactive refers to not connected. The Applications subsection includes the following details: Backed up applications Applications with assigned policies Applications with recent backup Applications that are backed up and the recent or latest backup was successful (Completed or PartiallyFailed). Backup in progress Applications with recent or latest ongoing backup.
Backup & Restore jobs summary	The Backup & Restore jobs summary includes the following details: Queued jobs It includes the number of in progress and number of pending jobs. Success rate Note: The Success rate and other fields are dependent on the frequency drop down. The Success rate subsection displays the percentage of success rate and the number of jobs completed out of the total number of jobs. It also gives a break up of the number of completed, failed, and canceled jobs. The All, Backup, and Restore options display the completed, canceled and failed jobs accordingly. The Backup job count is also represented in a graph bar chart.
Backup summary	The Backup coverage and Most recent backup are represented in a circular chart. It also shows a legend of the color representation. The Backup coverage includes the following details: Backed up applications Applications with assigned policies Not backed up applications Applications without assigned policies The Most recent backup includes the following details: Backup completed Applications that are backed up and its recent or latest backup was successful (Completed or PartiallyFailed) Backup failed Applications that are backed up and recent or backup was not successful.
Storage consumption	The Object storage section includes the amount of GiB used.
Backup & Restore activity	The Backup & Restore activity lists ongoing and recent events related to application, backup, backup policy, backup storage location, policy assignment, and restore.

Policies tab

A backup policy defines a set of rules to backup application data. The following table describes the different sections and actions you can perform in the Policies tab page.

Section	Description or action
Backup policies table	The Backup policies table lists the policies with Name, Status, Location, Backup scheduled, Retention period, Application. You can search a backup policy record by its name from the list.
Backup policy record actions	From the ellipsis overflow menu of a policy record, you can do the following operations: - Edit backup policy - Edit YAML - Delete backup policy
Create backup policy	- Click Create backup policy. The Create BackupPolicy page is displayed. - Enter the following details of the policy: - Enter the Policy name of the policy. - In the Backup location section, select whether you want In place snapshot or Object storage. If you select Object storage, then select the Location from the drop down list. - Select the Backup schedule for the backup. In Schedule, select the frequency. In At, select the time. In Time zone, select your zone. - In the Retention period, select number for Schedule and Duration in Days, Weeks, Months or Years. It is the duration to retain the backup. - Click Create.

Locations tab

A backup location is a prerequisite to create a policy. You must configure at least one location to store your backed-up data. IBM Fusion supports a variety of object storage types. The following table describes the different sections and actions you can perform in the Backup locations tab page.

Element or section	Description or action
Backup locations table	The Backup locations table includes Name, Status, Location type, Policies, Used capacity, and Protected applications.
Actions performed on a backup location record	From the ellipsis overflow menu of a backup location record, you can do the following operations: - Edit credentials - Update Endpoint, Access key, or Secret key values. - Click Save. - Edit YAML opens in YAML format. You can make changes and click Save. - Remove backup location In the confirmation window, click Remove to proceed with deletion.
Create a backup location	If you plan to use a certificate for a S3 compliant backup storage location, then as a prerequisite create a secret with the certificate as a prerequisite. For the procedure to create a secret, see Creating a secret. Note: IBM does not support the creation of two backup storage locations that have both identical endpoint and bucket names. - Click Create backup location. - Enter the details about the backup location: - Enter the Name of the backup location. - Select the Location Type of the backup location. The different location types are IBM Cloud (IBM Object Storage), Azure (Microsoft Object Storage), AWS (Amazon Object Storage), Spectrum Protect, and S3Compliant (Any Object Storage). Enter the following credentials to connect IBM Fusion to your backup location: Endpoint, Path/Bucket, Access key, and Secret key. If the location is Amazon Web Services, then you must also enter the Region. If the location is Microsoft Azure (Microsoft Object Storage), then enter the Account name and Account key instead of Access key and Secret key. - In the Certificate setting (optional), enter the Secret name for certificate.

Applications tab

Applications contain resources, such as microservices, databases, and other stateful data distributed across projects. IBM Fusion provides ways to do application-centric backup, which provides data loss protection for your applications. The following table describes the different sections and actions you can perform in the Applications tab page.

Element or section	Description or action
Applications table	The Applications table includes Name, Backup status, Backup policy, Location, Used/Total capacity, Last back up on, and Success rate. Here, the Backup status indicates the outcome of the most recent backup performed for an application. The Success rate indicates the number of successful backups performed for the application. It also indicates the availability of backup copies.

Element or section	Description or action
Actions performed on an application record	From the ellipsis overflow menu of an application record, you can do the following operations: - Assign backup policy - Restore It opens a Restore window. - In the Select a project destination section, select from the following options: - Use the same project the application is already using Select the project in the current cluster where the application gets restored to. Restoring to an existing cluster delete the contents of the project and replaces it with the restored application. - Use existing project - Create new project If you select Create a new project, then enter a new project. Note: If you choose Existing project or Create new project, you can only specify a single namespace. You cannot restore multiple namespaces to a single alternate namespace. - Select a backup from the available list of backups. - Optionally, select Include missing etc resource to restore any etc resources that are not present in the existing OpenShift project. - Select the PVCs. By default, all PVCs in the back are restored. If you want to restore only certain volumes, then you can select individual PVCs. - Click Restore.
Assign backup policy	If you plan to use a certificate for a S3 compliant backup storage location, then as a prerequisite create a secret with the certificate as a prerequisite. For the procedure to create a secret, see Creating a secret. Note: IBM does not support the creation of two backup storage locations that have both identical endpoint and bucket names. - Click Assign backup policy. Alternatively, you can also click Assign backup policy from the ellipsis overflow menu of an application record. You can search for backup policy and filter records. - Select one or more policies. - If you want to initiate a backup right away, set the Run backup now toggle button to on. - Click Assign. If you set the Run backup now toggle button is set to on, the Backup status of the application in the Applications page is initially New. It then changes to Queued, Inventory in progress, Snapshot inprogress, and Complete. You can also check the Backup & Restore Jobs list in the Jobs tab page for similar status.

Jobs tab

The Jobs page displays the details of all the backup and restore jobs. The following table describes the different sections and actions you can perform in the Jobs tab page.

Element or section	Description or action
Backup & Restore jobs table	The Backup & Restore jobs table includes Name, Operation, Status, Start time, Completion time (Duration), Application, and Policy. You can filter the records based on Status and Operation. The Operation values are Backup and Restore. You can select a field and enter keywords in the Search to filter records. You can also choose to view the list of jobs in last 24 hours, last 7 Days, or last 30 days.
Actions to perform on a jobs record	The ellipsis overflow menu of a job record are as follows: - Delete backup job If you click Delete backup job, a confirmation window appears. If you are sure to delete the job, click Delete. - Collect logs Click Collect logs to go to the Jobs page of the IBM Fusion user interface. In the Jobs page, click Collect logs. - Job summary Click Jobs summary to go to the Jobs page of the IBM Fusion user interface. Here, you can view details like Summary (Inventory and Backup sequence) and Details (Duration, Created, Size, Policy, Application. Backup ID, Backup location).

Service protection

The IBM Fusion Backup & Restore service protection involves the backup of the Backup & Restore data management service to a S3 bucket.

In case of cluster failure, use the IBM Fusion Service Protection to recover all namespaces from the failed cluster into a new cluster. However, it assumes that the service protection backup got created and all application backups exist before the cluster failure. The high-level steps to backup and restore the service:

- Create a new instance of OpenShift® Container Platform cluster or use an exiting healthy cluster.
- Install Backup & Restore service.
- The Service Protection Recover service uses the backup to restore all resources used by the Backup & Restore service such as backup policy, location, policy assignment, Backup CRs.
- Restore all other applications from Backup CRs.
- [Configuring service backups](#)
Backup a service configuration from the service backup.

- [Recovering service backups](#)
Restore a service configuration from the service backup.

Configuring service backups

Backup a service configuration from the service backup.

About this task

In the Configure Service backups, select the location type and enter the credentials to access the location. After the discovery of existing service backups, the Service protection page is displayed with a list of service backups. If no service backups are available, define a schedule with frequency and retention period, and initiate a backup.

In Backup & Restore, one hub cluster and more than one spoke clusters can be connected to manage application backups in multi-clusters. For various reasons, the OpenShift® Container Platform cluster may have problems and become unusable. If the cluster recovers after the expiry of the client cert, you must clean and setup to rejoin the recovered cluster to the Hub or Spoke. For the procedure to rejoin, see [Reconnecting OpenShift Container Platform cluster](#).

Note: Do not create virtual machines or PVCs on the IBM Fusion namespace, as it causes restoration failures of service protection backups.

Procedure

1. Go to Backup & Restore, > Service protection.
The Service protection page is displayed. Here, Configure Service backups and Recover service from backup tiles are available.
2. Select Configure Service backups.
The Connect backup location wizard page is displayed.
3. In the Location type tab, select the location type and click Next.
The available location types are Microsoft Azure, IBM Cloud®, S3 compliant object storage, Amazon Web Services, and Storage protect.
The Location credentials tab page is displayed.
4. In the Location type tab, enter the credentials to connect to your location. Enter the endpoint and bucket to use for the service protection backups. For SSL secured object storage locations, enter the Secret name for certificate.
There are two limitations that are not enforced:
 - While the user interface does not allow the created BSL to be assigned to any other policy, it is still possible to do so by using the CR. However, do not do this action.
 - The same endpoint or bucket must not be used for service protection configuration for more than one cluster deployments at a time.

Note: After you set the location or bucket details, you cannot edit it later.
5. Click Add.
Note: The discovery of existing service backups may take a minute or so. After the discovery completes, the BSL changes the status. For example, Connected.
The Service protection page is displayed with a Service backups table.
6. If no service backups are available, click Define schedule.
The Define schedule window is displayed.
7. In the Define schedule, enter the following details:

Frequency
The frequency of backup. It can be Hourly, Daily, Weekly, Monthly, or Custom. For Custom, choose a value in minutes, then select the time zone.

Retention period
How long does the backup reside before automatic deletion. Select the number and its unit. For example, 30 Days.

Initiate Service backup now
You can use this toggle to imitate the backup immediately.
8. Click Save.
The Service protection page is displayed. If you had initiated service backup, then you can monitor the progress of the backup in the Service backups table. The Service backup table has Time, Status, Location, and Size. The Backup summary section is updated with details of Available backup, Used capacity, Last successful backup, and Backup policy.
9. If you had not initiated any backup, then click Back up service now in the Service protection page.
The Backup summary section is updated with details of Available backup, Used capacity, Last successful backup, and Backup policy.

Recovering service backups

Restore a service configuration from the service backup.

Before you begin

- Ensure that the IBM Fusion Backup & Restore (Legacy) service is not installed. This recovery replaces all existing objects with the objects in the service backup.
- If service protection requires rebuilding the hub cluster, backup your application data to a cloud-based storage. Also, backup any defined local S3 storage on your cluster to a cloud storage. The recovery procedure in this topic restores only the metadata for backups, which got saved to the cloud storage.
For example, you have a MinIO storage service defined and configured with a backup storage location that uses the local storage. The MinIO application must have its cloud backup policy to restore the service first, and then any applications backed up to the local S3 storage.

You can use the local storage for sensitive applications, but ensure that you save the database to the cloud or another S3 location within the firewall. Restore the local storage location from a cloud backup before you attempt to restore other applications backed up to that storage service.

- The IBM Fusion namespace must remain the same between the service backup and service restore. When you recover a service backup to a new IBM Fusion deployment, make sure that the deployment uses the same namespace as backup.

Procedure

1. Go to Backup & Restore > Service protection.
The Service protection page is displayed. Here, Configure Service backups and Recover service from backup tiles are available.
2. Select Recover service from backup.
The Add a backup location wizard page is displayed.
3. In the Location type tab, select the location type and click Next.
The available location types are Microsoft Azure, IBM Cloud®, S3 compliant object storage, Amazon Web Services, and Storage protect.
The Location credentials tab page is displayed.
4. In the Location credentials tab, enter the credentials to connect to your location. For SSL secured object storage locations, enter the Secret name for certificate.
Provide the same S3 information or credentials as provided in the original Service Protection backup configuration.
5. Click Connect.

The discovery process looks for existing service backups.

Option	Description
No service backups available	If no service backups are available, then No service backups message is displayed. Click Define schedule to configure. Note: It may take a while for the discovery of existing service backups to complete.
Service backups are available	Initiate restore by using either of the following methods: • Click Restore service. • From the ellipsis overflow menu of a service backup, select Restore. • Click Backup to display the Backup details slide out pane, and then click the Restore.

The Restore service page is displayed.

6. Select a backup and click Restore.
Note: This restore action reverts all Backup & Restore objects to the selected backup.
When the Restore is in progress, the user interface disables Backup & Restore functions. However, you can still create CRs outside of the user interface.
7. Do the following steps based on the scenario existing on your cluster:

Option	Description
Empty cluster with no Backup & Restore	No action required
Empty cluster but Backup & Restore installed	a. Type Recover. b. Click Initiate service restore. Note: The recover action restores all backup policy, location, policy assignment, CRs including the ones used by Backup & Restore from service backup. However, any available Backup & Restore backups on the restore cluster get deleted. If you need them, copy the backup CRs.

The Service protection page is displayed. A Service restore is in progress notification message is displayed. You can monitor the progress of restore in the Summary section. When the restore begins, the service protection page gets replaced by a job summary page for restore.

What to do next

1. Application backups are available to restore before the backup storage locations are connected. Wait for the backup storage location to be connected before you attempt to restore.
2. Storage classes that are used by applications on the original cluster must exist or be created on the restored cluster before you attempt to restore the applications that use those classes.
3. Scheduled backups resume after the service restore is complete. However, these backups fail until the applications are restored from a backup. You can ignore these failed backups. After the application is restored from a backup, subsequent backups will be successful.
4. When you do a service protection restore, the Backed up applications page does not display the applications on the Spoke clusters that are not reconnected to the new Hub cluster. After a Spoke is manually reconnected, it may take a while for the backed up applications on that Spoke to appear on the page.

Self-service Backup & Restore

You can protect your namespace application with IBM Fusion Backup & Restore even as an application user without cluster rights or a user without IBM Fusion administration rights. Application owners can create IBM Fusion Backup & Restore Custom Resource (CRs) within the application's namespace to self-manage their application's backup and restore needs without the involvement of a cluster or IBM Fusion Backup & Restore administrator.

Important: This feature is only supported for applications by using Backup & Restore Custom Resources (CRs) and not through IBM Fusion user interface. All self-service Backup & Restore CRs, including scheduled Backup CRs exist in the namespace of the application.

To create Backup & Restore CRs in the application's namespace, you need to be an application namespace administrator, an application user, or service account with granted permission to the namespace. Application namespace administrators can directly create Backup & Restore CRs within their application namespace.

Non-admin application users and service accounts need the namespace administrator to first grant IBM Fusion Backup & Restore permissions through a standard OpenShift® RoleBindings. The RoleBindings grant permissions for the user or service account in the application's namespace with the specific Backup & Restore Role.

Each of the Backup & Restore CRs have an 'admin', 'crdview', 'edit', and 'view' Roles available for them. They are named in the following format:

`<CR Name>.data-protection.isf.ibm.com-v1alpha1-<Role>`

The following Backup & Restore CRs have Role available for them:

Role	CR
backuppolicies.data-protection.isf.ibm.com	Backup Policy
backups.data-protection.isf.ibm.com	Backup
backupstoragelocations.data-protection.isf.ibm.com	Backup Storage Location
deletebackupprequets.data-protection.isf.ibm.com	Delete Backup Request
policyassignments.data-protection.isf.ibm.com	Policy Assignment

Role	CR
recipes.spp-data-protection.isf.ibm.com	Recipe
recoverbackupcrs.data-protection.isf.ibm.com	Recover Backup CRs
restores.data-protection.isf.ibm.com	Restore

For example, the IBM Fusion Backup CR has the following Roles:

- backups.data-protection.isf.ibm.com-v1alpha1-admin
- backups.data-protection.isf.ibm.com-v1alpha1-crdview
- backups.data-protection.isf.ibm.com-v1alpha1-edit
- backups.data-protection.isf.ibm.com-v1alpha1-view

If you want to reference `backuppolicy` or `backupstoragelocation` that is in another namespace, then specify it in "namespace/BP" or "namespace/BSL" format. The user must have permissions for the namespace that is specific for the BSL or BP.

RoleBindings can be created with a mix of permissions to achieve the desired level of management. For example, the application administrator wants to restrict Restore actions while allowing another user to perform all other Backup actions. To achieve this, the application administrator must create RoleBindings in the application's namespace for that other user with all Backup & Restore administrative roles except the Restore CR. To create the RoleBindings, see [OpenShift documentation](#).

As an example, consider the following screen shot of the OpenShift RoleBinding creation page showing the process of creating a RoleBinding for the user1 user identity in the namespace1 namespace with the 'view' Backup & Restore PolicyAssignment Role.

Create RoleBinding

Associate a user/group to the selected role to define the type of access and resources that are allowed.

Binding type

- ☒ Namespace role binding (RoleBinding)
Grant the permissions to a user or set of users within the selected namespace.
- ☐ Cluster-wide role binding (ClusterRoleBinding)
Grant the permissions to a user or set of users at the cluster level and in all namespaces.

RoleBinding

Name *

User1PolicyView

Namespace *

 ibm-spectrum-fusion-ns

Role

Role name *

 backuppolicies.data-protection.isf.ibm.com-v1alpha1-view

Subject

- ☒ User
- ☐ Group
- ☐ ServiceAccount

Subject name *

user1

Create

Cancel

The same RoleBinding can be created from the `oc` command line:

```
oc create rolebinding User1PolicyView --role=backuppolicies.data-protection.isf.ibm.com-v1alpha1-view --user=user1 -n namespace1
```

Note: To retrieve logs and resources, see [Backup and restore as code](#).

Service Accounts

It is a time-consuming process to create RoleBindings to multiple users individually. The Service Accounts provide another option for the self-service capability to a broad group of non-admin users. When creating a RoleBinding, you can select ServiceAccount option in the Subject section instead of an individual user. For more information about service accounts, see [OpenShift documentation](#).

RecoverBackupCRs

If an application's namespace gets accidentally deleted or corrupted, the Backup & Restore CRs may prevent any potential recovery of the application from backups. It prevents the potential recovery of the application through an Backup CR.

Any successful **RecoverBackupCRs** action always recreates any prior Backup CRs. Recovery of other Backup & Restore CRs can be specified as options.

Example **RecoverBackupCRs** CR:

```
apiVersion: data-protection.isf.ibm.com/v1alpha1
kind: RecoverBackupCRs
metadata:
  name: example
  namespace: <replacement namespace>
spec:
  application: <deleted application namespace>
  reassignPolicies: true
  recreateDeleteBackupRequestCRs: false
  recreateRestoreCRs: false
```

All spec fields are optional.

- **application**
Name of the deleted application's namespace. If not specified, the Backup & Restore service makes use of the application name from the **metadata.namespace** field.
- **reassignPolicies:**
Boolean to recreate any prior Policy Assignment CRs or not. Default is false.
- **recreateDeleteBackupRequestCRs:**
Boolean to recreate any prior **DeleteBackupRequest** CRs or not. Default is false.
- **recreateRestoreCRs**
Boolean to recreate any prior Restore CRs or not. Default is false.

To recover from an accidental deletion or corruption of the namespace or Backup & Restore CRs, do the following steps:

1. Create a replacement application namespace
2. Re-create the Backup & Restore RoleBindings that is same as the original namespace.
3. Create a **RecoverBackupCRs** CR in the replacement namespace that refers to the original namespace.

The Backup & Restore service detects the presence of this CR and performs verification checks to ensure that the administrative RoleBindings in the new namespace matches the deleted application. If it matches, then the Backup & Restore service recreates from its metadata all the relevant Backup & Restore. The desired Backup CR can then be used to restore the application from a prior backup.

Custom Backup & Restore Administrator

Another mode of operation for managing the Backup & Restore service is to grant a non-admin user the admin of the Backup & Restore service. To do this, create the RoleBindings of the user in the IBM Fusion namespace with the Backup & Restore admin Roles.

This user does not have IBM Fusion user interface access but can manage Backup & Restore activity of all applications on both hub and spoke clusters through Backup & Restore CRs within the IBM Fusion namespace.

Limitations

Limitations that are applicable for both Hub and Spoke:

- Only command line support is available
- Cross-cluster restore is not available
- Self-service jobs are not shown in the IBM Fusion UI
- Spoke self-service policies and backup storage locations are not shown in the IBM Fusion UI
- Applications with only self-service policies or completed self-service backup or restore jobs do not appear in the Backed up applications table.
- Applications configured with self-service policies do not appear in the Backed Up Applications > Protect Apps.
- On the Topology table, the backed up apps ratio and success rate may also be inaccurate as it includes self-service applications and self-service backup jobs.

Managing backup for multi-cluster environment

You can connect and manage cluster connections in IBM Fusion. It includes steps to establish connections and manage existing connections. You can also reconnect an OpenShift® Container Platform cluster either after a disaster recovery event or a temporary unavailability.

- [Connecting and managing cluster connections](#)
You can connect clusters, manage actions on cluster records, and remove cluster configurations. You have options to connect clusters either through the Fusion UI or automated deployment.
- [Reconnecting OpenShift Container Platform cluster](#)
The OpenShift Container Platform cluster that is connected in a disaster recovery relationship or a Backup & Restore service with Hub and Spoke can face disasters, leading to a temporary unusable state. After recovery, it can still display an **Unhealthy** or **UnManaged** status in remote clusters. In such instances, this cluster must be reconnected to its corresponding connections.
- [Disabling the connection](#)
Disable the connection between Hub and Spoke.

Connecting and managing cluster connections

You can connect clusters, manage actions on cluster records, and remove cluster configurations. You have options to connect clusters either through the Fusion UI or automated deployment.

The Topology page displays the clusters' connections and you can perform the following activities:

- [Connect clusters](#)
- [Actions on a cluster record](#)
- [Remove cluster configuration](#)

Connect clusters

1. In the Backup & Restore menu, click Topology.
2. In the Topology page, click Connect clusters.
3. In the Connection method window, select Use the Fusion UI or Automate deployment.

Table 1. Cluster connection options

Option	Procedure
Use the Fusion UI	a. On your hub cluster, go to the Topology. b. Click Connect clusters. c. Select Use the Fusion UI. The connect your cluster > Use the Fusion UI window appears. The YAML starts to generate. d. After the YAML is generated successfully, click Copy snippet. e. Go to the Spoke cluster and install IBM Fusion. f. Go to the Services page and install Backup & Restore Agent. g. Paste the copied snippet to proceed with the agent install. Note: If you use a custom namespace, then do not use the Copy command because the encoded command is not editable and is of no value with a custom namespace.
Automate deployment	To connect multiple Spoke clusters: a. On your hub cluster, go to the Topology. b. Click Connect clusters. c. Select Automate deployment. The connect your cluster > Automate deployment window appears. d. Select the storage class to use on the spoke where you want to run the YAML. e. Click Generate. The YAML starts to generate. Here, you can either use the Deploy using YAML or Deploy using oc command option. f. In the Deploy using YAML option, copy or download the YAML. g. Apply the YAML on each of the Spoke clusters.

Actions on a cluster record

The Topology page lists the hub cluster and all spoke connections. Using the Actions, you can View details, View backed up apps, and remove connections.

In View details, a pane opens with the details of the cluster, namely Connection status, Service status, Job queue, any critical issues, and Backup success rate. You can also click View backed up apps in this pane to view applications that are local to a specific cluster.

In View backed up apps, view applications that are local to a specific cluster. The assumption here is that you assigned policies for these applications on the spoke.

You can also remove connections. See [Remove connections](#).

Remove connections

You can search and remove connections.

From the Hub cluster, you can remove a Spoke or Agent cluster connection.

Note: The Backup & Restore service operations stops after the removal, however, all backups that are associated with this cluster remain available until they expire.

If the selected cluster is involved in a Regional DR, remove the Regional DR configuration before you remove the connection to the selected cluster.

If you remove the connection from the user interface, it removes the connection on both hub and spoke for that spoke. On the hub, there exists a connection for every spoke, so you must only remove the connection for the spoke to be uninstalled. There exists only one connection on the spoke or agent and hence you can remove it from the agent side safely. When you remove the connection on one cluster, the action removes it from both clusters.

Remove the connection first and then uninstall the agent.

1. Search for a connection.
2. From the ellipsis overflow menu of a connection record, click Remove connection.
A Remove connection confirmation window is displayed.
3. Click Remove

A notification appears to confirm the successful removal of the connection. The cluster is not available in the table after the successful removal. From the removed Agent user interface, the following banner notification is displayed:

Unmanaged service The Backup & Restore Agent's connection to the Hub cluster has been removed.

Important: When a spoke cluster is removed, its application backups are deleted from storage when they expire. If the connection to the cluster is down but still configured, backups are retained until the connection is restored, and then deleted.

Alternatively, if you want to remove the connection from the hub side by using the **oc delete connection** command and more than one connection exists, then view the YAML and confirm the connected host that you want to remove.

If you want to remove the connection using **oc** commands, run the following commands:

```
oc get connection
```

```
NAME                               AGE
connection-7d9a76ce09             25h
```

```
oc delete connection connection-7d9a76ce09
```

```
connection.application.isf.ibm.com "connection-7d9a76ce09" deleted
```

Reconnecting OpenShift Container Platform cluster

The OpenShift® Container Platform cluster that is connected in a disaster recovery relationship or a Backup & Restore service with Hub and Spoke can face disasters, leading to a temporary unusable state. After recovery, it can still display an **Unhealthy** or **UnManaged** status in remote clusters. In such instances, this cluster must be reconnected to its corresponding connections.

About this task

If the cluster recovers before the expiration time, the cluster rejoins the connection automatically and no action is needed. However, if the cluster recovers after the expiration of the client cert, the connection must be cleaned and setup to rejoin the recovered cluster.

Procedure

1. Run the following example command to login to cluster-a and list the connection names.

```
oc login to cluster-a
```

2. List the connection names.

```
oc get connections
```

It lists all connection CRs that are used for Backup & Restore and disaster recovery. The following example shows connections among clusters:

- If cluster-a is in a DR relationship, a connection exists for the other cluster.
- If cluster-a is a Backup & Restore hub, there exists a connection for each spoke.
- If cluster-a is a Backup & Restore spoke, one connection to the hub exists.

The output includes the API endpoint of cluster-b.

Example output

NAME	API_ENDPOINT		PHASE	HEALTHY_TO	HEALTHY_FROM	AGE
connection-8414b9c84d	https://api.cluster-b.mydomain:6443	InProgress	Unhealthy	Unknown	25d	
%						

3. Save the name of connection CR in cluster-a (a cluster in the hub and spoke or DR clusters) in **connection-<id>** format.
4. Clean the connection.
For the procedure to clean the connection, see [Disabling the connection](#).
5. Setup the connection between clusters.
 - a. Log in to the cluster-b and get the bootstrap token for cluster-b.

```
oc login to cluster-b
```

```
oc create token isf-application-operator-cluster-bootstrap -n <Fusion Namespace of cluster-b>
```

Note: The version of **oc** command line must be greater or equal to 4.11.

- b. Log in to cluster-a.

```
oc login to cluster-a
```

- c. Create init secret on cluster-a with the bootstrap token and API endpoint of cluster-b.
For example:

```
apiVersion: v1
kind: Secret
metadata:
  name: <Init Secret Name>
  namespace: <Fusion Namespace of cluster-a>
stringData:
  apiserver: <cluster-b API Endpoint>
  bootstrapToken: <cluster-b Token Generated in Step 3.a>
```

- d. Create connection CR on cluster-a with this init secret in spec:

```
apiVersion: application.isf.ibm.com/v1
kind: Connection
metadata:
```

```
name: <Connection Name Saved in Step 1>
namespace: <Fusion Namespace of cluster-a>
spec:
  remoteCluster:
    apiEndpoint: <cluster-b API Endpoint>
    initSecretName: <Init Secret Name>
    connectionOperatorNamespace: <Fusion Namespace of cluster-b>
```

Disabling the connection

Disable the connection between Hub and Spoke.

About this task

In Hub and Spoke, there is a connection CR in each cluster that represents the connection to the another(remote) cluster. Delete connection CR in the Spoke or Hub. If the network is down, then use either method 1 or method 2 to manually delete the connection CR in another cluster also.

Important: Disabling a spoke connection results in the unassignment of policies from spoke applications, and no new backups are initiated subsequently. Custom Resources (CRs) of applications without backups are deleted, and these applications no longer appear in the user interface.

Method 1: Using command line or command prompt

Procedure

1. In the Spoke, use the following command to get all the connection CR:

```
oc get connection -n <fusion-namespace> -o=custom-
columns='NAME:.metadata.name,ClusterName:.metadata.annotations.connection\.isf\.ibm\.com/cluster-name'
```

Example command:

```
oc get connection -n ibm-spectrum-fusion-ns -o=custom-
columns='NAME:.metadata.name,ClusterName:.metadata.annotations.connection\.isf\.ibm\.com/cluster-name'
```

Example output:

NAME	ClusterName
connection-44ae8529aa	cp4d-vpc-98b7318c91b01bd72490e80cc2328915-0000.us-east.containers.appdomain.cloud

2. Check the **ClusterName** in connection CR, and delete the connection CR which has the same ClusterName with Hub:

```
oc delete connection <connection-name> -n <fusion-namespace>
```

Example command:

```
oc delete connection connection-44ae8529aa -n ibm-spectrum-fusion-ns
```

Method 2: By using OpenShift Container Platform console

Procedure

1. Log in to OpenShift Container Platform console.
2. Go to Administration > CustomResourceDefinitions > connections.application.isf.ibm.com > Instances.
3. Get the connection instance whose cluster name in the annotation is the same as the hub cluster name.
4. Delete this connection instance.

Backup consistencies

- [Achieving data consistency for containers](#)
IBM Fusion backs up application data consistently across all the Persistent Volumes (PVs). It ensures that the recovered data is error-free, reliable, and usable.
- [Achieving data consistency for virtual machine workloads](#)
IBM Fusion backs up the data of the Red Hat® Red Hat OpenShift Virtualization virtual machines consistently.
- [Orchestrate a backup or restore](#)
Use a custom, application-specific recipe to consistently automate and control the required backup or restore sequence of an application.

Achieving data consistency for containers

IBM Fusion backs up application data consistently across all the Persistent Volumes (PVs). It ensures that the recovered data is error-free, reliable, and usable.

The IBM Fusion supports application consistency and crash consistency approaches:

Application consistency

In this approach, application I/O must be paused before a snapshot is taken by using recipes. Though it achieves the highest level of consistency, it comes at the cost of application downtime that can be disruptive. Depending on the application, the pause can be for a long time. To know more about how to create and use recipes, see [Custom backup and restore workflows](#).

Crash consistency

If IBM Storage Scale is used for storage (and not Red Hat® OpenShift® Data Foundation), then you can consider crash consistency. In this approach, application I/O is not paused at all and hence results in zero disruption. It is achieved by what is called a consistency group. All the PVs of an application are placed in a consistency group. During backup, a snapshot is taken for all the PVs in the group at the same instant in time to ensure that all the PVs are consistent with each other. But the disadvantage of this approach is that the application might have some data in memory that is not flushed to the PVs and not included in the snapshot.

In IBM Fusion with IBM Storage Scale, all PVs in a namespace are placed in a consistency group automatically and you do not have to do anything.

Choose the type of data consistency that is appropriate for your application. If the application can restore itself without the data in memory with just what is there in the PVs, then backups are nondisruptive. Otherwise, you must pause I/O and disrupt the application.

Achieving data consistency for virtual machine workloads

IBM Fusion backs up the data of the Red Hat® Red Hat OpenShift Virtualization virtual machines consistently.

During virtual machine backups, consider the following options to provide data consistency within the virtual machine.

- **Crash consistency**- the backup includes data that is written to a disk. It is the equivalent to a virtual machine crash before a backup. To achieve this consistency, take a snapshot of the virtual machine PVCs without any additional orchestrations or hooks within the virtual machine.
- **File system consistency**- the file system freezes, writes, and flushes to the disk before a backup. The backup does not capture any data in the application buffers that is not yet written to the file system. Achieve this data consistency by using tools inside the virtual machine, which interacts with the file system to freeze write before a snapshot (backup) operation.
- **Application consistency**- data in memory buffers is written to disk before the application is backed up. It ensures that all application data is included in the backup. You can achieve this consistency by tools inside the virtual machine, which interacts with an application to take an application-specific action such as locking a database.

File system consistency

The following example diagram shows a virtual machine that runs within a namespace. Each virtual machine has a **virt-launcher** pod that runs the virtual machine instance. The **virt-launcher** pod runs an instance of **libvirt**, which is used to manage the virtual machine process.

When a namespace backup is requested, a virtual machine snapshot operation gets run. The **virt-launcher** pod includes Velero pre-snapshot (**pre.hook.backup**) and post-snapshot (**post.hook.backup**) annotations to run the **kubevirt** tool **virt-freezer**. It communicates to a file system driver inside the Linux® or Microsoft® Windows virtual machine guest to freeze and unfreeze i/o operations around the virtual machine snapshot.

Configure and validate file system consistency for Linux virtual machines:

1. Ensure that **virt-launcher** pod has the appropriate Velero annotations:

```
pre.hook.backup.velero.io/command:
  - ["/usr/bin/virt-freezer", "--freeze", "--name", "rhel9-lovely-louse",
    "--namespace", "test-vm-ns"]

post.hook.backup.velero.io/command:
  - ["/usr/bin/virt-freezer", "--unfreeze", "--name", "rhel9-lovely-louse",
    "--namespace", "test-vm-ns"]
```

2. Ensure that the QEMU guest agent (**qemu-guest-agent**) is installed in the Linux virtual machine. See [OpenShift® documentation](#).
3. Add the default service account security context constraint **kubevirt-controller**:

```
oc adm policy add-scc-to-user
  kubevirt-controller -z default -n <namespace>
```

4. Disable SELinux inside the virtual machine.

Configure and validate file system consistency for Microsoft® Windows virtual machines:

1. Ensure that **virt-launcher** pod has the appropriate Velero annotations:

```
pre.hook.backup.velero.io/command:
  - ["/usr/bin/virt-freezer", "--freeze", "--name", "rhel9-lovely-louse",
    "--namespace", "test-vm-ns"]

post.hook.backup.velero.io/command:
  - ["/usr/bin/virt-freezer", "--unfreeze", "--name", "rhel9-lovely-louse",
    "--namespace", "test-vm-ns"]
```

2. Ensure that the QEMU guest agent (**qemu-ga-x86_64**) is installed in the Microsoft Windows virtual machine and that the “QEMU Guest Agent” network service is running. See [OpenShift documentation](#).

3. Ensure that the **Volume Shadow Copy** service is running in the Microsoft Windows virtual machine.
4. Add the default service account security context **constraint** `"kubevirt-controller"`:

```
oc adm policy
    add-scc-to-user kubevirt-controller -z default -n
    <namespace>
```

Crash consistency

You can achieve crash consistency by taking a snapshot of the virtual machine without engaging the QEMU guest agent to do a file system freeze. It can be done in one of the following two ways:

Note: QEMU guest agent is a helper daemon. It is installed in the guest to exchange information between the host and guest, and to run command in the guest.

1. Remove the Velero pre-snapshot (**pre.hook.backup**) and post-snapshot (**post.hook.backup**) annotations from the **virt-launcher** pod. This change does not persist across instantiations of the **virt-launcher** pod. The Velero annotations are automatically created along with a virtual machine and must be removed for each new instantiation of the **virt-launcher** pod.
2. Ensure that the QEMU guest agents are not installed or running in a virtual machine guest.

Application consistency

If you have a specific application consistency requirement that cannot be met by using the file system consistency, you can create a backup workflow that communicates directly with the application by using the virtual shell tool (**virsh**) instead of the **virt-freezer** tool. The following diagram depicts the scenario:

Consider the following alternative approaches run an application command by using **virsh**:

- Velero annotations to run an application command by using **virsh**:
 - You can directly modify the Velero annotations on the **virt-launcher** pod to run **virsh** (/usr/bin/virsh) instead of **virt-freezer** (/usr/bin/virt-freezer).
 - The modifications to the Velero annotations do not persist across instantiations of the **virt-launcher** pod. The Velero annotations are automatically created along with the virtual machine and must be modified for each new instantiation of the **virt-launcher** pod.
- Using IBM Fusion backup and restore recipes to run an application command by using **virsh**:

Alternatively, you can create an IBM Fusion backup and restore recipe to run an application command by using **virsh**. Even though no differences exist in the outcome as compared to **virsh** by using the Velero annotations, consider the following points:

 - There might be instances wherein you must run more than one command to produce the wanted results. For example, issuing a command that locks a database for write and a second command to monitor or validate the lock. In these cases, an IBM Fusion recipe might be easier to work with.
 - If you decide to use an IBM Fusion recipe, the Velero annotations are also acceptable but it might produce undesirable results. For this reason, consider the removal of Velero annotations from the **virt-launcher** pod.
 - Use the recipe exec hooks to run **virsh** in the wanted sequence.

Orchestrate a backup or restore

Use a custom, application-specific recipe to consistently automate and control the required backup or restore sequence of an application.

For applications that support IBM Fusion Backup & Restore recipes, see [Fusion Backup & Restore Recipes - Supported Applications](#).

Important: In Backup & Restore service, it is recommended to remove all Velero hooks from your applications before you use the recipe. Otherwise, the recipe and Velero hooks can contradict each other without your knowledge. If you want custom actions, then the recommendation is to use the recipe and not Velero hooks.

- [Custom backup and restore workflows](#)
When you protect an application with Backup & Restore service, a default backup and restore workflow is used to protect an application. But while the backup and restore workflow is sufficient for some applications, there are some instances where you need to create a custom workflow for the backup and restore process.
- [Backup and restore of IBM Software Hub to the same or different cluster](#)
IBM Software Hub is integrated with IBM Fusion HCI, which enables you to create online backups and to restore them to the same cluster or to a different cluster.
- [IBM Fusion repository for recipes](#)
The IBM Fusion public GitHub repository provides helpful utilities for IBM Fusion and allows members of the broader IBM Fusion community to share and contribute tools and knowledge.

Custom backup and restore workflows

When you protect an application with Backup & Restore service, a default backup and restore workflow is used to protect an application. But while the backup and restore workflow is sufficient for some applications, there are some instances where you need to create a custom workflow for the backup and restore process.

- The default backup workflow that is used by the Backup & Restore service is as follows:

1. Backup all namespace-scoped resources that are associated with the application and any dependent cluster-scoped resources.
 2. Run any **Velero pre-backup** hooks that are specified through pod annotations in an arbitrary order.
 3. Create snapshots of all PVCs associated with the application.
 4. Run any **Velero post-backup** hooks that are specified through pod annotations in an arbitrary order.
 5. If the backup policy specifies backup to an object storage, then copy the data to object storage.
- The default restore workflow that is used by the Backup & Restore service is as follows:
 1. Restore all PVCs.
 2. Restore all resources in an arbitrary order.
 3. Run **Velero post-restore** hooks that are specified through pod annotations in an arbitrary order.

You need a recipe to create a custom workflow for the backup and restore process. For more information, see [Creating a Recipe](#).

- [Creating a Recipe](#)
You need a recipe to create a custom workflow for the backup and restore process.
- [Assigning a Recipe](#)
You can assign a recipe to your backup and restore operations.
- [Resource Transformation](#)
Use the instructions to create a transform CR.

Creating a Recipe

You need a recipe to create a custom workflow for the backup and restore process.

The recipe custom resource has three basic specification elements:

1. Groups: A group defines a set of resources or PVCs that are processed together within a backup or restore. For example, a group can be a subset of specific resources that are specified with an exclude statement or an include statement.
2. Hooks: A hook can be used to start external scripts before and after snapshots, scale deployments up and down, or wait for certain conditions. For example, pods starting up and so on.
3. Workflows: A workflow defines the sequence of steps for a backup or restore operation, specifically the order in which the groups of resources and PVCs must be processed and any hooks that need to be applied.

For example:

```
apiVersion: spp-data-protection.isf.ibm.com/v1alpha1
kind: Recipe
metadata:
  name: wp-recipe
  namespace: wordpress
spec:
  appType: wordpress
  groups:
    - name: mysql_data
      type: volume
      labelSelector: app=wordpress
    - name: frontend
      labelSelector: tier in (frontend),app=wordpress
    - name: backend
      type: resource
      labelSelector: tier notin (frontend)
  hooks:
    - name: demoexechook
      type: exec
      namespace: ${GROUP.wp-app.namespace}
      nameSelector: wordpress-mysql.*
      ops:
        - name: pre
          command: >
            ["/bin/bash", "-c", "echo 'This is pretest' > /tmp/cfg_map_pre.txt"]
          container: mysql
        - name: post
          command: >
            ["/bin/bash", "-c", "echo 'This is posttest' > /tmp/cfg_map_post.txt"]
          container: mysql
    - name: demoscalehook
      type: scale
      namespace: ${GROUP.wp-app.namespace}
      selectResource: statefulset
      nameSelector: wordpress$
  workflows:
    - name: backup
      sequence:
        - hook: demoscalehook/down
        - group: frontend
        - group: backend
        - hook: demoscalehook/sync
        - hook: demoexechook/pre
        - group: mysql_data
        - hook: demoexechook/post
        - hook: demoscalehook/up
    - name: restore
      sequence:
        - group: mysql_data
        - group: backend
        - group: frontend
```

Specifying a group

Groups that are defined in the recipe refine the scope of the parent group, which is completely defined by the application CR. For more information about specifying groups in the application CR, see [Assigning a Recipe CR with an application CR](#).

The following fields are mandatory for creating a group:

- **name**: name of the group that is specified in the workflow.
- **type**: type of group, either volume or resource.

The following fields are optional for creating a group:

- **LabelSelector**: Enables you to define multiple label selectors, and includes any resource or volume matching to the selectors in the backup and restore. For more on how to specify labels using or **LabelSelectors**, see [Velero Backup API documentation](#).
- **backupRef**: Reference to a group used in a backup workflow. It is helpful for creating a subset of a backup group for a restore workflow.
- **includeResourceTypes**: list of resource type names to include.
 - It applies to resource groups only. For example, deployments.
 - If this field is not specified, then all resource types are included.
- **excludeResourceTypes**: list of resource type names to exclude.
 - It applies to resource groups only. For example, deployments.
 - **excludeResourceTypes** has precedence over **includeResourceTypes**.
- **essential**: determines whether the group represents volumes or resources, which are essential to ensuring that the backup can produce a successful restore (true or false).
 - Groups specified as essential (default) need to be processed successfully. Otherwise, the overall backup operation fails.
 - If the backup operation fails, a rollback is initiated, and the workflow is not processed any further.
 - For non-essential groups, an unsuccessful operation of the group is tolerated; the processing of the workflow continues, and the overall backup is reported as successful while only this operation is marked as failed.
 - The flag is only considered whether the workflow is configured with **fail-on-essential-error**. See the workflow section for details.
- **labelSelector**: select volumes and resources by label. For more information about on specifying labels, see [Labels and Selectors](#).
- **nameSelector**: select volume or associated workloads by object name.
 - This field applies to volume groups only.
 - When combined with **labelSelector** or logic applies.
- **selectResource**: select which resource types the fields **labelSelector** and **nameSelector** must apply when you are selecting PVCs directly or indirectly through the workloads that the PVCs are associated with.
 - This field applies to volume groups only.
- **includeClusterResources**: determines how cluster-scoped resources are processed (true, false, or not specified).
 - **not specified**: include only cluster-scoped resources that are associated with the namespace-scoped resources that are included in the groups.
 - **false**: do not include any cluster-scoped resources.
 - **true**: include all cluster-scoped resources (still considering other clauses and label selectors).
 - This field applies to only resource groups.
- **includedNamespaces**: specify list of namespaces that are included.
 Note: Use **includedNamespaces** and **excludedNamespaces** when you have applications that can stretch multiple namespaces. If the application contains only one namespace, then the namespace that is used in the recipe is obtained from the application (applications.application.isf.ibm.com) resource. In this case, make sure that your recipe is more portable by avoiding including the namespace declaration explicitly.
- **excludedNamespaces**: specify a list of namespaces that are excluded.
 - This parameter has precedence over **includedNamespaces**.
 Note: Use **includedNamespaces** and **excludedNamespaces** when you have applications that can stretch multiple namespaces. If the application contains only one namespace, then the namespace that is used in the recipe is obtained from the application (applications.application.isf.ibm.com) resource. In this case, make sure that your recipe is more portable by avoiding including the namespace declaration explicitly.
- **restoreOverwriteResources**: Specify whether to overwrite resources during restore. By default, the value is false. If this field is set, then you must specify **backupRef**.
- **restoreStatus**: This field helps to preserves the statuses of the resources.
 For example:

```
- name: keycloak-resources
  type: resource
  includedNamespaces:
    - cp4i
  labelSelector: foundationservices.cloudpak.ibm.com=keycloak
  restoreStatus:
    includedResources:
      - integrationkeycloakclients.keycloak.integration.ibm.com
      - integrationkeycloakusers.keycloak.integration.ibm.com
```

In this example, the statuses of the **integrationkeycloakclients.keycloak.integration.ibm.com** and **integrationkeycloakusers.keycloak.integration.ibm.com** are backed up and restored.

Specifying a hook

Hooks can be used to start external scripts before and after snapshots, scale deployments up and down, or wait for certain conditions (such as pods starting up).

The following types of hooks are supported:

1. **exec**: Start arbitrary commands and scripts within target containers.
2. **scale**: scale workload resources up and down.

Note: New resource types are support for both **exec** and **scale** hooks:

- For **exec** hook: **daemonset**
- For **scale** hook: **daemonset**, **job** and **cronjob**.

Both Singular and fully qualified resource types are supported for **exec** and **scale** hooks.

For example:

Singular	Plural
pod	Pods
deployment	apps/v1/deployments

Singular	Plural
satatefulset	apps/v1/satatefulsets
daemonset	apps/v1/daemonsets
job	batch/v1/jobs
cronjob	batch/v1/cronjobs

3. **check**: check for conditions on workload resources (such as **readiness**, **replicaCount** and so on).

Important: You can have multiple logical expressions in check hooks using AND (&&) and OR (||) operators. It is also possible to create complex groupings using parentheses.

For example:

```
{$.spec.replicas} == {$.status.readyReplicas}

{$.spec.replicas} == {$.status.readyReplicas} || {$.metadata.generation} == {$.status.observedGeneration} &&
{$.spec.progressDeadlineSeconds} == {"500"}

({$.spec.replicas} == {$.status.readyReplicas}) || (({$.metadata.generation} == {$.status.observedGeneration}) &&
{$.spec.progressDeadlineSeconds} == {"500"})
```

4. The following are the additional hooks that you can create in the IBM Fusion recipe improve its ability to perform application backup and restore operations.

For more information, see [Additional hooks](#).

- Job hooks
- Label hooks
- Annotation hooks

The following fields are mandatory for creating a hook:

- **name**: the name of the hook that is specified in the workflow.
 - The name must be unique within the Recipe CR.
- **namespace**: the namespace to which the hook applies.
 - Namespace can be either specified directly (not recommended) or indirectly by the effective namespaces of a group `$.GROUP.namespace` or using a variable from the application CR `$.VARIABLE_NAME`. In either case, you need to resolve to a single namespace.
- **type**: the type of hook, either exec, scale, or check.
- **selectResource**: workload resource type to that a hook applies. Specify the resource by using the fully qualified resource name. For example, `orchestrator.aiops.ibm.com/v1alpha1/installations`. The exception to this rule is that you can use the short names for commonly used resources pod, deployment, or `statefulset` (fully qualified resource name not required for these resources).
 - For exec hooks, defaults to pod.
 - This field is only required for hook types of scale or check.

If you add a workload resource type that is specified by using the fully qualified resource name, add additional read permissions for the resource by updating the transaction manager `clusterroles` (`ibm-backup-restore` namespace) on the cluster (IBM Fusion hub or spoke) where the application is deployed.

For example, if you plan to add the custom resource `orchestrator.aiops.ibm.com/v1alpha1/installations`, update the transaction manager `clusterroles` with the following command:

```
oc edit clusterrole transaction-manager-ibm-backup-restore
```

Add the following fields to the `clusterrole`:

```
- verbs:
  - get
  - list
  apiGroups:
  - orchestrator.aiops.ibm.com
  resources:
  - installations
```

Note: If you specify a resource of type pod, deployment, or `statefulset`, you do not have to update the transaction manager `clusterroles`.

- **labelSelector** or **orlabelSelector**: If specified, then the workload resource needs to match this label selector.

Important:

- The **labelSelector** includes **AND** condition for labels and both volume and resources of the recipe groups. It is comma separated (label) string that translates to AND operation later during resource selection.
- The **orlabelSelector** includes **OR** condition for labels and both volume and resources of the recipe groups.
- Either select **labelSelector** or **orlabelSelector**.
- Either **labelSelector** or **nameSelector** is required. If both are specified, or logic applies.
- **nameSelector**: if specified, then the workload resource needs to match this expression.
 - Either **labelSelector** or **nameSelector** is required. If both are specified, or logic applies.

The following fields are optional for creating a hook:

- **singlePodOnly**: flag (true or false) that indicates whether to run a command on a single pod or on all pods that match the selector (when **selectResource=pod**). The hook is run on one of the matching pods only, but, which one is arbitrary.
 - For deployments and statefulsets (**selectResource=deployment** or **statefulset**), the option applies to each replicaset of the selected workload resources individually. For example, when two deployments are selected, the hook is run on one of the pods for each deployments replicaset, which pod is arbitrary.
 - This option applies only to exec hooks.
 - The default value is false.
- **essential**: flag (true or false) that indicates whether the hook is essential for a successful backup. Hooks that are defined as essential (which is the default) need to be processed successfully. Otherwise, the overall backup operation is considered as failed. In this case, a rollback is initiated, and the workflow is not processed any further.
 - For nonessential hooks, an unsuccessful execution is tolerated. The processing of the workflow continues, and the backup is reported as successful.
 - The flag is only considered whether the workflow is configured with **fail-on-essential-error**.
- **onError**: Determines the default behavior (fail or continue) if there is failures when an operation applies to multiple resources such as multiple pods. The option **fail** cancels the operation on the first occurrence of a failure, while **continue** continues processing of the remaining resources. In either case, the overall result of the operation is considered a failure.
- **timeout**: The default timeout (an integer value specified in seconds) applies to custom and built-in operations. If not specified in IBM Fusion 2.8.0, the default is 300 seconds. If not specified in IBM Fusion 2.8.1, the default is 10 days.

Ops specifications (optional)

- **ops**: set of operations that the hook can be started for.
 - Exec hooks provide you to specify any number of custom operations.
 - Other hook types have built-in operations.
- **ops/name**: name of the operation. This field needs to be unique within the hook.
- **ops/container**: the container where the command must be run.
 - The default is to pick an arbitrary container within the pod.
- **ops/command**: the command to run.
 - If you need multiple arguments, specify the command as a JSON array as single string, such as `["/usr/bin/uname", "-a"]`.
Note: If you want to save embracing quotation marks so that you can use it within the command, use `>` to start a block scalar.
 - Variable substitution is applied, both intrinsic group namespace variables (`${GROUP...}`) and variables from application CR can be used.
 - For intrinsic group namespace variables, if there are multiple namespaces it yields a comma-separated list without spaces.
- **ops/OnError**: specify fail or continue to provide the option to overwrite the identical option of the owning hook just for this operation. Defaults to the setting of the owning hook.
- **ops/timeout**: timeout (an integer value specified in seconds) applied to the specified operation. If specified, it overrides the timeout that is specified on the hook level. The hook is considered in error if the command exceeds the timeout.
 - Defaults to timeout set on hook level.
- **ops/inverseOp**: for rollback scenarios, it gives you the ability to rollback an operation by providing the name of another operation that reverses the effect of this operation.
For example, resume a database would be the revert operation for a failure on a suspend a database operation.

Chks specifications (optional)

- **chks**: set of checks that the hook can apply to the target workload. Check that hooks provide an option to specify any number of custom checks based on conditions that are formulated as **JsonPath** like expressions.
- **chks/name**: name of the check. The name must be unique within the hook.
- **chks/condition**: the condition that needs to be true to release the hook. Conditions are specified as **JsonPath** like expressions.
 - The expression is expected to be a Boolean.
- **chks/OnError**: specify fail or continue to overwrite the identical option of the owning hook just for this operation. Defaults to the setting of the owning hook.
- **chks/timeout**: timeout (an integer value specified in seconds) applied to the specified operation. If specified, it overrides the timeout that is specified on the hook level. The hook is considered in error if the command exceeds the timeout.

Examples of specifying conditions as **JsonPath** expressions:

1. Check to see if the number of available replicas matches the specified number of replicas.
`condition: "${spec.replicas} == ${status.readyReplicas}"`
2. Check if a replica is ready.
`condition: "${spec.replicas} ==
{status.readyReplicas}"`

`condition: "${status.containerStatuses[0].ready}
== {True}"`

Specifying a workflow

A workflow defines the sequence of steps for both backup and restore operations. At least one backup workflow (named "backup") and one restore workflow (named "restore") must be specified in the recipe CR. More or alternative workflows can be specified that can be referenced in on-demand backup or restore requests (overriding the default ones "backup" and "restore").

The following fields are mandatory for creating a workflow:

- **name**: name of workflow.
 - The names "backup" and "restore" are reserved and implicitly used by default for backup or restore.
- **sequence**: sequence of steps to be performed.
 - Sequence can refer to a series of groups, resources, and hooks in a specific order. The actions are processed sequentially in the specified order.

The following fields are optional for creating a workflow:

- **sequence/step/group**: refer to a group specified.
- **sequence/step/hook**: refer to a hook and one of its operations.
- **failOn**: determines the behavior if failures when processing groups or hooks. The following is one of these values:
 - **any-error**: If this value is specified, the operation fails and performs defined rollback operations if any step of the workflow fails.
 - **essential-error**: if this value is specified, the operation fails and performs defined rollback operations if any step of the workflow that is defined as essential fails.
 - **full-error**: if this value is specified, the entire workflow is attempted. The workflow is only considered a complete failure if all essential steps fail.
- [Additional hooks](#)
Use this section to understand the additional hooks and guidelines on how to create additional hooks.
- [Dynamic recipe](#)
Use this section to create a dynamic recipe and guidelines on how to create it.

Additional hooks

Use this section to understand the additional hooks and guidelines on how to create additional hooks.

The following newly added additional hooks in the IBM Fusion recipe improve its ability to perform application backup and restore operations.

- [Job hook](#)
- [Label hook](#)
- [Annotation hook](#)

Job hook

A job hook supports to run custom operations during specific events, such as backups, restores or other workflows. It provides a flexible way to run long-running commands, provide dedicated environments for tasks, or perform batch processing and one-time tasks.

Note: Ensure that you use job string format either JSON or YAML.

Sample JobHook: JobSpec as YAML string:

```
hooks:
  - jobs:
    - forceCreate: true
      name: my-job1
      onError: fail
      timeout: 60
      inverseOp: ""
      name: job-hook-test1
      namespace: workload
      onError: fail
      timeout: 60
      type: job
jobs:
  - my-job1: |
    apiVersion: batch/v1
    kind: Job
    metadata:
      name: sample-job
      labels:
        label-key1: value1
      annotations:
        annotation-key1: value2
    spec:
      template:
        spec:
          containers:
            - command:
              - perl
              - --version
              image: perl:5.34.0
              name: perl-version
              restartPolicy: Never
```

Sample JobHook: JobSpec as JSON string:

```
hooks:
  - jobs:
    - forceCreate: true
      name: my-job1
      onError: fail
      timeout: 60
      inverseOp: ""
      name: job-hook-test1
      namespace: workload
      onError: fail
      timeout: 60
      type: job
jobs:
  - my-job1: |
    {
      "apiVersion": "batch/v1",
      "kind": "Job",
      "metadata": {
        "name": "sample-job",
        "labels": {
          "label-key1": "value1"
        },
        "annotations": {
          "annotation-key1": "value2"
        }
      },
      "spec": {
        "template": {
          "spec": {
            "containers": [
              {
                "command": [
                  "perl",
                  "--version"
                ],
                "image": "perl:5.34.0",
                "name": "perl-version"
              }
            ],
            "restartPolicy": "Never"
          }
        }
      }
    }
```

The default fields for creating a job hook:

- Job hook jobs `forceCreate`: defaults to `false`
- Job hook jobs `timeout`: if not present, defaults to job hook timeout

- Job hook jobs **onError**: defaults to **fail**
- Job hook **timeout**: defaults to 864000 seconds
- Job string **name**: defaults to job hook job name
- Job string **namespace**: defaults to job hook namespace
- Job string **apiVersion**: defaults to **batch/v1**
- Job string **kind**: defaults to **Job**
- Job string missing **backoffLimit** value: defaults to 0

Label hook

A label hook modifies a resource by applying a new label or removing an existing one.

Sample LabelHook:

```
hooks:
- name: add-labels
  nameSelector: filebrowser*
  namespace: workload
  onError: fail
  timeout: 60
  ops:
  - labels: for-backup=true,myapp.io/app-name=filebrowser # add labels
    name: filebrowser-resources-add-labels
    onError: fail
    overwrite: true
    timeout: 60
    inverseOp: filebrowser-resources-remove-labels
  - labels: for-backup-,myapp.io/app-name- # remove labels
    name: filebrowser-resources-remove-labels
    onError: fail
    overwrite: true
    timeout: 60
  selectResource: pod
  type: label
```

The default fields for creating a label hook:

- Ops **timeout**: defaults to label hook **timeout**
- Ops **onError**: defaults to **fail**
- Ops **overwrite**: defaults to **false**
- Label hook **timeout**: defaults to 864000 seconds
- Label hook **onError**: defaults to **fail**

Annotation hook

An annotation hook modifies a resource by applying a new annotation or removing an existing one.

Sample AnnotationHook:

```
hooks:
- labelSelector: app=fb
  name: add-annotations
  namespace: workload
  onError: fail
  timeout: 60
  ops:
  - annotations: for-backup=true,myapp.io/app-name=filebrowser-workload # add annotations
    name: filebrowser-resources-add-annotations
    onError: fail
    overwrite: true
    timeout: 60
    inverseOp: filebrowser-resources-remove-annotations
  - annotations: for-backup-,myapp.io/app-name- # remove annotations
    name: filebrowser-resources-remove-annotations
    onError: fail
    overwrite: true
    timeout: 60
  selectResource: pod
  type: annotation
```

The default fields for creating an annotation hook:

- Ops **timeout**: defaults to annotation hook **timeout**
- Ops **onError**: defaults to **fail**
- Ops **overwrite**: defaults to **false**
- Annotation hook **timeout**: defaults to 864000 seconds
- Annotation hook **onError**: defaults to **fail**

Dynamic recipe

Use this section to create a dynamic recipe and guidelines on how to create it.

Dynamic recipe provides a capability to handle the backup and restore of applications with multiple sub-components dynamically. With a dynamic recipe, you can define a parent recipe that automatically discovers child recipes that provide extra workflow information, making your recipes more dynamic.

- [Creating a parent recipe](#)
- [Creating a child recipe](#)
- [Adding new workflows with priorities](#)
- [Adding new workflows without a sequence](#)
- [Pre-recipe inventory workflow \(Optional\)](#)
- [Parallel backup hook execution](#)
- [Parallel restore hook execution](#)

Some of the important considerations you should follow when you create a dynamic recipe:

- Ensure that child recipes correctly reference the parent recipe by using labels.
 - You can define new workflows apart from reserved **backup** and **restore** workflows.
 - If a child recipe uses the same workflow as the parent with a higher priority value, then the child recipe runs first.
 - If a child recipe shares the same workflow and priority value as its parent, then the execution order is random but they run sequentially.
- The priority value can range from **-2,147,483,648** to **1,000,000,000**.

For example:

- A workflow with priority **-2,147,483,648** contain the lowest precedence.
- A workflow with priority **1,000,000,000** contain the highest precedence.

Creating a parent recipe

In addition to the standard **backup** and **restore workflows**, you can define the new **workflows** in the dynamic recipe. These **workflows** enable dynamic behavior during the backup and restore processes.

Note: Parent and child can have same hook or group name but during recipe merge process child hook name is going to be prefixed automatically with child recipe name separated by period.

For example:

```
apiVersion: spp-data-protection.isf.ibm.com/v1alpha1
kind: Recipe
metadata:
  name: parent-recipe
  namespace: ibm-spectrum-fusion-ns
spec:
  ...
  hooks:
  ...
  workflows:
  - name: pre-hook
    priority: 4
    sequence:
    - hook: mysql-pod-exec/flush-tables-with-read-lock
  - name: post-hook
    priority: 4
    sequence:
    - hook: mysql-deployment-check/replicasReady
  - name: backup
    sequence:
    - group: mysql-resources
    - workflow: pre-hook
    - group: mysql-volumes
  - name: restore
    sequence:
    - group: mysql-volumes
    - group: mysql-resources
    - workflow: post-hook
```

Ensure that the names can be any valid string or similar to other workflow names like **backup** and **restore**. In this scenario, pre-hook is used in the backup workflow and post-hook is used in the **restore** workflow.

If a child recipe defines the same workflow, then it dynamically retrieves and runs.

Creating a child recipe

After a recipe linked to a another recipe through these labels **dp.isf.ibm.com/parent-recipe** and **dp.isf.ibm.com/parent-recipe-namespace**, then parent-child relationship gets created.

For example:

```
apiVersion: spp-data-protection.isf.ibm.com/v1alpha1
kind: Recipe
metadata:
  labels:
    dp.isf.ibm.com/parent-recipe: parent-recipe
    dp.isf.ibm.com/parent-recipe-namespace: ibm-spectrum-fusion-ns
  name: child-1
  namespace: ibm-spectrum-fusion-ns
spec:
  appType: mysql-child-1
  groups:
  ...
  hooks:
  ...
  workflows:
  - name: pre-hook
    priority: 5000
    sequence:
    - group: cm-child-1
    - hook: mysql-pod-exec-child-1/create-temp-file-pre
```

```
- name: post-hook
  priority: 5000
  sequence:
  - hook: mysql-pod-exec-child-1/create-temp-file-post
  - group: cm-child-1
```

Adding new workflows with priorities

A child recipe can define workflows that are present in the parent recipe.

Adding a new workflow

For example, add a new workflow named `demo-workflow` with priority 1 in the parent recipe.

```
workflows:
- name: demo-workflow
  priority: 1
  sequence:
  - hook: demo-hook/echo-test
```

Now, you can define the same workflow in the child recipe. The execution behavior depends on the assigned priority:

- High priority - Runs before the parent workflow
- Low priority - Runs after the parent workflow
- Same priority - Run order is arbitrary (either the parent or child might run first).

Child workflow with higher priority

For example, the child recipe defines a `demo-workflow` with priority 5, then it runs before the parent workflow.

```
workflows:
- name: demo-workflow
  priority: 5
  sequence:
  - hook: demo-child-hook/echo-child-test
```

Adding new workflows without a sequence

A parent recipe can define workflows that have no sequence. This allows child recipes to use these workflows and define their own sequences.

Defining a workflow in the parent recipe

For example, add a new workflow named `demo-workflow` in the parent recipe with no sequence and priority 0:

```
workflows:
- name: demo-workflow
  priority: 0
  sequence: []
```

Defining a workflow in the child recipe

Now, the child recipe can define the same workflow and specify its own sequence:

```
workflows:
- name: demo-workflow
  priority: 5
  sequence:
  - hook: demo-child-hook/echo-child-test1
  - hook: demo-child-hook/echo-child-test2
```

Important:

- If the parent has only one child and parent workflow sequence is empty, then priority does not matter, and the child workflow executes as defined.
- If the parent has multiple children defining the same workflow, execution occurs according to the assigned priorities.

Pre-recipe inventory workflow (Optional)

This is an optional workflow for the parent recipe, run before the backup workflow.

- It allows an application to define and run its own custom exec hook in the parent recipe before any child recipe is merged into parent.
- Upon successful execution, IBM Fusion continues processing and takes the child recipe inventory for dynamic recipe execution.
- The main objective is to construct child recipes that reflect the current state of the application in the cluster.

For example:

```
apiVersion: spp-data-protection.isf.ibm.com/v1alpha1
kind: Recipe
metadata:
  name: parent-recipe
  namespace: ibm-spectrum-fusion-ns
spec:
  appType: mysql-ns
  groups:
  ...
  hooks:
  - name: my-child-recipes
    type: exec
    ...
  - name: "manage"
  ...
  workflows:
  - name: prerecipeinventory
    sequence:
```

```
- hook: my-child-recipes/manage
...
```

Parallel backup hook execution

Running sequences in parallel within dynamic recipe workflows can significantly speed up the overall process. It is useful for workflows that involve tasks that depend heavily on I/O operations. If any one sequence fails, then the entire job aborts, but it waits for any currently running sequences in other parallel blocks to finish first. Note: Undo operations are still performed sequentially, but in the reverse order of workflow execution.

Parallel hook execution can be requested in a IBM Fusion recipe by assigning the same **priority** to the workflow step in each recipe.

Key considerations

- Parallel execution is available for both backup and restore workflows.
- Parallel execution only can be used with dynamic recipes (when there is a parent recipe and at least one child recipe).
- If there are multiple recipes, consider running them simultaneously to increase efficiency.
 - Workflows with same priority run in parallel only if all sequences are hooks.
 - Workflows with same priority run sequentially if they have at least one **group** sequence within the workflow.
 - Workflows with different priorities run sequentially.
 - Workflows with mixed priorities: For example, there is a shared workflow that is defined in three recipes, two have the same priority and one is a different priority. In this particular case, the workflows with identical priorities run in parallel and the recipe with the different priority runs sequentially, before or after depending on the relative priorities.
- Number of parallel workers are controlled by flag **hook-parallel-workers** in **guardian-configmap** (ibm-backup-restore namespace). The default value is 1 and can be set to higher values with maximum of 35. Minimum value 0 have special meaning - internally translates to number of usable CPUs.

Parallel restore hook execution

IBM Fusion's parallel restore mechanism follows the same approach as its backup process. During restoration, the system dynamically merges saved parent-child recipes at runtime to build the final restore workflow. If a child recipe is not eligible for restoration to an alternate namespace, the system skips it during the merge. The status field in the Fusion Restore Custom Resource (CR) records details of any skipped recipes.

To perform a parallel restore with modified recovery steps (distinct from the saved parent recipes), create a custom **Restore** CR. Specify the new recipe **name** and **namespace** in the **spec** field.

Key considerations

Parallel restore adheres to all the key considerations outlined for backup. Additionally, it possesses specific capabilities that further contribute to successful application recovery.

- The system excludes child recipes that are labeled with **dp.isf.ibm.com/alternate-namespace-restore=false** when you target alternate namespaces.
- To introduce slight variations in restore steps, you can specify a new recipe **name** and **namespace** in the custom **Restore** CR. This existing capability is valuable especially during parallel restores.

Sample custom **Restore** CR

```
apiVersion: data-protection.isf.ibm.com/v1alpha1
kind: Restore
metadata:
  name: <custom-restore-name>
  namespace: <custom-restore-namespace>
spec:
  recipe:
    name: <new-parent-recipe-name>
    namespace: <new-parent-recipe-namespace>
```

Parallel backup and restore can significantly optimize data protection times when processing Fusion recipes, which have multiple activities that can be executed in parallel.

Assigning a Recipe

You can assign a recipe to your backup and restore operations.

1. Assign a recipe with a backup policy assignment CR for backup and restore operations as follows:

Assign a recipe for backup operations

You can assign a recipe to an application or applications by specify the recipe in the PolicyAssignment CR to assign it to one or more applications. You can specify a single recipe in a PolicyAssignment CR.

To assign a recipe to an application, you can fix the PolicyAssignment CR by using the following example:

```
oc -n ibm-spectrum-fusion-ns patch policyassignment POLICY-ASSIGNMENT-NAME --type merge -p '{"spec":{"recipe":{"name":"RECIPE_NAME", "namespace":"RECIPE_NAMESPACE", "apiVersion":"spp-data-protection.isf.ibm.com/v1alpha1"}}}'
```

- **POLICY_ASSIGNMENT-NAME** is the name as specified in the PolicyAssignment CR.
- **RECIPE_NAME** is the name of the recipe as specified in the Recipe CR.
- **RECIPE_NAMESPACE** is the namespace where the Recipe CR is located.

Assign a recipe for restore operations when restoring to the original namespace

During a restore operation, a recipe must be started with the following precedence:

- If there is a Recipe CR with the same name and in the same namespace as the Recipe CR that was used during the backup operation, it must take precedence. It can be helpful in situations when you want to specify a different workflow or different hooks during the restore.
- If there is no Recipe CR with the same name and in the same namespace, the recipe that was used during the backup operation must be run. This information is stored as part of the backup metadata.

Assign a recipe for restore operations when restoring to a different namespace

If you are restoring to an alternative namespace, any namespaces that are specified in a hook cannot be run correctly as they refer to the original namespace.

If you want the hooks to run in the alternative namespace, change the Recipe CR as mentioned in [Assign a recipe for restore operations when restoring to the original namespace](#). So that any hook namespaces are referring to the alternative namespace.

2. Assign a recipe CR with an application CR as follows:

Reserved variables in application CR

The Backup & Restore service initializes the following reserved variables. Do not redefine these variables in your application CR, except for

ISF_ALLOWED_UNRESOLVED_VARS.

- **ISF_BACKUP_UID:** the UUID of the backup job.
- **ISF_NAMESPACE_MAPPINGS:** namespace mappings in a comma-separated string format, accessible in exec hook commands.

```
"<source_namespace-1>:<target_namespace-1>,<source_namespace-2>:<target_namespace-2>,..."
```

- **ISF_NOT_EQUAL_NAMESPACE_MAPPINGS:** an empty string when restoring to the same namespace, or the value of **ISF_NAMESPACE_MAPPINGS** when restoring to different namespaces.
- **SERVICE_NAMESPACE:** a predefined value, "common-service", used by cp4d.
- **`\${APP}.\${SERVICE\_NAMESPACE}.nameEmptyIfNotMapped`:** checks if **SERVICE_NAMESPACE** exists, used by cp4d.
- **ISF_ALLOWED_UNRESOLVED_VARS:** This is Application variable used to skip verification for not found variables. Possible values are: "true" or "false", default is "false".

ISF_ALLOWED_UNRESOLVED_VARS is an application variable that skips verification for unresolved variables when set to "true". Default is "false". Set it to "true" if your application recipe uses shell variables and array syntax instead of substituting variables from the recipe.

```
spec:
  variables:
    - name: ISF_ALLOWED_UNRESOLVED_VARS
      value: 'true'
```

Working with application CRs for single namespace

For applications that only has a single namespace, there are no changes that are required in the application CR to support a recipe. The recipe is associated with the application, in this case with the PolyAssignment CR, as defined in the [Assign a recipe for backup operations](#).

Working with application CRs for applications that span multiple namespaces

If you have an application that spans multiple namespaces and want to use a recipe for the application, you need to specify all of the namespaces included in the application that is in the application CR.

- **Using variable substitutions:**

- Variables can be used to permit a single recipe to be used in multiple, similar applications. Variables are defined in the application CR, and any number of variables can be defined.

```
- variables:
  - name: <variable name>
    value: <variable value>
```

- The variables that can be referenced within the Recipe CR.

```
${<variable name>}
```

Valid characters for variables are: a-zA-Z0-9_

- Each group exposes to the following variables automatically.

- Effective namespaces

These can be used within recipe by these patterns.

```
${GROUP.<groupname>.namespaces} - effective namespaces of group
${GROUP.<groupname>.namespace} - effective namespace of group - single namespace enforced, (runtime)
validation error otherwise
```

- Variables can solely be used for the following fields:

- Namespace field of hooks.
- Within commands of exec hooks.

Tip: When creating a Recipe CR, place the Recipe CR in the **ibm-spectrum-fusion-ns** (or another common namespace). During a restore operation, you might need to change the recipe and don't want the recipe CR to be in the application namespace, as this namespace might not be available during restore.

For example,

```
apiVersion: application.isf.ibm.com/v1alpha1
kind: Application
metadata:
  name: wp-app1
  namespace: ibm-spectrum-fusion-ns
spec:
  appType: wordpress
  includedNamespaces:
    - wordpress
  variables:
    - name: WORDPRESS_NAMESPACE
      value: wordpress
---
```

```
apiVersion: spp-data-protection.isf.ibm.com/v1alpha1
kind: Recipe
metadata:
  name: wp-recipe
  namespace: wordpress
spec:
  appType: wordpress
  groups:
    - name: mysql_data
```

```

    type: volume
    labelSelector: app=wordpress
  - name: frontend
    type: resource
    labelSelector: tier in (frontend),app=wordpress
  - name: backend
    type: resource
    labelSelector: tier notin (frontend)
hooks:
- name: demoexechook
  type: exec
  namespace: ${WORDPRESS_NAMESPACE}
  nameSelector: wordpress-mysql.*
  ops:
  - name: pre
    command: >
      ["/bin/bash", "-c", "echo 'This is pretest' > /tmp/cfg_map_pre.txt"]
    container: mysql
  - name: post
    command: >
      ["/bin/bash", "-c", "echo 'This is posttest' > /tmp/cfg_map_post.txt"]
    container: mysql
- name: demoscalehook
  type: scale
  namespace: ${WORDPRESS_NAMESPACE}
  selectResource: statefulset
  nameSelector: wordpress$
workflows:
- name: backup
  sequence:
  - hook: demoscalehook/down
  - group: frontend
  - group: backend
  - hook: demoexechook/pre
  - group: mysql_data
  - hook: demoexechook/post
  - hook: demoscalehook/up
- name: restore
  sequence:
  - group: mysql_data
  - group: backend
  - group: frontend

```

Resource Transformation

Use the instructions to create a transform CR.

Before you begin

Ensure that the Backup & Restore service is installed. For steps to install Backup & Restore, [Install Backup & Restore](#).

About this task

When restoring data to a different namespace or cluster, some resource definitions might need to be updated. For example, hardcoded storage classes or domain names that do not match the new environment.

While IBM Fusion Backup & Restore supports you to restore applications to alternative namespaces or storage classes. However, sometimes you need to change a resource before restoring it. This process is called a transformation.

Transformations are in-memory modifications that are applied to resources during the restore process, ensuring that they are correctly configured for the target environment before being written to disk or applied to the cluster.

Procedure

1. Define a transform CR that contains all the necessary transformations. The transform CR must be referenced in the restore CR, which ensures that the transformations get applied.
 - Create transform CR
 - Create restore CR with a transform CR
 - Apply the restore CR
2. A transform CR can consist of multiple transform rules. Each transform must have the following three sections:

Name

The name of each transform rule must be unique.

Patch type

There are four types of patches that can be defined:

- **Json patch**
- **Merge patch**
- **Strategic patch**
- **String patch**

Subject

The subject specifies the resources on which the patch gets to apply.

- **groupResource** - Fully qualified resource name, such as
 - Core API group (v1) - pods, services, configmaps, secrets, persistentvolumeclaims, and so on.
 - Named API groups (apps/v1) - deployments.apps, statefulsets.apps, and so on.
 - Batch (batch/v1): jobs.batch, cronjobs.batch
 - networking.k8s.io/v1 - ingress.networking.k8s.io, networkpolicies.networking.k8s.io
- **resourceNameRegex** - matching resource name
- **labelSelector** - matching resource label
- **namespaces** - the namespace where the resource is available

3. The four kinds of patches that can be applied in transform CR.

JSON patch

A JSON patch supports operations like test, add, remove, and replace on specific paths. There are three fields need to define in the JSON patch:

- **op** - operation name
 - **test** - to test if specific value is present on the given path
 - **add** - to add the value on the given path
 - **remove** - to remove the value on the given path
 - **replace** - to replace the value on the given path
 - **copy** - to copy the value from path to the path
 - **move** - to move the value from path to the path
- **path** - on which the operation applies
- **value** - value on which these operations acted upon
- **from** - from which the value is copied

Note: For PVC, **copy** and **move** operation are supported for labels and annotations

For example, transform CR to transform multiple storage classes with JSON patch:

```
apiVersion: data-protection.isf.ibm.com/v1alpha1
kind: Transform
metadata:
  name: transform-copy-move
  namespace: ibm-spectrum-fusion-ns
spec:
  transforms:
    - name: configmap-move-labels-to-annotations
      json:
        - op: move
          from: /metadata/labels/a
          path: /metadata/annotations/a
          subject:
            groupResource: configmaps
            labelSelector: c=d
    - name: configmap-move-annotations-to-labels
      json:
        - op: move
          from: /metadata/annotations/m
          path: /metadata/labels/m
          subject:
            groupResource: configmaps
            labelSelector: c=d
    - name: pvc-move-labels-to-annotations
      json:
        - op: move
          from: /metadata/labels/a
          path: /metadata/annotations/a
          subject:
            groupResource: persistentvolumeclaims
            labelSelector: c=d
    - name: pvc-move-annotations-to-labels
      json:
        - op: move
          from: /metadata/annotations/m
          path: /metadata/labels/m
          subject:
            groupResource: persistentvolumeclaims
            labelSelector: c=d
    - name: pvc-copy-labels-to-annotations
      json:
        - op: copy
          from: /metadata/labels/i
          path: /metadata/annotations/i
          subject:
            groupResource: persistentvolumeclaims
            labelSelector: i=j
    - name: pvc-copy-annotations-to-labels
      json:
        - op: copy
          from: /metadata/annotations/p
          path: /metadata/labels/p
          subject:
            groupResource: persistentvolumeclaims
            labelSelector: i=j
    - name: sts-copy-image
      json:
        - op: copy
          from: /spec/template/spec/containers/0/image
          path: /spec/template/spec/initContainers/0/image
          subject:
            groupResource: statefulsets.apps
            labelSelector: a=b
    - name: sts-copy-memory-request-to-limit
      json:
```

```
- op: copy
  from: /spec/template/spec/containers/0/resources/requests/cpu
  path: /spec/template/spec/containers/0/resources/limits/cpu
  subject:
    groupResource: statefulsets.apps
    labelSelector: a=b
```

Note: `_${SOURCE_STORAGE_CLASS_FS}`, `_${TARGET_STORAGE_CLASS_FS}`, `_${SOURCE_STORAGE_CLASS_RBD}`, `_${TARGET_STORAGE_CLASS_RBD}`, these are the placeholders here which can be pass dynamically using `transformMapping` in restore CR.

Merge patch

Merges provided fields into the target resource using a simple JSON structure. A specific field needs to be defined.

patchData - provide a JSON structure

For example, transform CR to add labels to `statefulsets` using merge patch.

```
apiVersion: data-protection.isf.ibm.com/v1alpha1
kind: Transform
metadata:
  name: transform-using-merge-patch
  namespace: ibm-spectrum-fusion-ns
  - name: statefulsets-with-merge-patch-labels
    mergePatches:
      - patchData: |
          {
            "metadata": {
              "labels": {
                "modify-by": "${MODIFY_BY}"
              }
            }
          }
    subject:
      groupResource: statefulsets.apps
      labelSelector: 'a=b'
```

Note: `_${MODIFY_BY}` is a placeholder here that can be pass dynamically using `transformMapping` in restore CR.

Strategic patch

Merges fields intelligently based on resource schema, preserving arrays like containers by name. A specific field needs to be defined.

patchData - provide a JSON structure

For example, transform CR to update image version and add a `env` variable using strategic patch.

```
apiVersion: data-protection.isf.ibm.com/v1alpha1
kind: Transform
metadata:
  name: transform-using-strategic-patch
  namespace: ibm-spectrum-fusion-ns
  - name: deployment-with-strategic-patch
    strategicPatches:
      - patchData: |
          {
            "spec": {
              "template": {
                "spec": {
                  "containers": [
                    {
                      "name": "nginx-main",
                      "image": "nginx:1.25.6",
                      "imagePullPolicy": "Always",
                      "env": [
                        {
                          "name": "test",
                          "value": "${MODIFY_BY}"
                        }
                      ],
                    }
                  ]
                }
              }
            }
          }
    subject:
      groupResource: deployments.apps
      resourceNameRegex: nginx-multi-container
```

String patch

Replaces specific strings in a target resource using key-value pairs. Two specific fields needs to be defined.

- **key** - fully qualified path where string need to be replaced
- **replaceStrings**
 - **old** - old string, which needs to be replaced
 - **new** - new string, which needs to be replaced on the place of old string.

For example, transform CR to transform data in the configmap using string patch.

```
apiVersion: data-protection.isf.ibm.com/v1alpha1
kind: Transform
metadata:
  name: transform-using-string-patch
  namespace: ibm-spectrum-fusion-ns
spec:
  transforms:
```

```
- name: configmap-with-string-patch
stringPatch:
- key: data/instance.json
  replaceStrings:
    - new: '\\"persistence.cachingpv.storageClass\\": \\"${TARGET_STORAGE_CLASS_FS}\\"'
      old: '\\"persistence.cachingpv.storageClass\\": \\"transform\\"'
subject:
  groupResource: configmaps
  resourceNameRegex: dv-instance-config
```

4. After the transform CR is defined, then create a restore CR with its reference.
For example:

```
apiVersion: data-protection.isf.ibm.com/v1alpha1
kind: Restore
metadata:
  name: restore-with-transform
  namespace: ibm-spectrum-fusion-ns
spec:
  backup: <backup-name>
  targetCluster: <target-cluster-name>
  transform: transform-storage-classes
  transformMapping:
    INGRESS_HOST: transformed.com
    SOURCE_STORAGE_CLASS_FS: ocs-storagecluster-cephfs
    TARGET_STORAGE_CLASS_FS: ocs-storagecluster-cephfs-1
    SOURCE_STORAGE_CLASS_RBD: ocs-storagecluster-ceph-rbd
    TARGET_STORAGE_CLASS_RBD: ocs-storagecluster-ceph-rbd-1
    MODIFY_BY: fusion-transform
```

Define the two new fields `transform` and `transformMapping` in the restore CR.

- `transform` - name of the transform CR.
- `transformMapping` - If required, pass the variable that can be substituted in the transform CR.

5. Apply the restore CR.

Note:

- Transform CR should be present on the target cluster where restoring the application.
- For `persistentvolumeclaims`, only JSON patch is supported, and all the 4 patches are supported for resources.
- The test operation in JSON patch is used in conjunction with other operations (**add**, **replace**, **remove**). If the test operation **fails**, the entire patch is aborted and none of the subsequent operations are run in that transform rule.
- Strategic Merge patch operates based on the name field within arrays (such as containers):
 - If the name field is missing, then the merge is skipped.
 - If a matching name field is present, then the existing entry is merged.
 - If a matching name field is not present, then a new entry is added to the array.
 - If a label key contains a slash (/), replace it with a (~) for it to be valid.
- For more examples of using Transform CR, see [Sample Transform CR](#).

Transformation with custom recipe:

Note: With default recipe, this setting is not applicable.

To use the transformation with custom recipe, you need to add the following field in the group of the recipe

```
"disableTransform: false"
```

For example:

```
apiVersion: spp-data-protection.isf.ibm.com/v1alpha1
kind: Recipe
metadata:
  name: db2-prod-backup-recipe
  namespace: ibm-spectrum-fusion-ns
spec:
  appType: db2
  groups:
    - includedNamespaces:
      - db2-prod
      name: db2-volumes
      type: volume
    - includedNamespaces:
      - db2-prod
      includedResourceTypes:
      - configmaps
      - secrets
      - services
      - serviceaccounts
      name: db2-resources
      type: resource
    - includedNamespaces:
      - db2-prod
      includedResourceTypes:
      - statefulsets.apps
      name: db2-statefulsets
      type: resource
  ...
```

To enable the transformation, include `disableTransform: false` for this group `db2-statefulsets`.

```
- includedNamespaces:
  - db2-prod
  includedResourceTypes:
  - statefulsets.apps
  name: db2-statefulsets
  type: resource
  disableTransform: false
```

Backup and restore of IBM Software Hub to the same or different cluster

IBM Software Hub is integrated with IBM Fusion HCI, which enables you to create online backups and to restore them to the same cluster or to a different cluster.

Warning: If you are restoring Software Hub, watsonx Orchestrate, or watsonx.ai that were installed through the IBM Fusion UI on IBM Fusion HCI 2.14 or earlier, additional steps are required before the restore to prevent the restore from failing. See the known limitation: [Fusion UI may not reflect the installed state of restored watsonx services](#).

To create IBM Software Hub backups with IBM Fusion or IBM Fusion HCI, see [Creating and scheduling online backups of IBM Software Hub with IBM Fusion](#).

To restore IBM Software Hub online backup and restore to the same cluster with IBM Fusion or IBM Fusion HCI, see [IBM Software Hub online backup and restore to the same cluster with IBM Fusion](#).

To restore IBM Software Hub backups to a different cluster with IBM Fusion or IBM Fusion HCI, see [IBM Software Hub online backup and restore to a different cluster with IBM Fusion](#).

Remember: IBM Cloud Paks instance backups cannot be created when continuous backup is enabled on the MongoDB service.

Note: You can restore backup data to a different StorageClass provisioner on an alternate cluster, for example, restore data that was originally backed-up from a CephFS provisioned StorageClass to a Scale provisioned StorageClass.

The Restore CR includes an optional `spec` field, `targetStorageClass` where you can specify a specific storage class for the restore. It is only available through manually created Restore CRs from the command line.

- If the `targetStorageClass` is not provided, the same storage class as the backup is attempted for the restore.
- If the `targetStorageClass` field is not provided and the same storage class as the backup is not available, the default storage class of the system is used.

The `targetStorageClass` is not supported for IBM Software Hub.

IBM Fusion repository for recipes

The IBM Fusion public GitHub repository provides helpful utilities for IBM Fusion and allows members of the broader IBM Fusion community to share and contribute tools and knowledge.

This repository hosts the following categories of artifacts that can be used with IBM Fusion HCI:

- Multiple application backup and restore recipes using IBM Fusion. It includes recipes for applications such as IBM Db2, PostgreSQL, Postgres EnterpriseDB, MongoDB, Redis, and others. Check the [Recipes repository](#) for the complete inventory of applications.
- Maximo Core and Manage application recipes. For the IBM Fusion GitHub repository, see [Maximo Fusion recipes](#).
- Helpful utilities and scripts to explore backup and restore
For example, you can run [getRecipeWorkflow.sh](#) scripts from the command line to view recipe workflow logs and run script [getResources.sh](#) to get complete list of resources backed up or restored.

If you like to develop recipes for other popular applications, read the following blog series on creating backup and restore recipes:

1. [How IBM Fusion Simplifies Backup and Recovery of Complex OpenShift® Applications - Part 1 "So Why is this Complex?"](#)
2. [How IBM Fusion Simplifies Backup and Recovery of Complex OpenShift Applications - Part 2 "Orchestrations and Recipes"](#)
3. [How IBM Fusion Simplifies Backup and Recovery of Complex OpenShift Applications - Part 3 "A Deeper Dive into Recipes"](#)

Also, for more recipes, see [Orchestrate a backup or restore](#).

Performance and scaling

Backup and restore performance depends on agent concurrency, data mover pod counts, and storage throughput. Tuning these parameters helps IBM Fusion meet capacity and latency requirements for large workloads.

- [Backup & restore resource self-monitoring](#)
The imposed load on the Backup & restore service has a direct correlation to the number of concurrent Backup & restore jobs in progress. While the service can catch up from periodic spikes in activity, a sustained elevated level of activity may cause any one Backup & restore microservice to fall behind in job processing, which may result in job failures.
- [Backup & restore hub performance and scaling](#)
Use this topic to understand the number of spokes you can scale up to and the number of spoke clusters that can be connected to a single hub. It outlines the capacities and the scalability considerations to ensure efficient backup and restore operations.
- [Backup & restore configuration parameters](#)
Configuration parameters allow customization of IBM Fusion Backup & restore settings.

Backup & restore resource self-monitoring

The imposed load on the Backup & restore service has a direct correlation to the number of concurrent Backup & restore jobs in progress. While the service can catch up from periodic spikes in activity, a sustained elevated level of activity may cause any one Backup & restore microservice to fall behind in job processing, which may result in job failures.

The **Backup and Restore hub microservices**—such as ``backup-service``, ``job-manager``, ``application-service``, ``backup-policy`` and ``backup-location``—now include built-in resource monitoring for Memory and CPU consumption. This monitoring capability helps identify potential resource shortages by providing a Warning alert through IBM Fusion events. This alert notifies the user of a sustained level of activity the current microservice cannot sustain and recommends scaling out the microservice with another replica to ensure successful Backup & restore job operations.

Resource Usage Monitoring and Thresholds

When Memory or CPU usage exceeds a defined threshold (default is 85%) for a specific duration (default is 5 minutes), a IBM Fusion event with a warning severity is triggered to notify about the increased resource usage. For instance, if the Memory or CPU usage for the `backup-service` pod crosses the threshold, the following event gets generated:

Pod backup-service-xxx in namespace ibm-backup-restore exceeded 85% of memory/CPU limit for 5 minutes. Consider scaling the deployment with an additional replica.

These alerts are marked as fixed after the Memory or CPU consumption falls behind the threshold limit.

To scale out with another replica, use the following command to get the existing replica count for the deployment from the 'AVAILABLE' column:

```
oc get deployment -n <backup-restore-namespace> <deployment-name>
```

Then perform the following command with an increase of 1 to the existing replica count:

```
oc scale deployment -n <backup-restore-namespace> <deployment-name> --replicas=<new-replica-count>
```

Configurable parameters

You can customize the threshold levels and monitoring duration by adding or modifying parameters in the `guardian-configmap`. Here are the parameters available for configuration:

memoryThresholdPercentage

Sets the memory usage threshold as a percentage. Default is “85” for 85%.

cpuThresholdPercentage

Sets the CPU usage threshold as a percentage. Default is "85" for 85%.

monitorDurationInSeconds

Defines the duration (in seconds) that usage must exceed the threshold to trigger an alert. Default is 300 seconds (5 minutes).

Example configuration:

```
memoryThresholdPercentage: '85'
cpuThresholdPercentage: '85'
monitorDurationInSeconds: '300'
```

Backup & restore hub performance and scaling

Use this topic to understand the number of spokes you can scale up to and the number of spoke clusters that can be connected to a single hub. It outlines the capacities and the scalability considerations to ensure efficient backup and restore operations.

The Backup & restore hub service is efficiently designed to handle large-scale backup and restore concurrent jobs across clusters. With proven scalability and performance. The system is tested successfully to handle up to 1000 concurrent jobs. It serves as a reference point and not a limitation; the hub can scale further with appropriate resource allocation.

Sizing blueprints for varying workloads

The following table provides the recommended configurations for each required service when handling different numbers of concurrent jobs. As the number of concurrent jobs increases, you can scale out (increase the replicas) or scale up (increase the resource limits) for the required services as outlined:

Note:

- Services not listed in the blueprint table do not require scaling. These services can handle the load without modification because they do not have scaling requirements for up to 1000 concurrent jobs.
- Some services, such as `mongodb-v2` or `operator-control-manager` pods in the `ibm-backup-restore` namespace, cannot be scaled out by increasing replicas. For these services, increase the CPU and memory resources to ensure optimal performance as the number of concurrent jobs increases.
- The `guardian-bridge` service automatically scales to handle the additional load and provides backward compatibility when connected spokes are at a version earlier than IBM Fusion 2.13.

Table 1. Sizing blueprints

Cluster servers	Mongodb-v2				Kafka broker pool	Backup service	Backup policy service	Application service	Job manager service
	Replicas	CPU	Memory	Ephemeral	Replicas	Replicas	Replicas	Replicas	Replicas

												r)
1 0 0	1 0 0	3	1	1 GiB	0.5 GiB	3	1	1	1	1	1	4
2 0 0	2 0 0	3	2	1 GiB	0.5 GiB	3	1	1	1	1	1	4
3 0 0	3 0 0	3	3	1.5 GiB	1 GiB	6	1	1	1	1	1	5
4 0 0	4 0 0	3	3.5	1.5 GiB	1 GiB	6	1	1	1	1	1	5
5 0 0	5 0 0	3	4	2 GiB	1.5 GiB	9	1	1	1	1	1	6
6 0 0	6 0 0	3	4.5	2 GiB	1.5 GiB	9	1	1	1	1	1	6
7 0 0	7 0 0	3	5	2 GiB	1.5 GiB	12	1	1	1	1	1	7
8 0 0	8 0 0	3	6	2.5 GiB	1.75 GiB	12	2	1	1	2	2	8
9 0 0	9 0 0	3	7	2.5 GiB	1.75 GiB	15	2	2	2	2	2	9
1 0 0 0 0	1 0 0 0 0	3	8	3 GiB	2 GiB	15	3	2	2	2	2	1 (

Scaling Services

Use the following commands to scale out the desired replicas or scale up resource limits for the required services:

mongodb-v2 - scale up resource limits

The `mongodb-v2 StatefulSet` cannot be scaled out. Increase CPU, memory, and ephemeral storage limits as the workload grows:

```
oc set resources sts mongodb-v2 --limits=cpu=<desired-cpu>,memory=<desired-memory>,ephemeral-storage=<desired-ephemeral> -n <backup-restore-namespace>
```

For example:

```
oc set resources sts mongodb-v2 --limits=cpu=8,memory=3Gi,ephemeral-storage=2Gi --containers=mongodb -n ibm-backup-restore
```

Kafka broker-pool - scale out replicas

The Kafka broker-pool is managed as a `KafkaNodePool` resource. Scale its replicas using:

```
oc patch kafkanodepool broker-pool -n <backup-restore-namespace> --type='json' -p='[{"op": "replace", "path": "/spec/replicas", "value": <desired-replicas>}]'
```

For example:

```
oc patch kafkanodepool broker-pool -n ibm-backup-restore --type='json' -p='[{"op": "replace", "path": "/spec/replicas", "value": 15}]'
```

backup-service - scale out replicas

```
oc scale deployment backup-service --replicas=<desired-replicas> -n <backup-restore-namespace>
```

For example with 100 clusters/1000 jobs (3 replicas):

```
oc scale deployment backup-service --replicas=3 -n ibm-backup-restore
```

backuppolicy-deployment - scale out replicas

```
oc scale deployment backuppolicy-deployment --replicas=<desired-replicas> -n <backup-restore-namespace>
```

For example with 90-100 clusters (2 replicas):

```
oc scale deployment backuppolicy-deployment --replicas=2 -n ibm-backup-restore
```

applicationsvc - scale out replicas

```
oc scale deployment applicationsvc --replicas=<desired-replicas> -n <backup-restore-namespace>
```

For example with 80-100 clusters (2 replicas):

```
oc scale deployment applicationsvc --replicas=2 -n ibm-backup-restore
```

job-manager - scale out replicas

```
oc scale deployment job-manager --replicas=<desired-replicas> -n <backup-restore-namespace>
```

For example with 80-100 clusters (2 replicas):

```
oc scale deployment job-manager --replicas=2 -n ibm-backup-restore
```

windowEndTime - update through BackupPolicy CR

The `windowEndTime` is a field under `spec.schedule` in the `BackupPolicy` CR. The value is in HH:MM format.

Note: `windowEndTime` must be set to a minimum of 4 hours later than the scheduled (cron) start time. This can also be updated from the IBM Fusion user interface by navigating to Backup & Restore, Policies and by editing the required policy.

Update the `windowEndTime` field (HH:MM format) under `spec.schedule`. Ensure the value is at least 4 hours after the policy cron schedule time:

```
oc patch fbp <policy-name> -n <ibm-spectrum-fusion-ns> --type='json' -p='[{"op": "replace", "path": "/spec/schedule/windowEndTime", "value": "<HH:MM>"}]'
```

For example with 100 clusters/1000 jobs (window ending at 10:00):

```
oc patch fbp <policy-name> -n <ibm-spectrum-fusion-ns> --type='json' -p='[{"op": "replace", "path": "/spec/schedule/windowEndTime", "value": "10:00"}]'
```

cancelJobAfter - update in job-manager deployment

The `cancelJobAfter` value is specified in milliseconds and is configured as an environment variable in the job-manager deployment.

Patch the `env` variable value (index 3 corresponds to `cancelJobAfter`):

```
oc patch deployment job-manager -n <backup-restore-namespace> --type='json' -p='[{"op": "replace", "path": "/spec/template/spec/containers/0/env/3/value", "value": "<milliseconds>"}]'
```

For example with 80 clusters/800 jobs (10800000 ms = 3 hours):

```
oc patch deployment job-manager -n ibm-backup-restore --type='json' -p='[{"op": "replace", "path": "/spec/template/spec/containers/0/env/3/value", "value": "10800000"}]'
```

MaxConcurrentReconciles - update in dp-operator CSV

`MaxConcurrentReconciles` is configured as an environment variable in the `guardian-dp-operator` cluster service version.

Patch the value (index 3 corresponds to `MaxConcurrentReconciles` based on the current CSV):

```
oc patch csv <guardian-dp-operator-csv-name> -n <backup-restore-namespace> --type='json' -p='[{"op": "replace", "path": "/spec/install/spec/deployments/0/spec/template/spec/containers/1/env/3/value", "value": "<desired-value>"}]'
```

For example with 80-100 clusters (20 reconciles):

```
oc patch csv guardian-dp-operator.v2.13.0-20260402145657 -n ibm-backup-restore --type='json' -p='[{"op": "replace", "path": "/spec/install/spec/deployments/0/spec/template/spec/containers/1/env/3/value", "value": "20"}]'
```

Backup & restore configuration parameters

Configuration parameters allow customization of IBM Fusion Backup & restore settings.

Change defaults for IBM Fusion Backup & restore agent

deleteBackupWait

Timeout for restic command to delete backup in S3 storage. Set in minutes. The default value is 20 minutes, and the allowed range is 10 to 120.

pvcSnapshotMaxParallel

Number of threads available to take concurrent snapshots. The default value is 20.

backupDatamoverTimeout

Maximum amount of time in minutes for the datamover to complete backup. The default value is 1200 seconds, and the allowed range is 10 to 14400. After you modify backupDatamoverTimeout, update cancelJobAfter.

restoreDatamoverTimeout

Maximum amount of time in minutes for datamover to complete restore. The default value is 1200 seconds, and the allowed range is 10 to 14400. After you modify restoreDatamoverTimeout, update cancelJobAfter.

snapshotRestoreJobTimeLimit

This parameter is not used.

pvcSnapshotRestoreTimeout

Timeout for creating PVC from snapshot in minutes. The default value is 15 minutes.

kafka-thread-size

Controls the number of concurrent backup or restore jobs processed by a transaction manager pod. The default value is 10.

snapshotTimeout

Timeout for snapshot to resolve to the ready state in minutes. The default value is 20, and the allowed range is 10 to 120.

datamoverJobpodEphemeralStorageLimit

Datamover pod ephemeral storage limit. The default value is 2000Mi.

datamoverJobPodDataMinGB

Minimum PVC capacity for each datamover pod before a new datamover pod is started. It is set in GB, and the default value is 10 GB.

datamoverJobpodMemoryLimit

It is the Datamover pod memory limit, and the default value is 15000Mi.

datamoverJobpodCPULimit

It is the Datamover pod CPU limit, and the default value is 2.

cancelJobAfter

If you modify backupDatamoverTimeout or restoreDatamoverTimeout, update the job-manager deployment configuration parameter cancelJobAfter. It is the maximum amount of time in milliseconds that the job-manager waits before it cancels the long-running job. The default value is 3600000 (1 hour).

MaxNumJobPods

Implement configurable MaxNumJobPods for datamovers.

This field helps to control the number of PersistentVolumeClaims that is attached to datamover pods during backup and restore to the **BackupStorageLocation**. It is set on a per install basis. If you have spoke clusters installed in your IBM Fusion installation, then set on each spoke cluster individually. It is not a global field that applies to all clusters in the installation.

It helps to distribute the storage load across multiple nodes of the cluster when available. Some StorageClasses impose a maximum number of PVCs that can be attached to an individual node of the cluster. This field helps to manage this StorageClass limitation. To find out whether your StorageClass has this limitation, check whether the CSINode of your storage provider has the spec.drivers[].allocatable.count field set. The VPC Block on IBM Cloud is one such storage provider with this limitation, typically 10 per node. If you increase the number of pods and the application has more than 30 PVCs, it decreases the number of PVCs attached to each node. If it goes below this, you can use the default, which is more than sufficient.

This field can increase or decrease the maximum number of datamover pods that are assigned in each backup or restore. More pods use more resources such as CPU and memory, and can help improve performance for backups and restores with larger numbers of PVCs. Increasing this value may help if the number of PVCs to be backed up or restored at the same time is more than 30.

This field does not guarantee the creation of more datamover pods. A number of heuristics are used at runtime to help determine the assignment of PVCs to datamovers, including total PVC capacity, number of PVCs, amount of data transferred during previous backups, total number of PVCs handled, storage providers involved, among others. This field changes the maximum allowed, and it does not guarantee the specified number of datamovers.

For more information about how to change the value, see [Change defaults for IBM Fusion Backup & restore agent](#).

DeleteBackupRequest CR cleanup

The **DeleteBackupRequest** CRs in the Completed state gets automatically deleted after a default retention of 14 days. You can set the **dbrCRRetention** configuration parameter in ConfigMap guardian-configmap to change the default. By default, the cleanup thread runs every 2 hours and cleans up a maximum of 100 **DeleteBackupRequest** CRs in one run. These two values can be overridden by specifying **dbrCleanupCheckInterval** and **dbrCleanupBatchSize** configuration parameters in the **guardian-configmap** ConfigMap.

dbrCRRetention

Number of days after which **DeleteBackupRequest** CRs in the Completed state get deleted. If not specified, then 14 days are the default.

dbrCleanupCheckInterval

Interval, in hours, at which the **DeleteBackupRequest** cleanup thread runs. If not specified, 2 hours is the default.

dbrCleanupBatchSize

Number of **DeleteBackupRequest** CRs to cleanup in one run of the cleanup thread. If not specified, 100 is the default.

Change defaults for IBM Fusion Backup & restore agent

Do the following steps to change the value:

1. In the OpenShift® Container Platform console, click Operators > Installed Operators.
2. Change the project to the IBM Fusion Backup and Restore namespace. For example **ibm-backup-restore**.
3. Click to open IBM Fusion Backup & Restore Agent.
4. Click the Data Protection Agent tab and click the DPA resource listed, dpagent on the Hub; the name differs on a Spoke. Alternatively, if you want to use the OC command:

```
oc edit -n ibm-backup-restore dataprotectionagent
```

5. Go to the YAML tab.
6. Edit spec.transactionManager.datamoverJobPodCountLimit. The value must be numeric and in quotes. For example, '3', '5', '10'

Backup and restore large number of files

When you back up and restore a large number of files located on CephFS, you must perform the following additional steps for the operations to succeed. The optimal values depend on your individual environment, but the following values are representative for a backup and restore of a million files.

- Prevent the transaction manager from failing long running backup jobs. In the **ibm-backup-restore** project, edit the config map named **guardian-configmap**. Look for **backupDatamoverTimeout**. This value is in minutes, and the default is 20 minutes. For example, increase this value to 8 hours (480).
- Prevent the job manager from canceling long running jobs. In the **ibm-backup-restore** project, edit the **job-manager** deployment. Under **env**, look for **cancelJobAfter**. This value is in milliseconds, and the default is 1 hour. For example, increase this value to 20 hours (72000000).
- Prevent the transaction manager from failing long running restore jobs. In the **ibm-backup-restore** project, edit the config map named **guardian-configmap**. Look for **restoreDatamoverTimeout**. This value is in minutes, and the default is 20 minutes. For example, increase this value to 20 hours (1200).
- In the same config map, increase the amount of ephemeral storage the data mover is allowed to use by increasing **datamoverJobpodEphemeralStorageLimit** to 4000Mi or more.
- OpenShift Data Foundation parameters.
 - Increase the resources available to OpenShift Data Foundation. Increase the limits and requests for the two MDS pods, a and b, for example to 2 CPU and 32 Gi memory. For more information about the changes, see [Changing resources for the OpenShift Data Foundation components](#).
 - Prevent SELinux relabelling
At restore time, OpenShift will attempt to relabel each of the files. If it takes too long, the restored pod will fail with **CreateContainerError**. This article explains the situation and some of the possible workarounds to prevent the relabeling: <https://access.redhat.com/solutions/6221251>.

Additional parameters are available when you backup and restore large number of files that are located on CephFS. The optimal values depend on your individual environment, but the values in this example represent backup and restore of a million files. For such large number of files, you must be on OpenShift Container Platform 4.14 or later, and Data Foundation 4.12 or later.

Set up the following Backup & Restore parameters:

- In the same config map, increase the amount of ephemeral storage the data mover is allowed to use. Increase **datamoverJobpodEphemeralStorageLimit** to 4000Mi or more.

Set up the following Red Hat® OpenShift Data Foundation parameters:

- Increase the resources available to Red Hat OpenShift Data Foundation. Increase the limits and requests for the two MDS pods, for example, to 2 cpu and 32 Gi memory. For the procedure to change, see [Changing resources for the OpenShift Data Foundation components](#).
- Set up to Prevent SELinux relabeling:
At restore time, OpenShift attempts to relabel each of the files. If it takes too long, the restored pod fail with **CreateContainerError**. This article explains the situation and some of the possible workarounds to prevent the relabeling: <https://access.redhat.com/solutions/6221251>.

Use the following steps to understand whether your backups fail due to a large number of files:

1. Run the following command to check whether the MDS pods are restarting:

```
oc get pod -n openshift-storage | grep mds
```
2. If they are restart, check the termination reason:
 - a. Describe the pod.
 - b. Check whether the termination is **OOM Kill**.
3. Run the following command to check the memory usage by the MDS pods and monitor for memory usage:

```
oc adm top pod -n openshift-storage
```

4. If the memory usage keeps spiking until the pod restarts, then see [Changing resources for the OpenShift Data Foundation components](#).

Backup and restore large number of resources

When you back up and restore a large number of cluster resources, the velero pod resource limits must be increased for the operations to succeed. The optimal values depend on your individual environment, but the following values are representative for backup and restore of 1500 resources.

```
oc patch dpa velero -n <backup-restore-namespace> --type merge -p '{"spec": {"configuration": {"velero": {"podConfig": {"resourceAllocations": {"limits": {"ephemeral-storage": "1Gi"}}}}}}'
```

```
oc patch dpa velero -n <backup-restore-namespace> --type merge -p '{"spec": {"configuration": {"velero": {"podConfig": {"resourceAllocations": {"limits": {"memory": "2Gi"}}}}}}}'
```

Configure DataMover type for Backup and Restore

The DataMover type dictates both the entity responsible for backing up data on PersistentVolumeClaims and the method of storage. **kopia** is the only allowed value.

- The default value is **kopia**.
- The **legacy** DataMover for versions equal to or lower than 2.8

The value can be set globally and per PolicyAssignment. The two different DataMover types are not cross-compatible. Backups with one DataMover type use that type during restore. Existing backups continue to expire normally per their Policy.

Change the DataMover type used across all new backups

From the OpenShift console:

1. Log in to OpenShift Console.
2. Go to Workloads > ConfigMaps.
3. Select the IBM Fusion install namespace.
4. Open **isf-data-protection-config** and update **data.Datamover** field.

Example command:

```
oc patch configmap -n ibm-spectrum-fusion-ns isf-data-protection-config -p '{"data":{"DataMover":"kopia"}}'
```

Here, replace namespace **ibm-spectrum-fusion-ns** with your Fusion namespace. Also, this example shows **kopia** DataMover. For **legacy** DataMover, replace **kopia** to **legacy**.

Choose DataMover during policy assignment

To facilitate a trial of the DataMover options, select it by annotating PolicyAssignment objects. Each PolicyAssignment object associates an existing Policy and BackupStorageLocation with an application to backup. By setting this value according to the following instructions, the global setting gets ignored. Consequently, all new backups associated with the PolicyAssignment use the specified DataMover type in the annotation.

1. Search by label to find the existing PolicyAssignment for your applications.
 - To search by application - **dp.isf.ibm.com/application-name=<\application name>**
 - To search by policy - **dp.isf.ibm.com/backuppolicy-name=<\policy name>**
 - To search by backpropagation - **dp.isf.ibm.com/backupstoragelocation-name=<\backupstoragelocation name>**

The general naming format is as follows:

```
<application name>-<\policy name>-<cluster url>
```

Example:

```
aws-20240716-220437-awsdaily-apps.bnr-hcp-munch.apps.blazehub01.mydomain.com
```

2. Change the value of DataMover.

From the OpenShift console:

- a. Go to Operators > Installed Operators.
- b. Select the IBM Fusion install namespace.
- c. Open IBM Fusion.
- d. Go to the Policy Assignment tab and change the DataMover value.

Using commands:

- a. Get the policy assignment object:

```
oc get policyassignment -n ibm-spectrum-fusion-ns
```

- b. Add the annotation to the PolicyAssignment object.

```
dp.isf.ibm.com/dataMover: <datamover type>
```

Example:

```
dp.isf.ibm.com/dataMover: legacy
```

Choose nodes for DataMovers for OADP DataMover

From 2.9 version onwards, the Backup & restore is transitioning from the in-house DataMover to OADP. DataMover controller using restic as the data transfer software to OADP, which uses its own implementation of DataMover and controller with kopia.

Path to locate the custom resource

Do the following steps:

1. In the OpenShift Container Platform console, click Operators > Installed Operators.
2. Change the project to the IBM Spectrum Fusion Backup and Restore namespace. For example **ibm-backup-restore**.
3. Click to open IBM Fusion Backup & Restore Agent.
4. Click the Data Protection Agent tab and click the DPA resource listed, dpagent on the Hub; the name differs on a Spoke.

spec.datamoverConfiguration

The field **spec.datamoverConfiguration** is used to configure the new OADP DataMovers. For backwards compatibility, you can continue to use the fields under **spec.transactionManager** to configure the DataMovers from the previous releases.

spec.datamoverConfiguration.nodeAgentConfig.env

This array enables you to specify environment variables inserted into the node-agent pods. The example value of HOME allows setting the folder used by kopia for local files.

It controls the on-container folder where cache files related to the storage repository are stored. The default value is `/home/velero` and it uses local ephemeral storage.

```
spec:
  datamoverConfiguration:
    nodeAgentConfig:
      env:
        - name: HOME
          value: /home/velero
```

`spec.datamoverConfiguration.nodeAgentConfig.labels`

This field adds additional labels to the node-agent daemonset and pods. It is an optional field to organize pods and does not affect backup and restore behavior. This field is a YAML object.

```
spec:
  datamoverConfiguration:
    nodeAgentConfig:
      labels:
        cloudpakbackup: datamover
```

`spec.datamoverConfiguration.nodeAgentConfig.tolerations`

This is an array field that specifies the conditions for nodes that permit the execution of Pods in resource-constrained environments or multi-architecture clusters. For more information about this field, see [Kubernetes documentation](#).

```
spec:
  datamoverConfiguration:
    nodeAgentConfig:
      tolerations:
        - key: "kubernetes.io/arch"
          operator: "Equal"
          effect: "amd64"
```

`spec.datamoverConfiguration.nodeAgentConfig.resourceAllocations`

This field defines the resource allocation for the node-agent controller, including both scheduling requirements and limits.

If backups or restores are causing evictions in the node-agent pods, increase the value of this field. Go through the Events in the Backup and Restore install namespace to check resource violations:

- The status field of the Daemonset node-agent
- The OpenShift Dashboard for resource monitoring in the Backup and Restore namespace
See [OpenShift documentation](#).
- Grafana in the Backup and Restore namespace if installed
See [OpenShift documentation](#)
- Other applications that use Prometheus metrics.

Example:

```
spec:
  datamoverConfiguration:
    nodeAgentConfig:
      resourceAllocations:
        limits:
          cpu: "2"
          ephemeral-storage: "50Mi"
          memory: "2048Mi"
        requests:
          cpu: "200m"
          ephemeral-storage: "25Mi"
          memory: "256Mi"
```

`spec.configuration.nodeAgent.podConfig.nodeSelector`

This field decides the nodes where the DaemonSet node agent must run. This feature is a crucial security feature to restrict the HostPath mount of the node-agent that exposes the following values:

- All PersistentVolumeClaims
- Projected API volumes such as configmaps and secrets through volume mount
- Kubernetes API tokens that are in use on the node

Note: As this field causes Restore failures, remove it before restore operations.

If needed, this field can isolate the Daemonset node-agent Pods to Nodes without any security concerns.

The pods are assigned to Nodes that match the labels attached to the Nodes. If more than one label is used, the labels are treated in a logical AND. Only Nodes that match all of the labels runs the Pod.

For example, if you set the nodeSelector to `"kubernetes.io/hostname: bnr-hcp-munch-6df6702b-2bv7z"`, then the Daemonset node-agent Pods run only the node with this label. If there is only one node with this label, Daemonset node-agent is restricted to deploying Pods to only the labeled node.

```
spec:
  configuration:
    nodeAgent:
      podConfig:
        nodeSelector:
          kubernetes.io/hostname: bnr-hcp-munch-6df6702b-2bv7z
```

`spec.datamoverConfiguration.datamoverPodConfig`

This setting manages the PVCs, resource allocations, and the location within the cluster where the datamover pods operate. The LoadConcurrency provides the number and LoadAffinity provides the location.

`spec.datamoverConfiguration.datamoverPodConfig.loadConcurrency`

This field controls the maximum number of datamovers assigned to nodes in the cluster.

If there is anything that appears to be in conflict, see [Velero documentation](#).

This setting controls the number of datamovers deployed per node-agent controller pod, and it consists of two parts:

- `spec.datamoverConfiguration.datamoverPodConfig.loadConcurrency.globalConfig`
This sets the maximum number of datamovers deployable from a single node-agent controller pod for a generic node in the cluster. The subsequent field overrides `globalConfig` and manages this setting independently. It is of type integer with default value of five and minimum value of 1. If `loadConcurrency` is added to the config, this value is REQUIRED.
- `spec.datamoverConfiguration.datamoverPodConfig.loadConcurrency.perNodeConfig` is optional.
This allows setting a maximum number of datamovers assigned to a node. Example:

```
loadConcurrency:
  globalConfig: 2
  perNodeConfig:
    - nodeSelector:
        matchLabels:
          kubernetes.io/hostname: node1
        number: 3
    - nodeSelector:
        matchLabels:
          beta.kubernetes.io/instance-type: Standard_B4ms
        number: 5
```

The `perNodeConfig` uses the default `nodeSelector` elements from Kubernetes to select nodes by using labels. When multiple labels are specified in a `matchLabels`, the selected nodes are found using an AND operation, meaning all the labels must be found. These also take a more complex `matchExpressions` field as an alternative to `nodeSelector`. For more information about assigning pods to nodes, see [Kubernetes documentation](#). In this example, the node with a label `kubernetes.io/hostname=node1` can run up to 3 DataMovers at once. And a node with label `beta.kubernetes.io/instance-type=Standard_B4ms` can run up to 5 DataMovers. With the `globalConfig` set to 2, all other nodes with matching storage to the PVC may run up to 2 DataMovers at the same time.

`spec.datamoverConfiguration.datamoverConfiguration.datamoverPodConfig.LoadAffinity`

This field controls the nodes in the cluster where the DataMovers must run. For more information, see [Velero reference documentation](#).

Restriction: The `storageClass` sub-field requires OpenShift Container Platform 4.22 or later. On earlier versions it is ignored.

Each element of the `loadAffinity` array may optionally include a `storageClass` field inside the `nodeSelector` object. When set, the node selection applies only to datamover pods handling PVCs created from that `StorageClass`. When omitted, the entry applies to all PVCs. There may be at most one array element with any given `storageClass` value. The existing example (no `storageClass` field) remains valid and applies to all PVCs.

Valid example — applies to all PVCs (no `storageClass` set):

```
loadAffinity:
- nodeSelector:
    matchLabels:
      beta.kubernetes.io/instance-type: Standard_B4ms
    matchExpressions:
      - key: kubernetes.io/hostname
        values:
          - node-1
          - node-2
          - node-3
        operator: In
      - key: xxx/critical-workload
        operator: DoesNotExist
```

Invalid example — duplicate `storageClass` values are not permitted:

```
loadAffinity:
- nodeSelector:
    matchLabels:
      beta.kubernetes.io/instance-type: Standard_B4ms
    storageClass: "cephfs"
- nodeSelector:
    matchLabels:
      beta.kubernetes.io/instance-type: Standard_B4ms
    storageClass: "cephfs"
```

Both entries use the same `storageClass` value, which is not allowed. A missing `storageClass` field applies to all unmentioned `StorageClasses`.

Valid example — unique `storageClass` values (OpenShift Container Platform 4.22 and later):

```
loadAffinity:
- nodeSelector:
    matchLabels:
      beta.kubernetes.io/instance-type: Standard_B4ms
    storageClass: "cephfs"
- nodeSelector:
    matchLabels:
      beta.kubernetes.io/instance-type: Standard_B4ms
```

The first element applies to PVCs of `StorageClass cephfs` and the second element applies to all PVCs of all other `StorageClasses`.

The value is a list of `nodeSelectors`. The selected nodes are controlled through a `nodeSelector` field that matches the labels. Each member of the list is evaluated independently. The nodes that match the element are combined to create the final list where the DataMovers can run. If the `loadConcurrency.globalConfig` is set to 0, then only the selected nodes in `loadAffinity` and `perNodeConfig` can run the backup and restore jobs.

Ensure that you meet the following criteria.

- The intersection of nodes matching `loadConcurrency.perNodeConfig` and `loadConcurrency.loadAffinity` is where the jobs run. Ensure the size of the intersection is at least one node.
- If the storage used during the backup or restore process is only available on a subset of nodes and `loadConcurrency.globalConfig` is set to 0, you must select at least one node where the storage is accessible. Otherwise, the job fails.
- If the `loadConcurrency.globalConfig` is set to 0 and the selected nodes do not have enough resources in CPU and memory to schedule a DataMover pod, then the backup or restore job fails.

`spec.datamoverConfiguration.datamoverPodConfig.podResources`

Controls the amount of CPU and memory that is made available by the DataMovers. It has the following sub-fields and default values are set for the missing fields. Example:

```
podResources:
  cpuRequest: 2
  memoryRequest: 4Gi
  ephemeralStorageRequest: 5Gi
  cpuLimit: 4
  memoryLimit: 16Gi
  ephemeralStorageLimit: 5Gi
```

For more information about the default Velero resource profile for large clusters, see [CPU and memory requirements in Red Hat documentation](#).

Resource limits must be sufficient to back up the most resource-intensive volumes in the cluster.

`spec.datamoverConfiguration.datamoverPodConfig.backupPVC`

This section defines the format for the PersistentVolumeClaim used in the backup process. See [Velero documentation](#).

During backup, each execution of a volumegroup in a Recipe (default Recipe is all PersistentVolumeClaims), a VolumeSnapshot gets created from a PersistentVolumeClaim representing the volume state at the time of the VolumeSnapshot timestamp. Some storage systems, such as CephFS from Data Foundation and IBM Storage Scale, implement shallow-copy backup volume exposure without file copy to address performance concerns compared to regular volume restores.

By default, the agent configures CephFS, IBM Storage Scale, and NFS PersistentVolumeClaims to be created in `ReadOnlyMany` mode during backups.

Setting values in `backupPVC` you can configure PersistentVolumeClaims from any StorageClass to use their "shallow-copy" implementation. This way, IBM Fusion does not need the specifics, and you can use alternative StorageClasses to access different storage features.

Restriction: The annotations sub-field requires OpenShift Container Platform 4.22 or later. On earlier versions it is ignored.

The optional annotations field is a map of key/value string pairs added to the `.metadata.annotations` of the backup PVC during the backup operation. Values must meet Kubernetes annotation key and value requirements. For more information, see [Kubernetes documentation](#).

Example:

```
backupPVC:
  storage-class-1:
    storageClass: backupPVC-storage-class
    readOnly: true
    annotations:
      storageset: mongodb
  storage-class-2:
    storageClass: backupPVC-storage-class
  storage-class-3:
    readOnly: true
```

In this example, a data transfer of PersistentVolumeClaims of StorageClass "storage-class-1" makes use of an alternative StorageClass "backupPVC-storage-class" to create the volume with `accessModes: ReadOnlyMany`. The storage-class-2 is same as storage-class-1 except that the `accessModes` remains unchanged.

In storage-class-3, no alternate StorageClass can be used, and the volume gets created with `accessModes: ReadOnlyMany`. All DataMovers mount the backup volume as `ReadOnly`, and this affects the behavior of storage on volume creation. The original application `PersistentVolumeClaim` is not modified. Only the `PersistentVolumeClaim` used for the backup is modified.

If the StorageClass belongs to storage systems CephFS or IBM Storage Scale, the setting overwrites the agent's internal behavior with the one configured.

Not all storage systems support `PersistentVolumeClaims` with `accessModes: ReadOnlyMany`. See your appropriate storage documentation.

OpenShift does not provide a way to check what `accessModes` are supported prior to `PersistentVolumeClaim` creation. Check your storage provider's documentation for allowed accessModes.

`spec.datamoverConfiguration.datamoverPodConfig.priorityClassName`

Restriction: Requires OpenShift Container Platform 4.22 or later. Ignored on earlier versions.

Name of a `PriorityClass` object in the IBM Fusion Backup and Restore install namespace. When set, Backup and Restore pods performing PVC data backup and restore use this priority class. If not set, the OpenShift cluster default priority applies.

PriorityClasses indicate which pods take priority when compute resources are limited. For more information, see [Kubernetes documentation](#).

Example:

```
spec:
  datamoverConfiguration:
    datamoverPodConfig:
      priorityClassName: datamover-priority
```

`spec.datamoverConfiguration.datamoverPodConfig.cachePVC`

Restriction: Requires OpenShift Container Platform 4.22 or later. Ignored on earlier versions.

An optional PVC used during Restore as a cache, replacing the need for local ephemeral storage. This field is the preferred alternative to the existing `spec.datamoverConfiguration.datamoverPodConfig.storage` field. If both storage and cachePVC are set, cachePVC takes precedence and storage is ignored. If neither is set, the existing behavior of using local ephemeral storage applies.

Unlike storage, the PVC size is calculated dynamically from the backup size rather than being fixed, enabling dynamic size allocation.

Sub-fields:

- **storageClass** (optional): the StorageClass used to create the cache PVC. Defaults to the cluster default StorageClass if not set.
- **residentThresholdInMB** (optional): the minimum backup data size above which a cache PVC is created for that datamover during Restore. Accepts a Kubernetes quantity value (for example, **50Gi**). Defaults to **0**, meaning a cache PVC is always created for each datamover restore.

Example:

```
datamoverConfiguration:
  datamoverPodConfig:
    cachePVC:
      storageClass: ceph-rbd
      residentThresholdInMB: 50Gi
```

In this example, a cache PVC with StorageClass **ceph-rbd** is created during Restore for PVC backups whose data exceeds 50 Gi.

`spec.datamoverConfiguration.datamoverPodConfig.maintenanceConfig`

Kopia requires periodic maintenance jobs on the backup repository. See [Velero documentation](#).

For each namespace, a Kopia repository is created and maintained. If a cloud object storage repository is used, automatic object expiration must not be used as it triggers repository corruption. The maintenance tasks enhance efficiency and reduce resource usage in future backup and restore jobs, typically lasting less than a minute. Their resource usage is similar to backup expiration tasks. These maintenance jobs run by default every 4 hours. The maintenance frequency can be adjusted by edited the **OADP DataProtectionAgents** under the field `spec.configuration.velero.args.default-repo-maintain-frequency`. These are the "Quick Maintenance Tasks" described by Kopia. See <https://kopia.io/docs/advanced/maintenance/>.

The "Full Maintenance Tasks" are run during backup expiration. The only available configuration item through the **DataProtectionAgent** object is the pod resources used during maintenance jobs.

`spec.datamoverConfiguration.datamoverPodConfig.maintenanceConfig.resourceAllocations`

This field is set using the Kubernetes **resourceAllocations** object format. <https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/>

The following example is also the default values. Missing values such as `requests.cpu` are set to unlimited.

```
datamoverConfiguration:
  datamoverPodConfig:
    podResources:
      cpuLimit: '4'
      cpuRequest: '2'
      memoryLimit: 16Gi
      memoryRequest: 4Gi
      ephemeralStorageRequest: 5Gi
      ephemeralStorageLimit: 5Gi
```

The default is 5Gi.

`spec.datamoverConfiguration.maintenanceConfig.jobSettings.ttl`

This adds a Time To Live to Velero maintenance jobs. Velero defaults to keeping a record of 3 previously completed maintenance jobs. IBM Fusion changes this default value to 1. When you add this field, the Velero maintenance jobs are removed within seconds after completion.

```
datamoverConfiguration
  maintenanceConfig:
    jobSettings:
      ttl: 240
    podResources:
      cpuLimit: '4'
      cpuRequest: '2'
      memoryLimit: '4Gi'
      memoryRequest: '500Mi'
      ephemeralStorageLimit: '5Gi'
      ephemeralStorageRequest: '5Gi'
```

If you do not set this field and you have `spec.datamoverConfiguration.maintenanceConfig.storage`, then it is automatically set to 300. For more information, see <https://kubernetes.io/docs/concepts/workloads/controllers/ttlafterfinished/>.

`spec.datamoverConfiguration.maintenanceConfig.storage`

This section enables you to use a PersistentVolumeClaim to act as a cache during Velero maintenance jobs. Most usage of ephemeral-storage during maintenance jobs originates from the kopia datamover cache. The addition of this field with a sufficiently sized PersistentVolumeClaim to handle the required cached data eliminates the aforementioned ephemeral-storage usage.

```
maintenanceConfig:
  jobSettings:
    ttl: 240
  storage:
    storageClassName: "ocs-external-storagecluster-ceph-rbd"
    size: 25Gi
  podResources:
    cpuLimit: '4'
    cpuRequest: '2'
    memoryLimit: '4Gi'
    memoryRequest: '500Mi'
    ephemeralStorageLimit: '5Gi'
    ephemeralStorageRequest: '5Gi'
```

If storage is configured, then you need the following fields:

- **storageClassName**
The name of the StorageClass to be used with the PersistentVolumeClaim. The StorageClass must support `accessMode: ReadWriteOnce`.

- **size**

The size of the volume to be created. This field uses the existing Kubernetes resources request format such as "5Gi" and "250Mi".

The size of the created PVC is to be used by each data mover pod.

During maintenance jobs, a PersistentVolumeClaim gets created. It is deleted when the job is removed based on the

spec.datamoverConfiguration.maintenanceConfig.jobSettings.ttl field. If

spec.datamoverConfiguration.maintenanceConfig.jobSettings.ttl is not specified and the storage configuration exists, then the ttl gets set to 300 (five minutes).

Tip: For OCP 4.22 and later, consider using **spec.datamoverConfiguration.datamoverPodConfig.cachePVC** instead. It provides dynamically sized cache PVCs and takes precedence over this field when both are set.

spec.datamoverConfiguration.maintenanceConfig.labels

Restriction: Requires OpenShift Container Platform 4.22 or later. Ignored on earlier versions.

A map of key/value pairs added as labels to the maintenance Pod objects for backup PVC data repository maintenance jobs. There are no restrictions other than those imposed by Kubernetes. For more information, see [Kubernetes documentation](#).

Example:

```
datamoverConfiguration:
  maintenanceConfig:
    labels:
      ibm.com/cpd: postgres
      ibm.com/ai: bob
```

spec.datamoverConfiguration.maintenanceConfig.annotations

Restriction: Requires OpenShift Container Platform 4.22 or later. Ignored on earlier versions.

A map of key/value pairs added as annotations to the maintenance Pod while it runs. There are no restrictions beyond those imposed by Kubernetes. For more information, see [Kubernetes documentation](#).

Example:

```
datamoverConfiguration:
  maintenanceConfig:
    annotations:
      test: annotation
```

spec.datamoverConfiguration.maintenanceConfig.priorityClassName

Restriction: Requires OpenShift Container Platform 4.22 or later. Ignored on earlier versions.

Name of a **PriorityClass** object in the IBM Fusion Backup and Restore install namespace. When set, periodic data compaction and expired backup removal pods use this priority class. If not set, the OpenShift cluster default priority applies.

PriorityClasses indicate which pods take priority when compute resources are limited. For more information, see [Kubernetes documentation](#).

Example:

```
datamoverConfiguration:
  maintenanceConfig:
    priorityClassName: low-priority
```

spec.datamoverConfiguration.maintenanceConfig.jobSettings.keepLatestMaintenanceJobs

Restriction: Requires OpenShift Container Platform 4.22 or later. Ignored on earlier versions.

Controls how many completed maintenance Job objects per volume namespace are retained on the cluster after they finish. Retaining completed jobs preserves their pod logs, which aids debugging and support. Defaults to 1. May be set to any whole number of 0 or more.

Example:

```
datamoverConfiguration:
  maintenanceConfig:
    jobSettings:
      keepLatestMaintenanceJobs: 1
```

Advanced: Per Namespace Configuration

The maintenance config values mentioned previously are applied globally. These fields can also be applied manually by editing the appropriate **maintenance-config** ConfigMap. It allows overrides by namespace in case of resource usage differences.

The format is the same as **DataProtectionAgent spec.datamoverConfiguration.maintenanceConfiguration** in JSON instead of YAML.

The configuration is applied using a JSON format where the key is the repository. If a value is set for a repository, the value overrides the global values. For instance, if the global values are as described in the following example:

```
kind: ConfigMap
apiVersion: v1
metadata:
  name: maintenance-config
  namespace: ibm-backup-restore
data:
  global: '{"jobSettings":{"ttl":300},"podResources":{
{"cpuRequest":"500m","cpuLimit":"4","memoryRequest":"500Mi","memoryLimit":"4Gi","ephemeralStorageRequest":"5Gi","ephemeralStorageLimit":"20Gi"},"storage":{"storageClassName":"ocs-external-storagecluster-ceph-rbd","size":"20Gi"}}}'
```

Additional keys are in the **<namespace>-<bsl name>-kopia** format:

```
kind: ConfigMap
```

```

apiVersion: vl
metadata:
  name: maintenance-config
  namespace: ibm-backup-restore
data:
  global: '{"jobSettings":{"ttl":300},"podResources":
{"cpuRequest":"500m","cpuLimit":"4","memoryRequest":"500Mi","memoryLimit":"4Gi","ephemeralStorageLimit":"5Gi","ephemeralStorageRequest":"5Gi"}}'
  zen-s3-kopia: '{"jobSettings":{"ttl":300},"podResources":
{"cpuRequest":"500m","cpuLimit":"4","memoryRequest":"500Mi","memoryLimit":"4Gi"}, "storage":{"storageClassName":"ocs-external-storagecluster-ceph-rbd","size":"25Gi"}}'

```

It ensures that the maintenance jobs related to data from the zen namespace connected to BSL S3 use a 25Gi PersistentVolumeClaim cache and do not set resource requests or limits on ephemeral storage.

node-agent-config

To configure the data mover pods to use PVCs as cache in place of ephemeral storage, add the following field into the node-agent-config config map:

```
storage:{"storageClassName":"ocs-external-storagecluster-ceph-rbd","size":"25Gi"}
```

To configure the data mover pods to use PVCs as cache in place of ephemeral storage.

Example value of the node-agent-config:

```

{"loadConcurrency": {"globalConfig": 5}, "podResources": {"cpuRequest": "2", "cpuLimit": "4", "memoryRequest": "4Gi", "memoryLimit": "16Gi", "ephemeralStorageRequest": "5Gi", "ephemeralStorageLimit": "5Gi"}, "storage": {"storageClassName":"ocs-external-storagecluster-ceph-rbd","size":"25Gi"}, "backupPVC": {"ocs-storagecluster-cephfs": {"storageClass": "ocs-storagecluster-cephfs", "readOnly": true, "spcNoRelabeling": true}}}

```

Latest permissible start time for the backup process

You can set the latest permissible start time for a scheduled backup. This setting is useful whenever multiple backups use the same policy or schedule and the agent gets overloaded frequently with jobs as they all start at the same time. Without the `windowEndTime` setting, jobs have, by default, up to one hour for the agent to start processing before they are considered hung and subsequently cancelled. You can manually spawn additional agent replicas to handle the spike in job activity and process the backlog of jobs sooner, but these replicas remain idle for the remainder of the day. With the `windowEndTime` option, the job can remain queued up for processing by the agent for a custom period of time before getting cancelled. This allows for a single agent replica to be fully active for a longer period of time throughout the day without the need to manually create multiple policies or schedules.

Set the `windowEndTime` field in the **BackupPolicy** CR in the 24 hour "HH:MM" format.

Example:

```

spec:
  backupStorageLocation: kn-aws
  provider: isf-backup-restore
  retention:
    number: 5
    unit: days
  schedule:
    cron: `45 14 * * *`
    timezone: America/Los_Angeles
    windowEndTime: `17:45`

```

In this example, the schedule is set to run daily at 14:45 (2.45 PM). By specifying a `windowEndTime` of 17:45, you can ensure that the backup has until 5:45 PM to start. If the backup does not start by 5.45 PM due to the load on the agent, it gets cancelled. If the agent does not pick it up and the `windowEndTime` setting does not exist, then backup gets cancelled after one hour.

Note: For all new **BackupPolicy** CRs that have a specific start time (not just a repeat interval), if the `windowEndTime` is not explicitly specified, a default end time gets set to 4 hours after the scheduled start time. Existing **BackupPolicy** CRs maintain their original behavior without `windowEndTime`, resulting in a one-hour limit before they are considered hung and subsequently cancelled. You can edit the existing Policy CRs to add the `windowEndTime` option.

Failed backup retention

By default, failed backups are automatically deleted after 7 days. You can change this retention period by updating the **failedBackupRetention** configuration parameter in the **guardian-configmap** configmap. To do so, add the following entry to the configmap: **failedBackupRetention: '5'**. This sets the retention period to 5 days.

FIPS-140-2

The Federal Information Processing Standard Publication 140-2 (FIPS-140-2) is a standard that defines a set of security requirements for the use of cryptographic modules. Law mandates this standard for the US government agencies and contractors and is also referenced in other international and industry specific standards.

IBM Fusion Backup & Restore service is FIPS compliant. It uses FIPS validated cryptographic modules provided by Red Hat® Enterprise Linux OS/CoreOS (RHCOS).

Backup & Restore service installation and upgrade issues

Use this troubleshooting information to resolve install and upgrade problems that are related to Backup & Restore service.

One or more Backup & Restore pods are in CrashLoopBackOff state due to startup/liveness/readiness probe failures

Problem statement

During installation or upgrade of IBM Fusion Backup & Restore service, a few pods might be in **CrashLoopBackOff** state due to startup/liveness/readiness probe failures. This causes the installation or upgrade to not progress further.

Cause

One or more Backup & Restore service pods enter a **CrashLoopBackOff** state due to startup/liveness/readiness probe failures. This can happen when the cluster load causes the pod CPU to be throttled leading to longer startup times.

Resolution

Increase the **periodSeconds** and **failureThreshold** values for the startup/liveness/readiness probes in the Backup & Restore service deployment. Updating these values allows additional time for the pods to start successfully and enables the service to complete the upgrade.

Backup & Restore service installation may hang at 75%

If the provided custom install namespace exceeds 24 characters in length, then the Fusion Backup & Restore service installation may hang at 75% completion. To resolve this issue, provide a custom namespace that is no more than 24 characters in length.

Application information not repopulated after service reinstallation

Problem statement

The application information gets removed during Backup & Restore service uninstallation. It does not get repopulated in MongoDB after the service reinstallation. Restore jobs validation fail with the following error message.

```
postJobRequest: Application Info not returned from application service for applicationId
```

Resolution

The workaround is to restart the **isf-application-operator-controller-manager** pod in the IBM Fusion namespace.

Backup & Restore server installation displays an Invalid Input error

Problem statement

The Backup & Restore service deployment fails with the following error in the IBM Fusion user interface:

```
Install Error: Invalid Input: Both the api Server and bootstrapToken fields need to be populated
```

Resolution

As a resolution, try with a private browser window.

Backup & Restore hub service in a custom namespace

Problem statement

In general, the Backup & Restore service is installed or upgraded to the default **ibm-backup-restore** namespace. To avoid issues during the installation or upgrade of the service with custom namespace, do the resolution steps.

Resolution

1. Go to Operators > Installed Operators > Fusion Service Definition.
2. Open the **ibm-backup-restore-service** CR and go to the YAML tab.
3. In **spec.onboarding.parameters**, search for parameter with **name** as namespace and change the **defaultValue** to the custom-namespace where the service must be installed.

Example:

```
parameters:
  - dataType: string
    name: namespace
    defaultValue: <custom-namespace>
    userInterface: false
    required: true
    descriptionCode: BMYSRV00003
    displayNameCode: BMYSRV00004
```

4. Store the following YAML in **server-fsi.yaml**, and replace **<custom-namespace>** with the namespace where the service must be installed.

```
apiVersion: service.isf.ibm.com/v1
kind: FusionServiceInstance
metadata:
  name: ibm-backup-restore-service-instance
  namespace: ibm-spectrum-fusion-ns
spec:
  parameters:
    - name: doInstall
      provided: false
      value: 'true'
    - name: namespace
      provided: false
      value: <custom-namespace>
    - name: storageClass
      provided: true
```

```
value: lvms-lmvg
serviceDefinition: ibm-backup-restore-service
triggerUpdate: false
enabled: true
doInstall: true
```

5. Run the following command to apply the changes:

```
oc apply -f server-fsi.yaml
```

6. For the upgrade procedure, upgrade the IBM Fusion operator, repeat step 1 of the resolution, and then upgrade the service.

Pods in Crashloopbackoff state after upgrade

Problem statement

The Backup & Restore service health changes to unknown and two pods go into Crashloopbackoff state.

Resolution

In the resource settings of `guardian-dp-operator` pod that is in `ibm-backup-restore` namespace, set the value of IBM Fusion operator memory limits to 1000 mi.

Example:

```
resources:
  limits:
    cpu: 1000m
    memory: 1000Mi
  requests:
    cpu: 500m
    memory: 250Mi
```

Backup & Restore service goes into unknown state

Problem statement

This Backup & Restore service might go into unknown state when you upgrade IBM Fusion from 2.6.x to 2.14.0.

Resolution

It automatically shows healthy on the IBM Fusion user interface after you upgrade the Backup & Restore service.

MongoDB pod crashes with CrashLoopBackOff status

Problem statement

The MongoDB pod crashes due to an OOM error.

Resolution

To resolve the error, increase the memory limit from 256Mi to 512Mi. Do the following steps to change the memory limit:

1. Log in to the Red Hat® OpenShift® web console as an administrator.
2. Go to Workloads > StatefulSet.
3. Select the project `ibm-backup-restore`.
4. Select the MongoDB pod, and go to the YAML tab.
5. In the YAML, change the memory limit for MongoDB container from 256Mi to 512Mi.
6. Click Save.

Backup & Restore service installation and upgrade issue with the IBM Storage Protect Plus catalog source

Problem statement

The backups can fail with a `FailedValidation` error after you install or upgrade the IBM Fusion and Backup & Restore service to 2.8.0.

```
validationErrors': ['an existing backup storage location wasn't specified at backup creation time and the default guardian-minio
Error: BackupStorageLocation.velero.io "guardian-minio" not found'
```

It occurs when the IBM Storage Protect Plus catalog exists in the OpenShift Container Platform clusters.

Resolution

The workaround is to upgrade the OADP, installed in the `ibm-backup-restore` namespace, to version 1.3.

Troubleshooting Backup & Restore service issues

List of known Backup & Restore issues in IBM Fusion.

Fusion UI may not reflect the installed state of restored watsonx services

Problem statement

After a Backup and Restore operation on IBM Fusion HCI 2.14 or earlier, the IBM Fusion UI may show Software Hub, watsonx Orchestrate, or watsonx.ai as available for installation, even though the services are successfully restored and running in the cluster.

Cause

The IBM Fusion UI uses the corresponding **FusionServiceInstance** (FSI) custom resource to determine whether a Fusion-managed service is installed. In the current Backup & Restore flow for IBM Fusion HCI 2.14, the service workloads may be restored successfully, but the associated **FusionServiceInstance** resources are not restored automatically. As a result, the IBM Fusion UI cannot identify the restored services as installed.

Important: This limitation applies to the Fusion state represented by the **FusionServiceInstance** resources. It does not indicate that the underlying service restore failed. The restored service custom resources can be healthy and operational while the IBM Fusion UI still shows the service as available for installation. Full support for backing up and restoring the Fusion state associated with these watsonx services is planned for a future release.

When to apply

This resolution applies only when you perform a same-cluster restore on IBM Fusion HCI 2.14 or earlier, and the affected services (Software Hub, watsonx Orchestrate, or watsonx.ai) were originally installed through the IBM Fusion UI.

Resolution

1. Take the required IBM Software Hub or Software Hub backup.
2. Confirm which **FusionServiceInstance** (FSI) resources are present, then export each one to a YAML file for safekeeping:

```
oc get fsi -n ibm-spectrum-fusion-ns

oc get fsi ibm-softwarehub-service-instance -n ibm-spectrum-fusion-ns -o yaml > fsi-ibm-softwarehub-service-instance.yaml
oc get fsi ibm-watsonxorchestrate-service-instance -n ibm-spectrum-fusion-ns -o yaml > fsi-ibm-watsonxorchestrate-service-instance.yaml
oc get fsi ibm-watsonxai-service-instance -n ibm-spectrum-fusion-ns -o yaml > fsi-ibm-watsonxai-service-instance.yaml
```

3. Delete the corresponding service manager custom resources (**SoftwarehubManager**, **WatsonxOrchestrateManager**, **WatsonxAIManager**) and their corresponding **FusionServiceInstance** (FSI) custom resources to prevent them from being recreated and triggering the recreation of the CPD namespaces during cleanup. Delete watsonx Orchestrate or watsonx.ai first, and Software Hub last:

```
oc delete watsonxorchestratemanager ibm-watsonxorchestrate-service-instance -n ibm-software-hub-operator &
oc delete fsi ibm-watsonxorchestrate-service-instance -n ibm-spectrum-fusion-ns &
wait
oc delete watsonxaimanager ibm-watsonxai-service-instance -n ibm-software-hub-operator &
oc delete fsi ibm-watsonxai-service-instance -n ibm-spectrum-fusion-ns &
wait
oc delete softwarehubmanager ibm-softwarehub-service-instance -n ibm-software-hub-operator &
oc delete fsi ibm-softwarehub-service-instance -n ibm-spectrum-fusion-ns &
wait
```

4. Perform the documented pre-restore cleanup procedure. For more information, see [IBM Software Hub online backup and restore to the same cluster with IBM Fusion](#).
5. Restore the IBM Software Hub environment.
6. Verify that the restored service workloads and their custom resources are in a healthy **Completed** or **Ready** state.
7. If the corresponding **FusionServiceInstance** resources are not present after the restore, restore or recreate the required FSI resources manually. Important: When recreating the FSI resources manually, verify that the **doInstall** flag is set to **true** in the FSI spec. If it is set to **false**, change it to **true** so that the service installation starts automatically. For example:

```
apiVersion: service.isf.ibm.com/v1
kind: FusionServiceInstance
metadata:
  name: ibm-watsonxorchestrate-service-instance
  namespace: ibm-spectrum-fusion-ns
spec:
  creator: User
  doInstall: true
  parameters:
    - name: namespace
      provided: false
      value: ibm-software-hub-operator
  serviceDefinition: ibm-watsonxorchestrate-service
  triggerUpdate: false
  updateServiceCRSpec: false
```

Apply with `oc apply -f <fsi-file>.yaml`.

8. After the **FusionServiceInstance** resources are available, refresh the IBM Fusion UI. The corresponding services are then recognized as installed.

Small IBM Scale PersistentVolumeClaims (PVCs) can cause failures

Small IBM Scale PersistentVolumeClaims (PVCs) are more prone to VolumeSnapshot failures. The smaller the PVC, the higher the likelihood. However, failures can occur regardless of size. According to IBM Scale, 10Gi is the threshold above which failures are quite unlikely, and below which they may begin to occur on a semi-regular basis.

Common issues

This section outlines common issues and their resolutions across multiple subcategories, such as backup, restore, service protection.

Rack shutdown in a multi-rack setup

Problem statement

A rack shutdown in a multi-rack HA setup can cause the Backup & Restore service to go to an unknown state.

Resolution

In the case of a rack shutdown, if a graceful shutdown is not working or the node is in a non-recoverable state, you can manually add an **out-of-service** taint on the node. For more information about how it works, see [Kubernetes Blogs](#).

Remove the taint on the affected node after the node is recovered.

Backup or restore fails because of PVCs

Problem statement

Backup & Restore fails with the following error message:

```
error to create persistentvolumeclaims "<claim name>" is forbidden: exceeded quota"
```

Cause

During backup or restore operations, the Backup & Restore service temporarily allocates additional storage through PersistentVolumeClaims to stage application data. The requested storage size can even match the application size backed up or restored.

Resolution

- **Scenario 1: Failure due to ResourceQuota:**
Adjust or remove the storage.capacity field from the **ResourceQuota** object to allow the Backup & Restore service to allocate staging PersistentVolumeClaims as needed. The quota must equal the total size of the largest application's PersistentVolumeClaims, plus an additional 10Gi for local in-place policy storage. A higher quota may be required when you perform parallel operations that span all applications backed up or restored simultaneously.
- **Scenario 2: Failure due to ClusterResourceQuota:**
During backup or restore operations, Backup & Restore service temporarily consumes additional storage using PersistentVolumeClaims to stage data. To ensure successful backup and restore, either exclude the Backup & Restore namespace from the quota or increase it sufficiently. The quota must be set to the total size of the largest application's PersistentVolumeClaims, plus an additional 10Gi for local in-place policy storage. A higher quota may be necessary when you perform parallel operations that span all applications backed up or restored simultaneously.

For more information about resource quotas, see [Red Hat® Documentation](#).

Backup issues

List of backup issues in the Backup & Restore service of IBM Fusion.

Backup storage location transitions to BucketMissing state after upgrade to IBM Fusion 2.12.x

Problem statement

After upgrading from IBM Fusion 2.11.x or earlier to 2.12.x or later, backup storage locations (BSLs) configured with **type: aws** and a custom endpoint for accessing AWS S3 might fail validation and transition to the **BucketMissing** state and fail validation.

This issue can occur when the BSL is configured to access AWS S3 through a custom corporate endpoint, gateway, or proxy instead of the native AWS S3 endpoint.

Diagnosis

Confirm that the affected BSL is configured with the following settings:

- **type:** `aws`
- **endpoint:** `https://<custom-endpoint>`

If the BSL uses **type: aws** with a non-AWS endpoint, the configuration requires updating.

Resolution

Update the affected BSL to use the generic **s3** BSL type while retaining the existing endpoint, region, and credentials.

Change the BSL configuration from:

```
type: aws
region: us-east-1
endpoint: https://<custom-endpoint>
```

To:

```
type: s3
region: us-east-1
endpoint: https://<custom-endpoint>
```

After changing the BSL type to **s3**, the backup storage location validates successfully and is available for backups.

Backup size for block volumes is not correct

When the policy backup storage location gets changed, the backup size for application backups with Ceph RBD block volumes is incorrectly displayed during the first backup. As the correct information is displayed after the first backup following the change in the backup storage location, you can ignore this issue.

Multiple VM backups failing with snapshot deadline exceeded error

Resolution

1. Run the following command to enable full auditing:

```
sudo auditctl -w /etc/shadow -p
```

2. Rerun the backup and run the following command to identify the file that is causing ownership or permission issues.

```
sudo ausearch -m avc -ts recent
```

3. If the **ausearch** command reports issues, then run the following commands to generate a local policy to allow access.

```
sudo ausearch -c 'qemu-ga' --raw | audit2allow -M my-qemuga
sudo semodule -X 300 -i my-qemuga.pp
```

Failed to create snapshot content

Problem statement

Failed to create snapshot content with the following error:

Cannot find CSI PersistentVolumeSource for directory-based static volume

Resolution

To resolve the error, see [Create a VolumeSnapshot](#).

Assign a backup policy operation fails

Problem statement

If you have a PolicyAssignment for an application on the hub and you create a PolicyAssignment for the same application on the spoke, then your attempt to assign a backup policy for the application fails. In both assignments, the application, backup policy, and short-form cluster name are the same. The current format of the PolicyAssignment CR name is **appName-backupPolicyName-shortFormClusterName**. The issue happens when the first string of the cluster names is identical. In this scenario, the creation gets rejected because the PolicyAssignment name exists in OpenShift® Container Platform.

For example:

Hub assignment creates **app1-bp1-apps**:

- Application - **app1**
- BackupPolicy - **bp1**
- AppCluster - **apps.cluster1**

Spoke assignment creates **app1-bp1-apps** (The OpenShift Container Platform rejects it)

- Application - **app1**
- BackupPolicy - **bp1**
- AppCluster - **apps.cluster2**

Resolution

To create the PolicyAssignment for the spoke application, delete the PolicyAssignment CR for the hub application assignment and attempt spoke application assignment again.

Backups do not work as defined in the backup policies

Problem statement

Sometimes, backups do not work as defined in the backup policies, especially when you set hourly policies. For example, if you set a policy for two hours and it does not run every two hours, then gaps exist in the backup history. The possible reason might be that during pod crash and restart, scheduled jobs were not accounting for the time zone, causing gaps in run intervals.

Diagnosis

The following are the observed symptoms:

- Policies with custom every X hour at minute YY schedules: the first scheduled run of this policy will run at minute YY after X hours + time zone offset from UTC instead of at minute YY after X hours.
- Monthly and yearly policies run more frequently.

Resolution

You can start backups manually until the next scheduled time.

Backup jobs are stuck in a running state for a long time and are not canceled

Resolution

Do the following steps to resolve the issue:

1. Ensure that all jobs are finished and the queue is empty before you do any disruptive actions like node restarts.
2. If jobs are running for a long period and do not progress, follow the steps to delete the backup or restore CR directly.
 - a. Log in to IBM Fusion.
 - b. Go to Backup & Restore > Jobs > Queue and get the name of the job that is stuck.
 - c. Run the following command to delete backup job.

```
oc delete fbackup <job_name>
```

- d. Run the following command to delete restore job.

```
oc delete frestore <job_name>
```

Policy creation

Problem statement

Sometimes, when you create a backup policy, the following errors can occur:

```
Error: Policy daily-snapshot could not created.
```

Resolution

Restart the `isf-data-protection-operator-controller-manager-*` pod in IBM Fusion namespace. It triggers the recreation of the in-place-snapshot BackupStorageLocation CR.

Policy assignment from Backup & Restore service page of the OpenShift Container Platform console

Problem statement

In the Backup & Restore service page of the OpenShift Container Platform console, the backup policy assignment to an application fails with a gateway timeout error.

Resolution

Use your IBM Fusion user interface.

Backup of multiple VMs attempt is failed

Problem statement

This issue occurs when some VMs are in a migrating state. The OpenShift Container Platform does not support snapshot of the VMs in migrating state.

Resolution

Follow the steps to resolve this issue:

1. Check whether the virtual machine is in a migrating state:
2. Run the following command to check migrating VM.

```
oc get virtualmachineinstancemigrations -A
```

Example output:

NAMESPACE	NAME	PHASE	VMI
fb-bml-fs-1-5g-10	rhel8-lesser-wildcat-migration-8fhbo	Failed	rhel8-lesser-wildcat
vm-centipede-bm2	centos-stream9-chilly-hawk-migration-57jyk	Failed	centos-stream9-chilly-hawk
vm-centos9-bml-1	centos-stream9-instant-toad-migration-bfyz6	Failed	centos-stream9-instant-toad
vm-centos9-bml-1	centos-stream9-instant-toad-migration-d9547	Failed	centos-stream9-instant-toad
vm-windows10-bm2-1	kubevirt-workload-update-4dm57	Failed	win10-zealous-unicorn
vm-windows10-bm2-1	kubevirt-workload-update-f2s5w	Failed	win10-zealous-unicorn
vm-windows10-bm2-1	kubevirt-workload-update-gt6nj	Failed	win10-zealous-unicorn
vm-windows10-bm2-1	kubevirt-workload-update-rjwmn	Failed	win10-zealous-unicorn
vm-windows10-bm2-1	kubevirt-workload-update-vfxfl	TargetReady	win10-zealous-unicorn
vm-windows10-bm2-1	kubevirt-workload-update-z2thw	Failed	win10-zealous-unicorn
vm-windows11-bm2-1	kubevirt-workload-update-9gr6v	Failed	win11-graceful-coyote
vm-windows11-bm2-1	kubevirt-workload-update-clbck	Failed	win11-graceful-coyote
vm-windows11-bm2-1	kubevirt-workload-update-j6pmx	Failed	win11-graceful-coyote
vm-windows11-bm2-1	kubevirt-workload-update-sfbbx	Pending	win11-graceful-coyote
vm-windows11-bm2-1	kubevirt-workload-update-th5dd	Failed	win11-graceful-coyote
vm-windows11-bm2-1	kubevirt-workload-update-zl679	Failed	win11-graceful-coyote
vm-windows11-bm2-2	kubevirt-workload-update-7dp6g	Failed	win11-conservative-moth
vm-windows11-bm2-2	kubevirt-workload-update-9nb9m	TargetReady	win11-conservative-moth
vm-windows11-bm2-2	kubevirt-workload-update-cdrf5	Failed	win11-conservative-moth
vm-windows11-bm2-2	kubevirt-workload-update-dm8fz	Failed	win11-conservative-moth
vm-windows11-bm2-2	kubevirt-workload-update-kwr6c	Failed	win11-conservative-moth
vm-windows11-bm2-2	kubevirt-workload-update-zt8wx	Failed	win11-conservative-moth

3. Exclude the migrating virtual machine from the backup. Reattempt it after the migration is complete.

Backup applications table does not show the new backup times for the backed-up applications

Problem statement

The backup applications table does not show the new backup times for the backed-up applications.

Resolution

Go to the Applications and Jobs view to see the last successful backup job for a given application. For applications on the hub, the Applications table has the correct last backup time.

Backups are failing for the virtual machines

Problem statement

The backups and snapshots are failing for the virtual machines that is mounted with second disk.

Resolution

1. Run the following command to get disks details for the virtual machine.

```
oc get virtualmachine -A -o json | jq '.items[] | [{name:.metadata.name, namespace:.metadata.namespace, volumes:.spec.template.spec.volumes}] | select(.[].volumes[] | .dataVolume | length > 1) | {name
```

```
: . [].name, namespace: . [].namespace}'
```

Example output:

```
{
  "name": "rhel9-absent-basilisk",
  "namespace": "vmtesting"
}
```

2. If you find the virtual machines are mounted with second disk, then follow the steps mentioned in the [Red Hat solution](#) to resolve the issue.

Known issues and limitations

- When the Backup & Restore Hub auto-upgrade setting is disabled, the Backup & Restore service may still be upgraded to IBM Fusion 2.13.0.
- Note: This issue only occurs with the first job after installation.
After a fresh installation, the first job might not process as expected. To resolve this issue, cancel the job and wait for the cancellation to complete. Then, retry the job to process it successfully.
- The OpenShift Container Platform cluster can have problems and become unusable. After you recover the cluster, rejoin the connections. For the steps to clean the connection and setup the connection between two clusters again, see [Connection setup after OpenShift Container Platform cluster recovery](#). OpenShift Container Platform cluster can have problems and become unusable.
- The S3 bucket must not have an expiration policy or an archive rule. For more information about this known issue, see [S3 buckets must not enable expiration policies](#).
- The Azure Endpoint URL must not contain the name of the bucket.
- When you backup an application present in namespace with high security context constraints privileges. The restored namespace will not have the same security context constraints privileges, resulting in restored pods in crashloopbackoff status.
Workaround:
 - Restart the application pod.
- When you configure node affinity for the Backup & Restore, consider the following limitations:
 - There is no way to add **nodeAffinity** in **DataProtectionApplication** CR. The Velero pod may get scheduled on the GPU nodes, even if other nodes are eligible for scheduling.
 - There is one **Node-agent** pod per node, which continues to run on GPU nodes as well.
For more information about Configuring the OpenShift API for Data Protection with Multicloud Object Gateway, see [Red Hat® documentation](#).
 - There is no way to specify **nodeAffinity** for AMQ and OAPD operator pods. These operator pods may get scheduled on the GPU nodes, even if other nodes are eligible for scheduling.
 - There is no way to specify anti **NodeAffinity** for OLM jobs pods, so these pods may get scheduled on the GPU nodes, even if other nodes are eligible for scheduling. However, these are very short lived pods.
 - The **datamover** pod for restore work may get scheduled on a GPU node. Currently, Kopia honors the setting for backup job pod, but not for restore job pod.
 - In summary, the following pods do not have the logic to avoid GPU nodes:
 - Velero
 - Datamover (for restore)
 - AMQ Operator
 - OAPD operator
 - Node Agent
 - OLM jobs

Restore issues

List of restore issues in Backup & Restore service of IBM Fusion.

Restore Fails with Timeout on Preparing Data Download error

Problem statement

The restore operation is inconsistent and sometimes fails with the error timeout on preparing data download in the data mover pod due to reason: failed to add finalizer. This issue is observed in certain environments, and the cause is not immediately apparent.

Symptoms

- Restore operation fails with a timeout error.
- Error message indicates a problem with preparing data download in the data mover pod.
- The specific error message is failed to add finalizer.

Cause

The cause of this issue is not definitively known but is related to the functioning of the IBM Storage Scale Container Storage Interface (CSI) pods. The pods may be experiencing issues that prevent the successful completion of the restore operation.

Resolution

To resolve this issue, follow these steps:

1. Run the following command to delete the IBM Storage Scale Container Storage Interface (CSI) pods. For versions of IBM Storage Scale Container Native Storage Access (CNSA) prior to 6.0.1, use **ibm-spectrum-scale-csi** as the namespace instead of **ibm-spectrum-scale**.

```
kubectl delete pod -l product=ibm-spectrum-scale-csi -n ibm-spectrum-scale
```

Example output:

```
pod "ibm-spectrum-scale-csi-attacher-86c4864c94-tlcqn" deleted
pod "ibm-spectrum-scale-csi-attacher-86c4864c94-wn6sr" deleted
pod "ibm-spectrum-scale-csi-bqtwj" deleted
pod "ibm-spectrum-scale-csi-dqsg" deleted
```

```
pod "ibm-spectrum-scale-csi-mskc6" deleted
pod "ibm-spectrum-scale-csi-provisioner-67b878b57-6lft1" deleted
pod "ibm-spectrum-scale-csi-resizer-84cf579d49-bx4jr" deleted
pod "ibm-spectrum-scale-csi-rrggd" deleted
pod "ibm-spectrum-scale-csi-snapshotter-8b69bc4dd-xkt4s" deleted
pod "ibm-spectrum-scale-csi-srh2z" deleted
```

2. Run the following command to verify that the IBM Storage Scale Container Storage Interface (CSI) pods restarted successfully.

```
oc get pods -l product=ibm-spectrum-scale-csi -n ibm-spectrum-scale
```

Example output:

NAME	READY	STATUS	RESTARTS	AGE
ibm-spectrum-scale-csi-attacher-86c4864c94-55z9p	1/1	Running	0	7s
ibm-spectrum-scale-csi-attacher-86c4864c94-t9sww	1/1	Running	0	7s
ibm-spectrum-scale-csi-frmtq	3/3	Running	0	6s
ibm-spectrum-scale-csi-g4mqr	3/3	Running	0	6s
ibm-spectrum-scale-csi-hxb4q	3/3	Running	0	6s
ibm-spectrum-scale-csi-provisioner-67b878b57-ltj4g	1/1	Running	0	7s
ibm-spectrum-scale-csi-q5jgp	3/3	Running	0	6s
ibm-spectrum-scale-csi-resizer-84cf579d49-wvgv2	1/1	Running	0	7s
ibm-spectrum-scale-csi-rgv5d	3/3	Running	0	7s
ibm-spectrum-scale-csi-snapshotter-8b69bc4dd-7cpq5	1/1	Running	0	7s

Restore fails because of ephemeral local storage exceeding limits error in Velero pod

Resolution

When you back up and restore a large number of cluster resources, Velero pod resource limits must be increased for the operations to succeed. The optimal values depend on your individual environment, but the following values are representative for backup and restore of 1500 resources. To change the local storage the Velero Pod is allowed to use from the default 500Mi (Mebibytes) to 1Gi (Gibibytes):

```
oc patch dpa velero -n <backup-restore-namespace> --type merge -p '{"spec": {"configuration": {"velero": {"podConfig": {"resourceAllocations": {"limits": {"ephemeral-storage": "1Gi"}}}}}}'
```

To change the memory limit of the Velero Pod from default 2Gi (Gibibytes) to 4Gi (Gibibytes):

```
oc patch dpa velero -n <backup-restore-namespace> --type merge -p '{"spec": {"configuration": {"velero": {"podConfig": {"resourceAllocations": {"limits": {"memory": "4Gi"}}}}}}'
```

Restore of applications from hub or spoke 2.9.0 to spoke at version 2.8.1 fails

Problem statement

Restore of applications from hub or spoke 2.9.0 to spoke at version 2.8.x fails with error in Transaction Manager service:

```
Argument of type 'NoneType' is not iterable.
```

Resolution

This is a known limitation so do not attempt restore 2.9.0 (kopia) based backups to a lower version 2.8.x (restic).

IBM Cloud Limitations with OADP DataMover

Problem statement

Backups of raw volumes fail for IBM Cloud with OADP 1.4.0 or lower.

Cause

The OADP 1.3 or higher expose the volume of the underlying host during backup or restore. The folders on the host are exposed in the Pods that are associated with the Daemonset node-agent. The `/var/lib/kubelet/{plugins,pods}` folder is exposed by default. The folders required to work on IBM Cloud are `/var/data/kubelet/{plugins,pods}`. As a result, the backup and restore of volumeMode: block volumes fail with the following example error:

```
Failed transferring data
```

```
[BMYBR0009] (https://ibm.com/docs/SSFETU_2.9/errorcodes/BMYBR0009.html) There was an error when processing the job in the Trans
```

The ID of the individual DataUpload varies for jobs.

Resolution

1. Set the DataMover type to **legacy** by either the global method or the Per PolicyAssignment method. For the procedure to update the type, see [Configure DataMover type for Backup and Restore](#).

Though this workaround allows continued use of DataMover **kopia** type, it has the following drawbacks:

It disables further changes to DataMover and Velero configurations, such as the ability to change resource allocations (CPU, Memory, and Ephemeral-storage) and nodeSelectors (datamover node placement) for Datamover type **kopia**.

Legacy is not affected by this workaround.

To avoid job failures, do not make these changes while a backup or restore job is in progress.

2. In the OpenShift® Console, go to Workloads, > Deployments.
3. Select **openshift-adp-controller-manager** and scale the number of Pods to 0.
4. Go to Workloads, > Daemonsets and select node-agent.
5. Select the YAML tab.
6. Under the volumes section, add the additional volume **host-data** as shown in the following example.
Note: It exposes an additional folder on the host other than the folders mention in the Cause of this issue.

```
volumes:
- name: host-pods
  hostPath:
    path: /var/lib/kubelet/pods
    type: ''
- name: host-plugins
  hostPath:
    path: /var/lib/kubelet/plugins
    type: ''
- name: host-data
  hostPath:
    path: /var/data/kubelet
    type: ''
- name: scratch
  emptyDir: {}
- name: certs
  emptyDir: {}
```

- Under `volumeMounts`, add the `host-data` volume as shown in the following example.

```
volumeMounts:
- name: host-pods
  mountPath: /host_pods
  mountPropagation: HostToContainer
- name: host-plugins
  mountPath: /var/lib/kubelet/plugins
  mountPropagation: HostToContainer
- name: host-data
  mountPath: /var/data/kubelet
  mountPropagation: HostToContainer
- name: scratch
  mountPath: /scratch
- name: certs
  mountPath: /etc/ssl/certs
```

- Save the changes and wait for a couple minutes for the Pods to restart.
The backups and restores of PersistentVolumeClaims with `volumeMode: block` succeeds on Red Hat® OpenShift of IBM Cloud.

Restore fails on IBM Power Systems

Restore failures are observed in a IBM Power Systems environment. If you have cluster(s) running on IBM Power Systems, do not upgrade the Backup & Restore service to 2.8.1 instead contact [Contact IBM Support](#).

exec format error

Problem statement

Sometimes, you may observe the following error message:

```
"exec <executable name>": exec format error
```

For example:

```
The pod log is empty except for this message: exec /filebrowser
```

The example error can be due to the wrong architecture of the container. For example, an amd64 container on s390x nodes or an s90x container on amd64 nodes.

Resolution

As a resolution, check whether the container that you want to restore and the local node architecture match.

Restore of namespaces that contains admission webhooks fails

Problem statement

Restore of namespaces that contains admission webhooks fails.

Example error in IBM Fusion restore job:

```
"Failed restore <some resource>" "BMYBR0003
RestorePvcsFailed There was an error when processing the job in the Transaction Manager
service"
```

Example error in Velero pod:

```
level=error msg="Namespace
domino-platform, resource restore error: error restoring
certificaterequests.cert-manager.io/domino-platform/hephaestus-buildkit-client-85k2v:
Internal error occurred: failed calling webhook "webhook.cert-manager.io": failed to call
webhook: Post "https://cert-manager-webhook.domino-platform.svc:443/mutate?timeout=10s\\":
service "cert-manager-webhook" not found"
```

Resolution

- Identify the admission webhooks that is applicable to the namespace being restored:

```
oc get mutatingwebhookconfigurations
oc describe mutatingwebhookconfigurations
```

- Change the failure Policy parameter from **Fail** to **Ignore** to temporarily disable webhook validation prior to restore:

```
failurePolicy: Ignore
```

Restore before upgrade fails with a BMYBR0003 error

Problem statement

When you try to restore backups before upgrade, it fails with a BMYBR0003 error.

Diagnosis

After you upgrade, your jobs may fail:

- Backup jobs with the status:

```
"Failed transferring data" "BMYBR0003 There was an error when processing the job in the Transaction Manager service"
```

- Restore jobs with the status:

```
"Failed restore <some resource>" "BMYBR0003 There was an error when processing the job in the Transaction Manager service"
```

Confirm the issue in the logs of the manager container of the Data Mover pod.

A sample error message:

```
2023-07-26T03:39:47Z ERROR Failed with error. {"controller": "guardiancopyrestore", "controllerGroup": "guardian.isf
github.ibm.com/ProjectAbell/guardian-dm-operator/controllers/util/Retry
/workspace/controllers/util/utls.go:39
github.ibm.com/ProjectAbell/guardian-dm-operator/controllers/kafka.(*kafkaWriterConnection).PublishMessage
/workspace/controllers/kafka/kafka_native_connection.go:71
github.ibm.com/ProjectAbell/guardian-dm-operator/controllers.(*GuardianCopyRestoreReconciler).updateOverallCrStatus
/workspace/controllers/status.go:191
github.ibm.com/ProjectAbell/guardian-dm-operator/controllers.(*GuardianCopyRestoreReconciler).doRestore
/workspace/controllers/guardiancopyrestore_controller.go:187

/go/pkg/mod/sigs.k8s.io/controller-runtime@v0.14.6/pkg/internal/controller/controller.go:122
sigs.k8s.io/controller-runtime/pkg/internal/controller.(*Controller).reconcileHandler
/go/pkg/mod/sigs.k8s.io/controller-runtime@v0.14.6/pkg/internal/controller/controller.go:323
sigs.k8s.io/controller-runtime/pkg/internal/controller.(*Controller).processNextWorkItem
/go/pkg/mod/sigs.k8s.io/controller-runtime@v0.14.6/pkg/internal/controller/controller.go:274
sigs.k8s.io/controller-runtime/pkg/internal/controller.(*Controller).Start.func2.2
/go/pkg/mod/sigs.k8s.io/controller-runtime@v0.14.6/pkg/internal/controller/controller.go:235
```

Resolution:

Search for the `guardian-dm-controller-manager` and kill it. A new pod starts in a minute. After the pod reaches a healthy state, retry backup and restores.

"Failed restore snapshot" error occurs with applications using IBM Storage Scale storage PVCs

- A "Failed restore snapshot" error occurs with applications using IBM Storage Scale storage PVCs.

Cause

The "disk quota exceeded" error occurs whenever you restore from an object storage location having applications that use IBM Storage Scale PVC with a size less than 10 GB.

Resolution

Increase the IBM Storage Scale PVC size to a minimum of 10 GB and do a backup and restore operation.

Restore to a cluster that does not have an identical storage class as the source cluster

You cannot restore to a cluster that does not have an identical storage class as the source cluster. However, the transaction manager still attempts to create PVCs with the non-existent storage class on the spoke cluster and eventually fails with **Failed restore snapshot** status.

Applications page does not show the details of the application

Problem statement

The new backed up applications page does not show the details of the application when you upgrade IBM Fusion to the latest version while leaving the Backup & Restore service in the older version.

Resolution

As a resolution, it is recommended to upgrade the Backup & Restore service to the latest version after an IBM Fusion upgrade.

S3 buckets must not enable expiration policies

Backup & Restore currently uses restic to move the Velero backups to repositories on S3 buckets. When a restic repository gets initialized, it creates a configuration file and several subdirectories for its snapshots. As restic does not update it after initialization, the modification timestamp of this configuration file is never updated.

If you configure an expiration policy on the container, the restic configuration objects get deleted at the end of the expiration period. If you have an archive rule set, the configuration objects get archived after the time defined in the rule. In either case, the configuration is no longer accessible and subsequent backup and restore operations fail.

Note: The S3 buckets must not enable expiration policies. Also, the bucket must not have an archive rule set.

Virtual machine restore failure

Problem statement

By default, the VirtualMachineClone objects are not restored due to the following unexpected behavior:

- If you create a VirtualMachineClone object and delete the original virtual machine, then the restore fails because the object gets rejected.
- If you create a VirtualMachineClone object and then delete the clone virtual machine, then the restore fails because the Virtualization ignores the `status.phase` "Succeeded" and clones the virtual machine again. As a result, the clone gets re-created every time you delete it.
- If you create a VirtualMachineClone and then do a backup with the original and clone virtual machine, the restore fails because it ignores the `status.phase` "Succeeded" and tries to clone again to the virtual machine that exists. The OpenShift Virtualization creates a snapshot of the original VirtualMachine, which adds an unwanted VirtualMachineSnapshot and a set of associated VolumeSnapshots after restore whose name starts with "tmp-". The clone operation does not complete and remains stuck in "RestoreInProgress" state because the requested VirtualMachine exists in the VirtualMachineClone.

Resolution

As a resolution, force the restore of the VirtualMachineClone objects by explicitly including it in the Recipe.

Change the OADP `DataProtectionApplication` object "velero" and add in the `spec.configuration.velero.args.restore-resource-priorities` field as follows:

```
velero:
  args:
    restore-resource-priorities:
"securitycontextconstraints,customresourcedefinitions,namespaces,managedcluster.cluster.open-cluster-
management.io,managedcluster.clusterview.open-cluster-management.io,kubernetesaddonconfig.agent.open-cluster-
management.io,managedclusteraddon.addon.open-cluster-
management.io,storageclasses,volumesnapshotclass.snapshot.storage.k8s.io,volumesnapshotcontents.snapshot.storage.k8s.io,vo
lumesnapshots.snapshot.storage.k8s.io,datauploads.velero.io,persistentvolumes,persistentvolumeclaims,serviceaccounts,secre
ts,configmaps,limitranges,pods,replicasets.apps,clusterclasses.cluster.x-
k8s.io,endpoints,services,-,clusterbootstraps.run.tanzu.vmware.com,clusters.cluster.x-
k8s.io,clusterresourcesets.addons.cluster.x-k8s.io,virtualmachines.kubevirt.io,virtualmachineclones.clone.kubevirt.io"
```

Service recovery involving a large number of CRs

Problem statement

When service recovery processes a large number of CRs, service discovery may fail after you add the backup storage location.

Resolution

1. Check whether `backup-location` pod is evicted due to the ephemeral storage limit exceeded.
2. If no `backup-location` pod is evicted, check the logs of backup-location pod for any of the following messages:
 - Processing service protection discovery was successful
 - Processing service protection discovery failed
 - Error processing service protection discovery

If you do not see any of these messages, then the service discovery may be still in running state.

3. If the `backup-location` pod restarts because of ephemeral storage limit, update the resources of backup location deployment temporarily. Increase the ephemeral storage limit from 512 Mi to 1 Gi, and the memory limit from 512 Mi to 2 Gi. These limits must be changed back after the service discovery completes populating the service backups that are available for restore.

```
oc set resources deployment backup-location-deployment --limits=ephemeral-storage=1Gi,memory=2Gi -n <backup-restore-namespace>
```

4. After the service discovery completes, search the `backup-location` pod logs for the following message, which includes the number of resources found in the latest, recoverable service backup:

```
Restic backup validation processed
```

Example resources:

- 363 Application CRs
- 40 Fusion BackupStorageLocation CRs
- 385 Secrets for BackupStorageLocation CRs
- 25 BackupPolicy CRs
- 565 PolicyAssignment CRs
- 12126 Backup CRs

Note: There may be more than one such message if service backups are not suitable for recovery, such as containing no Backup CRs.

For more information about Backup & Restore Hub performance and scaling, see [Backup & restore hub performance and scaling](#).

5. Update the resources of the transaction manager to temporarily increase the memory limit from 500 Mi to 2 Gi. For example:

```
oc set resources deployment transaction-manager --limits=memory=2Gi -n <backup-restore-namespace>
```

6. Update the resources of backup services to temporarily increase the number of replicas. For example, 8 for the previous step example, and increasing the memory limit from 1 Gi to 2 Gi.

```
oc set resources deployment backup-service --limits=memory=2Gi -n <backup-restore-namespace>
```

Sample output:

```
The following command isn't working; scale the number of replicas in OpenShift UI.
oc scale deployment backup-service --replicas=8 -n <backup-restore-namespace>
```

7. Update the resources of mongodb based on the number of CRs to be processed. In this example, temporarily increase the CPU limit to 4 and the memory limit to 4 Gi.

```
oc set resources sts mongodb --limits=cpu=4,memory=4Gi -n <backup-restore-namespace>
```

8. Update the resources of velero resources. Modify the `DataProtectionApplication` CR named Velero:

```

velero:
  customPlugins:
    - image: 'cp.icr.io/cp/fbr/guardian-kubevirt-velero-
plugin@sha256:bce6932338d8e2d2ce0dcca2c95bdfa8ab6e337a758e039ee91773f3b26ceb06'
      name: isf-kubevirt
  defaultPlugins:
    - openshift
    - aws
  noDefaultBackupLocation: false
  podConfig:
    labels:
      app.kubernetes.io/part-of: ibm-backup-restore
    resourceAllocations:
      limits:
        cpu: '2'
        ephemeral-storage: 500Mi
        memory: 2Gi
      requests:
        cpu: 200m
        ephemeral-storage: 275Mi
        memory: 256Mi

```

In this example, update the ephemeral-storage limit from 500Mi to 1Gi.

9. Wait for all pods that were modified to restart and be in running state.

Note: After the service recovers successfully, it may take time for the services to process the restored CRs.

10. Wait for all of the backup storage locations to be connected.

11. Check the backup service pods to determine if any CRs are still in progress.

12. After processing completes, revert the resources to their original values or adjust them based on the expected number of concurrent jobs.

More than one BackupRepository found for workload namespace

Problem statement

When you restore a namespace with multiple PVCs, the restore job might fail with the following error message:

```
error to initialize data path: error to ensure backup repository <repo>: failed to wait BackupRepository, errored early: more
```

Cause

It is due to a race condition during the creation of the Backup repository.

Resolution

To work around the problem, clean the restored namespaces and try again.

IBM Software Hub backup and restore issues

This section lists the troubleshooting tips and tricks during backup and restore of IBM Software Hub.

Original namespace as destination for IBM Software Hub application

Problem statement

OpenShift® restore from IBM Storage Protect Plus does not force you to select the original namespace as destination for IBM Software Hub application.

Impact

From IBM Storage Protect Plus user interface, IBM Software Hub restore fails whenever you do not select the original namespace as the target destination to restore to.

Resolution

Whenever you restore IBM Software Hub from IBM Storage Protect Plus user interface, ensure that you select the original namespace as the restore destination.

These steps are applicable while you backup and test restore of IBM Software Hub applications. For more information about the procedure, see

https://www.ibm.doc/docs/en/SSQNUZ_4.5_test/cpd/admin/online_bar_fusion_spp.html.

Tethered namespace issues

Problem statement

For IBM Software Hub Application type, you can tether secondary or other namespaces to the primary IBM Software Hub platform namespace. However, after a successful restore, the IBM Fusion application associated with the IBM Software Hub namespace does not restore the tethered namespace.

Resolution

1. Uninstall `cpdbr-oadp` and reinstall it.
2. After you add the tethered namespaces, restart the `isf-application-controller-manager` -xxxx pod that is within the `ibm-spectrum-fusion-ns` to force a reconcile..
3. In about five minutes, run the following command to verify whether the `fapp` is updated to include the tethered namespace in `spec.includedNamespaces`

```
oc get fapp -n ibm-spectrum-fusion-ns cpd-instance -o yaml
```

IBM Software Hub backup of zen namespace fails partially in IBM Storage Protect Plus user interface

Problem statement

For an on-demand backup of a single application from a policy that has multiple applications assigned, a snapshot backup is taken only for that selected application but the copy backup is initiated for all of the applications assigned to the policy. This behavior causes the copy backup of the applications without a snapshot backup to fail. This issue does not impact the application selected for the ad-hoc backup.

Backup fails for the platform with error in EDB Postgres cluster

Cause

Labels and annotations in the EDB Postgres cluster resources were not updated after a switchover of the EDB Postgres cluster's primary instance and replica.

Diagnosis

For example, in IBM Fusion, the backup fails at the **Hook: br-service hooks/pre-backup** stage in the backup sequence.

In the `cpdbr-oadp.log` file, you see the following error:

```
time=<timestamp> level=info msg=cmd stderr: Error: cannot take a cold backup of the primary instance or a target primary instance if the k8s.enterprisedb.io/snapshotAllowColdBackupOnPrimary annotation is not set to enabled
```

Resolution

The following workaround will automatically run before you create a backup. This workaround is useful if you set up automatic backups.

Note: This resolution works only for online backup and restore.

1. [Download the edb-patch-aux-ckpt-cm.yaml file.](#)

2. Run the following command:

```
oc apply -n ${PROJECT_CPD_INST_OPERATORS} -f edb-patch-aux-ckpt-cm.yaml
```

3. Retry the backup.

Hub and spoke connection issues

Procedure to debug issue in the hub and spoke connections. Backup & Restore service uses connection CR to setup hub and spoke connection.

You might encounter an error when you attempt setup connections between clusters.

Bootstrap token in init secret is not correct or expired: Unauthorized

Problem statement

Connection setup fails with the following message in the connection CR:

```
apiVersion: application.isf.ibm.com/v1
kind: Connection
metadata:
  name: <connection-name>
  namespace: <connection-namespace>
spec:
  remoteCluster:
    apiEndpoint: <cluster api endpoint>
    connectionOperatorNamespace: <connection-namespace>
    heartBeatInterval: 10m
    initSecretName: <init-secret-name>
status:
  conditions:
    - lastTransitionTime: '2023-06-15T02:31:01Z'
      message: 'Bootstrap token in init secret is not correct or expired: Unauthorized'
      reason: CreateBootstrapSecret
      status: 'False'
      type: BootstrapSecretAvaliable
  connectionFromRemoteClusterHealth:
    message: ''
    messageCode: ''
    messageType: ''
  connectionState: Failed
  connectionToRemoteClusterHealth:
    message: ''
    messageCode: ''
    messageType: ''
```

Cause

The bootstrap token in the `init` secret is not correct or expired.

Resolution

1. Get the bootstrap token again.

```
oc create token isf-application-operator-cluster-bootstrap -n <connection-namespace>
```

2. Replace the token in `init` secret:

```
oc edit secret <init-secret-name> -n <connection-namespace>
```

CA certificate of peer cluster is not correct

Problem statement

The CA certificate of peer cluster is not correct error occurs in connection CR.

Cause

The CAcert in the configmap `kube-root-ca.crt` in namespace `kube-public` of the remote cluster is not correct.

Resolution

In the remote cluster, place the right CAcert in the configmap `kube-root-ca.crt` and namespace `kube-public`. Connection pkg also provides a customized configmap.

If it is not possible to place the right CAcert in configmap `kube-root-ca.crt` and namespace `kube-public`, then place the right CAcert in `custom-ca.crt` and Fusion namespace:

```
kind: ConfigMap
apiVersion: v1
metadata:
  name: custom-ca.crt
  namespace: <connection-namespace>
data:
  ca.crt: <right CAcert>
```

Backup & restore service from OpenShift Container Platform console

List of issues in the Backup & Restore managed and monitored from the OpenShift® Container Platform console.

fusion-console plugin issue

Problem statement

The OpenShift Container Platform console pod gets into panic state initially with a connection error.

Cause

This error occurs because the inter-namespace communication gets blocked between OpenShift Container Platform console pod (`openshift-console` namespace) and `fusion-console` pod (running in IBM Fusion operator install namespace).

Resolution

1. Check whether any typo exists in the *.apps definition or there is a bad name resolution.
2. If the error persists even after you fix the issue in step 1, restart the Fusion proxy pods.
3. Verify that no `NetworkPolicy/NetworkPolicies` or networking plugin configurations exist that can prevent or interfere with inter-namespace communication.

Known issue

The Fusion Native Console plugin follows the n, n-1 & n-2 support matrix of OpenShift Container Platform, where "n" is an even OpenShift Container Platform version. For example, Fusion Console 2.10 on OpenShift Container Platform 4.18 release. In case of versions that are not supported, run the following command to disable the plugin:

```
oc patch -n ibm-spectrum-fusion-ns ISFConsolePlugin isf-console --type=merge -p '{"spec":{"enabled": "false"}}'
```

Here, the `ibm-spectrum-fusion-ns` is the namespace where the IBM Fusion operator is installed.

Data Cataloging

Companies need the ability to use unstructured data to meet their business priorities.

IBM Data Cataloging is a container native modern metadata management software that provides data insight for exabyte-scale heterogeneous file, object, backup, and archive storage on premises and in the cloud. The software connects to these data sources to rapidly ingest, consolidate, and index metadata for billions of files and objects.

IBM Data Cataloging provides a rich metadata layer that enables storage administrators, data stewards, and data scientists to efficiently manage, classify, and gain insights from massive amounts of data. It improves storage economics, helps mitigate risk, and accelerates large-scale analytics to create competitive advantage and speed critical research.

Many companies face significant challenges to manage their data. Some difficult challenges that companies face include:

- Pinpointing and activating relevant data for large-scale analytics.
- Lacking the fine-grained visibility needed to map data to business priorities.
- Removing redundant, trivial, and obsolete data.
- Identifying and classifying sensitive data.

Benefits of IBM Data Cataloging

IBM Data Cataloging can help you manage your unstructured data by reducing the data storage costs, uncovering hidden data value, and reducing the risk of massive data stores. See [Table 1](#).

Table 1. Benefits of IBM Data Cataloging

Optimize - Improve storage usage	Analyze - Uncover hidden data value	Govern - Mitigate risk and improve data quality	Data Management
----------------------------------	-------------------------------------	---	-----------------

Optimize - Improve storage usage	Analyze - Uncover hidden data value	Govern - Mitigate risk and improve data quality	Data Management
Decreases storage capital expenditure (CapEx) by facilitating data movement to colder, cheaper storage.	Accelerates data identification for large-scale analytics.	Perform data inspection and classification.	Automate tags for custom insight.
Increases storage efficiency by eliminating trivial or redundant data.	Operationalize tasks to reduce the burden of data preparation.	Helps ensure that data is compliant with governance policies by labeling sensitive data.	Create reports for analysis.
Reduces storage operating expenditure (OpEx) by improving storage administrator productivity.	Orchestrates the ML/DL and Platform Symphony® MapReduce process.	Helps reduce risk that is hidden in heterogeneous data sources.	GUI search for real-time results Search content for fast discovery.

IBM Data Cataloging architecture

IBM Data Cataloging is an extensible platform that provides exabyte scale data ingest, data visualization, data activation, and business-oriented data mapping.

Note: All references to "Spectrum Discover" in the images refer to "Data Cataloging".

Exabyte-scale data ingest

- Scan billions of files and objects in a day
- Real-time event notifications
- Automatic indexing

Data Visualization

- Fast queries of billions of records
- Multi-faceted search
- Drilldown Dashboard

Data Activation

- Application software development kit (SDK)
- Extensible architecture
- Solution blueprints

Business-oriented data mapping

- System-level data tagging
- Contextual data tagging
- Policy-driven workflows

The following figure illustrates a high-level view of the IBM Data Cataloging architecture.

Figure 1. IBM Data Cataloging architecture

IBM Fusion Data Cataloging

Data management

IBM Data Cataloging connects to the data sources shown in the architecture image (*IBM Data Cataloging architecture*), and automatically harvests and indexes the system metadata where the system metadata refers to certain information. This might include the following information.

- It might include the names of the files and objects.
- It might include the bucket or path where the data resides.
- It might include the size.
- It might include the time the data sources were last modified.

After the data is ingested, analytics are automatically applied to classify and group the data according to the different system metadata attributes. The data can be inspected automatically in IBM Data Cataloging by using built-in content search capabilities to identify sensitive and personally identifiable information and perform data classification. The content inspection capabilities can also be used by researchers and data scientists to extract content from their data sets. This easy-to-use extraction ability assists with data discovery.

The records that are maintained by IBM Data Cataloging can also be further enriched with custom metadata tags that map the data to business constructs and further increase the value of the data.

You can use IBM Data Cataloging catalog to gain insight about your data and to find your data.

The IBM Data Cataloging architecture also supports a community-supported catalog of open source applications that enhance and customize the capabilities of IBM Data Cataloging with third-party extensions. Users can find and install available applications and can develop and share new applications that use an SDK that contains sample code and a fully published API. For more information, see [Creating your own applications to use in the Data Cataloging application catalog](#). For more information, see the topic *Creating your own applications to use in the IBM Data Cataloging application catalog* in the Administration section.

Figure 2. Application SDK architecture

- [Role-based access control](#)

IBM Data Cataloging provides access to resources based on roles. You can restrict access to information based on roles.

- [Data source connections](#)
A data source connection specifies the parameters for cataloging of metadata from a source system to IBM Data Cataloging.
- [Cataloging metadata](#)
System metadata is created and updated by the host system, and not the application software. IBM Data Cataloging allows the addition of tags that can capture non-system metadata-specific attributes, which are stored in the IBM Data Cataloging catalog.
- [Enriching metadata](#)
IBM Data Cataloging can enrich the metadata from supported platforms with additional information by using policies, content inspection, custom tags, and custom applications.
- [Graphical user interface](#)
The IBM Data Cataloging graphical user interface is a portal that is used for running data searches, report generation, policy and tag management, and user Access Management. Based on a user's role, they might have access to one or more of these areas.
- [Reports for IBM Data Cataloging](#)
Reports for IBM Data Cataloging are grouped or non-grouped. Grouped reports have information for count and sum in columns and non-grouped reports have information in rows.

Role-based access control

IBM Data Cataloging provides access to resources based on roles. You can restrict access to information based on roles.

The role that is assigned to a user or group determines the privileges for that user or group. Users and groups can be associated with collections, which use policies that determine the metadata that is available to view.

User and group access can be authenticated by IBM Data Cataloging, an LDAP server, or the IBM Cloud® Object Storage System. The administrator can manage the user access functions.

Roles

Roles determine how users and groups access records or the IBM Data Cataloging environment.

Remember: If a user or group is assigned to multiple roles, the least restrictive role is applicable.

For example, if you are assigned the role of Data User, and you are also assigned the role of a Data Admin, you have the privileges of a Data Admin.

Admin

An admin can create users, groups, collections, manage LDAP, and IBM Cloud Object Storage connections for user access management.

Data Admin

Users with the Data Admin role can access all metadata that is collected by IBM Data Cataloging and is not restricted by collections.

Collection Admin

The Collection Admin role is as a bridge between the Data Admin role and the Data User role.

- Users with the Collection Admin role can list any type of tag and create or modify **Characteristic** tags. Users with the Collection Admin role cannot create, modify, or delete **Open** and **Restricted** tags. These permissions are the same permissions as the Data User role.
Note: The built-in **Collection** tag is a special tag that can be set only by users with the Data Admin role. All other tags can be set by any user with the Data User or Data Admin or Collection Admin role.
- Users with the Collection Admin role can
 - Create, update, and delete the policies for the collections they administer.
 - View, update, and delete policies of data users for the collections they administer. They cannot delete a policy if it has a collection that they do not administer.
 - Add users to collections that they administer. These data users can access a particular collection, which means that they can access the records that are marked with that collection value.

Collection User

Users with this role can access metadata that is collected by IBM Data Cataloging, but metadata access can be restricted by the collections that are assigned to users in this role.

- Users assigned with the Collection User role can:
 - Run scans of collections the user is assigned.
 - View policies of the collections the user is assigned.
 - List any type of tag.
- Users assigned with the Collection User role cannot:
 - Create, update, and delete any policies.
 - Create, modify, and delete any tags.

Data User

Users with the Data User role can access metadata that is collected by IBM Data Cataloging. Metadata access might be restricted by policies in the collections that are assigned to users in this role. A user with the Data User role can also define tags and policies based on the collections to which the role is assigned.

Service User

The Service User role is assigned to accounts for IBM® service and support personnel.

Data source connections

A data source connection specifies the parameters for cataloging of metadata from a source system to IBM Data Cataloging.

Without the proper connection information, ingesting metadata from a connected system fails. You can use the Data Source Connections page to view connection information for the data sources that are connected to your environment.

Cataloging metadata

System metadata is created and updated by the host system, and not the application software. IBM Data Cataloging allows the addition of tags that can capture non-system metadata-specific attributes, which are stored in the IBM Data Cataloging catalog.

Scans are jobs that are scheduled or on demand, and occur at a data source level. For example, a file system or object vault. A set of metadata records is generated with each record that captures the state of an individual file or object within the data source at the time of the scan.

IBM Data Cataloging supports scanning the following data sources:

- IBM Storage Scale
- IBM Elastic Storage® Server
- IBM Cloud® Object Storage
- IBM Storage Protect
- IBM Spectrum® Archive
- Red Hat® Ceph® Storage
- NetApp Storage Solutions
- Dell EMC Isilon Scale Out Network Attached Storage
- Amazon Simple Storage Service (Amazon S3)
- NFSv3 and NFSv4
- SMB

Live event notifications are triggered by user actions on the source data. Examples are reading, writing, moving, deleting data, changing permissions, or ownership. The events generate a metadata record in real time that is stored in IBM Data Cataloging. IBM Data Cataloging supports live event notifications for the following data sources:

- IBM Cloud Object Storage
- IBM Elastic Storage Server
- IBM Storage Scale
- Red Hat Ceph Storage

With IBM Storage Scale you can enable live events to start a watch folder on the specified file system. The IBM Storage Scale watch folder works with IBM Data Cataloging to capture file system event notifications and deliver them to IBM Data Cataloging by using Kafka.

Important: If the connection from IBM Storage Scale to IBM Data Cataloging is interrupted, the watch suspends. Additionally, events are no longer captured in IBM Data Cataloging, which requires a file system rescan to capture the lost updates.

Enriching metadata

IBM Data Cataloging can enrich the metadata from supported platforms with additional information by using policies, content inspection, custom tags, and custom applications.

Policies

Policies are used to add additional information about the source data that is indexed in IBM Data Cataloging. A policy determines the set of files to add tag values to, or to send to the built-in content inspection capabilities of IBM Data Cataloging, or to a custom application through filtering criteria. The policies give you the ability to run actions one time or on a set schedule. Policies work in batches and can be paused, resumed, stopped, or restarted. You can control the load on the IBM Data Cataloging system or source storage system for content inspection policies and policies that start custom applications.

Applications

A deep inspect application extracts information from source data records and returns it to IBM Data Cataloging to be indexed. For example, by using a custom application, you might create a DEEP-INSPECT policy to extract key characteristics from files of a certain type. The characteristics are applied to the metadata records for the files in IBM Data Cataloging as custom tags and made searchable. You can search for data by name, size, and content.

You can use custom applications to extend the capabilities that are performed by IBM Data Cataloging.

- [Policy engine](#)
Policies offer a method whereby you can schedule one-time or repetitive actions on a filtered set of records.
- [Applications](#)
IBM Data Cataloging policies might contain applications in the actions parameters.

Policy engine

Policies offer a method whereby you can schedule one-time or repetitive actions on a filtered set of records.

The policy management API service is a RESTful web service that is designed to create, list, update, and delete policies. You can use a policy to initiate action on a select set of indexed documents or data. You can do a task immediately or on a set schedule.

Several types of policies that are supported by IBM Data Cataloging enrich the metadata records. You can create policies with information to determine which set of documents to run, the action to take, and when to run policies periodically.

A policy includes

Policy ID
Name of the policy.

Filter
Selects a set of documents to work.

Action
ID, parameters, and schedule.

The following list is a description of the policies.

AUTOTAG
A policy that tags a set of records based on filter criteria with a pre-defined set of tags.

CONTENT SEARCH
A policy that uses the built-in content inspection capabilities of IBM Data Cataloging to extract content from source data and index it automatically into the IBM Data Cataloging catalog.

DEEP-INSPECT
A policy that passes lists of files based on filter criteria to the analytics application that opens the source data file and extracts metadata information from it. The policy passes the data back to IBM Data Cataloging in the form of tags so you can do a search, and do the following activities:

- Set up a filter to do a search query that finds the candidates to apply the policy.
For example, you can set an action for filtered candidates AUTOTAG: **tag1: value, tag2: value**
- Set a schedule to apply the policy by specifying the following methods:
 - Immediately
 - Periodically

Applications

IBM Data Cataloging policies might contain applications in the actions parameters.

Use an application when you want to do a specific action on data or metadata on IBM Data Cataloging.

You can define an application when you create a new DEEP-INSPECT policy. You can add parameters for an application during the process of creating a DEEP-INSPECT policy.

When you open the window for applications, you can see a view of a table with the following information:

Application
The name of the application.

Parameters
The parameters that were assigned to the application when the policy was created.

Action ID
Actions that are supported by the application for enriching metadata. For example, CONTENTSEARCH, DEEP-INSPECT.

View or Delete
Use the delete trashcan icon to remove the application from the database.

Graphical user interface

The IBM Data Cataloging graphical user interface is a portal that is used for running data searches, report generation, policy and tag management, and user Access Management. Based on a user's role, they might have access to one or more of these areas.

The IBM Data Cataloging environment provides access to users and groups. The role that is assigned to a user or group determines the functions that are available. Users and groups can also be associated with collections, which use policies that determine the metadata that is available to view.

User and group access can be authenticated by IBM Data Cataloging, an LDAP server, or the IBM Cloud® Object Storage System. The administrator can manage the user access functions.

Roles

Roles determine how users and groups can access records on the IBM Data Cataloging environment.

If a user or group is assigned to multiple roles, the least restrictive role is used. For example, if a user is assigned a role of Data User, and is included in a data administrator role, the user has the privileges of a data administrator.

Dashboard

An example of the IBM Data Cataloging dashboard is shown.

Figure 1. Example of the IBM Data Cataloging dashboard

Data administrators and users can view the following:

- Metrics for the overall capacity used by every data source
- Total number of files
- Amount of capacity that is used by records with specific tags and facets, for example, owner, cluster, and size range
- Distribution of those records across data sources

Users can click any of the dashboard widgets to initiate a search and further explore and drill down into the data. Administrators and user can also perform the following:

- Monitor storage usage and data recommendations
- View total indexed data and capacity
- View duplicate file or object candidates. For example:
 - Number
 - Capacity used
- Preview capacity use by data facet. For example:
 - Classification
 - Owner
 - File type
- View data capacity by group or collection. For example:
 - Customer defined
 - Lab or project

Understanding size and capacity differences

IBM Data Cataloging collects size and capacity information:

- Size refers to the size of a file or object in bytes.
- Capacity refers to the amount of space the file or object consumes on the source storage in bytes.

For objects, size and capacity values always match. For files, size and capacity values can be different because of file system block overhead or sparsely populated files.

Note: Storage protection overhead (such as RAID values or erasure coding) and replication overhead are not captured in the capacity values.

Reports for IBM Data Cataloging

Reports for IBM Data Cataloging are grouped or non-grouped. Grouped reports have information for count and sum in columns and non-grouped reports have information in rows.

Data Curation Reports are a way for administrators, also known as data curators, to view the state of their storage environment in different ways. They can range from high-level grouped information to individual record level information.

For example, you can sort a report by owner, project, and department, or you can generate a list of records that meet a specific criterion. Additionally, you can create a report that lists the records in a project, not been reviewed for over a year. The owner of the data can evaluate whether to archive or delete the report.

For more information, see [Reports](#) in *Data Cataloging: Administration Guide*.

For more information, see [REST API for IBM Data Cataloging](#). For more information, see *REST API* in the *IBM Data Cataloging: REST API Guide*.

Installing IBM Data Cataloging

IBM Data Cataloging service is a modern metadata management software that provides data insight for exabyte-scale heterogeneous file, object, backup, and archive storage on premises and in the cloud. It can help you manage your unstructured data by reducing the data storage costs, uncovering hidden data value, and reducing the risk of massive data stores.

Before you begin

- Meet the system requirements to install the IBM Data Cataloging service.
- The following details are a base line for finding the resources that are needed for IBM Fusion IBM Data Cataloging service deployment. Based on the following tables, the resources can be estimated based on the number of approximate files that are required. The following are the resource values that are calculated per compute node: You must have at least two worker nodes, each with the same amount of resources available.
- IBM Fusion IBM Data Cataloging service must have dedicated compute resources. Ensure that you have enough to cover the resources limits to perform as expected:

Table 1. Profile requirements

CPU	RAM	Disk space	Network	Storage	Workload
77	162 GB	120 GB	10 GB	1 TB	1 B

- The standard deployment for IBM Data Cataloging service project requests and limits. Ensure you set the resource quota values for IBM Data Cataloging as follows:

```
kind: ResourceQuota
apiVersion: v1
metadata:
  name: dcs-resource-quota
  namespace: ibm-data-cataloging
spec:
  hard:
    limits.cpu: '72'
    limits.memory: 115Gi
    pods: '120'
    requests.cpu: '18'
    requests.memory: 26Gi
```

- Important: For the IBM Data Cataloging service to run successfully on all platforms, ensure that the storage classes have the following attributes:
 - ReadWriteMany (RWX) permissions
 - volumeBindingMode set to Immediate
 - AllowVolumeExpansion set to true
- If you have not configured the IBM operator catalog, then configure it. For the procedure to add IBM operator catalog, see [Adding the IBM operator catalog](#).
- Go through troubleshooting information related to the installation of IBM Data Cataloging. See [IBM Data Cataloging service installation and upgrade issues](#).

Procedure

1. Go to Services page in IBM Fusion or IBM Fusion HCI user interface.
2. In the Available section, click Data cataloging tile.
3. In the Data cataloging window, go through the details of the service and click Install.
4. In the Install service message box, select a Storage class.

Important:

- If you want to use Global Data Platform as the storage provider, then it is recommended to select the default storage class **ibm-spectrum-fusion**. Otherwise, if you want to use Fusion Data Foundation, then select the **ocs-storagecluster-cephfs** storage class. You can also use a custom storage class that matches the requirements.
- For deployments operating in FIPS mode, you must specify or select a **storage class** that uses **encrypted storage**.
 - If the default storage classes (**ibm-spectrum-fusion** or **ocs-storagecluster-cephfs**) are **FIPS-compliant** and use encrypted storage, you can continue to use them.
 - If not, you must configure and select a custom encrypted storage class that meets FIPS requirements.
 - For storage based on node SSDs, ensure the SSDs are encrypted at deployment time using encryption methods that meets FIPS requirements.
 - For storage based on Red Hat® OpenShift® Data Foundation, configure encrypted Red Hat OpenShift Data Foundation storage and use a storage class from that encrypted pool.

5. Click Install. In case of failures, go through the downloaded logs to understand the cause of the failure and fix the issue. For more information about service issues in IBM Fusion, see [IBM Data Cataloging service installation and upgrade issues](#).
6. Validate the installation.

- IBM Fusion user interface:

After you enable the IBM Data Cataloging service, you can view the service version and health status. From the ellipsis menu, you can download logs and view documentation. After you successfully collect the logs, a success notification gets displayed. The notification disappears automatically after some time.

Table 2. Health states IBM Data Cataloging service

State	Description
Installing	Service installation is in progress
Upgrading	Service upgrade is in progress
Healthy	Service is healthy
Degraded	Service is not healthy

- Verify the IBM Data Cataloging installation from the OpenShift Container Platform web console:

- Run the following command to verify the installed operators.

```
oc -n ibm-data-cataloging get csv
```

Expected output

NAME	DISPLAY	VERSION	REPLAC
amqstreams.v2.3.0-1	Red Hat Integration - AMQ Streams	2.3.0-1	amqstr
db2u-operator.v3.1.0	IBM Db2	3.1.0	
ibm-spectrum-discover-operator.v210.0.0	IBM Storage Discover	210.0.0-1678324770	

- Run the following command to verify IBM Data Cataloging status.

```
oc -n ibm-data-cataloging get isd
```

Expected output

NAME	READY	SUMMARY	ERROR	AGE	HEALTHSTATUS
data-cataloging-service-instance	True	Awaiting next reconciliation		9d	Healthy

- Run the following command to verify that all Persistent Volume Claims are bounded.

```
oc -n ibm-data-cataloging get pvc
```

Expected output

- Run the following command to verify that workload is PUREDATA_OLAP.

```
oc exec -n ibm-data-cataloging -c db2u -it $(oc -n ibm-data-cataloging get po --no-headers --show-labels=true --selector name=dashmpp-head-0 | awk '{print $1}') -- sudo su - db2inst1 -c "db2set -all | grep DB2_WORKLOAD= | awk '{print \$2}'"
```

Expected output

DB2_WORKLOAD=PUREDATA_OLAP

- Run the following command to verify the database encryption configurations.

```
oc -n ibm-data-cataloging exec -c db2u $(oc -n ibm-data-cataloging get po --no-headers --show-labels=true --selector name=dashmpp-head-0 | awk '{print $1}') -- su - db2inst1 -c "db2 get db cfg for bludb | grep 'Encrypted database'"
```

Encrypted database = YES

- Run the following command to verify the Kafka CRs readiness.

```
oc -n ibm-data-cataloging get kafka
```

Expected output

NAME	DESIRED KAFKA REPLICAS	DESIRED ZK REPLICAS	READY	WARNINGS
isd-sasl	1	1	True	
isd-ssl	1	1	True	

- Run the following command to verify that the IBM® Spectrum Discover pods are running.

```
oc -n ibm-data-cataloging get pod -l component=discover
```

Expected output

console	console-ibm-data-cataloging.apps.ocp2.vmlocal		isd-svc	<all>	reencrypt	None

Uninstalling IBM Data Cataloging

Steps to uninstall IBM Data Cataloging by using command line interface.

Procedure

1. Run the following command and export IBM Fusion namespace as an environmental variable.

```
export FUSION_NS="<Fusion namespace>"
```

Important: Replace <Fusion namespace> with your namespace.

2. Run the following command to prevent catalog source creation.

```
oc -n ${FUSION_NS} patch fusion servicedefinition data-cataloging-service-definition --type='json' -p='[{"op": "replace", "path": "/spec/onboarding/serviceOperatorSubscription/triggerCatSrcCreate", "value": false}]'
```

3. Run the following command to scale down prerequisite operator.

```
oc -n ${FUSION_NS} scale --replicas=0 deployment/isf-prereq-operator-controller-manager
```

4. Run the following commands to delete all the IBM Data Cataloging workload, networking and storage resources.

```
oc project default
export DCS_CR=$(oc get SpectrumDiscover -n ibm-data-cataloging -o jsonpath="{.items[*].metadata.name}")
oc delete SpectrumDiscover ${DCS_CR} -n ibm-data-cataloging --timeout=2m --wait=true
oc delete project ibm-data-cataloging --timeout=1m --wait=true
```

5. Run the following command to delete the IBM Fusion IBM Data Cataloging service instance object.

```
oc -n ${FUSION_NS} delete fusion serviceinstance data-cataloging-service-instance
```

6. Run the following command to delete the `SecurityContextConstraints` objects.

Important: The SCC objects are based on their namespace, and the namespace must be included in the name of the SCC object. The default namespace is `ibm-data-cataloging`, but you must change it if you use a different one.

```
oc delete securitycontextconstraints/isd-scc-ibm-data-cataloging
oc delete securitycontextconstraints/ibm-data-cataloging-c-isd-scc
```

7. Run the following command to delete the IBM Data Cataloging `ConsoleLink` object.

```
oc delete consolelink/data-cataloging
```

8. Run the following command to delete IBM Data Cataloging `CustomResourceDefinitions` from the cluster.

```
oc delete customresourcedefinition/spectrumdiscovers.spectrum-discover.ibm.com
oc delete customresourcedefinition/spectrumdiscoverapplications.spectrum-discover.ibm.com
```

9. Run the following command to scale up prerequisite operator.

```
oc -n ${FUSION_NS} scale --replicas=1 deployment/isf-prereq-operator-controller-manager
```

Configuring IBM Data Cataloging

This section provides information on how to deploy and configure IBM Data Cataloging capabilities.

- [Setting up IBM Data Cataloging custom user and password](#)
Use this information to create a custom user and password for the IBM Data Cataloging service.
- [Configure data source connections](#)
Data source connections describe the source data systems for which IBM Data Cataloging indexes metadata.
- [Editing and using the TimeSinceAccess and Size Range buckets](#)
Users can group or aggregate data into three user-defined bucket ranges. The three user-defined bucket ranges are TimeSinceAccess, Size Range and FileGroup.
- [IBM Spectrum Storage software requirements](#)
Use IBM Data Cataloging to index metadata from other applications and to orchestrate the data management.
- [IBM Data Cataloging installation with alternative VLAN](#)
Install and configure IBM Data Cataloging that uses additional VLAN connected through the IBM Fusion upstream links.
- [Multiple connection managers](#)
Multiple connection managers are a new capability that is designed to enhance scanning performance and enable parallel ingestion. It proves especially valuable in scenarios where data sources are geographically dispersed and need to be scanned as remote sources.
- [Enabling feature for skipping the snapshot directories](#)
When the skipping feature is enabled, you can skip the metadata ingestion to the snapshot directories.
- [Managing IBM Data Cataloging rules when integrated with CAS](#)
IBM Data Cataloging provides the ability to integrate with Content-Aware Storage to configure file ingestion filtering. This feature enables you to filter files from a data source based on specific criteria, such as file type or content, and ingest them into the corresponding domain.

Setting up IBM Data Cataloging custom user and password

Use this information to create a custom user and password for the IBM Data Cataloging service.

About this task

It is required to perform this procedure before installation to prevent errors caused by the user being already initialized with the default values.

Procedure

1. Run the following command to create the `ibm-data-cataloging` namespace.

```
oc create namespace ibm-data-cataloging
```

2. Run the following command to create the keystone secret to hold the custom user and password.

```
oc -n ibm-data-cataloging create secret generic keystone --from-literal=user=<CUSTOM_USER> --from-literal=password=<CUSTOM_PASSWORD>
```

3. Deploy the IBM Data Cataloging service from the IBM Fusion user interface.

Configure data source connections

Data source connections describe the source data systems for which IBM Data Cataloging indexes metadata.

Creating data source connections in IBM Data Cataloging identifies source storage systems that are to be indexed by IBM Data Cataloging.

For some data source types, a network connection is (optionally) created to allow for automated scanning and indexing of the source system metadata. IBM Data Cataloging will not index data from unknown sources, so creating a data source connection is the first step towards cataloging any source storage system.

Remember: Depending on when the scan is stopped, stopping a running scan might result in an inconsistent database state for the connection.

You can add data connections to the source storage systems from the IBM Data Cataloging graphical user interface and REST API. For more information on configuring data source connections offline, see [Configuring data source connections offline](#). *Configuring data source connections offline* in the *IBM Data Cataloging: Concepts, Planning, and Deployment Guide*.

IBM Data Cataloging discards any data that comes in from an unknown connection. Therefore, connections must be established before data ingestion. To see the list of defined connections, use the Connections tab under the Data source management window of the GUI.

Remember: If you use a MAC, you might have to adjust the scroll bar settings in System Settings to see all available connection types. For example, activate the Show scroll bars: Always option.

Typically, a data source is equivalent to a single file system or object vault or bucket. A data source connection is an alias for the combination of a cluster name and a data source within the cluster. This allows multiple file systems or buckets or vaults with the same name to be indexed by IBM Data Cataloging when they are in separate clusters.

Remember:

- IBM Data Cataloging does not support file or file path names that use characters that are not part of the UTF-8 character set.
- After you do a manual scan, run a Metadata summarization database refresh:
 1. In Data source management > Metadata summarization database, go to Data connections > Discover information.
 2. Click refresh and wait for the process to complete successfully. The expected time of completion is based on the amount of records to process. For example, 30 minutes.
- [IBM Storage Scale data source connections](#)
You can create an IBM Storage Scale data source connection, scan a data source, and manually initiate a scan.
- [IBM Storage Archive data source connections](#)
You can define tags and policies in IBM Data Cataloging based on values that are derived from IBM Spectrum® Archive metadata to help in searching and categorizing files.
- [IBM Cloud Object Storage data source connection](#)
You can create the IBM Cloud® Object Storage (COS) connection and initiate a scan.
- [IBM Data Cataloging and S3 object storage data source connections](#)
Use this information to understand how IBM Data Cataloging works with S3-compliant object store.
- [Scanning an Elastic Storage Server data source connection](#)
Use the IBM Data Cataloging GUI to scan an Elastic Storage Server (ESS) data connection.
- [Creating a Network File System data source connection](#)
You can use the IBM Data Cataloging graphical user interface to create a Network File System (NFS) data connection.
- [Creating an SMB data source connection](#)
Creating an SMB data connection by using the IBM Data Cataloging graphical user interface.
- [Creating an IBM Storage Protect data source connection](#)
Creating the IBM Storage Protect data connection by using the IBM Data Cataloging graphical user interface.
- [Configuring data source connections offline](#)
Multiple source data connections can be added to the IBM Data Cataloging system through offline mode.

IBM Storage Scale data source connections

You can create an IBM Storage Scale data source connection, scan a data source, and manually initiate a scan.

Tip: If the data source connection is used by the ScaleILM application to tier data by using IBM Spectrum® Archive, the `host` setting of the IBM Storage Scale connection must specify one of the IBM Storage Archive nodes. For more information, see [Tiering data by using ScaleILM application](#). For more information, see the topic *Tiering data by using ScaleILM application* in the *Data Cataloging: Administration Guide*.

IBM Data Cataloging supports the following method of scanning IBM Storage Scale data sources:

Automated scanning

A data source connection is defined on IBM Data Cataloging, including details of how to connect to the IBM Storage Scale system. IBM Data Cataloging connects to the IBM Storage Scale system by using these details, scans the file system and sends the details back to IBM Data Cataloging. For more information, see [Prerequisites for automated scanning](#). For more information, see the topic *Prerequisites for automated scanning* in the *Data Cataloging: Administration Guide*.

- [IBM Storage Scale scanning considerations](#)
The following sections comprise considerations that you need to understand to scan IBM Storage Scale effectively.
- [Prerequisites for automated scanning](#)
You can use IBM Storage Scale automated scanning features.
- [Creating an IBM Storage Scale data source connection](#)
You can use the IBM Data Cataloging graphical user interface to create data connections from the source storage systems.
- [Automated scanning of an IBM Storage Scale data source](#)
As an administrator, you can initiate an IBM Storage Scale scan from IBM Data Cataloging to collect system metadata from IBM Storage Scale file system.
- [Manual scanning of an IBM Storage Scale data source](#)
How to configure IBM Data Cataloging to connect to IBM Spectrum Scale.

IBM Storage Scale scanning considerations

The following sections comprise considerations that you need to understand to scan IBM Storage Scale effectively.

- [Security considerations](#)
Use this information to securely scan a system connection.
- [Performance considerations](#)
Use this information to scan a system connection without degrading performance.

Security considerations

Use this information to securely scan a system connection.

Scanning an IBM Storage Scale instance involves the use of the **mmapplypolicy** command on the IBM Storage Scale system, which requires superuser permissions. When you are creating the data source connection for the target IBM Storage Scale system in the IBM Data Cataloging interface, you are prompted for a *userid* and *password* to enable automated scans. You are not required to provide these credentials if scans are run only manually on the target IBM Storage Scale system by an administrator. However, if you want to run automation and/or schedule scans, then the authentication credentials are required. By default, IBM Data Cataloging uses password authentication to the Scale cluster to run commands remotely. However, you can supply your own RSA private key by selecting the shared key authentication option when you are configuring the connection if you want to avail passwordless authentication.

Rather than providing root login credentials, an administrator must create a special user ID with limited permissions on the IBM Storage Scale system. The administrator must also enable a password-less **sudo** for the user ID, to the binaries needed for scanning. This prevents someone from gaining root access to the target IBM Storage Scale system if the IBM Data Cataloging system is somehow compromised.

Changing passwordless SSH keys

You can rotate RSA authentication key pairs for passwordless SSH on a frequency and remove old security keys from the `authorized_hosts` file on the IBM Storage Scale node that IBM Data Cataloging connects to. To update the authentication keys, follow these steps:

1. Ensure that the `id_rsa.pub` contents for the new authentication key pair are in the `~/.ssh/authorized_hosts` file for the user that is specified in the IBM Data Cataloging connection document for the IBM Storage Scale target file system.
2. Edit the connection and paste the contents of the new private key file (`id_rsa`) in the input form.

After you edit the connection with the new private key file, IBM Data Cataloging uses it to connect to the IBM Storage Scale target system.

Performance considerations

Use this information to scan a system connection without degrading performance.

Running a scan policy on an IBM Storage Scale system can be resource intensive and cause noticeable performance degradation on the IBM Storage Scale system. Often, system administrators choose to designate certain nodes or node classes for running the scans. The IBM Data Cataloging interface has an input field when creating IBM Storage Scale connections for the administrator to specify which nodes or node class(es) they would like to run the scan on. The value **a11** will run the scan across all nodes in the cluster. Any other list (comma separated) will be treated as a list of nodes or node classes on which to run the scan. Scan times vary by the size of the filesystem, how many nodes are used in the scan, how many CPUs are used per node, and whether or not the IBM Storage Scale cluster metadata is in flash memory.

Prerequisites for automated scanning

You can use IBM Storage Scale automated scanning features.

IBM Data Cataloging supports two levels of automated scanning of IBM Spectrum Scale systems. Both levels require that IBM Data Cataloging must establish a password-less Secure Shell (SSH) connection to the IBM Storage Scale clustered system that is being scanned.

The difference between the two levels lies in the manner in which the output is handled. The factors that are considered inspects whether:

- The output of the IBM Storage Scale policy that is run to do the scan is stored in a file (which then must be automatically copied back to IBM Data Cataloging and ingested locally); Or
- If the output is, instead, pushed to the ingest Kafka queue of IBM Data Cataloging system directly from the IBM Storage Scale policy output.

The Kafka queue of IBM Data Cataloging system is more space-efficient and time-efficient but has certain dependencies on the IBM Storage Scale clustered system that must be met so that it can function. The IBM Data Cataloging automated scan code determines whether the dependencies are met on the IBM Storage Scale clustered system.

If the dependencies are met on the IBM Storage Scale clustered system, it attempts to scan the system by using the optimized path. If the dependencies are not met on the IBM Storage Scale clustered system, it defaults to the file copy path.

The following sections list the prerequisites for creating a connection and performing automated scanning. These prerequisites consider security and performance factors. For more information, see [IBM Storage Scale scanning considerations](#).

- [Identify the IBM Storage Scale cluster and node list](#)
Identify a node to connect with the GPFS cluster.
- [Creating or identifying a user ID and password for scanning](#)
Identify a user to perform scanning or create a new user ID.
- [Validate scan user permissions and configuration](#)
Ensure that the user has the required permissions and configurations for scanning.
- [Check the dependencies for optimized scanning](#)
Identify the dependencies that must be met on the IBM Storage Scale system to optimize automated scan ingest.

Identify the IBM Storage Scale cluster and node list

Identify a node to connect with the GPFS cluster.

Identify a node in the target IBM Storage Scale cluster to use for the IBM Data Cataloging connection to the GPFS cluster.

You must identify the node list or node class that participates in the scanning activity.

Creating or identifying a user ID and password for scanning

Identify a user to perform scanning or create a new user ID.

About this task

You can identify an existing user to perform scanning or follow these steps on the IBM Storage Scale system to create a special user ID for scanning.

Procedure

1. Log in to the IBM Storage Scale management node as **root**.
Alternatively, you can **sudo** to root from another user ID.
2. Use the following **adduser** steps to ensure that you are able to ssh into the cluster:
 - a. **adduser** <user> -m
 - b. **passwd** <user>
3. Run: **visudo**.
 - a. Add the following line in the users section:
<user> ALL=NOPASSWD: /usr/lpp/mmfs/bin/mmapplypolicy,
/usr/lpp/mmfs/bin/mmrepquota
 - b. Write and quit: **:wq**
4. Create an IBM Data Cataloging working directory and ensure that <user> has write permissions.
For example: **mkdir -p /gpfs/fs1/sd_scan -m 770;**
chown <user> /gpfs/fs1/sd_scan
5. To execute a Data Mover policy for tiering data on the IBM Storage Scale cluster by using the ScaleILM application on the IBM Storage Scale connection, do the following:
 - a. Run: **visudo**
 - b. Add or update the following line in the users section:
<user> ALL=NOPASSWD: /usr/lpp/mmfs/bin/mmapplypolicy, /usr/lpp/mmfs/bin/mmrepquota,
/usr/lpp/mmfs/bin/mmlspool, /opt/ibm/ltfsee/bin/eeadm,/usr/bin/ls
 - c. Write and quit: **:wq**

For more information, see [Tiering data by using ScaleILM application](#). For more information, see the topic *Tiering data by using ScaleILM application* in the *Data Cataloging: Administration Guide*.
6. To execute a Data Mover policy for copying data to the IBM Storage Scale cluster by using the ScaleAFM application on the IBM Storage Scale connection, do the following:
 - a. Run: **visudo**.
 - b. Add or update this line in the users section:
<user>ALL=NOPASSWD:
/usr/lpp/mmfs/bin/mmapplypolicy, /usr/lpp/mmfs/bin/mmrepquota, /usr/lpp/mmfs/bin/mmlspool,
/usr/lpp/mmfs/bin/mmafmctl, /usr/lpp/mmfs/bin/mmafmcosctl, /usr/lpp/mmfs/bin/mmaddcallback,
/usr/lpp/mmfs/bin/mmdelcallback
 - c. Write and quit: **:wq**

For more information, see [Copying data using ScaleAFM application](#). For more information, see the topic *Copying data using ScaleAFM application* in the *Data Cataloging: Administration Guide*.

Validate scan user permissions and configuration

Ensure that the user has the required permissions and configurations for scanning.

You need to ensure that it is possible to use Secure Shell (SSH) to log in to the IBM Storage Scale system with the scanning user ID and password.

Run the **sudo /usr/lpp/mmfs/bin/mmapplypolicy**.

You also need to validate the listed factors for the scanning-related working directory:

- It exists.
- It is globally accessible by the scan worker nodes.
- The scan user has write permissions to the directory (ownership of the directory is preferred but not mandatory).

Place the **id_rsa** and **id_rsa.pub** files in **/opt/ibm/metaocean/data/connections/scale/** directory on the IBM Data Cataloging instance if a specific RSA key pair for password-less SSH is wanted.

You need to validate if the listed things are installed on the IBM Storage Scale node. This node is identified while you are identifying a node in the target IBM Storage Scale cluster. The node in the target is identified for use in the IBM Data Cataloging connection to the GPFS cluster:

- A python2 level of at least Python 2.7.5
- A sufficient level of librarian
- An appropriate level of confluent-Kafka

Note: This validation is recommended for optimized scan ingestion. However, it is optional and can be skipped.

Check the dependencies for optimized scanning

Identify the dependencies that must be met on the IBM Storage Scale system to optimize automated scan ingest.

The dependencies that must be satisfied on the IBM Storage Scale system to optimize automated scan ingest from IBM Data Cataloging are:

- A `librdkafka` library 0.11.4 or later
- A Python 3.0 or later with accompanying Python package installer (pip3)
- A `confluent-kafka` version that is greater than or equal to the installed `librdkafka` version.

If these dependencies are met, the scan output is pushed to the ingest Kafka queue of IBM Data Cataloging system directly from the IBM Storage Scale policy output.

An administrator can determine whether `librdkafka` is installed on the IBM Storage Scale node by running the `find /usr -name "*librdkafka*" or ls /lib64/librdkafka*` commands. The `librdkafka` package is included with newer levels of IBM Storage Scale on x86 and ppc64le platforms. However, it can also be built from the source code on older levels of IBM Storage Scale or ppc64 platforms. If the IBM Storage Scale system runs on Red Hat® Enterprise Linux® (RHEL) and is connected to a Red Hat Satellite, you can install it by running the Yellowdog Updater Modified (YUM) command `yum install librdkafka` as `root`. You can find source packages of `librdkafka` here: <https://github.com/edenhill/librdkafka>

The user ID specified in the data source connection must be able to locate the following two binaries by using the OS shell path:

1. A Python 3 binary as either `python` or `python3`
2. A Python package installer as `pip3`

Note: Symbolic links or aliases may be used to locate the Python executables.

After you install a sufficient version of Python, you can install `confluent-kafka` by using pip. To get pip, you must install the `python-setuptools` package, which provides a binary called `easy_install`. For more information, see <https://pypi.org/project/setuptools/#files>

After `easy_install` is available, you can install pip by running `easy_install-2.7 pip` as `root`. After you install pip, you can install `confluent-kafka` by running `pip install confluent-kafka` as `root`.

Creating an IBM Storage Scale data source connection

You can use the IBM Data Cataloging graphical user interface to create data connections from the source storage systems.

Procedure

1. Log in to the IBM Data Cataloging web interface with a user ID that has the Data Admin role that is associated with it.
The data admin access role is required for creating connections. For more information, see [Managing user access](#). For more information, see *Managing User Access in the Data Cataloging: Administration Guide*.
2. Click  menu and go to Data connections > Connections to display the different types of data source connection names, connection type, clusters, data source, site, state, scan status, next scan, and Add Connection button.
3. Click Add connection to display a new window that shows Add data source connection.
You can enter in the connection name and connection type. The connection types are:
 - IBM Storage Scale
 - IBM Cloud® Object Storage
 - Network File System (NFS)
4. Complete the following steps:
 - a. In the field for Connection name, define a Connection name.
 - b. Choose type of connection from Connection type drop-down list.
5. Set the connection type to IBM Storage Scale. The page displays the connection name, user, password, working directory, and scan directory information that you can enter. You can also schedule a data scan, select a collection, or enable live events.
If you click Enable live events, you can enable the IBM Storage Scale watch folder on the specified file system.
6. Complete updating values for all the fields to add the IBM Storage Scale connection type, and click Submit Connection.

For IBM Storage Scale connections, you can enter the following information:

Connection name

The name of the connection, an identifier for the user. For example, filesystem1.

Note: It must be a unique name within IBM Data Cataloging.

User

A user ID that has permissions to connect to the data source system and initiate a scan.

Password

The password for the user ID specified in user.

Authentication Type

The password authentication can be done by using the password that is provided to authenticate with the IBM Storage Scale cluster. The shared RSA key authentication performs a password less authentication by using a private key that is provided by the system administrator and whose public key exists in the authorized keys for the specified user on the Scale host.

Note: IBM Data Cataloging 2.0.3.1 removes the support for self-generated RSA key pair for IBM Data Cataloging. Any existing connections that use that method is updated to password based authentication and the self-generated key pair is removed during the upgrade to 2.0.3.1 or later. If the password for the scan user that is stored in IBM Data Cataloging is no longer valid, that can result in scan failures after the update. To rectify this, you must edit the connection and provide a valid password for the scan user or a valid RSA private key for authentication.

Working Directory

A scratch directory on the source data system where IBM Data Cataloging can put its temporary files.

Note: When you edit an existing connection and change the User from a root user to a non-root user, you must also change the Working Directory. This change is necessary because the non-root User cannot access the files that are previously created by the root user in the existing Working Directory.

Scan Directory

The root directory of the scan. All files and directories under this directory are scanned. Typically, this directory is the base directory of the file system. For example, /gpfs/fs1.

Connection Type

The type of source storage system this connection represents.

Site

An optional physical location tag that an administrator can provide to see the physical distribution of their data.

Cluster

The IBM Storage Scale or GPFS cluster name. To obtain, run the following command from the IBM Storage Scale file system: /usr/lpp/mmfs/bin/mmlscluster.

Host

The hostname or IP address of an IBM Storage Scale node from which a scan can be initiated, for example a quorum-manager node.

File system

The short name (omit /dev/) of the file system to be scanned. For example, fs1.

Note: It is important to exactly match the file system name (data source) that IBM Storage Scale populates in the scan file. Run the following command on the IBM Storage Scale system: /usr/lpp/mmfs/bin/mmlsmount all

Node list

The comma-delimited list of nodes or node classes that participates in the scan of an IBM Storage Scale file system. For example, scale01,scale02.

Node	Daemon node name	IP address	Admin node name	Designation
1	msys111-10g	172.16.8.111	msys111-dmz	quorum-manager-perfmon
2	msys112-10g	172.16.8.112	msys112-dmz	quorum-manager-perfmon
3	msys113-10g	172.16.8.113	msys113-dmz	quorum-manager-perfmon

Note: When you create data source connections for IBM Storage Scale file systems, it is important to exactly match the cluster name and the file system name (data source) that IBM Storage Scale populates in the scan file.

Run the following commands on the IBM Storage Scale system.

- Run the following command to display information about the GPFS cluster:

```
$ /usr/lpp/mmfs/bin/mmlscluster

GPFS cluster information
=====
GPFS cluster name:      modevml19.tuc.example.com,
GPFS cluster id:        7146749509622277333
GPFS UID domain:        modevml19.tuc.example.com
Remote shell command:   /usr/bin/ssh
Remote file copy command: /usr/bin/scp
Repository type:        CCR

Node  Daemon node name  IP address  Admin node name  Designation
-----
1      modevml19.tuc.example.com  203.0.113.24  modevml19.tuc.example.com  quorum-manager
```

- Run the following command to display information about file systems that are mounted: on the nodes:

```
$ /usr/lpp/mmfs/bin/mmlsmount all
File system gpfs0 is mounted on 1 nodes
File system Data_Science_8M is mounted on 7 nodes.
File system icp4D_data_fs_master1 is mounted on 8 nodes.
File system icp4D_data_fs_master2 is mounted on 8 nodes.
File system icp4D_data_fs_master3 is mounted on 8 nodes.
```

Automated scanning of an IBM Storage Scale data source

As an administrator, you can initiate an IBM Storage Scale scan from IBM Data Cataloging to collect system metadata from IBM Storage Scale file system.

Before you begin

You can include or exclude the files during initial IBM Storage Scale scan process by configuring the following environment variable:

INCLUDE_SCALE_SNAPSHOTS

When the INCLUDE_SCALE_SNAPSHOTS variable value is set to 'false' (default value), the IBM Storage Scale scan excludes all the files that are inside the .snapshots directories, otherwise, if the variable value is set to 'true', the scan includes all the files, including the .snapshots directories.

About this task

To set the INCLUDE_SCALE_SNAPSHOTS variable by using configmap, see [Enabling skip snapshot directories feature on Red Hat® OpenShift®](#) *Enabling skip snapshot directories feature on Red Hat® OpenShift* in the *IBM Storage Scale: Administration Guide*.

When a scan is initiated from the IBM Data Cataloging graphical user interface, the data moves asynchronously back to the IBM Data Cataloging.

Remember: Before you initiate a scan, see [IBM Storage Scale scanning considerations](#).

Automated scanning and data ingestion relies on an established and active network connection between the IBM Data Cataloging instance and the source IBM Storage Scale management node. If the connection cannot be established, the state of the data source connection displays 'unavailable' and the option for automated

scanning does not appear in the IBM Data Cataloging GUI for that connection.

Note: You cannot run scans unless you add override warnings in the configuration file.

Procedure

1. Log in to IBM Data Cataloging web interface.
 2. Click  menu and go to Data connections, > Connections.
 3. Select the data source connection name that you want to scan. Ensure that the connection is online for your system ready to scan. (There is an indicator in the State column.)
 4. Select Scan now to start the scan, and a small message appears to confirm that the connection name you specify is being scanned. You can view the status of the scan on the table in the Scan Status column for the target connection. After the Scan Status has a check mark next to it, the scan is complete.
Remember: You can also specify a time to begin the scan. Any time zones specified default to Coordinated Universal Time (UTC) time. So, if you specify your scan for 12 noon, it is 12 noon in UTC.
- [Automated scanning of an IBM Storage Scale fileset](#)
As an administrator, you can initiate the IBM Storage Scale scan from IBM Data Cataloging to collect system metadata from the IBM Storage Scale file set or file sets.

Automated scanning of an IBM Storage Scale fileset

As an administrator, you can initiate the IBM Storage Scale scan from IBM Data Cataloging to collect system metadata from the IBM Storage Scale file set or file sets.

Before you begin

This feature adds a requirement for non-root user IDs that are used for scanning IBM Storage Scale data source systems. This feature uses the **mmlsfileset** command to retrieve the list of available file sets from the target system when you have root-level permissions. So, if you use a non-root user ID it must have sudo access to **mmlsfileset** for this function to work.

There is already a requirement for a non-root scan user to have sudo access to **mmapplypolicy**, so this requirement adds **mmlsfileset** as an extra required command.

Note: You cannot query the available file sets on a target IBM Storage Scale connection or initiate a file set level scan unless you fulfill this requirement.

About this task

Scan the IBM Storage Scale file set or file sets to insert or update the records for the files that are found by IBM Data Cataloging in that file set or file sets. The scan is scoped to the specified file set, which ensures a faster total scan than scanning the entire file system. Multiple file sets can be specified in a single scan operation, but the scanning of each file set is done successively.

As the scan progresses, the status message is updated to indicate the following information:

- The status message indicates which file set is being scanned.
- The status message indicates when data operations (such as transferring files or indexing data) occur.

This status message can be seen in the GUI on the data source connections table or it can be queried by using the REST API.

This feature works irrespective of whether the data is returned to IBM Data Cataloging by using a direct Kafka connection or by using the file copy method. After a file set level scan completes, a scan generation is recorded or committed.

Additionally, an internal reclamation policy is generated to remove any deleted files that did not appear in the updated scan. The scope of this reclamation policy is limited to the file set that is scanned and does not affect other file sets or the actual file system. This limitation helps you achieve consistency with the source IBM Storage Scale system at file set level granularity.

Procedure

1. Go to the IBM Data Cataloging GUI.
2. Click  menu and go to Data connections, > Connections table.
Select the data source connection name and click Scan now, which opens the Select scan type dialog box.
You can select whether to scan the entire file system or to scan a list of file sets.
Important: Connection types other than IBM Storage Scale and SMB/CIFS do not open this dialog box. Additionally, Scan now continues to function as it has, which means that there is an immediate initiation of a full connection scan.
3. Select either Scan all to scan all file sets or Select Filesets to scan a specific file set.
Selecting Scan all initiates a full scan of the file system. If you choose to scan all file sets, click Scan to run the scan.

Selecting Select Filesets initiates a specific file scan. Click Next to open the Select Individual Filesets dialog box. Use this dialog box to select the specific file sets that you want to scan. Search the table by using the table search header:
 - a. You can select file sets by clicking the row of the table that represents that file set. Clicking the row highlights that row and the count under View X selected filesets increases by 1.
 - b. You can also select file set by filtering the search criteria. The table can be filtered to show only the selected file sets by clicking View X selected filesets, for ease of review. For example, you can enter **FS** to display all file set with those characters in that order. Click the file set in the table row that you want to select to run the scan on that file set.To go back to viewing all available file sets, click View X selected filesets again. The button changes to View all filesets when you view only the selected file sets.
4. After you select all wanted file sets, you can initiate the scan by clicking Scan. Clicking Scan takes you to the Connections table.
A notification indicates when the scan starts (or that the scan fails if there is a problem). You can view the status of the scan on the table in the Scan Status column for the target connection.

Remember: After the Scan Status has a check mark next to it, the scan is complete for all selected file sets.

Manual scanning of an IBM Storage Scale data source

How to configure IBM Data Cataloging to connect to IBM Spectrum Scale. After completing these steps, data can be ingested from an IBM Spectrum Scale data source to IBM Data Cataloging for metadata indexing.

Before you begin

Create the data source connection to IBM Storage Scale. For more information, see [Configure data source connections](#).

You can include or exclude the files during initial IBM Storage Scale scan process by configuring the following environment variable:

INCLUDE_SCALE_SNAPSHOTS

When the `INCLUDE_SCALE_SNAPSHOTS` variable value is set to 'false' (default value), the IBM Storage Scale scan excludes all the files that are inside the .snapshots directories, otherwise, if the variable value is set to 'true', the scan includes all the files, including the .snapshots directories.

To set the `INCLUDE_SCALE_SNAPSHOTS` variable by using configmap, see [Enabling skip snapshot directories feature on Red Hat® OpenShift®](#) *Enabling skip snapshot directories feature on Red Hat® OpenShift* in the *IBM Storage Scale: Administration Guide*.

The minimum connection parameters required for manual scanning are:

- Connection Name
- Connection Type
- Cluster
- Filesystem

Restriction: IBM Data Cataloging uses a unit separator (ASCII code 0x1F) as the field delimiter for ingestion into the database. This means that data which contains this character in path/file/object names results in improper parsing of the input data and the records are rejected by IBM Data Cataloging.

Procedure

1. Perform a file system scan to collect system metadata from IBM Spectrum Scale to be ingested into IBM Data Cataloging. For more information, see [Performing file system scan to collect metadata from IBM Storage Scale](#).
2. Copy the output of the file system scan to the IBM Data Cataloging master node. For more information, see [Copying the output of the IBM Storage Scale file system scan to the IBM Data Cataloging master node](#).
3. Ingest data from the file system scan in IBM Data Cataloging. For more information, see [Ingesting metadata from IBM Storage Scale file system scan in IBM Data Cataloging](#).
4. Ingest quota information from the file system. For more information, see [Ingesting quota information from the file system](#).

Performing file system scan to collect metadata from IBM Storage Scale

You can use the file system scanning tool, IBM Storage Scale Scanner, to collect system metadata from IBM Storage Scale to be ingested into IBM Data Cataloging.

About this task

The IBM Storage Scale Scanner tool uses the IBM Storage Scale information lifecycle management (ILM) policy engine to obtain the system metadata about the files stored on the file system. The system metadata is written to a file, which is then transferred to the IBM Data Cataloging master node. The file is then ingested within the node and analytics is carried out to provide search, duplicate file detection, archive data detection, and capacity show-back report generation. The following system metadata is collected from the file system scan:

Key name	Description
Site	The site where the file or object resides.
Platform	The source storage platform that contains the file or object.
Size	The size of the file.
Owner	The owner of the file.
Path	The subdirectory where the data resides.
Name	The name of the data.
Permissions	The permissions for the file (mode).
ctime	The change time of the file metadata (inode).
mtime	The time when the data was last modified.
atime	The time when the data was last accessed.
Filesystem	The name of the IBM Storage Scale file system that is storing the data.
Cluster	The name of the IBM Storage Scale cluster.
inode	The IBM Storage Scale inode that is storing the data.
Group	The Linux® group associated with the file.
Fileset	The file set that stores the file.
Pool	The storage pool where the file resides.
Migstatus	If applicable, indicates whether the data is migrated to tape or object.
migloc	If applicable, indicates the location of the data if migrated to tape or object.
ScanGen	Scan generation - useful to track rescans.

The IBM Storage Scale Scanner tool also collects quota information by calling `mmrepquota`.

The tool comprises the following files:

- `scale_scanner.py`: The tool that starts the IBM Storage Scale ILM policy.
- `scale_scanner.conf`: The configuration file used to customize the behavior of the `scale_scanner.py` tool.
- `createScanPolicy`: The script that is called internally by the tool.

Procedure

Install the IBM Storage Scale Scanner tool by unpacking the utility from the IBM Data Cataloging node to the required location on the IBM Storage Scale cluster node.

1. Log in to the IBM Data Cataloging node through Secure Shell (SSH) with the `modadmin` username and password:

```
ssh modadmin@data.cataloging.ibm.com
```

2. Change to the directory that contains the IBM Storage Scale scanning utility

```
/opt/ibm/metaocean/spectrum-scale
```

3. Copy the `createScanPolicy`, `_init_.py`, `scale_scanner.conf`, and `scale_scanner.py` files to a node in the IBM Storage Scale cluster:

```
scp * root@spectrumscale.ibm.com:/my_scanner_directory

createScanPolicy 100% 3320 3.2KB/s 00:00
init.py 100% 427 0.4KB/s 00:00
scale_scanner.conf 100% 1595 1.6KB/s 00:00
scale_scanner.py 100% 13KB 13.2KB/s 00:00
```

4. On the IBM Storage Scale node where you install the scanning utility, edit the configuration file (`scale_scanner.conf`) as follows:

- a. Use the IBM Data Cataloging UI to create a connection to the SS system on which you start a manual scan for. Set the `filesystem` and `scandir` fields, and optionally set the `outputdir` and `site` fields in the `[spectrumscale]` stanza of the file.

```
[spectrumscale]
# Spectrum Scale Filesystem which hosts the scan directory
# example: /dev/gpfs0
filesystem=/dev/gpfs0
# The directory path on Spectrum Scale Filesystem to perform scan on
# example: /gpfs0
# specifies a global directory to be used for temporary storage during
# mmapplypolicy command processing. The specified directory must be
# mounted with read/write access within a shared file system
mountpoint=mount point of the gpfs filesystem
# It is unclear what the mount_point should be, but setting the mount point
# to the mount point of the scale file system on the IBM Spectrum Scale node works.
scandir=/gpfs0
# The directory to store output data from the scan in (default is
# scandir)
outputdir=
# The site tag to specify a physical location or organization identifier.
# If you use this field, remove the comment (#)
#site=
```

- b. Set the `scale_connection`, `master_node_ip`, and `username` fields in the `[datacataloging]` stanza of the file.

Note: `scale_connection` refers to the name of the IBM Storage Scale file system that is scanned and ingested into IBM Data Cataloging. The `scale_connection` value must match the value that is defined in the **Data Source** column of the Data Connections page in the IBM Data Cataloging GUI. The username must be a valid name of the IBM Data Cataloging user who has the `dataadmin` role. The username field takes the format of `<domain_name>/<username>`. To determine a domain and username with the `dataadmin` role, go to the Access Users page in the IBM Data Cataloging GUI and click the view for the defined users.

For the local domain, it is not necessary to specify the domain as part of the username field as it is the default domain. For example, to define username for `user1` in the local domain that is assigned the `dataadmin` role, in the configuration file, enter the following value: `username=user1`

```
[datacataloging]
# Name of the Spectrum Scale connection to scan files from
# Check using the Spectrum Discover connection manager APIs
scale_connection=fs3
# Data Cataloging Master Node IP
master_node_ip=203.0.113.23
# Data Cataloging user name, having 'dataadmin' role
# Use format <domain name>/<username>
# e.g. username=Scale/scaleuser1
username=user1
```

Note: The scanner output file generates approximately 1 K of metadata for every file in the system. If there are 12 M files, the size is expected to be approximately 12 GB. By default, the output file is written to the same directory that is being scanned. The log file output location can be customized by setting the `outputdir` field.

5. Run the scan by using the following command:

```
./scale_scanner.py
```

Note: While you run the `./scale_scanner.py` command, you can start another scan. If you start another scan, ensure that you run the scan with another connection that is online and is not being scanned currently. When the scanner is running, the scanner hides the scan now automatically.

Note: As you run the `scale_scanner.py` script, you are prompted for the password for the IBM Data Cataloging user that is configured in the `scale_scanner.conf` file with the username under the `datacataloging` section. You must provide the correct password for the configured user. As described in the configuration file, this user needs to be a valid user configured in the IBM Data Cataloging Authentication service (Access management). Also, this user must be assigned to the `dataadmin` role.

For example:

```
$ ./scale_scanner.py
Enter password for SD user 'user1':
Scale Scan Policy is created at: ./scanScale.policy
```

Note:

- After you see a line similar to "0 'skipped' files and/or errors", press enter to return to the command prompt.
- The scan takes approximately 2 minutes 30 seconds for every 10 M files on the following configuration:

```
x86 -based Spectrum Scale Cluster
•4 M4 NSD client nodes
•2 M4 NSD server nodes
•DCS3700 350 2TB NL SAS drives & 20 200GB SSD
•QDR InfiniBand cluster network
```

Copying the output of the IBM Storage Scale file system scan to the IBM Data Cataloging master node

After you have scanned your IBM Spectrum Scale file system and have the list.metaOcean output file, copy it to the IBM Data Cataloging master node.

Procedure

As an IBM Data Cataloging administrator, use the **scp** command to copy the list.metaOcean file from the scan output directory to the /opt/ibm/metaocean/data/producer directory on the master node.

Note: If there are multiple file systems in the same cluster that are being scanned, you can rename the list.metaOcean file to avoid name conflicts and to not overwrite an existing list.metaOcean file that is in use. For example:

```
$ mv list.metaOcean list.metaOcean.myfilesystem
$ scp list.metaOcean.myfilesystem moadmin@MasterNodeIP:/opt/ibm/metaocean/data/producer
```

Ingesting metadata from IBM Storage Scale file system scan in IBM Data Cataloging

Records are inserted into IBM Data Cataloging for indexing when they are pushed to a Kafka connector topic corresponding to the type of data being ingested. In the case of IBM Storage Scale, the Kafka connector topic type is **scale-scan-connector-topic**.

About this task

A Kafka client producer is required to put the IBM Storage Scale file system scan file records onto the Kafka connector topic. The following steps show how to use the **ingest** alias command to push the records in the list.metaOcean file (or another named file) onto the Kafka connector topic.

Procedure

1. Run the following command to ingest the data:

```
$ ingest /opt/ibm/metaocean/data/producer/list.metaOcean
```

2. Replace the list.metaOcean path with the path of the file that you want to ingest.

Ingesting quota information from the file system

The file system scanning tool, IBM Storage Scale Scanner, has the ability to harvest and send quota information to IBM Data Cataloging.

Procedure

To perform quota ingestion, run the following command on the IBM Storage Scale cluster node:

```
./scale_scanner.py --quota-only
```

For example:

```
$ sudo ./scale_scanner.py --quota-only
Enter password for SD user 'user1':
```

IBM Storage Archive data source connections

You can define tags and policies in IBM Data Cataloging based on values that are derived from IBM Spectrum® Archive metadata to help in searching and categorizing files.

IBM Data Cataloging integrates with IBM Storage Archive to display search results that include the following archive state of files:

Migration status **migstatus**

Search results display details for the following migration status:

migrtd

Indicates that the file is migrated to tape.

resdnt

Indicates that the file is resident in the file system.

premig

Indicates that the file is pre-migrated to tape.

Migration "location" **migloc**

Search results display information on the tape cartridge in the following format: "1 *tape cartridge volser@tape storage pool id@tape library serial number*". Any additional copies must be separated by colons.

Actual size of file in the associated IBM Storage Scale file system **Size Consumed Bytes**

IBM Data Cataloging displays a zero if the file is moved to tape.

Remember: The migration state information is collected and summarized in the IBM Data Cataloging State facet. You can access this facet by using IBM Data Cataloging visual search. For more information, see [Searching](#). For more information, see the topic *Searching* in the *Data Cataloging: Administration Guide*. The IBM Data Cataloging interface displays the search results including the metadata information.

Important: The location information that is displayed in IBM Data Cataloging is provided by IBM Storage Scale. It corresponds to the **dmapi . IBMTPS** attribute for the file. Run the **mmlsatr -L** command for more details.

IBM Cloud Object Storage data source connection

You can create the IBM Cloud® Object Storage (COS) connection and initiate a scan.

IBM® COS uses a connector residing on the storage system to push events to a Kafka topic residing in the IBM Data Cataloging cluster. When configured, the IBM Data Cataloging consumes the events and indexes them into the IBM Data Cataloging database.

Restriction: IBM Data Cataloging uses a unit separator (ASCII code 0x1F) as the field delimiter for ingestion into the database. This means that data which contains this character in path/file/object names results in improper parsing of the input data and the records are rejected by IBM Data Cataloging.

- [Prerequisites](#)

The IBM Cloud Object Storage Scanner and Replay prerequisites are listed:

- [Creating an IBM Cloud Object Storage data source connection](#)

You can create an IBM Cloud Object Storage (COS) data source connection and from the storage system.

- [Scanning an IBM Cloud Object Storage data connection](#)

You can initiate an IBM connection scan to collect system metadata from an IBM Cloud Object Storage system.

- [Best practices for scanning IBM Cloud Object Storage systems](#)

Use best practices for scanning IBM Cloud Object Storage (IBM COS) systems.

- [Enabling bucket notifications for Ceph Object Storage](#)

Use this information to enable bucket notifications for Ceph® Object Storage.

- [Enabling bucket notifications for Ceph Object Storage on Red Hat OpenShift](#)

Use this information to enable bucket notifications for Ceph Object Storage on Red Hat® OpenShift®.

- [Replaying IBM Cloud Object Storage notifications](#)

Use the IBM Cloud Object Storage (COS) Replay feature to resend notifications that failed because of an outage or loss of data.

- [Configure IBM Cloud Object Storage notifications for IBM Data Cataloging](#)

Ingesting IBM Cloud Object Storage event records into IBM Data Cataloging requires the user to enable the Notification service on the IBM Cloud Object Storage system. Thereafter, the user must connect the IBM Cloud Object Storage system to the IBM Cloud Object Storage connector Kafka topic on the IBM Data Cataloging cluster. The name of this connector topic is **cos-le-connector-topic**.

- [Enabling IBM Cloud Object Storage notification services](#)

The IBM Cloud Object Storage notification service can be enabled with the information that follows:

- [Testing the IBM Cloud Object Storage notification service](#)

To test the IBM Cloud Object Storage notification service, the tester can populate the IBM Cloud Object Storage vault with test data.

Prerequisites

The IBM Cloud® Object Storage Scanner and Replay prerequisites are listed:

IBM Cloud Object Storage Scanner prerequisite

For the Scanner, you must enable the Get Bucket Extension for all accesser devices.

To enable the Get Bucket Extension, you must set the **s3.listing-name-only-enabled** equal to true in the Manager System Advanced Configuration.

See [Figure 1](#).

Figure 1. Example of the system advanced configuration

Remember: You do not need to restart the Accesser, but you might need to wait for 5 minutes before the setting takes effect if you do not restart it.

IBM Cloud Object Storage Replay prerequisite

For the Replay, `access_logs` are uploaded to the management vaults within 1 hour after rotation. Rotation can be triggered earlier by setting the Rotation Period to the minimum value of 15 minutes in Manager under Maintenance/Logs/Device Log Configuration. Refer to the [IBM Cloud Object Storage System documentation](#) to make sure that this is configured, and the relevant access logs are present before you run the Replay.

Creating an IBM Cloud Object Storage data source connection

You can create an IBM Cloud® Object Storage (COS) data source connection and from the storage system.

Procedure

1. Log in to the IBM Data Cataloging web interface with a user ID that has the Data Admin role that is associated with it.
The data admin access role is required for creating connections. For more information, see [Role-based access control](#).
2. Click  menu and click Data connections.
Clicking Connections displays the different types of data source connection names, connection type, clusters, data source, site, state, scan status, next scan , and Add Connection.

Figure 1. Displaying the source names for data source connections

Connection name	Connection type	Cluster	Data source	Site	State	Scan status	Next scan
e2e_SMB	SMB/CIFS	9.11.201.170	lukeskywalker	SMBsite	Online	✓	
e2e_cos	IBM COS	e09cdac0-80b8-73be-00ed-cb8edeede242	e2e_ui_cos	COSsite	Online	✓	
e2e_nfs	NFS	9.11.201.172	Isilon	NFSsite	Online	✓	
e2e_s3	S3	s3.eu-west-1.amazonaws.com	e2e-ui-ta	S3site	Online	✓	
e2e_ss_roof	Spectrum Scale	modevms19.tuc.stglabs.ibm.com	scale0	SSsite	Online	✓	

3. Click Add connection to display a new window that shows Add data source connection.

Figure 2. Example of window that shows Data Connections Add data source Connection

Add data source connection

Connection name:

Connection type: Cloud Object Storage

☐ Select a collection

☐ Schedule data scans

Manager API user:

Manager API Password:

Manager API Password:

UUID:

Manager host:

4. Do the following steps:
 - a. In the field for Connection name, define a Connection name.
 - b. Choose the type of data source connection from the Connection type list.
5. Select the connection type Cloud Object Storage.

[Figure 3](#)

Figure 3. Example of the screen for an IBM® COS connection

The figure consists of two screenshots of IBM software interfaces. The top screenshot shows the 'IBM Spectrum Discover' interface with a modal dialog titled 'Add data source connection'. The dialog has a 'Connection name' field with 'Test1' entered, a 'Connection type' dropdown set to 'Cloud Object Storage', and checkboxes for 'Select a collection' and 'Schedule data scans'. On the right side of the dialog, there are input fields for 'Manager API user', 'Manager API Password', 'UUID', and 'Manager host'. The bottom screenshot shows the 'IBM Fusion Data Cataloging' interface with a similar modal dialog. This dialog includes fields for 'Manager host', 'Vault', 'Accessor Host', 'Accessor access key', 'Accessor secret key', and 'Site (optional)'. Both dialogs have 'Cancel' and 'Submit Connection' buttons at the bottom.

6. In the screen for Cloud Object Storage, complete fields, and click Submit Connection.

For Cloud Storage Object Connections Manager

Manager API user

A user ID that has permissions to connect to the data source system.

Manager API Password

The password for the user ID specified in the previous field.

UUID

The unique ID of the DSNet cluster. To obtain the UUID, log in to the COS Manager GUI and click Help>About this system on the upper-right corner of the window.

Host

The IP or hostname of the manager node within the DSNet.

Vault

The specific data vault represented by this connection.

Site

An optional physical location tag that an administrator can provide to see the physical distribution of their data.

Accessor

The IP address or hostname of the Accesser® node on DSNet.

Accessor access key

The Accesser access key that has permission to access data in the data vault that is to be scanned. If the accessor access key value is blank, the value is retrieved (for the manager API user) from the manager API.

Accessor secret key

The Accesser secret key that has permission to access data in the vault that is to be scanned. If the secret access key value is blank, the value is retrieved (for the manager API user) from the manager API.

Scanning an IBM Cloud Object Storage data connection

You can initiate an IBM® connection scan to collect system metadata from an IBM Cloud® Object Storage system.

About this task

When you initiate a scan from the IBM Data Cataloging graphical user interface (GUI), the metadata is transferred asynchronously back to the IBM Data Cataloging instance.

Note:

IBM Data Cataloging does not support scanning of vaults in a dsNet that has any of the following things:

- Proxy vault
- Mirrored vault
- Vault setup for migration

Automated scanning and data ingestion relies on an established and active network connection between the IBM Data Cataloging instance and the IBM Cloud Object Storage storage source. If the connection cannot be established, the state of the data source connection shows as unavailable, and the option for automated scanning does not appear in the IBM Data Cataloging GUI for that connection.

Note: If a scan does not complete successfully, check the log file for errors and warnings. If the error or warning message indicates a need to check the configurations file or the settings file, then you must modify the file as required. For example, in some cases you must update the override warnings in the settings file by adding:

"override_warnings": true at the root level.

The settings or the configuration file is available in the following location: /opt/ibm/metaocean/data/connections/cos/scan/scanner-settings.json

Procedure

1. Log in to the IBM Data Cataloging graphical user interface (GUI).
2. Click  menu and go to Data connections, > Connections.
The following example shows the Data connections menu page:

Figure 1. Data source connections

The screenshot shows the 'Data source management' page in the IBM Fusion Data Cataloging GUI. It features a table with columns: Connection name, Connection type, Cluster, Data source, Site, State, Scan status, and Next scan. There are five connections listed, all with a state of 'Online' and a green checkmark in the 'Scan status' column. A search bar and an 'Add connection' button are at the top right. At the bottom, there is a pagination control showing '1 - 5 of 5 items'.

Connection name	Connection type	Cluster	Data source	Site	State	Scan status	Next scan
e2e_SMB	SMB/CIFS	9.11.201.170	lukeskywalker	SMBsite	Online	✓	
e2e_cos	IBM COS	e09cda0-80f8-73be-00ed-cb8edeede242	e2e_ui_cos	COSsite	Online	✓	
e2e_nfs	NFS	9.11.201.172	Isilon	NFSsite	Online	✓	
e2e_s3	S3	s3.eu-west-1.amazonaws.com	e2e-ui-ta	S3site	Online	✓	
e2e_ss_roof	Spectrum Scale	modevym19.tuc.stglabs.ibm.com	scale0	SSsite	Online	✓	

3. Select the data source connection name that you want to scan. Ensure that the **State** is listed as **Online** to make your system scan ready.
The following example shows how to connect to the IBM Data Cataloging library.

Figure 2. Selecting a data source connection to scan

4. Select Scan now to change the status to Scanning.
The following example shows an active scan.

Figure 3. Active scans

5. When the scan finishes, the state field returns to a status of Online.

Best practices for scanning IBM Cloud Object Storage systems

Use best practices for scanning IBM Cloud® Object Storage (IBM® COS) systems.

It is recommended to check the log files in the following directories after each scan:

/opt/ibm/metaocean/data/connections/cos/<connection_name>/debug/<scan_timestamp>/scanner.debug indicates whether the scan was successful or not.

/opt/ibm/metaocean/data/connections/cos/<connection_name>/error/<scan_timestamp>/scanner.error contains a list of all the messages that are not delivered to IBM Data Cataloging.

This file contains a list of all the messages that are not delivered to IBM Data Cataloging.

/opt/ibm/metaocean/data/connections/cos/<connection_name>/data/<scan_timestamp>/ contains a subfolder with the scanned data source name. There is a stats folder inside this folder that contains information about the number of objects in the data source or the number of objects or scanned files.

You can also compare the total size of the bucket that is reported in IBM Data Cataloging with the total size of the IBM COS at its source (if it is available).

Enabling bucket notifications for Ceph Object Storage

Use this information to enable bucket notifications for Ceph® Object Storage.

Before you begin

Ensure you have the following features set up:

- IBM Data Cataloging 2.0.2.1
- Red Hat® Ceph Storage 4.0 (available starting with version Beta 8)
- A Ceph Object Gateway node that is set up with an HTTPS endpoint

Restriction:

- Ceph Object bucket names must be unique across all data sources. You cannot use the same bucket name to reach a Ceph data source. For example, if there is the IBM Cloud® Object Storage or Amazon S3 bucket with the name **"my_bucket"**, you cannot reach a Ceph data source with the bucket name **"my_bucket"**.
- Notifications from versioned buckets are not supported.
- Only one IBM Data Cataloging node can be configured for push notifications from Ceph Object Storage cluster at a time.

About this task

Use the following steps to enable bucket notifications for Ceph Object Storage.

Procedure

1. Create a data source connection to the Ceph Object Storage cluster.
A Ceph Object Storage source is established as an Amazon S3 data source connection.
Remember: Each bucket must have its own data source connection entry in IBM Data Cataloging.
2. To enable Ceph Object Storage bucket notifications:
 - a. Copy the ca.crt file from IBM Data Cataloging node to a directory on the Ceph Object Gateway nodes.
 - b. Locate the file in the /etc/kafka directory on the IBM Data Cataloging node.
 - c. Give this file a unique name on the Ceph node after it is copied over.
Remember: Ensure that the file has the same name and in the same location on each Ceph Object Gateway node.
You can choose to use /etc/ssl/certs as the copy target directory on the Ceph Object Gateway node.
3. Create a topic entity by using Ceph bucket notification REST API. The topic contains the push endpoint on IBM Data Cataloging where the notifications are sent to.
Remember: To enable notifications to be sent to IBM Data Cataloging you must provide push endpoint parameters when you create the topic entity.
These parameters include the IBM Data Cataloging Kafka topic and credentials that are required to securely produce messages to the topic. For more information about the REST API, see [Create a Topic](#) in the Ceph documentation.
The following parameters must be in the POST request:

```
POST
Action=CreateTopic
&Name=ceph-le-connector-topic
&push-endpoint=<endpoint>
&Attributes.entry.5.key=use-ssl&Attributes.entry.5.value=true
&Attributes.entry.6.key=ca-location&Attributes.entry.6.value=<file path>
```

In this example:

```
<endpoint>
    Indicates the URI of the IBM Data Cataloging Kafka broker in this format: kafka://cos:<password>@<discover_fqdn>:9092
<password>
    Indicates the password that can be obtained by an administrator on the IBM Data Cataloging node from the following location: /etc/kafka/sasl_password
<discover_fqdn>
    Indicates the fully qualified domain name of the IBM Data Cataloging node.
<file path>
    Indicates the location and file name of the Kafka certificate authority (CA) file on the Ceph Object Gateway Node.
```

The following example shows topic creation by using the s3curl utility:

```
$ ./s3curl.pl --id=rhceph -- -k -X POST https://<ceph object gateway address>:8080/ -d
"Action=CreateTopic&Name=ceph-le-connector-topic&push-endpoint=kafka://cos:
<password>@<discover_fqdn>:9092&Attributes.entry.5.key=use-ssl&Attributes.entry.5.value=true&
Attributes.entry.6.key=ca-location&Attributes.entry.6.value=/etc/ssl/certs/ca.crt"
```

The --id parameter identifies the credentials to use in the s3curl configuration file.

4. Create a notification entity by using the Ceph bucket REST API. This associates events on a specific bucket to a topic. For more information, see [CREATE NOTIFICATION](#) in the Ceph documentation.
The following example shows how to establish a bucket notification by using the s3curl utility:

```
$ ./s3curl.pl --id=rhceph --put=notif.xml -- -k https://<ceph object gateway address>:8080/<bucket>?notification
```

```
Contents of notif.xml:
<NotificationConfiguration xmlns="http://s3.amazonaws.com/doc/2010-03-31/">
  <TopicConfiguration>
    <Id>id1</Id>
    <Topic>arn:aws:sns:default::ceph-le-connector-topic</Topic>
  </TopicConfiguration>
</NotificationConfiguration>
```

You can now capture events on objects within the configured buckets.

Enabling bucket notifications for Ceph Object Storage on Red Hat OpenShift

Use this information to enable bucket notifications for Ceph® Object Storage on Red Hat® OpenShift®.

Before you begin

Ensure you have the following features set up:

- IBM Data Cataloging 2.0.4
- Red Hat Ceph Storage 4.1z2 or later
- A Ceph Object Gateway node that is set up with an HTTPS endpoint

Restriction:

- Ceph Object bucket names must be unique across all data sources. You cannot use the same bucket name to reach a Ceph data source. For example, if an IBM Cloud® Object Storage or Amazon S3 bucket exists with the name **"my_bucket"**, you cannot reach a Ceph data source with the bucket name **"my_bucket"**.
- Notifications from versioned buckets are not supported.
- Only one IBM Data Cataloging node can be configured for push notifications from Ceph Object Storage cluster at a time.

About this task

Use the following steps to enable bucket notifications for Ceph Object Storage.

Procedure

1. Create a data source connection to the Ceph Object Storage cluster.
A Ceph Object Storage source is established as an Amazon S3 data source connection.
Remember: Each bucket must have its own data source connection entry in IBM Data Cataloging.
2. To enable Ceph Object Storage bucket notifications:
 - a. Issue the following command to transfer the ca.crt file from IBM Data Cataloging node to the Ceph Object Gateway nodes.

```
oc get secret kafka -n ibm-data-cataloging -o jsonpath='{.data.sasl_ca\.crt}' | base64 -d > ca.crt
```
 - b. Give this file a unique name on the Ceph node after it is copied over.
Remember: Ensure that the file has the same name and in the same location on each Ceph Object Gateway node.
You can choose to use `/etc/ssl/certs` as the copy target directory on the Ceph Object Gateway node.
3. Create a topic entity by using Ceph bucket notification REST API. The topic contains the push endpoint on IBM Data Cataloging where the notifications are sent to.
Remember: To enable notifications to be sent to IBM Data Cataloging, you must provide endpoint parameters when you create the topic entity.
These parameters include the IBM Data Cataloging Kafka topic and credentials that are important to securely produce messages to the topic. For more information about the REST API, see <https://docs.ceph.com/docs/master/radosgw/notifications/#create-a-topic>.
The following parameters must be in the POST request:

```
POST
Action=CreateTopic
&Name=ceph-le-connector-topic
&push-endpoint=<endpoint>
&Attributes.entry.5.key=use-ssl&Attributes.entry.5.value=true
&Attributes.entry.6.key=ca-location&Attributes.entry.6.value=<file path>
```

The parameters that are shown in the example are explained in the following section.

<endpoint>

Indicates the URI of the IBM Data Cataloging Kafka broker in this format: `kafka://cos:<password>@<discover_fqdn>:443`

<password>

Indicates the password that can be obtained by an administrator on the Red Hat OpenShift node. Issue the following command to obtain the password:

```
oc get secret kafka-sasl-password -n ibm-data-cataloging -o jsonpath='{.data.password}'
```

<discover_fqdn>

Indicates the fully qualified domain name of the IBM Data Cataloging node.

<file path>

Indicates the location and file name of the Kafka certificate authority (CA) file on the Ceph Object Gateway Node.

The following example shows topic creation by using the `s3curl` utility:

```
$ ./s3curl.pl --id=rhceph -- -k -X POST https://<ceph object gateway address>:8080/ -d
"Action=CreateTopic&Name=ceph-le-connector-topic&push-endpoint=kafka://cos:
<password>@<discover_fqdn>:9092&Attributes.entry.5.key=use-ssl&Attributes.entry.5.value=true&
Attributes.entry.6.key=ca-location&Attributes.entry.6.value=/etc/ssl/certs/ca.crt"
```

The `--id` parameter identifies the credentials to use in the `s3curl` configuration file.

4. Create a notification entity by using the Ceph bucket REST API. This associates events on a specific bucket to a topic. For more information, see: <https://docs.ceph.com/docs/master/radosgw/s3/bucketops/#create-notification>

The following example shows how to establish a bucket notification by using the `s3curl` utility:

```
$ ./s3curl.pl --id=rhceph --put=notif.xml -- -k https://<ceph object gateway address>:8080/<bucket>?notification
```

Contents of `notif.xml`:

```
<NotificationConfiguration xmlns="http://s3.amazonaws.com/doc/2010-03-31/">
  <TopicConfiguration>
```

```
<Id>id1</Id>
<Topic>arn:aws:sns:default::ceph-le-connector-topic</Topic>
</TopicConfiguration>
</NotificationConfiguration>
```

You can now capture events on objects within the configured buckets.

Replaying IBM Cloud Object Storage notifications

Use the IBM Cloud® Object Storage (COS) Replay feature to resend notifications that failed because of an outage or loss of data.

The IBM® COS Replay reads object metadata from vaults and submits the metadata to IBM Data Cataloging by using Kafka notifications.

- [Overview of architecture](#)
This topic describes a high-level overview of IBM Cloud Object Storage Scanner architecture.
- [Configuration file](#)
The configuration file is used by the Notifier and Replay.
- [Replay performance](#)
The number of requests that are issued by IBM Cloud Object Storage Replay is throttled to ensure that overall dsNet performance remains at the agreed level.
- [Replay tasks and vault settings](#)
A few scenarios exist that prevent the Replay from operating correctly.
- [Including and excluding vaults](#)
You can set the vaults that you scan with various settings in the configuration file.
- [Stats files](#)
The IBM Cloud Object Storage Scanner tracks each LIST process status to a stats file.
- [Replay](#)
When a severe outage occurs and causes the loss of notifications sent by the system to IBM Data Cataloging, the IBM Cloud Object Storage Scanner Replay feature can be used to recover lost notifications.
- [Initialization for Replay](#)
During the startup, Replay reads the configuration file and issues requests to the Manager of the dsNet device similar to the Scanner.
- [Error conditions](#)
Sometimes Replay does not have enough information to replay the original notification. If this occurs, you must fix the problems manually.
- [Output](#)
Messages are batched by 1,000 or to the Scanner list objects size configuration setting, if specified.
- [Renaming a vault for Replay](#)
When you rename a vault, it is possible that Replay can abort.
- [Starting the Replay](#)
The guidelines and rules for using Replay are documented in this topic.
- [Debug mode for Replay](#)
Run Replay in debug mode to troubleshoot problems.
- [Notifier](#)
The Notifier is the component that reads the JSON notifications that are written by Scanner or Replay and sends notifications to the Kafka cluster.
- [Limitations](#)
Limitations apply when the Notifier uses a Kafka configuration retrieved from the Manager API.
- [Starting the Notifier](#)
Running the Notifier has rules and limitations.
- [Notifier operation](#)
The Notifier enumerates and processes all .log files in the Scanner data directory.
- [Stopping the Notifier](#)
You might need to stop and restart the Notifier.
- [Restarting the Notifier](#)
When you stop the Notifier following a shutdown with the kill.notifier file, you must rename the file manually or delete the file before you do a restart.
- [Progress report](#)
The Progress Report provides an instant snapshot of status for the Scanner and Notifier.
- [Logging](#)
You can view the list of directories that are generated by scanner, notifier, and replay.
- [IBM Cloud Object Storage Scanner output data](#)
The Scanner generates a directory beneath the output data directory for each vault or vault prefix as defined in the configuration file.
- [Appendix](#)
The appendix shows an example of a log file and examples of Scanner debug data.

Overview of architecture

This topic describes a high-level overview of IBM Cloud® Object Storage Scanner architecture.

The following figure shows a high-level overview of IBM Cloud Object Storage Replay architecture.

Figure 1. IBM Cloud Object Storage Replay architecture

The /opt/ibm/metaocean/data/connections/cos/replay/output/data folder puts the replay output and the notifier reads Kafka messages from the directory. Putting replay output onto disk means that a cold restart is possible.

The IBM Cloud Object Storage Replay consists of two major components:

Replay

Downloads system's logs and re-creates notifications that are sent during a defined time period.

Notifier

Submits the extracted information to IBM Data Cataloging.

Configuration file

The configuration file is used by the Notifier and Replay.

The configuration file includes:

- Information regarding the net
- Runtime parameters for the Notifier and Replay
- A list of vaults to scan

The configuration file is named scanner-settings.json and must sit in the /opt/ibm/metaocean/data/connections/cos/replay directory.

The rules for IBM Cloud® Object Storage Replay settings are:

- All access logs are scanned.
- All objects that are created or updated since Coordinated Universal Time (UTC) 00:00:01 from 11 April 2018 to Coordinated Universal Time (UTC) 10:01:53 on 21 September 2018 are scanned in batches of 1000.
- Custom metadata is retrieved for each object or version.
- Ten vaults are processed in parallel.
- Each vault has a single process LIST that issues requests and 15 processes that issue HEAD requests.

The following example shows every setting. Most settings have default values and can be omitted, but these screens show a typical example by using default values.

Example of the Cloud Object Storage Replay settings

```

IBM Cloud Object Storage Scanner is highly configurable. Each element in the file is described in [Table 1](#). Remember: IBM Data Cataloging does not support file or file path names that use characters that are not part of the UTF-8 character set.

Table 1. Explanation of the configuration file

Element	Description	Optional	Default value	Restart scanner if changed	Restart notifier if changed
System section					
name	Free-text name of the dsNet. Appears in the 'system_name' element in all Kafka messages.	✓	Retrieved from Manager API if configured. If not, the name does not appear in Kafka messages.	✓	✗
uuid	UUID of the dsNet. Appears in the 'system_uuid' element in all Kafka messages.	✓	Retrieved from Manager API.	✓	✗
manager_ip	Single IP address or host name of the manager device.	✗	Not applicable	✓	✗
accesser_ip	Single IP address or host name of an accesser device or load balancer that routes to the accessers.	✗	Not applicable	✓	✗
accesser_sup ports_https	Boolean value that indicates whether http or https can be used when you send requests to the accesser or load balancer.	✓	true	✓	✗
manager_user name	Username for accessing the manager API. For testing only. Not to be used in production.	✓	Supplied by user at prompt	✓	✗
manager_pass word	Password for accessing the Manager API. For testing only. Not to be used in production.	✓	Supplied by user at prompt	✓	✗
is_ibm_cos	Boolean value that indicates whether the system is an IBM Cloud Object Storage or another s3 compliant system. If true, the IBM® Get Bucket Extension is used to retrieve object keys from the vaults. Note: Setting the value to false is not currently supported by the Scanner and Notifier.	✓	True	✓	✗
accesser_acc ess_key	Access key ID for S3 calls to the accessers or load balancer. For testing only. Not to be used in production.	✓	Supplied by user at prompt if you cannot retrieve it from Manager API for the user account that is specified in dsNet/manager_username.	✓	✗
accesser_sec ret_key	Secret key for S3 calls to the accesser or load balancer. For testing only. Not to be used in production.	✓	Supplied by user at prompt if you cannot retrieve from Manager API.	✓	✗
Time stamps section					

Element	Description	Optional	Default value	Restart scanner if changed	Restart notifier if changed
System section					
min_utc	Only objects or version in the vaults that have a LastModified datetime on or after this timestamp is submitted to IBM Data Cataloging. Needs to be less than the max_utc value. Note: Changing min_utc and restarting scanner applies only to objects not yet scanned. Objects scanned before restart might have a LastModifiedDate value that is earlier than the min_utc value.	X		✓ See note.	X
max_utc	Only objects or version in the vaults that have a LastModified datetime on or before this time stamp is submitted to IBM Data Cataloging. Needs to be more than min_utc and less than current time. Note: Changing max_utc to a more recent time and restarting does not mean that new objects written since the old max_utc is scanned. The scanner continues from the last object's key that is scanned in lexicographic order. This means that new objects with names smaller than the last object scanned are not scanned.	✓		✓ See note.	X
Policy engine section		(Only required for IBM Data Cataloging 2.0.0.3 and later)			
spectrum_discover_host	Host name or IP address of the policy engine service from which the Kafka certificate is retrieved.	X	none	✓	✓
user	Username for authorization on policy engine.	X	none	✓	✓
password	Password for authorization on policy engine.	X	none	✓	✓
Replay section					
access_log_directory	The access_log_directory is where the dsNet access log files are stored after download. Access logs must be in the root input folder. Files in subdirectories are not processed.	✓	[IBM Cloud Object Storage Replay]/ access_logs	Restart Replay if changed	Restart Replay if changed
download	If download is set to false, access logs are not downloaded and are assumed to already be present in access_log_directory .	✓	true	Restart Replay if changed	Restart Replay if changed
Notifier section					
kafka_format	Format of the Kafka message.	✓	1	X	✓
kafka_endpoint	IP address and port of the Kafka endpoint.	✓	Retrieved from Manager API	X	✓
kafka_topic	Name of the Kafka topic.	✓	Retrieved from Manager API	X	✓
kafka_username	The username for authentication with Kafka. Note: For testing only. Not to be used in production.	✓	Supplied by user at prompt if you cannot retrieve from Manager API.	X	✓
kafka_password	The password for authentication with Kafka. Note: For testing only. Not to be used in production.	✓	Supplied by user at prompt if cannot be retrieved from Manager API.	X	✓
kafka_pem	The certificate PEM for authentication with Kafka. Must include '\n' characters to ensure correct formatting. Note: For testing only. Not to be used in production.	✓	Supplied by user at prompt if it cannot be retrieved from the system	X	✓
Logging section					
debug_log_max_bytes	The scanner.debug and notifier.debug roll over when this size is reached.	✓	1,000,000	✓	✓
debug_log_backup_count	The number of scanner.debug and notifier.debug files to retain.	✓	10	✓	✓
notification_log_max_b	The notification.log rolls over when this size is reached.	✓	1,000,000	✓	✓
notification_log_backup_count	The number of notification.log files to retain.	✓	10	✓	✓
notification_log_all	Boolean value that controls the level of Notifier logging. When true: an entry is written to notification.log for message you send to the Kafka cluster. When false: only failed sends are written to notification.log.	✓	False	X	✓
Root-level items					
include_all_vaults	Boolean value that determines whether all vaults in the dsNet are scanned. If false, the details of the vaults to be scanned must be specified in the 'vaults' element. Boolean value that determines whether custom metadata and content type are retrieved for each object by using individual HEAD requests.	✓	False	✓	X
has_custom_metadata	This value is only relevant when a versioned vault is scanned. For IBM Cloud Object Storage systems, non-versioned vaults always require a HEAD request for every object. Can be overridden for each vault in the 'vaults' element.	✓	True	✓	X

Element	Description	Optional	Default value	Restart scanner if changed	Restart notifier if changed
System section					
override_warnings	Boolean value that allows the scanner to run and ignore any warnings that are generated on start-up. For example, a warning is raised on start-up if versioning is suspended on a vault.	✓	False	✓	✗
exclude_vaults	Comma-separated list of vault names to be excluded from scanning, such as: "exclude-vaults": ["COSVault", "COSVault-V"]	✓	[] Empty list	✓	✗
vaults	List of vaults to be scanned. If include_all_vaults is true, the vaults list can be left empty. This list can be used to define more detailed scanning parameters for individual vaults. Any settings that are defined here take precedence over the settings that are described. Each element in the list contains: The vault_name is the name of the vault. The has_custom_metadata is an optional Boolean that overrides the has_custom_metadata that is described. The prefix is an optional string that is used to filter the objects or versions that are retrieved from the vault.	✓	Dependent on settings include_all_vaults and exclude_vaults	✓	✗

Replay performance

The number of requests that are issued by IBM Cloud® Object Storage Replay is throttled to ensure that overall dsNet performance remains at the agreed level.

You can control throttling by the number of settings in a configuration file. All settings are optional. The following screen shows an example of the default values.

```
"replay": {
  "max_requests_per_second": 1000,
  "max_parallel_list": 10,
  "parallel_head_per_list": 15,
  "list_objects_size": 1000
}
```

Process count

The following list shows an example of how 161 processes are divided. [Figure 1](#) shows a caution message of how the number of processes should not exceed 161.

- One main process
- 10 List worker processes
- 150 HEAD worker processes

Figure 1. Python process count

Maximum Replay performance

Replay and Notifier maximize performance on a 64 core Intel(R) Xeon(R) CPU E5-2690 v3 @ 2.60GHz server is 2300 objects that are scanned and notified per second with a dsNet with 6 accessers and 12 slicestors under customer load at 50 percent capacity.

```
"replay": {
  "max_requests_per_second": 2300,
  "max_parallel_list": 10,
  "parallel_head_per_list": 15,
  "list_objects_size": 1000
}
```

The recommendation is to start the replay at a rate of 1000 objects scanned per second. Measure the latency degradation of customer traffic and increase the scanning rate until the maximum acceptable degradation is reached.

One thousand objects per second on the net, which is a 5 - 27 percent increase of write operations, the latency (larger increase for smaller size files) and around 10 percent for read operations latency were measured.

At 2000 objects a second, a 10 - 50 percent increase of write operations latency and in the range 18 - 28 percent, and 10 percent for read operations latency were measured.

Replay tasks and vault settings

A few scenarios exist that prevent the Replay from operating correctly.

Certain combinations of the following IBM Cloud® Object Storage vault settings prevent the Replay from running a full scan:

- Vault versioning
- Name index
- Recover listing

[Figure 1](#) shows settings for the first three items on the vault configuration page in the DsNet Manager user interface.

Figure 1. Settings for three items on the vault configuration page in the net Manager user interface

The scenarios that are invalid are reported at startup.

Remember: You must correct the scenarios before you can run the Replay.

If a scan does not complete successfully, make sure that you check the log file for errors and warnings. In some cases, you must modify the settings file as detailed in the errors and warning messages. The settings file is located at: `/opt/ibm/metacocean/data/connections/cos/scan/scanner-settings.json`

[Table 1](#) shows the behavior for the Replay for different combinations of the four variables.

Table 1. Behaviors for Replay for four variables

ID	Name index	Recovery listing	Versioned	Cloud Object Storage Replay behavior
0	X	X	X	❌ Stop start-up and report error in config file: Error: Objects cannot be listed because Name Index and Recovery Index are both disabled. You might enable Recovery Listing on the vault or add this vault to the "exclude_vaults" list in the configuration file. For example: <pre>"exclude-vaults": ["vault-name"]</pre>
1	X	X	✓	❌ Stop start-up and report error in config file: Error: Objects cannot be listed because Name Index and Recovery Index are both unavailable. You might enable Recovery Listing on the vault or add this vault to the "exclude_vaults" list in the configuration file. For example: <pre>"exclude-vaults": ["vault-name"]</pre>
2	X	✓	X	☑ Object Listing is run.
3	X	✓	✓	☑ Object Listing runs. Only the most recent version of each object is listed. A warning is logged: Warning: Versions cannot be listed as Name Index is unavailable. An object scan is run and only the most recent version of each object is listed. You must add override_warnings: true in the configuration file to ignore this warning. Switching Name Index on does not enable scanning of a full version history. Objects created while Name Index is off is not present when it is enabled.
4	✓	X	X	☑ Object Listing is run.
5	✓	X	✓	☑ Object Listing is run.
6	✓	✓	X	☑ Object Listing is run.
7	✓	✓	✓	! Stop start-up and report warning: This is a versioned vault but version scanning is not possible as Recovery Listing is enabled. You might either disable Recovery Listing on the vault to allow version scanning, or rerun the Replay with the argument override-warnings: true to allow object scanning.

Important: You might receive system errors about records not being scanned to the database if you scan a IBM Cloud Object Storage vault with Name Index disabled and Recovery Listing enabled. You cannot specify a prefix listing on a vault that has Recovery Listing enabled (you cannot specify a blank prefix either).

Including and excluding vaults

You can set the vaults that you scan with various settings in the configuration file.

Use the following settings in the configuration file to scan the vaults:

- `include_all_vaults` (Boolean)
- `exclude_vaults` (List)
- `vaults` (Dictionary)

When `include_all_vaults` is true, all vaults in the system are scanned except for any vaults specified in the `exclude_vaults` list.

You might consider `exclude_vaults` a list of vaults to ignore and `vaults` is a list that specifies details of individual vaults to be scanned.

If `include_all_vaults` is true and the vaults list is populated, the list of vaults that are scanned is the superset of all vaults that are returned by the Manager that are merged with the vaults list from the config file.

An error is raised and the Scanner aborts on start-up if the same vault appears in both `vaults` and `exclude_vaults`.

Mirror, Proxy, Data Migration

IBM Cloud® Object Storage Scanner does not support scanning of the following:

- Mirrored vaults
- Proxy vaults
- Vaults that are set up for migration

Any vaults of these types are ignored by the scanner and a warning logged in the debug log.

Examples for including and excluding vaults

To summarize the rules for including and excluding vaults, following are some examples:

Example 1

- The system contains 1000 vaults.
- Five of the 1000 vaults are management vaults (named mgmt-1 to mgmt-5).
- The scan includes all vaults except the management vaults.

```
"include_all_vaults": true,
"exclude_vaults": ["mgmt-1", "mgmt-2", "mgmt-3", "mgmt-4", "mgmt-5"]
```

Example 2

- The system contains 1000 vaults.
- 5 of the 1000 vaults are management vaults (named mgmt-1 to mgmt-5).
- The scan includes all vaults except the management vaults.
- The scan includes a filter for scanning a vault that is named vault-x.
- The scan includes only a scan of the objects whose key starts with **production/finance**.

```
"include_all_vaults": true,
"exclude_vaults": ["mgmt-1", "mgmt-2", "mgmt-3", "mgmt-4", "mgmt-5"],
"vaults": [
  { "vault_name": "vault-x", "prefix": "production/finance" }
]
```

Example 3

- The system contains 1000 vaults.
- 5 of the 1000 vaults are management vaults (named mgmt-1 to mgmt-5).
- The scan includes all vaults except the management vaults.
- The scan includes a filter for scanning a vault that is named vault-x.
- The scan includes only a scan of the objects whose key starts with **production/finance** or **production/marketing**.

```
"include_all_vaults": true,
"exclude_vaults": ["mgmt-1", "mgmt-2", "mgmt-3", "mgmt-4", "mgmt-5"],
"vaults": [
  { "vault_name": "vault-x", "prefix": "production/finance" },
  { "vault_name": "vault-x", "prefix": "production/marketing" }
]
```

Example 4

- The system contains 1000 vaults.
- Run a test on three vaults named vault-a, vault-b, and versioned-vault-c.
- Run a scan on versioned-vault-c and issue LIST requests. Do not issue HEAD requests because the objects do not have custom amz headers.

```
"include_all_vaults": false,
"vaults": [
  { "vault_name": "vault-a"
  { "vault_name": "vault-b"
  { "vault_name": "vault-c", "has_custom_metadata": false}
]
```

Stats files

The IBM Cloud® Object Storage Scanner tracks each LIST process status to a stats file.

During a scan, the Scanner runs multiple processes. Each LIST processes and tracks the progress, saves the **next_key**, and optionally the **next_version** to a stats file named task.stats that is stored with the log files in the /opt/ibm/metaocean/data/connections/cos/replay/output/data directory.

```
{
  "estimated_object_count": 1000,
  "list_objects_size": 100,
  "next_key": "",
  "next_version": "",
  "prefix": "",
  "scan_type": "Object Scan",
  "status": "Complete",
  "total_bytes_output": 1126809,
  "total_bytes_scanned": 1126809,
  "total_objects_output": 47,
  "total_objects_scanned": 47,
  "vault_name": "dsmgmt-spl",
  "vault_uuid": "868daa21-9e56-4c41-b6fd-845a4c85cea9"
}
```

From the Scanner, you can start, stop, recover files from a crash, and restart at the point where the scan was interrupted.

When you start the scanner:

1. Processing of the Scanner continues from **next_key** and **next_version**.
2. Queue of the Notifier is optimized by reloading from the files in the data folder instead of requerying the dsNet.
3. Batches that were processed partially are reprocessed. Duplicate Kafka notifications might occur, but are handled safely by the IBM Data Cataloging system.

Replay

When a severe outage occurs and causes the loss of notifications sent by the system to IBM Data Cataloging, the IBM Cloud® Object Storage Scanner Replay feature can be used to recover lost notifications.

Replay parses the access logs of a system and reconstitutes the notifications. Also, the Notifier can resend the notifications.

Initialization for Replay

During the startup, Replay reads the configuration file and issues requests to the Manager of the dsNet device similar to the Scanner.

Data from the configuration file is validated to ensure that appropriate permissions are granted in the dsNet. This allows access to management vaults and regular vaults. Startup errors or warnings are logged and printed to the console.

After initialization, Replay extracts accesser log files from the management vaults of dsNet and enables Replay to process and write notifications to the output directory.

Error conditions

Sometimes Replay does not have enough information to replay the original notification. If this occurs, you must fix the problems manually.

For example, if vault versioning was suspended when you made the request and you receive an s3 DeleteObject for an object or delete marker, the following error is logged:

```
error_code=True, error_description="Delete operation with [no version_id|null
version_id|version_id] for vault with versioning = [suspended/enabled]"
```

The error message displays because Replay cannot distinguish when a notification with s3:CreateDeleteMarker or s3:CreateDeleteMarker:NullVersionDeleted is sent.

If vault versioning is disabled, and an s3 PutObject request is received for an object that is deleted, the following error is logged:

```
error_code=404, error_message="Not Found"
```

The error message displays because Replay cannot determine the tag of the object that was deleted.

Output

Messages are batched by 1,000 or to the Scanner list objects size configuration setting, if specified.

The messages are written to the output folder with the same Notification format used by the Scanner.

```
{
  "system_name": "Test",
  "object_etag": "\"de37d2cee49596916f62a233dfc790a4\"",
  "request_time": "2018-09-24T18:49:29.383Z",
  "format": 1,
  "bucket_uuid": "ac89915b-d4ec-7ff1-00be-9c32b2aca580",
  "system_uuid": "f7d033c2-9066-499a-a883-829860d4d865",
  "object_length": "12319",
  "object_name": "test_version",
  "bucket_name": "vault3",
  "content_type": "binary/octet-stream",
  "request_id": "17451c3d-e81e-40ed-939a-4534780daaa8",
  "operation": "s3:PutObject"
}
```

If an error occurs, the error messages are written to the `/opt/ibm/metaocean/data/connections/cos/replay/output/data/access_log_error/` directory. Take note of the extra `error_code` and `error_description` elements.

```
{
  "system_name": "Test",
  "object_version": "null",
  "request_time": "2018-09-24T17:07:59.471Z",
  "format": 1,
  "bucket_uuid": "ac89915b-d4ec-7ff1-00be-9c32b2aca580",
  "system_uuid": "f7d033c2-9066-499a-a883-829860d4d865",
  "object_length": "12319",
  "object_name": "object5.2",
  "bucket_name": "vault3",
  "request_id": "ebc472a1-f955-4605-895b-840867b12e01",
  "operation": "s3:PutObject",
  "error_description": "Not Found",
  "error_code": 404
}
```

Renaming a vault for Replay

When you rename a vault, it is possible that Replay can abort.

Replay aborts when you:

- Delete the vault.
- Rename the vault.
- Discover that the read permission is revoked for the credentials that are supplied by the operator or manager API.

All other scans of a vault continue scanning until complete.

You can find the details of the errors that include stack trace in the `replay.debug` file in the `/opt/ibm/metaocean/data/connections/cos/replay/debug/replay/[timestamp]` directory.

Starting the Replay

The guidelines and rules for using Replay are documented in this topic.

To start Replay, run the following command:

```
cos-replay
```

The following rules apply for Replay:

- Configure Replay according to the guidelines in [Table 1](#).
- Replay component requires `min_utc` and `max_utc` time stamps defined in the [Configuration file](#).
- Only notifications sent between `min_utc` and `max_utc` are parsed and replayed.
- Replay automatically shuts down when all accessor logs are downloaded and processed. The message Complete Replay Process appears in the console.

This is an example of how to start Replay:

```
Starting COS Replay - Version 0.1 Log file and config file are in directory /Users/weebrew/
Documents/Development/ibmworkspace/cosscanner/output/debug/scanner/20180925-125528-232131
Starting Accessor Log Extraction Downloading files...
('Downloaded', 10, 'of', 36)
('Downloaded', 20, 'of', 36)
('Downloaded', 30, 'of', 36)
Download complete.
Total files: 36
Complete Accessor Log Extraction
Starting Replay process
Complete Replay process
```

Debug mode for Replay

Run Replay in debug mode to troubleshoot problems.

To start debug mode, run the following command:

```
cos-replay --log=DEBUG
```

Running debug mode creates large log files and creates a significant drop in performance. Do not run debug mode for long periods especially when you are in production mode.

Notifier

The Notifier is the component that reads the JSON notifications that are written by Scanner or Replay and sends notifications to the Kafka cluster.

When notifications are acknowledged by Kafka, the Notifier moves the file to the archive folder.

On start-up, Notifier calls the Manager API and retrieves details of any Notification Service Configurations (NSC) configured in the dsNet for IBM Data Cataloging. If more than one is found, the first one is used.

Retrieval of NSCs is overridden by defining the details of the Kafka configuration in the config file.

```
"notifier":{
  "kafka_format": 1,
  "kafka_endpoint": "192.168.1.34:9092",
  "kafka_topic": "cos-le-connector-topic"
}
```

Limitations

Limitations apply when the Notifier uses a Kafka configuration retrieved from the Manager API.

- If more than one NSC exists, the first one is used for all vaults.
- If more than one host name is defined in the NSC, the first one is used for all vaults.

Starting the Notifier

Running the Notifier has rules and limitations.

To start the Notifier, run the following command:

```
cos-notify
```

After you start the Notifier, you are prompted for security credentials for the manager API and Kafka cluster.

```
Starting COS Notifier - Version 0.1
Enter the Manager API username: admin
Enter the Manager API password:
Enter the Kafka username: cos
Enter the Kafka password:
Enter the Kafka pem:
Creating Kafka producer...
Done
Notifier is running
Log file and config file are in directory C:\dev\cos-scanner\output\debug\notifier\20180912-121641-283000
Checking for files in \data
- 11 files found Checking for files in output\data
- 256 files found
```

Rules and limitations

The following rules and limitations apply to the Notifier:

- You cannot start the Notifier in the background because the Notifier requires user input at the terminal window.
- You can stop the Notifier and force the Notifier to run in the background.
- The passwords and pem do not display when you type and paste the passwords in the console.
- The certificate pem is approximately 1600 characters. If you use an SSH connection, the certificate pem might be truncated to 1000 characters.
- If the number is truncated to 1000 characters, include the certificate pem in the config file.

Notifier operation

The Notifier enumerates and processes all .log files in the Scanner data directory.

After all files are processed, the Notifier repeats the process so that new .log files that are generated by the Scanner are processed. The Notifier sleeps repeatedly in 1-second intervals if no new files are found in the /opt/ibm/metaocean/data/connections/cos/replay/output/data directory.

The Notifier does not automatically shut down. The Notifier continues to monitor the Scanner data directory for new .log files. Monitor the progress of the Notifier by using the status report. When the operator or administrator determines that all scanned objects are submitted successfully to the IBM Data Cataloging, shut down the Notifier by using the kill switch.

Stopping the Notifier

You might need to stop and restart the Notifier.

Before you stop and restart the Notifier:

1. Create a file named kill.notifier in the /opt/ibm/metaocean/data/connections/cos/replay/output/command directory.
2. Ensure that the processing of any batches is complete before you stop the Notifier.

Stopping the Notifier displays the following output:

The shutdown is complete when the **"Shutdown is complete"** message displays.

```
Starting COS Notifier - Version 0.1
Enter the Manager API username: admin
Enter the Manager API password:
Enter the Kafka username: cos Enter the Kafka password:
Enter the Kafka pem: Creating Kafka producer...
Done
Notifier is running
Log file and config file are in directory C:\dev\cos-scanner\output\
  debug\notifier\20180912-121641-283000
Checking for files in output\data
- 11 files found Checking for files in output\data
- 256 files found Detected the kill trigger file. Shutting down...
Shutdown is complete
```

Restarting the Notifier

When you stop the Notifier following a shutdown with the kill.notifier file, you must rename the file manually or delete the file before you do a restart.

If you do not rename or delete the kill.notifier file, the system finds the file and displays the following message:

```
C:\dev\cos-scanner>python main_notifier.py Starting COS Notifier - Version 0.1
The file 'kill.notifier' is preventing the notifier from running.
You should delete or rename the file and re-start the notifier.
File location: 'C:\dev\cos-scanner\command\kill.notifier'
```

The Scanner and Notifier are separate solutions that share the config file. The files operate independently, so you can start and stop either file independently any time.

Progress report

The Progress Report provides an instant snapshot of status for the Scanner and Notifier.

To create a progress report, run the following command:

```
cos-report
```

The progress report displays in plain text format to the console in a static HTML file that is named: /opt/ibm/metaocean/data/connections/cos/replay/output/cos-scanner-report.html

If a progress report exists, the new progress report overwrites the existing progress report. See [Figure 1](#).

Figure 1. IBM Cloud Object Storage Scanner progress report

IBM COS Scanner Progress Report

Scans in progress: 6
Scans complete: 17
Scan progress: 12.00%

Notes

- Est. Object Count may not accurately reflect the number of objects in the vault. The discrepancy is typically very small.

pov00021

See [Table 1](#) for a description of information in the progress report.

Table 1. Description for IBM Cloud Object Storage Scanner progress report

Column name	Description
Scan Type	Either Object or Version. Non-Versioned vaults show Object. Versioned vaults show Version. However, there are some exceptions. If the Name Index for a versioned vault is unavailable but Recovery Listing is enabled, an object scan might be run. The user is alerted that an object scan can be done, but this object scan requires changes to the configuration file.
Vault Name	The name of the vault. Any prefix that is defined in the configuration file is also shown. Example: mega_vault?prefix=test
Vault UUID	The UUID of the vault.
Estimated Object Count	The estimated number of objects in the vault, as reported by the Manager API. This value is refreshed from the Manager API each time the scanner is started, regardless of the status of each scan. Given that the number of objects in each vault might be constantly changing, the number of objects that are reported in this column becomes out of date during long running scans. Note: This issue affects only the status report but does not affect the data integrity of the Scanner.
Scan Status	Shows the status of the scanner. Not started The task is queued but not started. In progress The task is running. Complete The task finished. Aborted The task encountered an unrecoverable error and aborted. Shut down the Scanner and the debug file, and inspect the file to investigate the problems. After you resolve the problems, restart the Scanner. The debug file is in the /opt/ibm/metaocean/data/connections/cos/replay/output/data/<vault-name>/<prefix> directory. For each vault, see the /opt/ibm/metaocean/data/connections/cos/replay/output/data/<vault-name>/<prefix> directories.
Last scan activity	The last time data was retrieved from the vault.
Scanned	Number of objects or versions that are scanned. For a versioned vault, this value shows a figure that is higher than the Estimated Object Count.
Output	Number of objects or versions that are scanned AND whose LastModified time stamp is inside the time window that is defined in the configuration file. The figure in the column is Queued + Notified + Error.
Queued	Number of objects or versions that are Output and are waiting to be sent to the Kafka cluster.
Notified	Number of objects or versions that are submitted successfully to the Kafka cluster.
Error	Number of objects or versions that failed to send to the Kafka cluster. Details of all errors are logged to notifier.debug.
Approximate percentage scanned	Scanned as a percentage of Est. Object Count. The cell background shows a progress bar.

Column name	Description
Approximate percentage scanned	Notified as a percentage of Output. The cell background shows a progress bar.

Table 2. What is reported beneath the report title

Measure	Description
Scans in progress	Number of scans with the status " In Progress ". Applies to Scanner only.
Scans complete	Number of scans with the status " Complete ". Applies to Scanner only.
Scan progress	Sum (number of objects scanned) as a percentage of sum (estimated object count).

Logging

You can view the list of directories that are generated by scanner, notifier, and replay.

[Table 1](#) lists the directories that are generated on start-up by the Scanner, Notifier, and Replay.

Table 1. List of directories generated by scanner, notifier, and replay

Directory	Description
For IBM Data Cataloging: <code>/opt/ibm/metaocean/data/connections/cos/replay/output/data</code>	Contains .log files (Kafka messages), stats files and debug information for each scanned vault. 
For IBM Data Cataloging: <code>/opt/ibm/metaocean/data/connections/cos/replay/output/debug/[scanner replay]/</code>	Contains Scanner and Replay debug or troubleshooting information. A new subdirectory is created each time the Scanner and Replay starts. Each subdirectory contains a copy of the configuration file and scanner.debug (replay.debug). 
For IBM Data Cataloging: <code>/opt/ibm/metaocean/data/connections/cos/replay/output/debug/notifier</code>	Contains Notifier debug or troubleshooting information. A new subdirectory is created each time the Notifier starts. It contains a copy of the configuration file and notifier.debug. Same directory-naming convention as shown for the scanner. The notifier.debug rolls over when it reaches a predefined size as defined in the configuration file. See Configuration file .
For IBM Data Cataloging: <code>/opt/ibm/metaocean/data/connections/cos/replay/output/archive/</code>	Contains all .log files that are successfully processed by the Notifier, and their contents are successfully submitted to the Kafka cluster. Remember: Files in this directory are truncated – they contain only the object key and they can also contain the version.
For IBM Data Cataloging: <code>/opt/ibm/metaocean/data/connections/cos/replay/output/error/</code>	Contains any .log files that failed to submit to the Kafka cluster.

Directory	Description
For IBM Data Cataloging: /opt/ibm/metaocean/data/connections/cos/replay/output/notification_log/	The notification.log file contains details of any errors (including stack trace) that occur when it attempts to send notifications to the Kafka cluster. If <code>logging/notification_log_all</code> is true in the config file, all successful sends are also logged. The notification.log file rolls over when it reaches a predefined size as defined in the configuration file. See Configuration file.

IBM Cloud Object Storage Scanner output data

The Scanner generates a directory beneath the output data directory for each vault or vault prefix as defined in the configuration file.

The /opt/ibm/metaocean/data/connections/cos/replay/output/data directory is the Scanner output data directory.

The following screen shows an example of a configuration file and also shows that all vaults are scanned, but mega_vault has four separate prefixes that are defined which means the four scans of the vault occurred.

```
"include_all_vaults": true,
"vaults": [
  {"vault_name": "mega_vault", "prefix": "main/production/finance"},
  {"vault_name": "mega_vault", "prefix": "main/production/sales"},
  {"vault_name": "mega_vault", "prefix": "main/production/marketing"},
  {"vault_name": "mega_vault", "prefix": "main/production/hr"}
]
```

[Figure 1](#) shows the directory structure.

Figure 1. Directory structure from the configuration file

The status and progress of each scan must be maintained so a separate directory structure is created for each scan. [Table 1](#) shows the leaf directories that contain the file names and description.

Table 1. Leaf directory file names

File name	Description
-----------	-------------

File name	Description
_LISTProcessN.debug	The N in the file name is different for each process (0 - 9 if there are 10 processes). Contains detailed debug information and details of any errors that are encountered when you scan the vault. Figure 2 shows an example of running in debug mode. Figure 2. Example of running in debug mode  <pre> 12-Sep-2018 15:58:13 LISTProcess-2 test_vault2 +++ Adding batch 16 12-Sep-2018 15:58:13 LISTProcess-2 test_vault2 16 Working batches: 1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16, 12-Sep-2018 15:58:13 LISTProcess-2 test_vault2 16 Working batches: 1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16, 12-Sep-2018 15:58:13 LISTProcess-2 test_vault2 --- Removing batch 1 12-Sep-2018 15:58:13 LISTProcess-2 test_vault2 Buffer is full. task.stats	Scanner starts in JSON format for a single vault. Updated following successful processing of each batch of objects. <pre> "estimated_object_count": 1718, "list_objects_size": 50, "next_key": "", "next_version": "", "prefix": "", "scan_type": "Object Scan", "status": "Complete", "total_bytes_output": 45257, "total_bytes_scanned": 45257, "total_objects_output": 1717, "total_objects_scanned": 1717, "vault_name": "test_vault2", "vault_uuid": "06c1641d-082f-7ba2-011b-c7550651a780" </pre>

File name	Description
*.log	The Scanner creates multiple .log files for each vault. Each .log file contains up to 1000 Kafka messages, ready to be submitted to the Kafka cluster by the Notifier. The naming convention for the log files is <pre><date>-<time>-<milliseconds>-<batch number>-<number of messages in file>.log</pre> 

pov00008

Appendix

The appendix shows an example of a log file and examples of Scanner debug data.

Log file

[Figure 1](#) shows an example with extra line breaks.

Configure IBM Cloud Object Storage notifications for IBM Data Cataloging

Ingesting IBM Cloud® Object Storage event records into IBM Data Cataloging requires the user to enable the Notification service on the IBM Cloud Object Storage system. Thereafter, the user must connect the IBM Cloud Object Storage system to the IBM Cloud Object Storage connector Kafka topic on the IBM Data Cataloging cluster. The name of this connector topic is `cos-1e-connector-topic`.

A combination of SASL and TLS is used to authenticate and encrypt the connection between the IBM Cloud Object Storage source system and the Kafka brokers which reside in the IBM Data Cataloging cluster. The certificate and credentials required to establish this connection might be obtained directly from the IBM Data Cataloging cluster by the IBM Data Cataloging storage administrator.

For information on how to enable and configure the IBM Cloud Object Storage Notification service with the IBM Data Cataloging provided credentials, see [IBM Cloud Object Storage Administration System documentation](#).

The following information is required to establish a secure connection between IBM Cloud Object Storage and IBM Data Cataloging:

Hosts

One or more of the IBM Data Cataloging Kafka brokers is in the format: *host1:port,host2:port*. The Kafka producers on the IBM Cloud Object Storage system will retrieve the full list of IBM Data Cataloging Kafka brokers from the first host that is alive and responding. The broker's host and port (the list configured might contain more than one broker) for SASL SSL can be obtained by the IBM Data Cataloging storage administrator from the following location on the IBM Data Cataloging master node: */etc/kafka/server.properties*.

Authentication credentials

The username is **cos** and the password can be obtained by the IBM Data Cataloging storage administrator from the following location on the IBM Data Cataloging master node: */etc/kafka/sasl_password*.

Certificate PEM for TLS encryption

This is the CA certificate that is used to sign the Kafka server and client certificates for the IBM Data Cataloging cluster. It might be obtained by the IBM Data Cataloging storage administrator from the following location on the IBM Data Cataloging master node: */etc/kafka/ca.crt*.

This file is in the PEM format and the entirety of its contents must be pasted into the Certificate PEM field of the COS Notifications configuration panel.

Enabling IBM Cloud Object Storage notification services

The IBM Cloud® Object Storage notification service can be enabled with the information that follows:

Procedure

1. Log in to the IBM Cloud Object Storage Manager Admin console (https://manager_host/manager/login.adm) with a username of **admin** and a password of **password**.
If you defined your own password, use your pre-defined password. If you do not have a pre-defined password use the default password.
2. Select the Administration tab.
3. Scroll to the end of the page and select Configure the Notification Service.

Figure 1. Configurations

Before you add a notification service to the IBM Cloud Object Storage platform, you must obtain some information from the IBM Data Cataloging server.

To authenticate the IBM Cloud Object Storage notification service, you can capture the Kafka user name and password from the files on the IBM Data Cataloging platform.

If the Transport Layer Security (TLS) is enabled in the IBM Cloud Object Storage notification service, you can also copy the certificate authority (CA) in PEM format from the IBM Data Cataloging platform. After you collect the information, you can add the information to the notification service configuration.

- [Authenticating, encrypting, and enabling](#)
Configure Kafka authentication, TLS encryption, and notification service settings by extracting certificates and credentials from the IBM Spectrum Discover server configuration files.
- [Authenticating, encrypting, and enabling services on Red Hat OpenShift](#)
Follow the procedure shown to authenticate, encrypt, and enable services on Red Hat® OpenShift®:

Authenticating, encrypting, and enabling

Configure Kafka authentication, TLS encryption, and notification service settings by extracting certificates and credentials from the IBM Spectrum Discover server configuration files.

- Log in to the IBM Data Cataloging server and extract the information from the following example, which contains an example of Kafka user name and password.

```
moadmin@server kafka]$ cd /etc/kafka

[moadmin@server kafka]$ cat kafka_server_jaas.conf
KafkaServer {
  org.apache.kafka.common.security.plain.PlainLoginModule required
  user_cos="meezDMxFNZJMSxdyWQKSjVbs";
};
```

```
User= cos
Password = meezDMxFNZJMSxdyWQKSjVbs
```

Encryption

The following information shows an example of a certificate of authority for the PEM file.

1. Log in to the IBM Data Cataloging server as moadmin.
2. In the /etc/kafka/ca.crt file, copy the block of text that starts with **BEGIN CERTIFICATE** and that ends with **END CERTIFICATE**. The following example displays what the copied block of text might look like:

```

```

Notification service configuration setup

1. Check Enable Configuration.

```
NAME: <NAME>
Topic: cos-le-connector-topic
Hosts: <SD hostname> :9093
Type: IBM Spectrum Discover
```

Enabling authentication

- Check Enable authentication.

```
Username: cos
Password: <PASSWORD>
```

Enabling encryption

1. Check Enable TLS for Apache Kafka network connections.
2. Add the certificate PEM file from the IBM Data Cataloging platform. See [Figure 1](#).

Figure 1. Add a storage vault to the configuration

Authenticating, encrypting, and enabling services on Red Hat OpenShift

Follow the procedure shown to authenticate, encrypt, and enable services on Red Hat® OpenShift®:

- ```
oc get secret kafka-sasl-password -n ibm-data-cataloging -o jsonpath='{.data.password}'
```

The following information shows an example of a certificate of authority for the PEM file:

- ```
oc get secret kafka -n ibm-data-cataloging -o jsonpath='{.data.sasl_ca\.crt}' | base64 -d
```

- [illegible]

```
NAME: <NAME>
Topic: cos-le-connector-topic
Hosts: <SD ipaddress> :443
Type: IBM Spectrum Discover
```

```
Username: cos
Password: <PASSWORD>
```

Figure 1. Add a storage vault to the configuration

IBM Fusion HCI 421

To test the IBM Cloud® Object Storage notification service, the tester can populate the IBM Cloud Object Storage vault with test data.

About this task

You can use a number of methods to write files to an IBM Cloud Object Storage vault, but you can use cURL directly on IBM Data Cataloging platform. cURL is a computer software project that provides a library and command-line tool for transferring data that uses various protocols.

Procedure

1. Create a test file, for example, object_1.txt.
The test file can be any file that contains data.
2. Write a file to the IBM Cloud Object Storage vault by using cURL.

IBM® COS Vault Name (vault1) [anonymous access enabled]
IBM COS Accesser IP address

Example

- curl -X PUT -i -T object_1.txt http://9.11.200.208/vault1/object_1.txt
- HTTP/1.1 200 ContinueHTTP/1.1 200 OK
- Date: Fri, 04 Jan 2019 13:21:14 Greenwich mean time
- X-Clv-Request-Id: a9ad657a-a919-4b13-9b72-961ae8c57e3c
- Server: 3.14.0.23
- X-Clv-S3-2.5
- x-amz-request-id: a9ad657a-a919-4b13-9b72-961ae8c57e3c
- ETag: "7c517c7108f7180377e7b37db2e39261"
- Content-Length: 0
- [Monitoring the IBM Cloud Object Storage accesser logs](#)
To determine whether a file is successfully written to the IBM Cloud Object Storage vault and a notification is successfully sent to the IBM Data Cataloging server, the accesser logs can be monitored on the IBM Cloud Object Storage Accesser server.
- [Monitoring the IBM Data Cataloging producer IBM Cloud Object Storage logs](#)
When the IBM Data Cataloging server receives a notification from the IBM Cloud Object Storage platform, the IBM Data Cataloging producer IBM Cloud Object Storage records a transaction.
- [Monitoring the IBM Data Cataloging dashboard for IBM Cloud Object Storage ingestion](#)
You can monitor the IBM Data Cataloging dashboard for IBM Cloud Object Storage ingestion.

Monitoring the IBM Cloud Object Storage accesser logs

To determine whether a file is successfully written to the IBM Cloud® Object Storage vault and a notification is successfully sent to the IBM Data Cataloging server, the accesser logs can be monitored on the IBM Cloud Object Storage Accesser server.

In the following example, an object that is written to vault1 results in the sending of one notification to the IBM Data Cataloging server. The user must have access privileges to log on to the IBM Cloud Object Storage Accesser host to check the log files.

Confirm that an object is stored in the IBM Cloud Object Storage vault.

```
root@ibm_accesser:/var/log/dsnet-core# tail -f http.log
9.11.201.78 - "" - [04/Jan/2019:13:21:14 +0000] "PUT /vault1/object_1.txt HTTP/1.1" 200 0 "-" "curl/7.29.0" 22
```

Confirm that a notification is sent to the IBM Data Cataloging server.

```
root@ibm_accesser:/var/log/dsnet-core# tail -f notification.log
{"time":"2019-01-04T13:21:14.668Z","request_id":"a9ad657a-a919-4b13-9b72-961ae8c57e3c","retried":true,"success":true,
"request_time":"2019-01-04T13:21:14.567Z","kafka_config_uuid":"d842c7a0-9c36-412e-8908-8ad5120a261e","topic":"cos-le-connector-
topic"}
```

Monitoring the IBM Data Cataloging producer IBM Cloud Object Storage logs

When the IBM Data Cataloging server receives a notification from the IBM Cloud® Object Storage platform, the IBM Data Cataloging producer IBM Cloud Object Storage records a transaction.

A successful notification is recorded as an offset value of one, when a notification is received from IBM Cloud Object Storage platform.

```
[moadmin@data_cataloging]$ oc logs -f -n producercos kindled-alligator-producer-cos-producer-9f6966b4-8jsg7
break time. waiting for work...
2019-01-04 13:21:19.187 > offset_commit_cb: success, offsets:[{part: 0, offset: 1, err: none}]
```

Monitoring the IBM Data Cataloging dashboard for IBM Cloud Object Storage ingestion

You can monitor the IBM Data Cataloging dashboard for IBM Cloud® Object Storage ingestion.

After IBM Cloud Object Storage notifications are ingested from the IBM Cloud Object Storage platform, the IBM Data Cataloging dashboard displays the total number of indexed records.

Note: The IBM Data Cataloging dashboard can take approximately 30 minutes to display the total number of indexed records.
See [Figure 1](#).

Figure 1. Total number of indexed records

IBM Data Cataloging and S3 object storage data source connections

Use this information to understand how IBM Data Cataloging works with S3-compliant object store.

- [Creating an S3 object storage data connection](#)
Use this information to create a connection to an S3-compliant object store.
- [Scanning an S3 object storage data connection](#)
Use this information to scan a connection for an S3-compliant object store.
- [Best practices for scanning an S3 object storage system](#)
Use best practices for scanning S3-compliant object storage systems.

Creating an S3 object storage data connection

Use this information to create a connection to an S3-compliant object store.

About this task

To create the S3-compliant connection:

Note: The storage host supports SSL by default. If `http` is required, then explicitly add `http://` prior to the hostname or IP address.

Procedure

1. Log in to the IBM Data Cataloging graphical user interface (GUI) with a user ID that is associated with data administration role.
The data administration access role is required for creating connections. For more information about role-based access control, go to [Role-based access control](#).
2. Click  and go to Data connections > Connections.
Clicking Connections displays the different types of data source connection names, platforms, clusters, data source, size, and Add Connection.

Figure 1. Displaying the source names for Data Source Connections

3. Click Add Connection to display a new window that shows Add Data Source Connection.

Figure 2. Example of the Add Data Source Connection GUI window

4. Complete the following steps:
 - a. In the field for Connection name, define a Connection name.
 - b. Choose data source connection type from Connection type list.
5. Select the connection type Simple Storage Service (S3).

Figure 3. Selecting Simple Storage Service (S3)

6. In the screen for S3, complete the fields and then click Submit Connection for the S3 connections manager.

Figure 4. Completing the S3 information fields

S3 access key

Indicates the access key ID for the S3 object store.

S3 secret key

Indicates the secret key ID for the S3 object store.

Site

Indicates the physical location of the records.

Storage host

Indicates the IP address or host of the storage system.

Bucket name

Indicates the name of the bucket that you are going to scan.

Scanning an S3 object storage data connection

Use this information to scan a connection for an S3-compliant object store.

About this task

When you initiate a scan from the IBM Data Cataloging graphical user interface (GUI), the metadata is transferred asynchronously back to the IBM Data Cataloging instance.

Automated scanning and data ingestion relies on an established and active network connection between the IBM Data Cataloging instance and the S3 storage source. If the connection cannot be established, the state of the data source connection shows as unavailable, and the option for automated scanning does not appear in the IBM Data Cataloging GUI for that connection.

Procedure

1. Log in to IBM Data Cataloging web interface.
2. Click  go to Data connections > Connections.
The following figure shows the data connections lists:

Figure 1. Data source connections

3. Select the data source connection name that you want to scan. Ensure that the **State** is listed as **Online** to make your system scan ready. The following figure shows how to select a data source connection to scan.

Figure 2. Selecting a data source connection to scan

4. Select Scan now to change the status to Scanning. The following figure shows an active scan.

Figure 3. Active scans

5. When the scan finishes, the state field returns to a status of Online.

Best practices for scanning an S3 object storage system

Use best practices for scanning S3-compliant object storage systems.

It is recommended to check the log files in the following directories after each scan:

`/opt/ibm/metaocean/data/connections/s3/<connection_name>/debug/<scan_timestamp>/scanner.debug` indicates whether the scan was successful or not.

`/opt/ibm/metaocean/data/connections/s3/<connection_name>/error/<scan_timestamp>/scanner.error` contains a list of all the messages that are not delivered to IBM Data Cataloging.

`/opt/ibm/metaocean/data/connections/s3/<connection_name>/data/<scan_timestamp>/` contains a subfolder with the scanned data source name. There is a stats folder inside this folder that contains information about the number of objects in the data source or the number of objects or scanned files.

You can also compare the total size of the bucket that is reported in IBM Data Cataloging with the total size of the S3 object store at source (if it is available).

Scanning an Elastic Storage Server data source connection

Use the IBM Data Cataloging GUI to scan an Elastic Storage Server (ESS) data connection.

Procedure

1. Log in to IBM Data Cataloging web interface with data admin privileges.
2. Open an internet browser to the IP address or host name of your IBM Data Cataloging cluster.
The default credentials to put into the IBM Spectrum Discover dialog box are:

Default user: `sdadmin`
Default Password: `Passw0rd`

3. Click  menu and go to Data connections. Add data source connection.
4. Enter the EMS node as the host system name:

Connection Name

Indicates the connection name, such as `ESS_test`.

Connection Type

Indicates the connection type, which is `Spectrum Scale`.

User

Indicates the user that initiates the scan, such as `root`.

Password

Indicates the password for the user that initiates the scan.

Working Directory

Indicates the working directory for the scan, such as `/gpfd/icp4D_data_fs_master1/sd_scan`.

Scan Directory

Indicates the scan directory, such as `/gpfd/icp4D_data_fs_master1`.

Site (optional)

Indicates the scan site. This field is optional.

Cluster

Indicates the clustered system name that is being scanned, such as `heliumess.tuc.stglabs.ibm.com`.

Host

Indicates the host system name that is being scanned, such as `9.11.103.45`.

Filesystem

Indicates the file system name that is being scanned.

Node List

Indicates the node list of nodes that are being scanned. Enter `gss_ppc64` as the node class to perform the scan.

5. After you complete all fields, select Submit Connection.
6. Select your data source from the table (click the row) and then select Scan Now.
7. You can monitor the status of the scans from Data Connections Overview.
8. You can also search for documents from that data source by using the search navigation icon in the left side of the GUI.
In the search icon you must:
 - a. Enter a query.
 - b. Click Search.
 - c. Indicate the files that are found in the search results.

Creating a Network File System data source connection

You can use the IBM Data Cataloging graphical user interface to create a Network File System (NFS) data connection.

About this task

Note: For NFS scanning that uses Data ONTAP 8.1.2 or later, export the file system with the following configuration:

Protocol

NFSv3 and NFSv4

Security type

UNIX

Client permissions

A minimum of read-only access is necessary.

Anonymous users

Root access must be granted.

Setuid and Setgid executable routines are not necessary.

Creating data source connections in IBM Data Cataloging identifies source storage systems that are to be indexed by IBM Data Cataloging.

For some data source types, a network connection can be created to allow for automated scanning and indexing of the source system metadata. IBM Data Cataloging will not index data from unknown sources, so creating a data source connection is the first step towards cataloging any source storage system.

Procedure

1. Log in to the IBM Data Cataloging web interface with a user ID that has the data admin role that is associated with it.
Note: The data admin access role is necessary for creating connections.
2. Click  menu and go to Data connections to display the connection's source name, platform, cluster, data source, site, next run time, and state of existing data source connections.
3. Click Add connection to display the Add data source connection window.
4. Enter a name in the Connection name field.
5. Select the connection type Network File System from the Connection type list.
6. Complete the fields for the NFS parameters, and click Submit Connection.

Parameters for NFS connections

Connection name

The name of the connection, an identifier for the user, for example `filesystem1`.

Note: It must be a unique name within IBM Data Cataloging.

Connection type

The type of source storage system this connection represents.

Enable NFSv4 ACL scans

Enables the scan of NFSv4 ACL permission entries.

Data source

The full name of the data source.

Export path

The data path from which data is to be exported.

Host

The host name of the node from which a scan can be initiated.

Site

The location in which the data source facility is located.

Creating an SMB data source connection

Creating an SMB data connection by using the IBM Data Cataloging graphical user interface.

About this task

Create data source connections in IBM Data Cataloging to identify and index source storage systems.

For some data source types, a network connection is (optionally) created to allow for automated scanning and indexing of the source system metadata. IBM Data Cataloging does not index data from unknown sources, so creating a data source connection is the first step towards cataloging any source storage system.

Procedure

1. Log in to the IBM Data Cataloging web interface with a user ID that is associated with the data admin role.
Note: The Data admin access role is required for creating connections.
2. Click  menu and go to Data connections > Connections to display the source connection name, platform, cluster, data source, site, next run time, and state of existing data source connections.
3. Click Add connection to display the Add data source connection window.
4. Enter a name in the Connection name field.
5. Select the connection type Server Message Block (SMB) / CIFS from the Connection type list.
6. Complete the fields for the SMB parameters, and click Submit Connection.

Parameters for SMB connections

Connection Name

Indicates the name of the connection, an identifier for the user, for example Share1.

Note: It must be a unique name within IBM Data Cataloging.

Share

Indicates the path name of the SMB/CIFS file share, for example //server/share.

User

Indicates the user ID that has access permissions to the SMB share, for example DOMAIN1\user1

Password

Indicates the authentication password for the user ID provided.

Site (Optional)

Indicates the location in which the data source facility is located.

Creating an IBM Storage Protect data source connection

Creating the IBM Storage Protect data connection by using the IBM Data Cataloging graphical user interface.

About this task

Creating data source connections in IBM Data Cataloging identifies source storage systems that are to be indexed by IBM Data Cataloging.

For some data source types, a network connection is (optionally) created to allow for automated scanning and indexing of the source system metadata. IBM Data Cataloging will not index data from unknown sources, so creating a data source connection is the first step towards cataloging any source storage system.

Procedure

1. Log in to the IBM Data Cataloging web interface with a user ID that has the data admin role that is associated with it.
Note: The data admin access role is required for creating connections.
2. Click  menu and go to Data connections > Connections to display the source name, platform, cluster, data source, site, next run time, and state of existing data source connections.
3. Click Add connection to display the Add data source connection window.
4. Enter a name in the Connection name field.
5. Select the connection type IBM Spectrum Protect from the Connection type list.
6. Complete the fields for the IBM Storage Protect connection type, and click Submit Connection.

Parameters for IBM Storage Protect connections

Connection Name

The name of the connection, an identifier for the user, for example filesystem1.

Note: It must be a unique name within IBM Data Cataloging.

Spectrum Protect Server IP

The IP address or host name of the IBM Storage Protect server.

ODBC Port

The ODBC (open database connector) port for the Protect server (default is 51500).

Instance User

The name of the IBM Storage Protect database instance user. The default is tsminst1.

Instance user password

The password for the database instance user.

Site (Optional)

The location in which the data source facility is located.

Configuring data source connections offline

Multiple source data connections can be added to the IBM Data Cataloging system through offline mode.

Before you begin

- You must have the `SD_USER`, `SD_PASSWORD` & `OVA` environment variables set in the IBM Data Cataloging system. To verify the details, enter `gettoken`.
- Enter the connection values inside the JSON file and add it to IBM Data Cataloging host by using `load_connection`

`<nameofjsonfile>`.

A sample JSON file with connection values as shown.

```
{
  "name": "SpectrumScale2Million",
  "platform": "Spectrum Scale",
  "cluster": "ctolib.cluster1",
  "datasource": "scale0",
  "site": "Offline Scale"
}
```

Procedure

- Log in to the IBM Data Cataloging host system with following credentials.

```
Host: <IBM Data Cataloging_hostname>
login: moadmin
Password: Passw0rd
```

- SCP the `list.metaocean` file to the IBM Data Cataloging VM by using the following command before you run the ingestion script.

```
sudo scp moadmin@modevdump:/mnt/datadump/scans/<file_name>/home/moadmin/
```

- After the `list.metaocean` file is copied to the IBM Data Cataloging host, issue the following command to ingest the file.

```
$ ingest <file_name>
```

- To monitor the ingestion process by following the producer log, issue the following commands.

```
$ kp | grep spectrum-discover-producer-<connection_name>-scan
```

Note: The preceding command returns the producer pod log.

```
$ oc logs -f -n ibm-data-cataloging spectrum-discover-producer-<connection_name>-scan-<randomchars>
```

Editing and using the TimeSinceAccess and Size Range buckets

Users can group or aggregate data into three user-defined bucket ranges. The three user-defined bucket ranges are TimeSinceAccess, Size Range and FileGroup.

The TimeSinceAccess bucket groups files and objects based on the time they were last accessed. The SizeRange bucket groups files and objects based on their size. The File Group bucket groups files based on their file type or extension. All three buckets can be customized to better align with the user's requirements. Both the TimeSinceAccess and the SizeRange buckets have up to five custom ranges with user-defined labels.

Note: The **FileGroup** bucket cannot be edited through the user interface and must be modified using REST APIs. For more information, see [/db2whrest/v1/buckets/<bucket>: PUT](#). For more information, see the topic `/db2whrest/v1/buckets/<bucket>: PUT` in the *IBM Data Cataloging: REST API Guide*. To access the SizeRange bucket groups, select Metadata  Tags  edit icon for the SizeRange tag. For example, SizeRange can be broken up into 'T-shirt size' ranges where the ranges and labels are:

Table 1. Examples of size ranges and sizes of buckets with user-defined labels

Size range	Size
0 - 4 K	XS
4 K - 1 M	S
1 M - 1 G	M
1 G - 1 T B	L
1 TB+	XL

After you change or update a bucket definition, IBM Data Cataloging summarizes the current set of files and objects into their respective bucket ranges. The changes are updated periodically every half an hour; thus, it may take a half an hour or more before the changes are reflected in the Spectrum Discover GUI.

Note: Ensure that the maximum value for each bucket is greater than the value assigned to the previous bucket.

See the [Figure 1](#)

Figure 1. Example of how to define the settings for a SizeRange bucket

pov00054

To open the menu for the TimeSinceAccess buckets select Metadata_>Tags_>edit icon for the TimeSinceAccess tag. See the [Figure 1](#) for an example.

[Figure 2](#) shows an example of how to modify and define the settings of a bucket that is older than one year.

Figure 2. Example of how to modify and define the settings of a bucket that is older than one year old

IBM Spectrum Storage software requirements

Use IBM Data Cataloging to index metadata from other applications and to orchestrate the data management.

IBM Cloud Object Storage

IBM Data Cataloging indexes metadata from IBM Cloud® Object Storage by receiving notifications that contain metadata from IBM Cloud Object Storage. IBM Data Cataloging also supports scanning IBM Cloud Object Storage to harvest metadata.

The following table shows the minimum required IBM Cloud Object Storage software version to enable metadata harvesting with IBM Data Cataloging:

Table 1. IBM Cloud Object Storage software requirements

Component	Version
IBM Cloud Object Storage	3.14.0 and higher

IBM Storage Scale

IBM Data Cataloging indexes metadata from IBM Storage Scale by scanning IBM Storage Scale file systems. The IBM Storage Scale watch folders technology preview also enables IBM Storage Scale to send events that contain metadata to IBM Data Cataloging.

The following table lists the minimum required IBM Storage Scale software versions:

Table 2. IBM Spectrum Scale software requirements

Component	Feature	Version
IBM Storage Scale	Scanning	4.2.3.x and higher
IBM Storage Scale	Live events	(Advanced and Data Management Editions, only) 5.0.4.1 and higher
IBM Storage Scale	Data management that uses ScaleAFM Application	5.1 and higher

The following requirements are needed to enable live events:

- You must use IBM Storage Scale 5.0.3.x. Due to an IBM Storage Scale performance issue that might result in the unexpected suspension of the IBM Storage Scale watch, IBM Data Cataloging recommends the use of IBM Storage Scale 5.0.4.x.
- Watch folder must be enabled for the Scale cluster.
- A minimum of three nodes on the IBM Storage Scale cluster are required to act as Kafka brokers.
- The IBM Storage Scale nodes that act as brokers must meet a minimum local space requirement of 20 GB each to successfully enable the watch with a secondary sink.

IBM Storage Protect

IBM Data Cataloging indexes metadata from IBM Storage Protect by scanning IBM Storage Protect file systems.

The following table lists the minimum required IBM Storage Protect software versions to enable metadata harvesting with IBM Data Cataloging:

Table 3. IBM Spectrum Protect software requirements

Component	Version
IBM Storage Protect	7.x and higher

IBM Storage Archive

IBM Data Cataloging supports the advanced tiering function with the ScaleILM application.

The following table lists the minimum IBM Spectrum® Archive software version that is required to control the data placement by IBM Data Cataloging.

Table 4. IBM Storage Archive software requirements

Component	Version
IBM Storage Archive Enterprise Edition (EE)	1.3.0.6 and higher

IBM Data Cataloging installation with alternative VLAN

Install and configure IBM Data Cataloging that uses additional VLAN connected through the IBM Fusion upstream links.

For security reasons, the target VLAN network is not available for the IBM Fusion cluster through the default IBM Fusion public network.

There are several approaches available to access alternate VLANs that do not have routable access through the default IBM Fusion network.

The reminder of this document covers the option of OpenShift® **NetworkAttachmentDefinitions** to provide IBM Data Cataloging access to alternative VLAN access. It explains the setup and implementation of **NetworkAttachmentDefinitions** and the required modifications to the IBM Data Cataloging definitions.

IBM Fusion VLAN Configuration

1. Add VLAN. For procedure, see [Adding VLANs](#).
2. Add VLAN to link.
3. Check switches to ensure that VLAN is available on bond250 and ports.
4. Check the compute node to ensure that VLAN is added.

IBM Data Cataloging Configuration

1. Log in to the Red Hat® OpenShift Container Platform web console.
2. Go to Networking > NetworkAttachmentDefinitions.
3. Click Project drop-down and select ibm-data-cataloging namespace from the list.
4. Click the NAD that you want and check the Container and VM NAD details.

For example:

For container access

Note: Adding extra VLANs to the IBM Fusion switch link creates an additional bridge interface for each additional VLAN on the worker nodes **bond0** interface automatically.

```
apiVersion: k8s.cni.cncf.io/v1
kind: NetworkAttachmentDefinition
metadata:
  annotations:
    k8s.v1.cni.cncf.io/resourceName: bridge.network.kubevirt.io/br4001
  name: br4001-c
  namespace: ibm-data-cataloging
spec:
  config: >-
{ "cniVersion": "0.3.1", "name": "br4001", "type": "macvlan", "master": "br4001", "mode": "bridge", "ipam": { "type":
"static", "routes": [ { "dst": "10.140.20.0/24", "gw": "10.100.100.1" } ] } }
```

Item	Value	Description
Name	br4001-c	Network Attachment Definition
dst	10.140.20.0	Destination subnet
gw	10.100.100.1	Router
Name	br4001	Bridge 4001 (auto generated)

For VM access

Note: After attached to any VM, additional configuration on the VM interface must be necessary, including IP and routing information.

```
apiVersion: k8s.cni.cncf.io/v1
kind: NetworkAttachmentDefinition
metadata:
  name: br4001
  namespace: ibm-datacataloging
spec:
```

```
nodeSelector:
  vmtest: "true"
config: >-
  {"name": "br4001", "type": "cnv-bridge", "cniVersion": "0.3.1", "bridge": "br4001", "macspoofchk": true, "ipam": {}}
```

Item	Value	Description
Name	br4001	Network Attachment Definition
Bridge	br4001	Bridge interface (auto generated)

Container updates

Important: The container updates might change based on your connection type such as NFS, S3, SMB, and Scale. The following example shows the Scale connection type.

The following IBM Data Cataloging containers require updates for Scale scanning through secondary VLAN as follows:

- `isd-connmgr-main`
- `isd-consumer-scale-le`
- `isd-consumer-scale-scan`

Assign a unique IP address for each container pod set.

For example:

Container	IP address	Resource
<code>isd-connmgr-main</code>	10.100.100.11	Statefulset
<code>isd-consumer-scale-le</code>	10.100.100.12	Deployment
<code>isd-consumer-scale-scan</code>	10.100.100.13	Deployment

```
apiVersion: apps/v1
metadata:
  name: isd-connmgr-main
  ....
spec:
  template:
    annotations:
      k8s.v1.cni.cncf.io/networks: |-
        [
          {
            "name": "br4001-c",
            "interface": "br4001",
            "namespace": "ibm-data-cataloging",
            "ips": ["10.100.100.11/24"]
          }
        ]
```

Activate changes

1. Do a graceful shutdown of the IBM Data Cataloging service. For the procedure, see [Graceful shutdown](#).
2. Edit `Statefulset isd-connmgr-main` in the components. You can append the new annotation to the current annotations.
3. Edit `Deployments` for the consumer type. In this case it depends on the connection type.
For example for scale it must be the `isd-consumer-scale-scan`.
4. Return the IBM Data Cataloging service to the running state. For the procedure, see [Returning IBM Data Cataloging to a running state](#).

Example Scaling Commands:

- Scale down IBM Data Cataloging:

```
oc get deployments |grep consumer
oc get deployments |grep consumer|awk '{ print $1}'|xargs -L 1 echo oc scale --\ replicas=0 deployment |bash

oc get deployments |grep producer
oc get deployments |grep producer|awk '{ print $1}'|xargs -L 1 echo oc scale --\ replicas=0 deployment |bash

oc get deployments |grep isd-producer-scale-le
oc get deployments |grep isd-producer-scale-le|awk '{ print $1}'|xargs -L 1 echo oc \ scale --replicas=0 deployment
|bash

oc get statefulset |grep connmgr
oc scale --replicas=0 statefulset.apps/isd-connmgr-main

oc get deployments |grep db2whrest
oc scale --replicas=0 deployment db2whrest
```

- Scale up IBM Data Cataloging:

```
$oc scale --replicas=1 deployment <deployment_name isd-db2whrest
$oc get deployments |grep db2whrest
isd-db2whrest          1/1          1          1          6d20h

oc get deployments |grep consumer
oc get deployments |grep consumer|awk '{ print $1}'|xargs -L 1 echo oc scale --\ replicas=10 deployment |bash

oc get deployments |grep producer
oc get deployments |grep producer|awk '{ print $1}'|xargs -L 1 echo oc scale --\ replicas=10 deployment |bash

oc get deployments |grep connmgr
oc scale --replicas=1 statefulset.apps/isd-connmgr-main
```

VLAN Testing

Use the following commands to verify that the VLAN is present in the containers.

Note: Addresses are hex byte reverse.

```
sh-4.4# cat /proc/net/route

```

Iface	Destination	Gateway	Flags	RefCnt	Use	Metric	Mask	MTU	Window	IRTT
br4001	0064640A	00000000	0001	0	0	0	00FFFFFF	0	0	0
br4001	0064640A	0164640A	0003	0	0	0	00FFFFFF	0	0	0

```
sh-4.4#
```

This is what expecting to see for the 10.100.100.0 network through 10.100.100.1 router.

A utility container can be used with more commands like **apline** or **centos** to confirm that the network endpoints are reachable.

Using **/proc** to determine assigned IP address.

```
sh-4.4# cat /proc/net/fib_trie | grep "|--" | egrep -v "0.0.0.0"
|-- 10.100.100.0
|-- 10.100.100.11
...
|-- 127.0.0.0
|-- 127.0.0.1
|-- 10.100.00.0
|-- 10.100.100.11
...
|-- 127.0.0.0
|-- 127.0.0.1
|-- 127.255.255.255
```

Testing pods:

From the virtual machine or target cluster, ping the container or pod IP through VLAN.

After completion of all steps, create IBM Data Cataloging data connection. For the procedure, see [Creating an IBM Storage Scale data source connection](#).

Multiple connection managers

Multiple connection managers are a new capability that is designed to enhance scanning performance and enable parallel ingestion. It proves especially valuable in scenarios where data sources are geographically dispersed and need to be scanned as remote sources.

With this new capability, users can take advantage of two primary deployment scenarios:

- The first scenario involves deploying multiple connection managers within the same cluster, allowing for efficient coordination and distribution of scanning tasks. It enables optimized resource utilization and faster processing of data.
- The second scenario involves adding external nodes to the system and deploying one or more connection managers on these nodes. This distributed setup further enhances scanning performance by using extra computing resources and enabling parallel execution of scanning operations across multiple nodes.

Note:

- Multiple connection managers improve scanning performance, but it is necessary to understand that the increase in scanning speed does not increase in the performance of indexing records into the database. The indexing process might have its own limitations and dependencies that might impact overall performance.

Example deployment scenario:

- Main cluster located in Mexico with 2 connection managers deployments.
- One remote worker located in France with 3 connection manager deployed to scan France data sources.
- One remote worker located in Canada with 2 connection manager deployed to scan Canada data sources.

Example:

```
kind: SpectrumDiscover
apiVersion: spectrum-discover.ibm.com/v1alpha1
metadata:
  name: spectrumsdiscover-sample
  namespace: discover
spec:
  license:
    accept: true
    doInstall: true
    rx_storage_class: ibmc-file-gold-gid
  connmgr:
    site: mexico
    replicas: 2
    extraLocations:
      - site: france
        locationType: remote
        replicas: 2
      - site: canada
        locationType: remote
        replicas: 3
    affinity:
  tolerations:
    - effect: PreferNoSchedule
      key: isd
      operator: Exists
```

If modifying the main location is required, specify it in the onsite property as follows:

```
connmgr:
  site: france
```

Note: In case site does not exist in a statefulset as example.com or empty, for instance, internal scheduler assigns it to any type local connection manager available.

Enabling feature for skipping the snapshot directories

When the skipping feature is enabled, you can skip the metadata ingestion to the snapshot directories.

Before you begin

- You must set the following environment variables in the IBM Data Cataloging:
 - `NFS_SKIP_SNAPSHOT_DIRS`
 - `INCLUDE_SCALE_SNAPSHOTS`
- Set the environment variable by using the configmap '`connmgr`'.

About this task

To enable the feature for skipping `NFS_SKIP_SNAPSHOT_DIRS` the snapshot directories, you need to set the following environment variable in IBM Data Cataloging.

`NFS_SKIP_SNAPSHOT_DIRS`

This environment variable is used specifically for an NFS connection. When the variable is set to 'True', IBM Data Cataloging skips the scanning of snapshot directories. When the variable is set to 'False' or not set at all, it scans the snapshot directories.

`INCLUDE_SCALE_SNAPSHOTS`

When the `INCLUDE_SCALE_SNAPSHOTS` variable value is set to 'false' (default value), the IBM Data Cataloging scan excludes all the files that are inside the .snapshots directories, otherwise, if the variable value is set to 'true', the scan includes all the files, including the .snapshots directories.

- [Enabling skip snapshot directories feature on Red Hat OpenShift](#)
The following procedure helps you set the configuration for skipping snapshot directories by using `NFS_SKIP_SNAPSHOT_DIRS` and `INCLUDE_SCALE_SNAPSHOTS` variable.

Enabling skip snapshot directories feature on Red Hat® OpenShift®

The following procedure helps you set the configuration for skipping snapshot directories by using `NFS_SKIP_SNAPSHOT_DIRS` and `INCLUDE_SCALE_SNAPSHOTS` variable.

Before you begin

Add the following variables as needed to the configmap and set the value to 'True'.

- `NFS_SKIP_SNAPSHOT_DIRS`
- `INCLUDE_SCALE_SNAPSHOTS`

Procedure

- Issue the following command to change the current project:

```
oc project ${PROJECT_NAME}
```

- Issue the following command to edit the configmap:

```
oc edit configmap connmgr
```

After you run the preceding command, the output looks similar to the following as shown here. You can modify the following file and add or update the variables and its value in the `data` section.

```
# Please edit the object below. Lines beginning with a '#' will be ignored,
# and an empty file will abort the edit. If an error occurs while saving this file will be
# reopened with the relevant failures.
#
apiVersion: v1
data:
  CONNMGR_ENDPOINT: /connmgr/v1/
  CONNMGR_PROTOCOL: http
  NFS_SKIP_SNAPSHOT_DIRS: "True"
kind: ConfigMap
metadata:
  creationTimestamp: "2022-08-26T19:55:39Z"
  name: connmgr
  namespace: spectrum-discover
  ownerReferences:
  - apiVersion: spectrum-discover.ibm.com/v1alpha1
    kind: SpectrumDiscover
    name: spectrumdiscover
    uid: 001fb331-c2ef-4b28-8827-5c7d6a702904
  resourceVersion: "13761646"
  uid: bf621847-4c00-44c9-a7f2-4d3430ede67b
```

- Save the preceding updated object and issue the following command to verify that data is updated.

```
oc get configmap connmgr -o yaml
```

After you run the preceding command, the output looks similar to the following as shown here:

```

apiVersion: v1
data:
  CONNMGR_ENDPOINT: /connmgr/v1/
  CONNMGR_PROTOCOL: http
  NFS_SKIP_SNAPSHOT_DIRS: "True"
kind: ConfigMap
metadata:
  creationTimestamp: "2022-08-23T11:33:40Z"
  name: connmgr
  namespace: spectrum-discover
  ownerReferences:
  - apiVersion: spectrum-discover.ibm.com/v1alpha1
    kind: SpectrumDiscover
    name: spectrumsdiscover
    uid: 64aa30c1-d621-47f5-9ee8-763ee9386bbd
  resourceVersion: "293269249"
  uid: e54ebffa-bell-4d05-82e4-03bc94edbce6

```

4. Issue the following command to verify that the update is made in the connection manager pod:

```
oc -n ibm-data-cataloging delete sts/isd-connmgr-main
```

Managing IBM Data Cataloging rules when integrated with CAS

IBM Data Cataloging provides the ability to integrate with Content-Aware Storage to configure file ingestion filtering. This feature enables you to filter files from a data source based on specific criteria, such as file type or content, and ingest them into the corresponding domain.

1. Ensure that you have IBM Fusion 2.11.0 version.
2. Install the IBM Data Cataloging to 2.3.0 version. For more information, see [Installing IBM Data Cataloging](#).
Important: If you face any issues during the installation of the IBM Data Cataloging 2.3.0, then see [Data Cataloging upgrade issues](#) to resolve the issue.
3. Connection to Scale Remote Filesystem from IBM Data Cataloging with live events enabled. For more information, see [IBM Storage Scale data source connections](#).
4. Configure file-ingestion filtering using IBM Data Cataloging on the Content-Aware Storage. For more information, see [Integrating IBM Data Cataloging for file filtering](#).
5. When IBM Fusion Data Cataloging is enabled to perform file filtering on Content-Aware Storage, a default rule is automatically created. This rule filters files based on the file types such as pdf, doc, docx, txt, html, markdown, md, pptx, jpeg, png, bmp, xslx, asciidoc, adoc, xhtml, csv, webp, wav, ogg, opus, mp3. For example:

```

apiVersion: datacataloging.ibm.com/v1alpha1
metadata:
  name: rule-allowed-filetypes
  namespace: ibm-data-cataloging
spec:
  metadata:
    - field: filetype
      operator: in
      value:
        - pdf
        - doc
        - docx
        - txt
        - html
        - markdown
        - md
        - pptx
        - jpeg
        - png
        - bmp
        - xslx
        - asciidoc
        - adoc
        - xhtml
        - csv
        - webp
        - wav
        - ogg
        - opus
        - mp3

```

6. Use the following command to extend the list of supported files, you can update the default rule by patching the current Rule object.
For example, to include the file types such as pdf, txt, html, json, md, docx, pptx, bmp, jpeg, png, tiff, and sh.

```

DCS_NS=ibm-data-cataloging
oc patch rule allowed-filetypes -n $DCS_NS --type merge -p '{"spec": {"metadata": [{"field": "filetype", "operator": "in", "value": ["doc", "docx", "pdf", "txt", "gif", "html", "json", "md", "pptx", "bmp", "jpeg", "png", "tiff", "sh"]}]}'}

```

7. In addition to metadata rule filtering, you can perform a complementary filter based on content using regex-based content search capability. For more information, see [Identifying the required regex expressions](#).
For example, to filter files based on the presence of an email pattern, you can add a content requirement to the default rule:

```

DCS_NS=ibm-data-cataloging
oc -n $DCS_NS patch rule allowed-filetypes --type=merge -p '{"spec":{"content":> [{"field":"email","operator":"regex","value":"\\b[\\w\\.=-]+@[\\w\\.=-]+\\. [\\w]{2,3}\\b"}]}'

```

Administering IBM Data Cataloging

This section provides information on how to administering the IBM Data Cataloging capabilities.

- **[AI-enabled capabilities](#)**
IBM Fusion Data Cataloging is expanding its AI-driven data management capabilities with two significant innovations. The new IBM Data Cataloging Model Context Protocol (MCP) server that enables multiple large language models (LLMs) to connect to and operate across a unified set of cataloging tools.
- **[Managing user access](#)**
The Data cataloging environment provides access to users and groups. The role that is assigned to a user or group determines the functions that are available. Users and groups can also be associated with collections that use policies that determine the metadata that is available to view.
- **[Managing metadata policies](#)**
Policies might be used to automatically tag a set of documents on a periodic basis. In addition, policies might be used to send sets of documents to be deep-inspected by a registered application.
- **[Using content search policies](#)**
You can define regular expressions to search for and create policies that use the regular expressions.
- **[Tiering data by using ScaleILM application](#)**
Use the IBM Data Cataloging ScaleILM application to move data to different tiers (pools) that are configured on the IBM Storage Scale connection.
- **[Copying data by using ScaleAFM application](#)**
The ScaleAFM application supports copy function between IBM Storage Scale connection and IBM Cloud® Object Storage connection.
- **[Exporting metadata to IBM Watson Knowledge Catalog](#)**
IBM Data Cataloging Watson Knowledge Catalog (WKC) connector supports export of the metadata to either an IBM Cloud instance or to an On-Premise Instance of the Watson Knowledge Catalog.
- **[Importing externally curated tags for COS/S3 using import tags application](#)**
The import tags application is used to import a set of externally curated tags for Cloud Object Storage and S3 services.
- **[Performing retention analytics on IBM Storage Protect archive data](#)**
Use IBM Data Cataloging to perform retention analytics on archive data managed by IBM Storage Protect.
- **[Managing tags](#)**
A tag is a custom metadata field used to enhance system metadata with organization-specific information. For instance, an organization may categorize its storage by project, cost center, or region but the attributes not provided by the storage system itself. Tags enable data classification, search, and reporting based on these organizational dimensions. Use tags to store this additional information and to manage or locate data using metadata that reflects your organizational context.
- **[Discover data](#)**
By discovering your data, you can apply policies that assign tags to your data. You can apply tags to the results of a single search, or you can use policies to automatically apply tags on a periodic basis.
- **[Managing applications](#)**
An application is a program that interfaces with IBM Data Cataloging and can access the source storage. There are many use cases for application, including data content inspection for enriching metadata, data movement or migration, data scrubbing or sanitation, and more. Data is identified by IBM Data Cataloging by policy filter and passed to the application as pointers through a messaging queue. Then, the application performs whatever work is appropriate on the source data and returns a completion status back to IBM Data Cataloging, which might or might not include enriched metadata for the records. If it does include enriched metadata, IBM Data Cataloging catalogs that metadata and makes it immediately searchable.
- **[Reports](#)**
Reports can be generated upon applying tags to a set of data.
- **[Creating a IBM Data Cataloging application for metadata-based policies](#)**
Provides information about how to create IBM Data Cataloging application for metadata-based policies.
- **[Graceful shutdown](#)**
Provides detailed instructions to put IBM Data Cataloging in idle state on an OpenShift® environment.
- **[REST API for IBM Data Cataloging](#)**
REST API reference documentation provides endpoint specifications, request and response formats, and authentication details for programmatic access to IBM Spectrum Discover services.
- **[Data protection](#)**
Data protection features in IBM Spectrum Discover support backup, disaster recovery, and restore operations to protect catalog metadata and system configurations.
- **[Using a third-party data movement application to manage data](#)**
Introduction to data movement with IBM Data Cataloging.

AI-enabled capabilities

IBM Fusion Data Cataloging is expanding its AI-driven data management capabilities with two significant innovations. The new IBM Data Cataloging Model Context Protocol (MCP) server that enables multiple large language models (LLMs) to connect to and operate across a unified set of cataloging tools.

Complementing this, IBM Fusion Data Cataloging is introducing a technology preview of Content-based AI-enabled autotagging, which enables you to selectively analyze data and automatically generate tags based on document content.

Together, these capabilities enhance governance, automation, and intelligent discovery across enterprise data ecosystems.

- **[IBM Data Cataloging MCP server](#)**
IBM Data Cataloging Service offers a new capability of a Model Context Protocol (MCP) server. It is designed to enable seamless interoperability between multiple large language models (LLMs) and a unified suite of cataloging and data management tools. Through a centralized control layer, the MCP server allows LLMs to securely connect, interact, and run operations by using tools that are registered within the MCP environment.
- **[AI-powered content-based tagging](#)**
IBM Data Cataloging provides AI-powered content-based tagging to automatically classify unstructured data by using the actual content of files, not only their metadata. This capability uses an inference model that is connected through the IBM LLM proxy to propose and apply business-relevant tags across large datasets with minimal manual effort. The LLM proxy can route requests to multiple upstream providers: a self-hosted Ollama model, an OpenAI-compatible endpoint, Anthropic, watsonx.ai, or an internal model gateway, through a single configuration block in the **SpectrumDiscover** custom resource.

IBM Data Cataloging MCP server

IBM Data Cataloging Service offers a new capability of a Model Context Protocol (MCP) server. It is designed to enable seamless interoperability between multiple large language models (LLMs) and a unified suite of cataloging and data management tools. Through a centralized control layer, the MCP server allows LLMs to securely connect, interact, and run operations by using tools that are registered within the MCP environment.

Integrated with IBM Data Cataloging, the MCP server enhances how AI-driven systems access, analyze, and organize metadata from diverse data sources. It provides a consistent interface for tool discovery, execution, and lifecycle management, reducing the need for direct integrations between individual LLMs and the underlying cataloging infrastructure.

Key capabilities

Natural language queries on Data Cataloging Services (DCS)

It enables the user to explore and query cataloged information by using natural language, without requiring knowledge of query syntax. This capability improves data accessibility and empowers business users to retrieve insights more intuitively.

LLM-based tags and labels catalog suggestions

It assists the user in creating, managing, and discovering tags more efficiently. The LLM can use the MCP tools to suggest relevant tags based on dataset content and highlight existing tags across the catalog. This capability helps maintain metadata consistency, reduces manual effort, and enhances the overall accuracy of data classification.

Policy-driven auto-tagging and management

It enables you to view existing catalog policies and create or run auto-tagging policies that are powered by AI. These policies automatically classify and label datasets based on predefined rules and model insights. This helps enforce governance standards, improves compliance, and ensures that metadata remains accurate and up to date over time.

Before you begin

Before you enable and use the MCP server within the IBM Data Cataloging environment, ensure that your system meets the following requirements. These prerequisites are necessary to authenticate with your cluster, enable the MCP components, and verify the available service endpoints.

Ensure that the following tools are installed and accessible from your local environment:

- Red Hat® OpenShift® CLI (oc)
- curl

After verifying the prerequisites, log in to your OpenShift cluster by using CLI.

Setting up the MCP server

To enable MCP server capabilities, ensure that the Data Catalog has the required features that are enabled for the MCP server.

Note: The `DCS_NS` variable specifies the namespace where the DCS instance is deployed. By default, it is `ibm-data-cataloging`, and adjusts according to the namespace where it is installed.

Run the following command:

```
DCS_NS=ibm-data-cataloging
```

```
oc -n ${DCS_NS} patch SpectrumDiscover $(oc -n ${DCS_NS} get spectrumdiscover -o jsonpath='{.items[*].metadata.name}') \
--type=merge -p '{
  "spec": {
    "enabled_features": {
      "natural-language-queries": {
        "enabled": true
      }
    }
  }
}'
```

After the patch is successfully applied, the `SpectrumDiscover` loads the MCP server with new capabilities.

Verifying that MCP server is running

After enabling the features, verify that the MCP server pods are up and running.

Run the following command:

```
oc -n ${DCS_NS} get pod -l 'app=isd,role=dc-s-ai-mcp-server'
```

Example output:

```
isd-dcs-ai-mcp-server 1/1 Running 0 3h
```

If you see pods in the Running state, the MCP server is successfully up and operational.

Connecting to MCP server

After the MCP server is deployed and prerequisites are met, you can retrieve the service endpoints to enable LLMs or interact with its tools. The MCP server exposes both SSE and HTTP endpoints for integration.

Retrieve MCP endpoints on Linux/macOS

```
oc get routes -n ${DCS_NS} -o json \
| jq -r '.items[]' \
| select(.metadata.name | test("mcp")) \
| "Route: \(.metadata.name)\nHost: \(.spec.host)\nSSE Endpoint: https://\(.spec.host)/mcp\nHTTP Endpoint: https://\
(.spec.host)/mcp/http\n"
```

Example output:

```
Route: dcs-mcp-route
Host: dcs-mcp-route-ibm-data-cataloging.apps.com
SSE Endpoint: https://dcs-mcp-route-ibm-data-cataloging.ibm.com/mcp
HTTP Endpoint: https://dcs-mcp-route-ibm-data-cataloging.com/mcp/http
```

The command outputs -

- **Route:** The OpenShift route for the MCP server.
 - **Host:** The host URL assigned by OpenShift.
 - **SSE Endpoint:** The URL to connect through server-sent events.
 - **HTTP Endpoint:** The URL to connect through standard HTTP requests.
- This connection provides the necessary endpoints to integrate LLMs or other clients with the MCP server.

Initialization

Example of how to initialize the MCP server:

```
curl -i -X POST \
  <MCP http endpoint> \
  -H "Content-Type: application/json" \
  -H "Accept: application/json, text/event-stream" \
  -d '{
    "jsonrpc": "2.0",
    "id": 1,
    "method": "initialize",
    "params": {}
  }' --insecure
```

Replace all placeholder values before sending the request.

Example Output:

```
HTTP/1.1 200 OK
access-control-allow-headers: Content-Type
access-control-allow-methods: GET, POST, OPTIONS
access-control-allow-origin: *
cache-control: no-cache, no-transform
content-type: text/event-stream
mcp-session-id: xxxxxxxxxxxxxxxxxxxxxx
date: Tue, 16 Dec 2025 19:17:50 GMT
transfer-encoding: chunked
set-cookie: xxxxxxxxxxxxxxxxxxxxxx; path=/; HttpOnly; Secure; SameSite=None
```

Save the `mcp-session-id`, it is necessary to send requests.

List Tools

```
curl -X POST \
  <MCP http endpoint> \
  -H "Content-Type: application/json" \
  -H "Accept: application/json, text/event-stream" \
  -H "mcp-session-id: <mcp-session-id>" \
  -d '{
    "jsonrpc": "2.0",
    "id": 1,
    "method": "tools/list",
    "params": {}
  }' \
  --insecure
```

Replace all placeholder values before sending the request.

MCP server - Tools

The following section describes the new tools that are introduced in the MCP server, which is designed to improve interaction with data sources, manage credentials, policies, and tagging. Each tool serves a specific purpose and can be used independently or together to optimize data management and automation workflows.

dcs_set_credentials

The Set Credentials tool enables you to configure the credentials that are required to connect the MCP server to the Data Cataloging Service.

Tool name	Arguments	Request
dcs_set_credentials	DCS URL, Username, Password	curl -X POST <mcp http endpoint> -H "Content-Type: application/json" -H "Accept: application/json, text/event-stream" -H "mcp-session-id: <mcp-session-id>" -d '{ "jsonrpc": "2.0", "id": 1, "method": "tools/call", "params": { "name": "dcs_set_credentials", "arguments": { "cluster_url": "<DCS URL>", "username": "user", "password": "password" } } }' --insecure

Tool name	Arguments	Request
	DCS URL, Authentication token	<pre>curl -X POST <mcp http endpoint> -H "Content-Type: application/json" -H "Accept: application/json, text/event-stream" -H "mcp-session-id: <mcp-session-id>" -d '{ "jsonrpc": "2.0", "id": 1, "method": "tools/call", "params": { "name": "dcs_set_credentials", "arguments": { "cluster_url": "<DCS URL>", "token": "<token>" } } }' --insecure</pre>

Usage: It is used when starting a new session or when you need to update your connection credentials.

Replace all placeholder values before sending the request.

Obtaining a username and password:

You can retrieve the user and password by using the following commands:

macOS

```
#User
oc get secret keystone -n ${DCS_NS} -o jsonpath="{.data.user}" | base64 -D; echo

#Password
oc get secret keystone -n ${DCS_NS} -o jsonpath="{.data.password}" | base64 -D; echo
```

Linux

```
#User
oc get secret keystone -n ${DCS_NS} -o jsonpath="{.data.user}" | base64 --decode; echo

#Password
oc get secret keystone -n ${DCS_NS} -o jsonpath="{.data.password}" | base64 --decode; echo
```

Obtaining DCS URL:

Retrieve the DCS URL by using the following command:

```
DCS_CONSOLE=$(oc -n ${DCS_NS} get route console -o jsonpath='{ "https://" }{.spec.host} ')
echo $DCS_CONSOLE
```

Obtaining token:

Retrieve the token by using the following command:

```
curl -k -I -u <username>:<password> ${DCS_CONSOLE}/auth/v1/token | grep x-auth-token
```

Response:

```
x-auth-token: <token>
```

dcs_file_search

The File Search tool enables you to search across cataloged data sources by using natural language queries. It automatically converts user input into structured queries that retrieve relevant files, datasets, or metadata entries.

With this capability, you can find information quickly without needing to understand query syntax or underlying database languages. By bridging natural language with structured search, File Search improves accessibility for both technical and non-technical users, and accelerates data discovery.

Tool name	Argument	Request
dcs_file_search	Query	<pre>curl -X POST <mcp http endpoint> -H "Content-Type: application/json" -H "Accept: application/json, text/event-stream" -H "mcp-session-id: <mcp-session-id>" -d '{ "jsonrpc": "2.0", "id": 1, "method": "tools/call", "params": { "name": "dcs_file_search", "arguments": { "query": "SELECT * FROM METAOCEAN LIMIT 1" } } }' --insecure</pre>

Replace all placeholder values before sending the request. Replace the query as needed.

Example prompt:

```
Show all CSV files containing customer transactions from 2023
```

The tool retrieves matching entries from the registered data sources.

dcs_get_registered_tags

The Get Registered Tags tool retrieves a complete list of all tags that are registered in the cataloging system. It helps users and AI agents review existing classifications before creating or suggesting new ones, ensuring that tag definitions remain consistent and non-duplicative.

This tool is useful for maintaining a clean and standardized tagging structure across multiple datasets and departments.

Tool name	Request
dcs_get_registered_tags	<pre>curl -X POST <mcp http endpoint> -H "Content-Type: application/json" -H "Accept: application/json, text/event-stream" -H "mcp-session-id: <mcp-session-id>" -d '{ "jsonrpc": "2.0", "id": 1, "method": "tools/call", "params": { "name": "dcs_get_registered_tags", "arguments": { } } }' --insecure</pre>

Replace all placeholder values before sending the request.

Example use case:

Before adding a new Financial tag, you can check whether a similar tag exists in the catalog.

dcx_get_recommend_tags

The Recommend Tags tool uses LLM-powered analysis to suggest relevant tags for cataloged files and datasets. By examining metadata and contextual information, the tool recommends tags that help classify data more accurately and consistently.

This feature significantly reduces the time that is spent on manual tagging and enhances catalog quality by ensuring that all datasets are properly labeled.

Tool name	Argument	Request
dcx_get_reco mmend_tags	Query	<pre>curl -X POST <mcp http endpoint> -H "Content-Type: application/json" -H "Accept: application/json, text/event-stream" -H "mcp-session-id: <mcp-session-id>" -d '{ "jsonrpc": "2.0", "id": 1, "method": "tools/call", "params": { "name": "dcx_get_recommend_tags", "arguments": { "query": "SELECT * FROM METAOCEAN LIMIT 10" } } }'</pre>

Replace all placeholder values before sending the request. Replace the query as needed.

Example prompt:

Recommend me some tags to classify my CSV files

The tool retrieves tags recommendation based on the metadata.

dcx_create_tag

The Create Tag tool enables you to define and create new tags.

Tool name	Arguments	Request
dcx_create_t ag	tagName, type	<pre>curl -X POST <mcp http endpoint> -H "Content-Type: application/json" -H "Accept: application/json, text/event-stream" -H "mcp-session-id: <mcp-session-id>" -d '{ "jsonrpc": "2.0", "id": 1, "method": "tools/call", "params": { "name": "dcx_create_tag", "arguments": { "tagName": "TEST", "type": "VARCHAR(256)" } } }'</pre>

Replace all placeholder values before sending the request.

Example prompt:

Create the tags that you recommend me.

The tool creates tags based on the recommendations.

dcx_get_policies

The Get Policies tool retrieves and lists all existing cataloging policies within the system. Policies define automated rules or governance conditions that are applied to data, metadata, or tags.

This tool provides visibility into the active policies that govern cataloged assets. It also helps users understand which rules are being enforced and how they affect data classification or compliance workflows.

Tool name	Request
dcx_get_polic ies	<pre>curl -X POST <mcp http endpoint> -H "Content-Type: application/json" -H "Accept: application/json, text/event-stream" -H "mcp-session-id: <mcp-session-id>" -d '{ "jsonrpc": "2.0", "id": 1, "method": "tools/call", "params": { "name": "dcx_get_policies", "arguments": { } } }'</pre>

Replace all placeholder values before sending the request.

Example use case:

A data steward can use this tool to view all current auto-tagging and compliance policies before creating new ones.

dcx_create_policy

The Create AutoTag Policy tool enables you to define and deploy new auto-tagging policies that automatically assign tags to cataloged assets based on predefined rules and AI insights. It streamlines governance by automating repetitive classification tasks and ensuring that policies remain consistent across data sources.

This tool currently supports auto-tag policy types, allowing AI models to dynamically apply tags based on metadata patterns or user-defined contextual rules.

Tool name	Arguments	Request
dcx_create_p olicy	polFilter, policyName, schedule, tags	<pre>curl -X POST <mcp http endpoint> -H "Content-Type: application/json" -H "Accept: application/json, text/event-stream" -H "mcp-session-id: <mcp-session-id>" -d '{ "jsonrpc": "2.0", "id": 1, "method": "tools/call", "params": { "name": "dcx_create_policy", "arguments": { "polFilter": "filetype='pdf'", "policyName": "TEST", "schedule": "NOW", "tags": { 'tagtest': 'valtest' } } }'</pre>

Replace all placeholder values before sending the request.

Example prompt:

Explore the catalog for security-related flaws and recommend me 5 different tags with proposed values that can be used for identify and classify the data on the catalog, make sure they are not duplicate.

AI-powered content-based tagging

IBM Data Cataloging provides AI-powered content-based tagging to automatically classify unstructured data by using the actual content of files, not only their metadata. This capability uses an inference model that is connected through the IBM LLM proxy to propose and apply business-relevant tags across large datasets with minimal manual effort. The LLM proxy can route requests to multiple upstream providers: a self-hosted Ollama model, an OpenAI-compatible endpoint, Anthropic, watsonx.ai, or an internal model gateway, through a single configuration block in the `SpectrumDiscover` custom resource.

Overview

Traditional metadata-based tagging relies on file attributes such as name, size, or type. Content-based tagging goes further: the system reads file content through Apache Tika, combines it with a business context that you define, and asks an LLM to propose the most relevant tag names and values.

The feature operates in two stages:

Stage 1: Tag proposal (dry run)

The system analyzes a sample of files in the configured path, generates tag name suggestions that are aligned with your business context, and stores them in the business context ConfigMap. No tags are created or applied in IBM Data Cataloging service. Review the proposals and activate the ones that you want.

Stage 2: Tag application

On subsequent runs, the system detects active tags and proceeds to apply them: it creates the tags in IBM Data Cataloging service if they do not already exist. Then retrieves untagged files from the catalog, calls the LLM once per file to determine the appropriate value for each active tag, and loads the results through a bulk insert.

The two stages are controlled entirely through the business context ConfigMap and run automatically on a 30-minute schedule through a Kubernetes CronJob. This approach enables consistent metadata assignment such as employee status, job role, department, or compliance category without manual categorization. The integration standardizes content organization across large repositories and improves discovery and governance capabilities.

Key capabilities

The content-based AI-enabled autotagging capability provides:

- **Context-aware tagging:** Incorporates user-defined business context for accurate tagging that is aligned with your organizational needs.
- **AI-driven recommendations:** Suggests tags based on content analysis through a hosted large language model (LLM).
- **Automated classification:** Processes documents automatically to extract meaningful metadata without manual intervention.
- **Flexible file type support:** Works with multiple document formats including PDF, DOCX, TXT, and others.
- **Multi-provider LLM support:** Route inference through a self-hosted Ollama model, an OpenAI-compatible endpoint, Anthropic, watsonx.ai, or an internal model gateway, which is selected per deployment through the `provider` field.

Use cases

Human Resources document classification

HR departments store large volumes of sensitive documents including contracts, performance reviews, and compliance records. Content-based tagging automatically classifies these files with tags such as `employee_status`, `job_role`, `salary_indicator`, or `compliance_category`, enabling governance and discovery without manual effort.

Workforce analytics

Data engineers building analytics pipelines can tag files with dimensions such as `location`, `department`, or `contract_type` to create filtered subsets for downstream processing without modifying the source data.

Before you begin

Before enabling this feature, verify the following attributes:

- IBM Data Cataloging is installed and an IBM Data Cataloging service connection to an IBM Storage Scale file system is configured and online.
- IBM Fusion is deployed with access to the IBM Storage Scale file system through a Global Data Platform remote mount.
- An LLM inference engine or provider is accessible from the cluster: a self-hosted Ollama model, or a hosted or gateway endpoint for OpenAI, Anthropic, or watsonx.ai. For more information, see [Supported LLM providers](#).
- The `ai-suggestions` feature toggle is available in your `SpectrumDiscover` custom resource.
- Red Hat® OpenShift® CLI (oc) is installed and accessible from your local environment.
- You are authenticated with your OpenShift cluster by using the CLI.

System requirements

- **Connections:** Works with IBM Storage Scale connections only.
- **File processing:** Supports a limited number of files per session for optimal performance.
- **Supported file types:** PDF, DOCX, TXT, and other text-based formats that can be processed by Apache Tika.

Supported LLM providers

The LLM proxy speaks the native protocol of each upstream provider, so you can point `inferenceEngineHost` at any of the following, selected with the `provider` field in the `SpectrumDiscover` custom resource:

Provider	provider value	Endpoint example	Credentials required
watsonx.ai	watsonx	https://us-south.ml.cloud.ibm.com	API key, plus <code>projectId</code> or <code>spaceId</code>

Provider	provider value	Endpoint example	Credentials required
Ollama (self hosted)	ollama (or omitted)	http://ollama.internal:11434	None
OpenAI or OpenAI-compatible gateway	openai	https://api.openai.com, or an internal gateway URL	API key or bearer token
Anthropic (Claude)	anthropic	https://api.anthropic.com (informational, as go-proxy uses a fixed endpoint)	API key

The **provider** defaults to **ollama** when omitted, so existing deployments that use only a self-hosted model continue working unchanged. Every other provider requires an API key that is supplied through **providerSecrets**. If an endpoint is signed by a private Certificate Authority (CA), you must supply that CA through the same secret for connection trust. This requirement applies to internal gateways exposed through an IBM Fusion or OpenShift Route. Otherwise, requests fail with **x509: certificate signed by unknown authority**.

Activating content-based tagging

1. Create the business context ConfigMap.

Create a ConfigMap named **ai-tag-extraction-context** in the IBM Data Cataloging namespace. This ConfigMap defines the data source, the path to analyze, and the business context that guides the LLM.

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: ai-tag-extraction-context
  namespace: ibm-data-cataloging
data:
  connection_names: "<dcs-connection-name>"
  filesystem: "<storage-scale-filesystem-cr-name>"
  path: "/gpfs/<filesystem>/path/to/your/dataset"
  allowed_filetypes: "pdf,txt,docx"
  context: >
    Describe your business use case here. The more specific the context,
    the more relevant the proposed tags. For example: "This dataset contains
    HR profiles including job role, employment status, and salary information.
    The goal is to classify these files for talent management and compliance."
```

Field	Description
connection_names	Name of the IBM Data Cataloging service connection as registered in the catalog.
filesystem	Full name of the <code>filesystems.scale.spectrum.ibm.com</code> custom resource in the <code>ibm-spectrum-scale</code> namespace. Run <code>oc get filesystems.scale.spectrum.ibm.com -n ibm-spectrum-scale</code> to find the correct name.
path	Full GPFS path to the directory containing the files to tag.
allowed_filetypes	Comma-separated list of file extensions to process.
context	Business context description that guides the LLM tag proposals.

To retrieve the correct file system custom resource name, run:

```
oc -n ibm-spectrum-scale get filesystems.scale.spectrum.ibm.com
```

This command lists all available file system resources in your cluster. Use the full name (for example, `ibm-spectrum-scale-fs-aifmifs1-18248649`) in the ConfigMap.

2. Create the provider secret (skip for plain Ollama).

Skip this step only if you use a self-hosted Ollama endpoint reachable over plain HTTP, or HTTPS signed by a public CA. Every other provider and any endpoint that is signed by a private CA needs a single Kubernetes secret that is referenced from the custom resource through the **providerSecrets** field.

The operator does not create this secret. Create it yourself in the same namespace as the **SpectrumDiscover** CR (typically `ibm-data-cataloging`) before applying a CR that references it.

For API key only (OpenAI, Anthropic, watsonx.ai):

```
oc create secret generic openai-secret \
  -n ibm-data-cataloging \
  --from-literal=api-key='sk-your-openai-api-key'
```

For API key and private CA (internal model gateway):

A private CA commonly signs endpoints behind an IBM Fusion or OpenShift Route. Extract it from a machine that can reach the gateway, such as your workstation or a bastion host, not the operator pod, which has no network path to it:

```
export GATEWAY_HOST=model-gateway-model-gateway.apps.example.com
echo | openssl s_client -connect ${GATEWAY_HOST}:443 -showcerts 2>/dev/null \
| awk '/BEGIN CERTIFICATE/,/END CERTIFICATE/{print}' > model-gateway-ca.crt
```

Then create a single secret carrying both the bearer token and the CA bundle:

```
oc create secret generic model-gateway-secrets \
  -n ibm-data-cataloging \
  --from-literal=token='your-bearer-token' \
  --from-file=ca.crt=model-gateway-ca.crt
```

Discover the model name exposed by the gateway before configuring the CR:

```
curl -k https://model-gateway-model-gateway.apps.example.com/v1/models \
-H 'Authorization: Bearer your-bearer-token'
```

Use the **id** from the response as **model** in the next step.

Field In <code>providerSecrets</code>	Purpose	Required when
<code>name</code>	Name of the secret created prior	Always, when <code>providerSecrets</code> is set
<code>apiKey</code>	Data key inside the secret holding the API key or bearer token	Provider is <code>openai</code> , <code>anthropic</code> , or <code>watsonx</code>
<code>caKey</code>	Data key inside the secret holding a PEM-encoded CA bundle	A private CA signs the endpoint

3. Enable the feature in the `SpectrumDiscover` custom resource.

Edit the `SpectrumDiscover` custom resource to enable both the LLM proxy and the AI suggestions feature:

```
spec:
  enabled_features:
    ai-suggestions:
      enabled: true
      inferenceEngineHost: "http://<ollama-host>:<port>"
      model: "granite4"
      # provider defaults to "ollama"; see "Supported LLM providers" for other options
```

You can apply this configuration by using the `oc patch` command:

`DCS_NS=ibm-data-cataloging`

```
oc -n $DCS_NS patch SpectrumDiscover $(oc -n $DCS_NS get SpectrumDiscover -o name) \
--type=merge -p '{
  "spec": {
    "enabled_features": {
      "ai-suggestions": {
        "enabled": true
      }
    }
  }
}'
```

Field	Description
<code>inferenceEngineHost</code>	URL of the upstream provider endpoint.
<code>model</code>	Model alias to use. Defaults to <code>granite4</code> .
<code>provider</code>	Upstream protocol: <code>ollama</code> (default), <code>openai</code> , <code>anthropic</code> , or <code>watsonx</code> .
<code>providerSecrets.name</code>	Name of the secret created in Step 2.
<code>providerSecrets.apiKey</code>	The data key inside the secret holding the API key or token. Required for every provider except <code>ollama</code> .
<code>providerSecrets.caKey</code>	Data key inside the secret holding a PEM CA bundle. Required when a private CA signs the endpoint.
<code>projectId / spaceId</code>	<code>watsonx.ai</code> project or space scope. One is required for the <code>watsonx</code> provider.

Example: internal gateway with a private CA

```
spec:
  enabled_features:
    ai-suggestions:
      enabled: true
      model: "qwen2-5-72b-instruct"
      provider: "openai"
      inferenceEngineHost: "https://model-gateway-model-gateway.apps.example.com"
      providerSecrets:
        name: model-gateway-secrets
        apiKey: token
        caKey: ca.crt
```

Example: `watsonx.ai`

```
spec:
  enabled_features:
    ai-suggestions:
      enabled: true
      model: "ibm/granite-3-8b-instruct"
      provider: "watsonx"
      inferenceEngineHost: "https://us-south.ml.cloud.ibm.com"
      projectId: "my-watsonx-project-id"
      providerSecrets:
        name: watsonx-secret
        apiKey: api-key
```

After saving the custom resource, the operator deploys the following resources automatically:

- LLM proxy deployment and service (`isd-llm-proxy`)
- Remote content search deployment and service (`isd-rcs-ai-tags`)
- AI tag extraction CronJob (`isd-ai-tag-extraction`, runs every 30 minutes)
- Upstream CA ConfigMap (`isd-llm-proxy-upstream-ca`), only when `providerSecrets.caKey` is set)

Once the patch is successfully applied, the `SpectrumDiscover` operator loads the resources for the new capabilities.

Using content-based tagging

First run: tag proposal

On the first CronJob execution, the system performs a dry run:

1. Reads the business context ConfigMap.
2. Analyzes a sample of files in the configured path by using the LLM.
3. Proposes tag names and their possible values.
4. Writes the proposals to a new key `suggested_tags` in the same ConfigMap.
5. Exits without creating or applying any tags in the IBM Data Cataloging service.

After the first run, inspect the ConfigMap to review the proposals:

```
oc get cm ai-tag-extraction-context -n ibm-data-cataloging -o jsonpath='{.data.suggested_tags}' | python3 -m json.tool
```

Example output:

```
{
  "EMPLOYEE_STATUS": { "active": false },
  "JOB_ROLE":         { "active": false },
  "LOCATION":          { "active": false },
  "SALARY_INDICATOR": { "active": false },
  "WORK_ARRANGEMENT": { "active": false }
}
```

On subsequent dry runs without any active tags, the system forwards the existing proposals to the LLM so it does not repropose the same names. New complementary tags might be added to the list.

Activating tags

Edit the `suggested_tags` value in the ConfigMap to set `"active": true` on the tags you want to apply:

```
oc edit cm ai-tag-extraction-context -n ibm-data-cataloging
```

Change the required entries:

```
{
  "EMPLOYEE_STATUS": { "active": true },
  "JOB_ROLE":         { "active": true },
  "LOCATION":          { "active": false },
  "SALARY_INDICATOR": { "active": true },
  "WORK_ARRANGEMENT": { "active": false }
}
```

On the next CronJob run (within 30 minutes, or triggered manually), the system:

1. Detects the tags marked `active: true`.
2. Creates those tags in IBM Data Cataloging service if they do not exist.
3. Scans the configured connection to refresh the catalog.
4. Queries for untagged files matching the allowed filetypes and path.
5. Calls the LLM once per file to extract tag values.
6. Applies the values to the catalog through a bulk update.

Triggering a manual run

To run the job immediately without waiting for the next scheduled execution:

```
oc create job --from=cronjob/isd-ai-tag-extraction manual-run-$(date +%s) -n ibm-data-cataloging
```

Monitor the run:

```
oc logs -n ibm-data-cataloging -l job-name=manual-run-<timestamp> --follow
```

Monitoring

Verify deployed resources

```
# Business context ConfigMap
oc get cm ai-tag-extraction-context -n ibm-data-cataloging

# Remote content search service (must exist before the CronJob can reach the LLM)
oc get svc isd-rcs-ai-tags -n ibm-data-cataloging

# CronJob schedule and last execution
oc get cronjob isd-ai-tag-extraction -n ibm-data-cataloging

# Recent job runs
oc get jobs -n ibm-data-cataloging -l role=ai-tag-extraction

# RemoteContentSearch CR status
oc describe remotecontentsearch ai-tags -n ibm-data-cataloging
```

Verify that AI Suggestions is enabled

To verify whether the AI Suggestions feature is enabled, run:

```
DCS_NS=ibm-data-cataloging
```

```
oc -n $DCS_NS get SpectrumDiscover $(oc -n $DCS_NS get SpectrumDiscover -o name) \
-o jsonpath='{.spec.enabled_features.ai-suggestions.enabled}'
```

Expected output: `true`

Verify the LLM proxy and the selected provider

Confirm that the proxy uses the credential block for the provider you configured:

```
oc get cm isd-llm-proxy-config -n ibm-data-cataloging -o jsonpath='{.data.config\.yaml}' | grep -A5 credentials
```

If you set `providerSecrets`, confirm that the secret exists and, when a CA is supplied, that it is wired into the proxy:

```
oc get secret <providerSecrets.name> -n ibm-data-cataloging
```

```
# Only relevant when providerSecrets.caKey is set
```

```
oc get cm isd-llm-proxy-upstream-ca -n ibm-data-cataloging
```

```
oc get cm isd-llm-proxy-config -n ibm-data-cataloging -o jsonpath='{.data.config\.yaml}' | grep -A3 '^tls:'
```

Check the proxy logs for authentication or TLS errors:

```
oc logs deploy/isd-llm-proxy -n ibm-data-cataloging
```

If you see `x509: certificate signed by unknown authority`, the endpoint certificate authority is not supplied or does not match the value at `providerSecrets.caKey`. Re-extract the CA and update the secret as described in [step 2](#).

Verify that the inference engine is running

If you use a self-hosted Ollama deployment, check that the inference engine pod is in Running state:

```
oc -n $DCS_NS get pod -l app=isd,role=inference-engine
```

Example output:

NAME	READY	STATUS	RESTARTS	AGE
isd-inference-engine-1/1	Running	0	3h	

This check does not apply to hosted providers (OpenAI, Anthropic, watsonx.ai) or external gateways, since the inference engine runs outside the cluster in those cases.

Verify Remote Content Search AI tags

Verify that the Remote Content Search AI tags service is running:

```
oc -n $DCS_NS get pod -l app=isd,role=racs,datasource=ai-tags
```

If pods are in the Running state, the Remote Content Search AI tags are successfully up and operational.

Check the CronJob status

Verify that the CronJob is scheduled correctly:

```
oc get cronjob isd-ai-tag-extraction -n ibm-data-cataloging
```

Example output:

NAME	SCHEDULE	SUSPEND	ACTIVE	LAST SCHEDULE	AGE
isd-ai-tag-extraction	* / 30 * * * *	False	0	15m	2d

Check feature conditions

```
oc get spectrumdiscover -n ibm-data-cataloging \
-o jsonpath='{.items[0].status.conditions}' | python3 -m json.tool
```

Look for `AISuggestions` with `status: "True"` to confirm that the feature is running correctly.

Limitations

Content-based AI-enabled autotagging has the following limitations:

- **File processing capacity:** Supports a limited number of files per session. For large datasets, the system processes files in batches across multiple CronJob executions.
- **Connection type:** Works exclusively with Scale connections. Other connection types are not supported.
- **File types:** While the system supports PDF, DOCX, TXT, and other text-based formats, binary files or formats require Apache Tika support for successful processing.
- **Performance:** Processing time depends on file size, content complexity, and LLM response time. Large files or complex documents might take longer to analyze.
- **TLS trust for private endpoints:** The LLM proxy does not automatically discover certificate authorities for HTTPS endpoints. If your provider endpoint is signed by a private CA, you must extract and supply it manually through `providerSecrets.caKey`. There is no auto-discovery fallback, since cluster network policies typically prevent the operator from reaching external or cross-namespace endpoints directly.
- **Anthropic:** The proxy targets a fixed `https://api.anthropic.com/v1` endpoint. The `inferenceEngineHost` parameter is informational only and is not passed to the upstream credential block.
- **CA rotation:** The upstream CA is mounted with a `subPath`, so an already-running proxy pod does not pick up a rotated CA automatically. After updating the secret, restart the deployment with `oc rollout restart deployment/isd-llm-proxy -n ibm-data-cataloging`.

Disabling content-based autotagging

Set `enabled: false` in the `SpectrumDiscover` custom resource:

```
spec:
  enabled_features:
    ai-suggestions:
      enabled: false
```

Or use the `oc patch` command:

`DCS_NS=ibm-data-cataloging`

```
oc -n $DCS_NS patch SpectrumDiscover $(oc -n $DCS_NS get SpectrumDiscover -o name) \
--type=merge -p '{
  "spec": {
    "enabled_features": {
      "ai-suggestions": {
        "enabled": false
      }
    }
  }
}'
```

Result

The deployed resources (LLM proxy, Remote Content Search service, and CronJob) are removed from the cluster. The operator does not delete `providerSecrets` and any provider secret you created. It can be removed manually if no longer needed.

Managing user access

The Data cataloging environment provides access to users and groups. The role that is assigned to a user or group determines the functions that are available. Users and groups can also be associated with collections that use policies that determine the metadata that is available to view.

User and group access can be authenticated by Data Cataloging, a Lightweight Directory Access Protocol (LDAP) server, the IBM Cloud® Object Storage, or using the Red Hat®OpenShift® credentials. If you use Data Cataloging, LDAP, or IBM COS as authentication methods, then it is required to follow the same authentication process by entering the associated username and password to access the Data Cataloging user interface.

If you use Red HatOpenShift as authentication method, then log in by default through Single-Sign On, unless this option is explicitly disabled. The administrator role can manage the user access functions. For more information, see [Initial login](#).

Note: A local user that is created on the Data cataloging system must use a user name and password to log in. Users from an external LDAP or IBM Cloud® Object Storage domain must include the domain name as a prefix to the user name with a forward slash (/), such as "`<domain>/<user>`". The domain name is the name that is given to the external authentication domain in Data cataloging.

Roles

Roles determine how users and groups can access records or the Data cataloging environment.

If a user or group is assigned to multiple roles, the least restrictive role is used. For example, if a user is assigned to the Data User role but is also included in a group that is assigned to the Data Admin role, that user has the privileges of the Data Admin role.

The following roles are available:

Admin

This role can create users, groups, and collections. This role can also manage connections to Lightweight Directory Access Protocol (LDAP) and IBM Cloud Object Storage domains. This role can use the Application Management APIs to install, upgrade, or delete Data cataloging applications that use the Data cataloging API service.

Data Admin

Users with this role can access all metadata that is collected by Data cataloging and is not restricted by policies or collections. This role can also define tags and policies, including policies that assign a collection value to a set of records.

Note:

The built-in **Collection** tag is a special tag. This tag can be set only by users with the Data Admin role. All other tags can be set by any user with the Data User or Data Admin or Collection Admin role.

Users with this role can also edit local users and local groups and assign roles and collections to users and groups.

Collection Admin

The Collection Admin role is a bridge between the Data Admin role and the Data User role. Users with the Collection Admin role can:

- Create, update, and delete the policies for the collections that they administer.
- View, update, and delete policies of data users for the collections they administer. They cannot delete a policy if it has a collection that they do not administer.
- Add users to collections that they administer. These data users can access to a particular collection, which means that they can access to the records marked with that collection value.
- List any type of tag and create or modify **Characteristics** tags. They cannot create, modify, or delete **Open** and **Restricted** tags. These permissions are the same as the ones associated with the Data User role.

Collection User

Users with this role can access metadata that is collected by IBM Data Cataloging, but metadata access can be restricted by the collections that are assigned to users in this role.

- Users assigned with the Collection User role can:
 - Run scans of collections the user is assigned.
 - View policies of the collections the user is assigned.
 - List any type of tag.
- Users assigned with the Collection User role cannot:
 - Create, update, and delete any policies.
 - Create, modify, and delete any tags.

Data User

Users with this role can access metadata that is collected by Data cataloging, but metadata access can be restricted by the collections that are assigned to users in this role. This role can also define tags and policies, based on the collections to which the role is assigned.

Service User

This role is assigned to accounts for IBM® service and support personnel.

- [Initial login](#)
To log in IBM Data Cataloging graphical user interface, use the following information.
- [Resetting the sdadmin password](#)
If the **sdadmin** password changes and you forget the password, you can access the keystone container and run the **reset_sdadmin_details.sh** script to reset the password to the original password.
- [Password policies](#)
Data cataloging 2.0.2.1 introduces password policies for the local users who are configured in the default authentication domain.
- [Changing password](#)
To change the password, you need to provide the existing and new password.
- [Managing user accounts](#)
The administrator can add and manage local user accounts, which are authenticated by IBM Data Cataloging. The administrator can also assign local or LDAP and IBM Cloud Object Storage-managed users to roles and collections.
- [Managing groups](#)
The administrator can create and manage local groups that are authenticated by IBM Data Cataloging. The administrator can also assign local or Lightweight

Directory Access Protocol (LDAP) and IBM Cloud Object Storage system-managed groups to roles and collections.

- [Managing collections](#)

Collections are logical groups of metadata that share a common member access list. For example, a collection can restrict metadata within a research project to the members of the project only. Members outside of the project cannot see the metadata.

- [Managing LDAP and IBM Cloud Object Storage System connections](#)

The administrator can create and manage connections to LDAP or IBM Cloud Object Storage System servers that provide authentication for IBM Data Cataloging users.

Initial login

To log in IBM Data Cataloging graphical user interface, use the following information.

IBM Data Cataloging service provides SSO capability. To know more about SSO, see <https://www.ibm.com/topics/single-sign-on>.

Use your OpenShift® Container Platform credentials to log in IBM Data Cataloging user interface by using SSO.

When Single Sign-On (SSO) is disabled as the default authentication method, the following default login credentials can be used for the IBM Data Cataloging graphical user interface:

Username

sdadmin

Password

Passw0rd

Important:

- When the SSO is disabled, the administrator must change the password during the initial login.
- If you have been using SSO login for a long time, it is not recommended to switch to traditional USERNAME/PASSWORD login because you can face authentication issues.

Log in to IBM Data Cataloging Dashboard with SSO enabled

Follow the steps to log in to the IBM Data Cataloging Dashboard:

1. Start the IBM Data Cataloging graphical user interface, and you get the logging screen validation as follows.

2. Wait for the validation for OpenShift Platform session. If you have an active session, you are redirected to Data Cataloging Dashboard, otherwise you are redirected to the OpenShift authentication client.

3. Enter your OpenShift credentials and click Log in button.
You are redirected to IBM Data Cataloging main dashboard.

Note: Consider that IBM Data Cataloging for security renews the session every hour, and there are cases in which it is necessary to re-enter the OpenShift Container Platform credentials.

Log in to IBM Data Cataloging Dashboard with SSO disabled

If you see a previous user logged in, you need to click on the Not you? button to see the following screen.

1. Enter your username in the User id field to access regular login and click Continue.

2. Enter your password in the Password field and click Login.

3. After the credentials are validated, IBM Data Cataloging main dashboard is displayed as follows.

Note:

Regardless of which user appears in the User id field, clicking the Login with OpenShift Platform button will redirect you to the OpenShift authentication client and you can access using your OpenShift credentials.

Disabling SSO login

The single sign-on (SSO) enable by default when you install the IBM Data Cataloging service. Follow the steps to disable the SSO:

1. Login to OpenShift Container Platform web console.
2. Go to Operators, > Installed Operators > and select the IBM Data Cataloging.
3. Under the **data-cataloging-service** instance, go to Details tab.
4. Scroll down to the Enabled Features section and clear the Single Sign-On checkbox.
5. Go to Workloads, > Deployments and look for the **isd-ui-backend** deployment.
6. Go to YAML tab and change the **OCPAUTH_DEFAULT** envvar value from **True** to **False**.
7. Click Save and wait until a pod is created.
8. After the pod is created, clean cookies, cache, and reload the IBM Data Cataloging GUI.

When SSO is disabled as the default authentication method, the following default login credentials can be used for the IBM Data Cataloging graphical user interface:

Username
sdadmin
Password
Passw0rd

Resetting the sdadmin password

If the **sdadmin** password changes and you forget the password, you can access the keystone container and run the **reset_sdadmin_details.sh** script to reset the password to the original password.

Procedure

1. Issue the following command to get the keystone pod name:

```
c -n ibm-data-cataloging rsh deployment/isd-keystone
```

The system returns the pod details similar to the following:

Name	READY	STATUS	RESTARTS	AGE
spectrum-discover-keystone-599cf9fb77-bpqc8	1/2	Running	0	3d21h

2. Go to the directory `cd /` and run the `reset_sdadmin_details.sh` script to reset the details or the original password.

Password policies

Data cataloging 2.0.2.1 introduces password policies for the local users who are configured in the default authentication domain.

The password policies that are introduced for all local user accounts, enhance their security.

Note:

Data cataloging does not enforce password policies for the user accounts that are imported to the Data cataloging authentication scheme. These policies include all user accounts imported from the external domains like LDAP or IBM® Cloud Object Store that are configured with Data cataloging. Any password policies that are configured for these external authentication providers (LDAP/IBM Cloud Object Store), would apply to the corresponding users from these authentication domains.

Password policies

Data cataloging local users must follow the password policies that are defined in the 2.0.2.1 release.

Password strength requirements

- Passwords must have a minimum length of seven characters.
- Passwords must contain at least one letter.
- Passwords must contain at least one digit.

Unique password history requirements

- Users must create a unique password each time the password is changed. The new password cannot be any of the last five passwords previously used.

Password expiration requirements

- The User password expires after 90 days from the time it is changed.

Password change requirements

Data cataloging users with Admin roles (like the "sdadmin" user) can create a new user or reset the password of an existing user. However, this password expires when the user logs in for the first time and must be changed immediately.

Account lockout requirements

A user account is locked out for 1 hour after five successive failed login attempts.

Password upgrade for existing users

Data cataloging deployments, upgraded from versions earlier than 2.0.2.1, include the new password policies that are applied to local user accounts. Existing user accounts are also impacted in the following ways:

- Existing users can continue to use their current passwords to log in to the system.
- Passwords for existing user accounts expire only in the following situations:
 - Passwords expire when users change their password. In this scenario, the new password will expire after 90 days.
 - Passwords expire when the administrative user resets the user password. In this scenario, the updated password expires immediately after the first login and the user must create a new unique password.
- When the user password is changed, the following password policies are enforced:
 - **Password strength requirements**
 - **Unique Password history requirements** - This policy restricts users from reusing any of the last five passwords.
- On completing the product upgrade, the **Account lockout requirements** policy is immediately enforced for all local users that includes all existing users.

Note: To apply all the password policies to the local user accounts after they upgrade to 2.0.2.1 or later releases, follow the listed recommendations:

- The Admin user resets passwords for all the existing local user accounts and communicates the new password to the respective users.
- All the local users use the UI Password change REST API to change their passwords. For more information, see [Changing password](#) and [/auth/v1/users/<user_ID>/password: POST /auth/vi/users/<user_ID>/password: Post in IBM Data Cataloging: REST API Guide](#).

Changing password

To change the password, you need to provide the existing and new password.

About this task

To change your password, follow these steps.

Procedure

1. Click the user icon.
2. Under Account Settings, click Change Password.
3. Enter the existing password, new password, and new password confirmation.
4. Click Save.

Note: When the password is changed successfully, you are logged out of IBM Data Cataloging. You need to relogin with the new password.

Managing user accounts

The administrator can add and manage local user accounts, which are authenticated by IBM Data Cataloging. The administrator can also assign local or LDAP and IBM Cloud® Object Storage-managed users to roles and collections.

Use the Users tab on the Access page to view information about user accounts that are authenticated by the local domain or either an LDAP or IBM Cloud Object Storage server. You can also use the tab to create, edit, or delete local users. You cannot create or delete either LDAP or IBM Cloud Object Storage user accounts, but you can assign these users to roles and collections.

Adding a local user account

To add a local user account that is authenticated by IBM Data Cataloging, click Create new user and the Add local User window opens. For more information, see [Creating user accounts](#).

Editing a user account

You can edit account information for a local user. You cannot edit the details of either Lightweight Directory Access Protocol (LDAP) or IBM Cloud Object Storage user accounts, but you can assign these users to roles and collections.

To edit a local user account, select the user that you want to edit and click Edit. Use the Edit User window to edit the local user account.

To edit an LDAP or IBM Cloud Object Storage user account roles, select the user that you want to edit and click Edit. Use the Edit User window to assign these users to roles and collections.

Deleting a local user account

To delete a local user account, select the user that you want to delete and click Delete.

User information

The Users tab lists the users that are available from the local domain and from either LDAP or IBM Cloud Object Storage connections. The tab includes the following user account information:

User Name

Indicates the username for the account.

Domain

Indicates the domain that provides authentication for the user. For authentication by IBM Data Cataloging, the domain name is Default.

Description

Indicates the description of the user.

Figure 1. The Users tab

- **Creating user accounts**

The administrator can add local user accounts, which are authenticated by IBM Data Cataloging, and assign roles to users.

Creating user accounts

The administrator can add local user accounts, which are authenticated by IBM Data Cataloging, and assign roles to users.

About this task

Go to the Users tab on the Access management page to add a local account.

- You can also assign roles and passwords to users.
- You can also add a user to a group.

Procedure

1. Log in to the IBM Data Cataloging web interface.
2. Click  menu and go to Access management > Users. Click Create new users to open Add local User window.

Figure 1. The Add local User window

3. Enter a User Name and Email address for the user.
4. Enter a Password for the user.
5. Choose the available role from the Assign User to Role list to assign one or more roles to the user.

Note:

- This step is optional. For more information about roles, see [Roles](#).
- Users that are assigned the Data User or Collection Admin role must also be associated with at least one collection.

6. Use the Assign User to Group list to assign the user to one or more user groups.

Note: This step is optional. You can also use the Groups tab to assign users to groups.

7. Provide description about user in the Description field.
Note: This step is optional.
8. Click Save.

Managing groups

The administrator can create and manage local groups that are authenticated by IBM Data Cataloging. The administrator can also assign local or Lightweight Directory Access Protocol (LDAP) and IBM Cloud® Object Storage system-managed groups to roles and collections.

Use the Groups tab on the Access management page to view information about groups accounts that are authenticated by either a local domain, an LDAP server, or the IBM Cloud Object Storage server. You can also use the tab to add, edit, or delete local groups. You cannot edit or delete LDAP or IBM Cloud Object Storage groups, but you can assign these groups to roles and collections.

Adding a local group

To add a local group, click Create new group to open the Add Local Group window. For more information, see [Creating groups](#).

Editing a group

To edit a group, select the group that you want to edit and click Edit. Use the Edit Group window to edit the local group.

Deleting a local group

To delete a local group, select the group that you want to delete and click Delete.

Group information

The Groups tab includes the following information:

Group Name

Indicates the name for the group.

Domain

Indicates the domain that provides authentication for the group. For authentication by IBM Data Cataloging, the domain name is Default.

Description

Indicates the description of the group.

Figure 1. The Groups tab

- [Creating groups](#)

The administrator can add local groups that are authenticated by IBM Data Cataloging and assign users and roles to the groups.

Creating groups

The administrator can add local groups that are authenticated by IBM Data Cataloging and assign users and roles to the groups.

About this task

Go to the Groups tab on the Access management page to add local groups. You can assign users and roles to the group and add the group to a collection.

Procedure

1. From the Groups tab of the Access management page, click Create new group to open the Add Local Group window.

Figure 1. The Add Local Group Window

2. Enter a Group Name.
3. Use the Assign Role to Group list to assign one or more roles to the group.
Note:
 - This field is optional.
 - For more information, see [Roles](#).
 - Groups that are assigned the Data User role or Collection Admin role must be associated with at least one collection.
4. Click Add Users to open the Add Users window and add one or more local users to the collection.
 - a. Enter a username that you want to add to the group and press Enter. The window lists each name that you enter. Click a name to remove it from the list. Click Add to add the users to the group.
The Users list displays the following details for users that are added to the group.

Username	The username or email address of the member.
Domain	The domain that provides authentication for the member.
5. Enter the group detail in the Description field for the group.
Note: This step is optional.
6. Click Save.

Managing collections

Collections are logical groups of metadata that share a common member access list. For example, a collection can restrict metadata within a research project to the members of the project only. Members outside of the project cannot see the metadata.

The administrator can:

- Create collections.
- Assign users and groups to collections.
- Create a policy to associate specific metadata that is collected by IBM Data Cataloging with the collection.
- Assign a collection to a connection to associate specific metadata from that connection data source that is collected by IBM Data Cataloging with the collection.

Users with the Data Admin role can view all metadata that is collected by IBM Data Cataloging and are not restricted by collections. Users with the Data Admin role can create policies that assign a collection value to a set of records, thus grouping a set of records under a collection.

Users with the Collection Admin role can add the Data User role to user for collections that they administer. Adding this role gives data users access to a particular collection, which allows the users to access the records that are marked with that collection value.

Collection User

Users with this role can access metadata that is collected by IBM Data Cataloging, but metadata access can be restricted by the collections that are assigned to users in this role.

- Users assigned with the Collection User role can:
 - Run scans of collections the user is assigned.
 - View policies of the collections the user is assigned.
 - List any type of tag.
- Users assigned with the Collection User role cannot:
 - Create, update, and delete any policies.
 - Create, modify, and delete any tags.

Use the Collections page to manage collections.

Creating a collection

To create a collection, click Create Collection. For more information, see [Creating collections](#).

Editing a collection

To edit a collection, select the collection that you want to edit and click Edit Collection. Use the Edit Collection window to edit the collection.

Deleting a collection

To delete a collection, select the collection that you want to edit and click Delete Collection.

Collections information

The Collections page includes the following information:

Collection Name

- Indicates the name of the collection.
- Description
- Indicates the description of the collection.

Figure 1. The Collections tab

- **Creating collections**

The administrator can create collections or assign users and groups to collections. A Collection Admin administrator can assign users and groups only to collections that they administer. A Data Admin administrator can use the AUTOTAG policy to associate metadata records with a collection.

Creating collections

The administrator can create collections or assign users and groups to collections. A Collection Admin administrator can assign users and groups only to collections that they administer. A Data Admin administrator can use the AUTOTAG policy to associate metadata records with a collection.

About this task

Collections are logical groups of records. Access to these record groups is restricted to specific users or groups. The administrator can associate policies with an appropriate collection value so that searches can be restricted to only the scope that a user or group has permissions to see.

Use the Collections tab on the Access management page to create collections.

Procedure

1. From the Collections tab of the Access management page, click Create collection to open the Create Collection window.

Figure 1. Create a Collection

2. Enter a collection Name and the details in the Description field.
Note: The Description field is optional.
3. Click Start to Add Members to open the Add Members window and add one or more users or groups to the collection.
 - a. Enter a username, group name, or email address of a member to include in the collection and press Enter. The window lists each name or address that you enter. Click a name or address to remove it from the list. Click Add member to add the members to the collection.
 - b. Select the role for the member on the collection. The default role is Data User.
The Members area lists the following details for the members of the collection.

Name	The username, group name, or email address of the member.
Type	The account type: user or group.
Domain	The domain that provides authentication for the member.
Role	The role on the collection that is assigned to the member.
4. To create a policy for the collection, select Create policy to tag files for this collection. For more information, see [Managing metadata policies](#).
5. Click Create.

Managing LDAP and IBM Cloud Object Storage System connections

Use the Authentication Domains tab on the Access page to create, test, manage, or delete LDAP connections.

Creating a connection

For steps to create a connection to an LDAP server, see [Creating an LDAP connection](#).

Editing a connection

Deleting a connection

Note: You cannot map the LDAP roles from your connection and must use an admin user to make the role assignment because the roles between IBM Data Cataloging and your LDAP server might be different.

- ## Creating an LDAP connection

About this task

Note: You cannot map the LDAP roles from your connection and must use an admin user to make the role assignment because the roles between IBM Data Cataloging and your LDAP server might be different.

Procedure

- Figure 1. Create an LDAP connection

cn=relative distinguished name dc=domain component

For example,

```
cn=Randy Marsh,dc=example,dc=com
```

Password

Indicates the password for the user name.

Suffix/Base DN

Indicates the DN that is the base of entry searches in the directory. For example:

- **dc=test**
- **dc=org**

Group Name Attribute

Indicates the LDAP attribute that is mapped to the group name.

Group ID Attribute

Indicates the LDAP attribute that is mapped to the group ID.

Group Member Attribute

Indicates the LDAP attribute that is mapped to show group membership.

Group Object Class

Indicates the LDAP object class for groups.

Group Tree DN

Indicates the DN that is the base for group searches.

Username Attribute

Indicates the LDAP attribute that is mapped to the user name.

User ID Attribute

Indicates the LDAP attribute that is mapped to the user ID.

User Object Class

Indicates the LDAP object class for users.

User Tree DN

Indicates the DN that is the base for user searches.

4. Click Connect.

- [Configuring self-signed certificates to secure LDAPS connection](#)

Establish secure LDAPS connections with self-signed certificates to protect the confidential data.

Configuring self-signed certificates to secure LDAPS connection

Establish secure LDAPS connections with self-signed certificates to protect the confidential data.

About this task

IBM Data Cataloging supports LDAPS domain connections with LDAP servers that are deployed with trusted (CA signed) certificates. To use self-signed certificates, you need to add the self-signed certificate to the IBM Data Cataloging keystone pod trusted certificates list.

Procedure

1. Ensure that the cacerts directory exists in the following path, which is accessible to the keystone pod:

```
/opt/ibm/metaocean/data/keystone/cacerts/
```

If the directory is not available, create it by running the following command:

```
oc -n ibm-data-cataloging exec deployment/isd-keystone -- mkdir -p /opt/ibm/metaocean/data/keystone/cacerts
```

Then, retrieve the keystone pod name and copy the self-signed certificate to the directory:

```
KEYSTONE_POD=$(oc -n ibm-data-cataloging get pod -o jsonpath='{.items[0].metadata.name}' -l role=keystone)
oc -n ibm-data-cataloging cp cert.crt $KEYSTONE_POD:/opt/ibm/metaocean/data/keystone/cacerts/cert.crt
```

2. Update the certificates within the keystone pod by running the following command:

```
oc -n ibm-data-cataloging exec deployment/isd-keystone /update-cacerts.sh
```

3. Restart the keystone pod to apply the changes by executing:

```
oc -n ibm-data-cataloging delete pod -l role=keystone
```

Creating an IBM Cloud Object Storage connection

The administrator can create a connection to an IBM Cloud® Object Storage server that provides authentication for IBM Spectrum® Discover users and groups from the corresponding domain.

About this task

Use the Authentication Domains tab on the Access page to create a connection to an IBM® Cloud Object Storage System server. You must provide credentials for the IBM Cloud Object Storage security administrator.

All users and groups that are managed by the IBM Cloud Object Storage are available for IBM Data Cataloging. You cannot specify a member range for these connections.

Note: You cannot run scans unless you add override warnings in the configuration file.

Procedure

1. From the Authentication Domains tab of the Access page, click Add Domain Connection to open the Add Domain Connection window.
2. From the Type list, select IBM Cloud Object Storage.

Figure 1. Create an IBM Cloud Object Storage Connection

3. Enter the following information for the IBM Cloud Object Storage connection:

- Name
 - Indicates the IBM Cloud Object Storage domain name.
- Host
 - Indicates the IBM Cloud Object Storage hostname.
- Port
 - Indicates the IBM Cloud Object Storage port number.
- User name
 - Indicates the IBM Cloud Object Storage security administrator name.
- Password
 - Indicates the IBM Cloud Object Storage security administrator password.

4. Click Connect.

Managing metadata policies

Policies might be used to automatically tag a set of documents on a periodic basis. In addition, policies might be used to send sets of documents to be deep-inspected by a registered application.

Roles and permissions

Data User

Users with this role can create, modify, and view their policies. Policies can be applied only to the collections the user has access to. Users with the Data User role cannot use a **COLLECTION** tag when they create or modify policies.

Collection Admin

Users with this role can create, modify, and view their policies. Policies can be applied only to the collections that they administer. Users with the Collection Admin role cannot use a **COLLECTION** tag when they create or modify policies.

Collection User

Users with this role can access metadata that is collected by IBM Data Cataloging, but metadata access can be restricted by the collections that are assigned to users in this role.

- Users assigned with the Collection User role can:
 - Run scans of collections the user is assigned.
 - View policies of the collections the user is assigned.
 - List any type of tag.
- Users assigned with the Collection User role cannot:
 - Create, update, and delete any policies.
 - Create, modify, and delete any tags.

Data Administrator

Users with this role can create, modify, view, and delete policies.

Security Administrators

Users with this role cannot create, modify, view, or delete policies.

Service User

Users with this role cannot create, modify, view, or delete policies.

- [Adding policies](#)
You can add policies to help with data management.
- [Running policies](#)
You can configure policies to run at specified or scheduled times, at policy creation time, or when the system is manually started, paused, restarted, or stopped.
- [Viewing policies](#)
You can view your policy information.
- [Modifying policies](#)
You can modify your policies to work with and use your data more effectively.
- [Deleting policies](#)
You can delete policy information.

Adding policies

You can add policies to help with data management.

About this task

To add a policy, you must define the policy and its parameters, establish a schedule to run the policy, and save the policy. You can add custom metadata values to all or a subset of the records based on filter criteria. For example, you can add a project name to records based on their location within the file system or owner ID.

You can add a policy filter, which is similar to the **where** clause in an SQL query. The filter must be constructed by using standard SQL syntax:

- To enact a policy on all files not accessed in one year, the filter might be written as:
`atime < (NOW() - 365 DAYS)`
- To enact a policy on all files owned by **Smithers**, the filter might be written as:
`owner='Smithers'`
- To enact a policy on all PDF files in cluster **c11** and data source **fs1**, the filter might be written as:
`cluster='c11' and datasource='fs1' and filetype='pdf'`

Procedure

1. Go to Metadata > Tag Management.
2. Under Policies click Add Policy.
3. Enter a name for the policy in the Name box (for example, *MyPolicy*).
4. Select the required policy type from the Policy Type menu.
The policy types are:
 - AUTOTAG
 - CONTENT SEARCH
 - DEEP-INSPECT
5. Click Next step.
6. Complete the policy information:
 - a. Select the list of Collections the policy applies to. If no collections are selected, the policy applies to all collections available to the user when run.
 - b. You must use a filter for the policy. The filter defines which set of records the policy acts on. Enter your filter into the Filter box (for example, `size > 100`).
 - c. Complete the policy-specific parameters based on which policy type you select in step 3:
 - i. You can set parameters for **AUTOTAG** policy types. For more information, see [Adding auto-tagging policy parameters](#).
 - ii. You can set parameters for **DEEP-INSPECT** policy types. For more information, see [Adding deep-inspection policy parameters](#).
 - iii. You can set parameters for **CONTENT SEARCH** policy types. For more information, see [Adding content search policy parameters](#).
7. Click Next step
8. Now that your policy parameters are defined, you must schedule the frequency.
9. Click the slider control to set the status to one of the following values:

Active
An *Active* policy is run whenever its scheduling event is reached.

Inactive
An *Inactive* policy is not run when its scheduling event is reached, including the **Now** event.
10. Select a Schedule to apply the policy. Indicate whether you want to schedule the policy *Now*, *Daily*, *Weekly*, or *Monthly*.
Note: Policy schedule times are entered in Coordinated Universal Time (UTC).

Now
Indicates that the policy is applied immediately unless the policy's status is **Inactive**.

Daily
Indicates a specific time of day to apply the policy. Enter the time of day by clicking the hour and minute from the widget that is shown. The policy is applied daily at the specified time.

Weekly
Indicates a specific day and time in which to apply the weekly policy:

 - a. Enter the time of day to apply the policy by clicking the hour and minute from the widget that is shown.
 - b. Select the day of the week from the list of days.
 The policy is applied once a week on the specified day and time.

Monthly
Indicates a specific day and time in which to apply the monthly policy:

 - a. Enter the time of day to apply the policy by clicking the hour and minute from the widget that is shown.
 - b. Select the date by clicking the month and day from the widget that is shown.

The policy is applied once a month on the specified day and time.

11. Click Next step.
12. Review the data and click Save to save the new policy.
The new policy displays in the list of policies under the Policies tab.

- [Adding auto-tagging policy parameters](#)
You can add specific parameters for auto-tagging policies after you define the policy type and set up the mandatory filter or optional collection information.
- [Adding deep-inspection policy parameters](#)
You can add DEEP-INSPECT policies.
- [Adding content search policy parameters](#)
You can add search content parameters for your policies.

Adding auto-tagging policy parameters

You can add specific parameters for auto-tagging policies after you define the policy type and set up the mandatory filter or optional collection information.

Procedure

1. Associate one or more tags with this policy by using one of the following methods:
 - a. Click +Add Tag.
 - b. Select a tag name from the Field menu.
The Fields can also be specified by going to Metadata > Tags.
 - c. Select which Tag to apply (for example, TEMPERATURE) and then enter the appropriate Values.
Note: If you do not know the valid values for a tag, go to Search in the main menu and select the tag from the Start a visual exploration list. Click the Go "circle arrow" icon. The valid values of the tag are displayed.
 - d. To delete a Field, click the Delete "minus" icon next to a field.
 - e. You can add more tag values by clicking the +Add Tag control.
Each new Field defaults to the next item in the Field menu.
Or you can automatically extract the tag from the directory path by clicking the Extract tag from box. For example, you might have files in a directory structure by department and want to extract the department name into a tag. Automatically extract the tag:
 - i. Select the Extract tag from path checkbox.
 - ii. Select a tag from the Field menu.
 - iii. Specify the Depth in the path to be used as the value of the tag.

To create a new tag, see [Creating tags](#).
2. Click Next Step.

Adding deep-inspection policy parameters

You can add DEEP-INSPECT policies.

About this task

You can enrich metadata through an external deep inspection application. For more information, see [Managing applications](#). For example, you can extract patient names from medical records and index the names. Indexing the names helps when you search for files that pertain to patients by name. Deep inspection policies can send lists of files to an application, which can examine the contents of files and return the values that it finds paired with defined tag keys.

Important: If the deep-inspect application returns a `tag:value` pair that is not requested by the deep-inspect policy, the tag:value pair is still updated by the deep-inspect policy as long as the tag resides in IBM Data Cataloging.

Procedure

Do the following to add parameters for deep-inspection policies:

1. Add the Application name (for example, `example-application`).
Note: To add an application, see [/policyengine/v1/applications: POST](#) in the *IBM Data Cataloging: REST API Guide*.
2. Click +Add Tag.
3. Select which Parameter to apply (for example, `extract-tags`), and then select the appropriate Values (for example, `TEMPERATURE`).
4. You can add more parameters by clicking the +Add parameter control. This is optional.
5. You can delete a parameter by clicking the Delete "minus" icon next to the parameter's Value. This is optional.
6. Click Next Step.

Adding content search policy parameters

You can add search content parameters for your policies.

About this task

You can enrich metadata through the built-in content search application. For more information, see [Using content search policies](#).

You can add specific parameters for content search policies by using the following steps:

Procedure

1. Select `contentsearchagent` for the Application.
2. Click +Add Row to open the Parameter dialog.
3. Enter a tag name in the Parameter box and select one or more Search Expressions from the dropdown list.
4. For the Value, select either True/False or Value matching expression.
5. Repeat steps 1 - 3 to set other tags that use the same policy.
6. Click Next Step.

Running policies

You can configure policies to run at specified or scheduled times, at policy creation time, or when the system is manually started, paused, restarted, or stopped.

Procedure

To configure a policy to run:

1. Go to Metadata
2. Click a policy to select it. The following screen displays:

Figure 1. Policies table

Policy	Type	Schedule (UTC)	Status	Progress	Collection	Last Modified by	Last Modified
cs_spl_016	DEEPINSPECT	Done	Running	100%	spl016	spl016	2019-10-28T17:21:29.000Z
cs_spl_017	DEEPINSPECT	Done	Stopped	0%	spl017	spl017	2019-10-28T17:21:29.000Z

From the screen, you can perform the following actions on the selected policy:

Pause

Click the "vertical bars" icon to pause a policy that is running. When a policy is paused, it enters a `Paused` state. A policy cannot be paused until the current batch that is being processed finishes.

Start

Click the "right-arrow" icon to resume a paused policy or to start a stopped policy from its beginning. When a policy is started, it enters a `Running` state.

Stop

Click the "square" icon to stop a policy that is in progress. When a policy is stopped, it enters a `Stopped` state.

When a policy completes, it enters a `Stopped` state. The progress column indicates the success or failure status of the policy. If there are failures, you can examine the per policy execution log files to obtain more details of the failures.

For more information, see [Viewing policies](#).

Viewing policies

You can view your policy information.

About this task

You can see a list of the active and inactive policies and their status.

Figure 1. Policies table

Policy	Type	Schedule (UTC)	Status	Progress	Collection	Last Modified by	Last Modified
archived	AUTOTAG	Done	Running	100%	spl016	spl016	2020-01-21T12:13:31.000Z
archived2	AUTOTAG	Done	Stopped	0%	spl017	spl017	2020-01-21T12:13:31.000Z

Procedure

1. Go to Metadata > Tag Management
2. Under Policies, view a table of the specified policies with the following aspects:

Policy

Displays the name of a policy.

Type

Displays the policy type. There are three types:

- **AUTOTAG:** You can apply custom metadata values to some, or all of the records based on filter criteria.
- **CONTENT SEARCH:** You can enrich metadata by using the built-in CONTENTSEARCH application.
- **DEEP-INSPECT:** You can enrich metadata through content inspection of source data.

Schedule

Displays the frequency at which a policy is applied. Policy schedule times are displayed in Coordinated Universal Time (UTC).

Done

Indicates that the policy is applied.

Daily: 00:00

Indicates that the policy is applied one time a week on the displayed day and time.

Weekly:[day], 00:00

Indicates that the policy is applied one time a week on the displayed day and time.

Monthly:[date], 00:00

Indicates that the policy is applied one time a month on the displayed date and time.

Status

Displays the status and current state of the policy.

- A policy's **Inactive** status shows the **None** state.
- A policy's **Active** status can have a state of **Initialized**, **Running**, **Paused**, or **Stopped**.

Progress

Displays the percentage of completion of a policy.

If there is an Error "yellow triangle" icon, you can hover the cursor over it to see more information.

If there are some records that met the filter criteria but fail to be tagged, the number of failed records and the total number of records are displayed below the percentage of completion.

If there are failures, the per policy execution log files can be examined to obtain more details of the failures. For more information, see [Viewing policy history details and logs](#).

Collections

Displays the name of the collection that the policy applies to or the number of collections the policy applies to if there is more than one collection.

Last modified by

Displays the name of the user who last modified the collection.

Last modified

Displays the date and time that the collection was last modified.

You can add a policy by clicking Add Policy +. For more information, see [Adding auto-tagging policy parameters](#) or [Adding deep-inspection policy parameters](#) on page 19.

3. Click a policy to select it. The following screen displays:

Figure 2. Policies table

Policy	Type	Schedule (UTC)	Status	Progress	Collections	Last Modified by	Last Modified
CTE_TAG_JPM	DEEPEXPECT	Daily	Active	100%	jpm	admin	2019-10-08T17:17:25.000Z

From the screen, you can perform the following actions:

Start, Pause, Stop, or delete

You can start, pause or stop a policy. For more information, see [Running policies](#).

Edit/Delete

Use the Edit "pencil" icon to modify a policy. Use the Delete "trashcan" icon to delete a policy. You cannot delete a policy that is running (The "trashcan" icon is made unavailable).

View

Preview the details of the selected policy.

- [Viewing policy history details and logs](#)

You can view the history details, execution statistics and debug log data for all older or current metadata policies.

Viewing policy history details and logs

You can view the history details, execution statistics and debug log data for all older or current metadata policies.

About this task

Follow the procedure to view policy history details and logs.

Procedure

1. Go to Metadata > Tag Management.
2. Under Policy History, view the following information for the policy that ran recently or was run in the past.

Policy name

The name of the policy that was run.

Type	The policy type that was run.
Started	The time when the policy execution started.
Ended	The time when the policy execution was completed. This column remains blank if the policy is running.
Status	The current or final status of the policy execution.
Total records	The number of indexed records that matched the policy filter criteria for this policy execution.
Successful	The number of records that were processed successfully by the policy execution.
Skipped	The number of records that matched the filter criteria, but were skipped by the policy execution.
Failed	The number of records that the application failed to process.

- Note: Click the table header for each column to sort the tables. You can sort tables in both ascending or descending order.
- Click to select a row in the policy history table.
 - Click View log to view the run log contents for the selected policy execution.
- Note: The run log also displays the details of all failed records. You can download and debug the logs if necessary.

Modifying policies

You can modify your policies to work with and use your data more effectively.

About this task

You can modify a policy from the table on the Policies page. You cannot change the Name or Type of a policy.

Procedure

- Go to Metadata > Tag management
- Under Policies, select a policy you want to modify and click the Edit "pencil" icon on the header.
The Edit policy page appears. The policy parameters displayed depends on the policy type. The policy configuration area changes depending on the Extract tag from path setting.
Note: You cannot modify the name and the policy type.
- Modify the collections that the policy applies to (if required).
- Modify or enter a filter in the Filter box.
The filter must be constructed by using standard SQL syntax. For more information, see [example filters](#) on page 17.
- Modify the parameters specific to the policy type (if required).
 - For more information about **AUTOTAG** policy types, see [Adding auto-tagging policy parameters](#).
 - For more information about **DEEP - INSPECT** policy types, see [Adding deep-inspection policy parameters](#).
 - For more information about **CONTENT SEARCH** policy types, see [Adding content search policy parameters](#), [Adding deep-inspection policy parameters](#), or [Managing user accounts](#).
- Click the slider control to set the status to one of the following values:

Active
An *Active* policy is run whenever its scheduling event is reached.

Inactive
An *Inactive* policy is not run when its scheduling event is reached, including the **Now** event.
- Specify a Schedule to apply the policy. Policy schedule times are entered in Coordinated Universal Time (UTC).

Now
The policy is applied immediately, unless the policy's status is **Inactive**

Daily
Indicates a specific time of day to apply the policy. Enter the time of day to apply the policy by clicking the hour and minute from the widget that displays.
The policy is applied daily at the specified time.

Weekly
Indicates a specific day and time in which to apply the weekly policy:

 - Enter the time of day to apply the policy by clicking the hour and minute from the widget that displays.
 - Select the day of the week from the list of days.
 The policy is applied one time a week on the specified day and time.

Monthly
Indicates a specific day and time in which to apply the monthly policy:

 - Enter the time of day to apply the policy by clicking the hour and minute from the widget that displays.
 - Select the date by clicking the month and day from the widget that displays.
 The policy is applied one time a month on the specified day and time.
- Under Review check all the changes you have made.
- Click Save to save the changes.
The modified policy is displayed in the list of policies on the Policies tab.

Deleting policies

You can delete policy information.

About this task

A policy can be deleted from the table on the Policies page. You cannot delete a policy that is running. A user with the role Data User can delete only their own policies.

Procedure

1. Go to Metadata > Policies.
2. Click the Delete "trashcan" icon in the Edit/Delete column of the policy you want to delete.
If the "trashcan" icon is unavailable, then the policy is not available for deletion.
3. Click Delete in the confirmation window.
The policy is removed from the table in the Policies tab.

Using content search policies

You can define regular expressions to search for and create policies that use the regular expressions.

About this task

You can enrich metadata through content inspection of source data by using the built-in CONTENTSEARCH application. To use this function, you can define regular expressions to search for and create policies that use these regular expressions.

When the policy runs, the documents are retrieved from the source system by the CONTENTSEARCH application, converted to text format if necessary, and searched by using the defined regular expressions. The results of the search are returned to Data cataloging and the metadata of the files that are updated. To create a CONTENT SEARCH policy, see [Adding policies](#).

When you create a CONTENT SEARCH policy, you can select:

- Any tag type (including **Open**, **Restricted**, and **Characteristics** tags) for the **CONTENTSEARCH** application.
- Any regular expression.
- Either **"True/False"** or **"Value matching expression"**. **"True/False"** sets the tag value to either **True** or **False** if a match is found or not found. **"Value matching expression"** sets the tag value to the extracted content match.

Remember:

- If you select a **Restricted** tag with a defined set of values and choose to extract the value from a document, the value that is extracted must match one of the **RESTRICTED** values in the tag.
- If the content extracted exceeds the minimum tag value length, the extracted content is truncated.
- [Identifying the required regex expressions](#)
The following information can help you identify required regex expressions.
- [Creating a content search policy](#)
You can create a content search policy to filter a search query that finds candidate documents to which you can apply the policy.
- [Viewing content search application logs](#)
The following information describes how to view the content search application logs.
- [Hints and tips for using content search](#)
Following are some best practices for using the content search feature.

Identifying the required regex expressions

The following information can help you identify required regex expressions.

About this task

Validate that the regular expressions that are required for the policy are present. You can create or modify them if necessary.

Procedure

1. On the metadata page, select the Regular Expression tab.
The list of available expressions is displayed.

Figure 1. Preinstalled regular expressions

2. Search through the list of regular expressions to find any that match the content to be searched.

As shown in [Figure 1](#) that includes a selection of regular expressions.

For example, an expression with an embedded value that might be extracted.

```
^( [\w\.-]+@[ \w\.-]+\.[\w]{2,3} )$
```

This regular expression matches an email address, and the value that is returned for the tag is the matched email address. This sort of regex is appropriate to use in a value type match.

Another example is an expression with no embedded value, for a straight match.

```
^Patient Name:.*$
```

This expression detects the presence of the literal string "Patient Name:" and subsequent string in a fixed format file, but it does not extract the value. This is appropriate for use in a Boolean find search.

3. If there are no suitable regular expressions, select the Create icon.
4. If a regular expression exists but requires modifications select the expression and click the "Modify" icon. If this regular expression is in use by any other policy, this modification affects those policies.
5. Enter a suitable name, description, and the regular expression pattern.
6. Select Save.

Creating a content search policy

You can create a content search policy to filter a search query that finds candidate documents to which you can apply the policy.

About this task

For information about creating a content search policy, see [Managing metadata policies](#) and [Adding policies](#).

Viewing content search application logs

The following information describes how to view the content search application logs.

About this task

If you want to view the content search application logs, perform the following actions.

Procedure

1. Run the following command for enter in the project:

```
oc project ibm-data-cataloging
```

2. Any failures of download or inspection are logged in the application log file.
The following command provides the application log file:

```
oc logs deployment/isd-contentsearchagent
```

Hints and tips for using content search

Following are some best practices for using the content search feature.

Testing on a subset of documents

Running a content search policy on a set of documents has several steps that includes retrieving the document, formatting it as text, if necessary, and searching the document. Depending on the number, formatting, and size of the documents, searching the document can be a time-consuming process.

Therefore, it is best to test the policy and corresponding expressions on a small subset of documents to determine whether the policy and the regular expressions you select are correct. One way to run the test is to use a policy filter that selects only a small set of documents. After you confirm that the policy and search criteria is operating as expected, you can run it against the required set of documents.

The test on a subset of documents can also help you estimate how long the policy might take to run on the complete set of documents.

Avoiding retagging

When you rerun a policy against a set of documents that is previously tagged, the documents are retagged. If the values returned are different than the previous search, they are updated. This difference might occur if the policy or the set of expressions is modified, or if the set of documents is modified.

To avoid retagging the documents, add a criteria to the filter to not select documents that are already tagged.

Modifying regular expressions

If you modify a regular expression, it affects all policies that use that expression. Rerunning these policies might cause the documents to be tagged differently. To avoid changing the behavior of existing policies, create a new regular expression and use it in the specific policies where it is required.

Converting files with Apache Tika

Data cataloging uses Apache Tika to convert files to text before it searches the content. This conversion has an impact on the overall content search performance.

Therefore, files that are text format must be configured in the `contentsearch` agent to prevent them from being processed unnecessarily by Apache Tika. The default configuration treats JavaScript Object Notation (JSON) and Variant Call Format (VCF) file types as text. To add more text file types to the configuration, edit the file:

```
/opt/ibm/metaocean/data/agents/contentsearch/conf/contentsearch.conf
```

And add more types to the line:

```
text_filetypes=vcf,json
```

Apache Tika runs in a Kubernetes pod within Data cataloging. You can increase Apache Tika pod instances to improve performance. For example, run this command to scale the number of Tika instances to three:

```
oc -n ibm-data-cataloging scale --replicas=3 deploy/isd-tikaserver
```

Apache Tika is resource-intensive, so make sure that the number of Apache Tika instances does not exceed the host resources.

Supported connection types

Content search on Data cataloging supports the following connection types:

- Spectrum Scale
- COS
- NFS
- S3
- SMB

For more information, see the topic *IBM Spectrum® Scale data source connection* in *IBM Data Cataloging: Concepts, Planning, and Deployment Guide*. For more information, see [IBM Storage Scale data source connections](#).

Tiering data by using ScaleILM application

Use the IBM Data Cataloging ScaleILM application to move data to different tiers (pools) that are configured on the IBM Storage Scale connection.

Before you begin

- Configure IBM Storage Scale with one or more internal pools. For more information, see: [Internal storage pools](#) For more information, see *Internal Storage pools* in the *IBM Storage Scale: Administration Guide*.
- If you want to, you can configure IBM Spectrum® Archive and its pools.
- Create the IBM Storage Scale connection in IBM Data Cataloging. If the external pool that is managed by IBM Storage Archive is used as the destination tier, then the "host" setting of IBM Storage Scale connection must specify one of the IBM Storage Archive nodes.
- IBM Data Cataloging ScaleILM application uses the same user, that is configured in IBM Data Cataloging to scan the IBM Storage Scale and run the Data Movement policies. For this data movement, the IBM Storage Scale connection is used as the 'source_connection'. For more information, see [Creating or identifying a user ID and password for scanning](#). For more information, see the topic *Creating or identifying a user ID and password for scanning* in the *IBM Data Cataloging: Concepts, Planning, and Deployment Guide*.

About this task

The IBM Data Cataloging ScaleILM application provides the advanced data tiering function through the IBM Storage Scale connection. It uses the system metadata and custom metadata of documents that are collected by IBM Data Cataloging for this advanced data tiering function. This capability eliminates the need to scan file systems during IBM® License Manager (ILM) execution. It also provides cognitive tiering capability by using the results of IBM Data Cataloging's AUTOTAG, CONTENT SEARCH, and DEEP-INSPECT policies.

IBM Storage Scale provides the built-in Information Lifecycle Management (ILM) capability that optimizes the cost-effectiveness of data by moving the physical location of data between the storage pools with different cost or performance characteristics. IBM Storage Scale's ILM supports the data movement between its internal storage pools and between both the internal pool and the external storage repository. The movement from external storage repository is managed by external applications, such as IBM Storage Archive Enterprise Edition (EE) and IBM Storage Protect for Space Management.

Ensure that you know the IBM Storage Archive Enterprise Edition (EE) software versions that are supported. For more information, see [IBM Spectrum Storage software requirements](#). For more information, see the topic *IBM Spectrum Storage software requirements* in the *IBM Data Cataloging: Concepts, Planning, and Deployment Guide*.

While tiering data in external pools, the current location of the data is indicated in its file state. The data locations and the corresponding file states that indicate these locations, are listed in the following table:

Table 1. Data locations and File States

Data locations	File states
The data location is only in the internal pool.	The file state is resident.
The data location is both internal and external pool.	The file state is premigrated.
The data location is only in the external pool.	The file state is migrated.

Note: The functions of the ScaleILM application depend on the capability of underlying storage hardware and its management software. For more information, see the following topics:

- *Information Lifecycle Management for IBM Storage Scale* in the *IBM Storage Scale: Administration Guide*
- *IBM Storage Archive Enterprise Edition (EE) IBM Documentation*

Procedure

1. Log in to IBM Data Cataloging GUI.
2. Go to Admin > Management Policies page.
3. Click Add Policy to create a policy.
4. Click the slider control and set the status to one of the following values:

Active

An active policy is run whenever its scheduling event is reached.

Inactive

An inactive policy is not run even when its scheduling event is reached, including the Now event.

5. Enter a policy name.
6. Enter a Policy filter. The policy filter includes the criteria for selecting the files for tiering, such as `filetype="pdf"`.
Note: If the destination tier is the external pool that is managed by IBM Storage Archive, define the policy filter criteria as "state in 'resdnt'". For example, `filetype='txt' and state in 'resdnt'`.
If the filter criteria do not include `state in 'resdnt'` while tiering data to an external pool, the ScaleILM application skips the files that are not in resdnt state.
7. Click Next Step to select the type of policy.
8. Select **TIER** as the Policy type.
9. Select **ScaleILM** as the Agent.
10. Select the `source_connection` from the drop-down list. The source connection is the source from where the data is being moved, such as the name of the defined IBM Storage Scale connection.
11. Enter the `destination_tier` where you want to move your data, such as:
 - Internal Pools
Gold, silver, bronze, flash system
 - External Pools
 - `archive:pool1@library1`
 - `archive:pool2@library2`
 - `archive:pool1@library1, pool2@library3`

Note: When you specify an IBM Storage Scale internal pool as the "destination_tier", you need to ensure that you specify a valid internal pool name. That internal pool name must be configured in the IBM Storage Scale source connection for the corresponding data source (file system). These internal pools can be listed by using the following IBM Storage Scale command:

```
mmlspool <device> all
```

When you specify an external pool that is managed by IBM Storage Archive as the "destination_tier", you must specify a valid archive pool. This archive pool must be defined in the IBM Storage Archive that is configured on the IBM Storage Scale cluster node.

Additionally, you must specify the name of the pools that are defined in the IBM Storage Archive configuration, with the prefix "archive:". The pool names must be specified in the same format as defined in the -p option of IBM Storage Archive Enterprise Edition (EE) CLI (eadm). The syntax must be as follows:

```
archive:<poolName>@<libraryName>
```

or

```
archive:<poolName1>@<libraryName1>,<poolName2>@<libraryName2>,...
```

The policy execution fails when you do not follow the instructions.

12. Select Next Step to enter a schedule. The schedule indicates when you want to start the tiering.
13. Select Next Step to review the policy.
14. Select Submit to create the policy.
15. When the policy is created, view the files on the IBM Data Cataloging Search catalog page to ensure that they are moved to the new tier. The following metadata are updated:

Tier

Displays the name of the internal pool in IBM Storage Scale where the data is stored.

Note: Even if the file is in the migrated state (migrtd), the tier field shows the name of the original internal pool.

State

Displays the current state as one of the following values:

- resdnt
- premig
- migrtd

Migloc

Displays the location information of the external pool when the file is in premigrated (premig) or migrated (migrtd) state. If the file is in a resident (resdnt) state, this field shows NA.

SizeConsumed

Displays the actual size of the file in bytes, that is associated with the IBM Storage Scale file system field SizeConsumed Bytes.

- [Viewing ScaleILM application logs](#)

The following section describes how to view the ScaleILM Data Mover application logs.

Viewing ScaleILM application logs

The following section describes how to view the ScaleILM Data Mover application logs.

About this task

Follow the procedure to view the ScaleILM Data Mover application logs.

Procedure

1. Run the following command:

```
oc -n ibm-data-cataloging logs deployment/isd-scaleilmdatamover
```

2. Any failures that occur while the files are processed for tiering by ScaleILM Data Mover application, are logged in the application log file. A sample error log from the ScaleILM Data Mover application logs is shown in the following section. These error logs occur when the file is not on the specified 'source_connection' while the application is processing the Tiering policy.

```
2020-04-28 14:44:36,439 - __main__ - ERROR - File not found:
/ibm/scale0/unicode_test/migrateDir.popFSDir.19824/unicodedir/test010.\n.test
2020-04-28 14:44:36,440 - __main__ - ERROR - File not found:
/ibm/scale0/unicode_test/migrateDir.popFSDir.19824/unicodedir/test137..test
2020-04-28 14:44:36,440 - __main__ - ERROR - File not found:
/ibm/scale0/unicode_test/migrateDir.popFSDir.19824/unicodedir/test147..test
2020-04-28 14:44:36,440 - __main__ - ERROR - File not found:
/ibm/scale0/unicode_test/migrateDir.popFSDir.19824/unicodedir/test157..test
```

A sample error log from the ScaleILM Data Mover application logs for an invalid 'destination_tier', is shown in the following section:

```
2020-04-28 14:35:39,566 - __main__ - ERROR - Invalid destination_tier: 'gold:abcd'.
```

A sample error log from the ScaleILM Data Mover application logs when the 'destination_tier' does not exist on the IBM Storage Scale connection, is shown in the following section:

```
2020-05-12 14:32:38,436 - __main__ - ERROR - Provided internal pool goldflower does not exist on system: 9.11.212.29
```

3. Run the following command to view policy engine pod logs:

```
oc -n ibm-data-cataloging logs deployment/isd-policyengine
```

A sample policy engine pod log is shown in the following section. This log shows information that is received from the ScaleILM Data Mover application. It describes errors that are encountered while a Tiering policy is processed and when a file is not found on the specified 'source_connection':

```
2020-04-28 14:44:37,455 - policy.policyapiservice - ERROR - [policy_id: scale-tier-unicode-modevml9-pol]: Agent reported
'status: failed' for fkey: 'modevml9.tuc.stglabs.ibm.comscale0121547', path:
'/ibm/scale0/unicode_test/migrateDir.popFSDir.19824/unicodedir/test237..test', reason: 'File not found:
/ibm/scale0/unicode_test/migrateDir.popFSDir.19824/unicodedir/test237..test', errno: 'ENOENT'
2020-04-28 14:44:37,455 - policy.policyapiservice - ERROR - [policy_id: scale-tier-unicode-modevml9-pol]: Agent reported

```

Copying data by using ScaleAFM application

The ScaleAFM application supports copy function between IBM Storage Scale connection and IBM Cloud® Object Storage connection.

Before you begin

- You must know the IBM Storage Scale versions that are supported. For more information, see [IBM Spectrum® Storage software requirements](#). For more information, see *IBM Spectrum Storage software requirements* in the *IBM Data Cataloging: Concepts, Planning, and Deployment Guide*.
- You need to configure the Active File Management (AFM) functions on IBM Storage Scale filesets under a filesystem. With this configuration, AFM now works as a cache for a bucket or vault on a IBM Cloud Object Storage, or other Cloud Object Storage data source that supports Amazon S3 protocol as a target.

For more information, see the topic *Introduction to AFM to cloud object storage* in the *IBM Storage Scale Concepts, Planning, and Installation Guide*.

- You need to create the IBM Storage Scale connection in IBM Data Cataloging by configuring the filesystem in the IBM Storage Scale cluster, which contains the AFM fileset, with the Cloud Object Store target vault that is already configured.
- IBM Data Cataloging ScaleAFM application uses the same user that is configured in IBM Data Cataloging to scan the IBM Storage Scale connection and run the data movement policies. For this data movement, the IBM Storage Scale connection is used as the destination_connection. For more information, see [Creating or identifying a user ID and password for scanning](#). For more information, see *Creating or identifying a user ID and password for scanning* in the *IBM Data Cataloging: Concepts, Planning, and Deployment Guide*.

About this task

The IBM Data Cataloging ScaleAFM application provides the advanced copy function between the IBM Storage Scale connection and the IBM Cloud Object Storage connection (IBM Cloud Object Store or an S3 connection).

The application uses the system metadata and custom metadata of the documents that are collected by IBM Data Cataloging. The IBM Data Cataloging collects the metadata for advanced data management function to copy the select set of data from a vault on the IBM Cloud Object Storage connection to an AFM fileset configured on a IBM Storage Scale connection.

The application also provides the cognitive data management capability by analyzing the results of IBM Data Cataloging's AUTOTAG, Content Search, and Deep Inspect policies.

The AFM to Cloud Object Storage is an IBM Storage Scale feature that enables placement of files or objects in an IBM Storage Scale cluster to a Cloud Object Storage. Cloud object services such as Amazon S3 and IBM Cloud Object Storage offers industry-leading scalability, data availability, security, and performance.

The AFM to Cloud Object Storage allows associating an IBM Storage Scale fileset with a Cloud Object Storage. You can use a Cloud Object Storage to store large amount of data for use cases: mobile applications, backup and restore, enterprise applications, and big data analytics. The data is stored locally on IBM Storage Scale filesets and on a Cloud Object Storage. For more information, see the topic *Introduction to AFM to cloud object storage* in the *IBM Storage Scale Concepts, Planning, and Installation Guide*.

Note:

The functions of ScaleAFM application depend on the capability of the underlying storage hardware and its management software, specifically the IBM Storage Scale's AFM functions for Cloud Object Store.

For more information, see the topic *Active File Management for IBM Spectrum Scale* in the *IBM Spectrum Scale: Administration Guide*.

Procedure

1. Log in to IBM Data Cataloging GUI.
2. Go to Administration > Data Management page.
3. Click Add Policy to create a policy.
4. Enter a policy name.
5. Select COPY from the Type list.
6. Click Proceed to Configure.
7. Select ScaleAFM from the Application list.
8. Enter a Policy filter in the Filter field.

The policy filter includes the criteria for selecting the files for copying from source Cloud Object Store datasource to a destination IBM Storage Scale datasource. For example, the policy filter can be like `filetype="pdf"`.
9. Select the connection type from the Source Connection list.

It comprises connections that are configured with IBM Data Cataloging of type "Cloud Object Storage" or "Simple Storage Service (S3)". The source connection is the source from where the data is being copied, such as the name of the defined IBM Cloud Object Storage connection.
10. Select the connection type from the Destination Connection list.

It comprises connections that are configured with IBM Data Cataloging of type 'Spectrum Scale'. The destination connection is the target where the data is being copied, such as the name of the defined IBM Spectrum Scale connection.

Note: The IBM Storage Scale file system which is configured as the datasource for the destination IBM Storage Scale connection needs to be already configured with a fileset with IBM Storage Scale AFM functions enabled and configured with a Cloud Object Storage vault as the target. This vault must match with the one configured as Source Connection in step 9.
11. Enter the fileset value in Spectrum scale_afm_fileset field.

It is configured as the AFM fileset under the destination IBM Storage Scale connection, as explained in step 10.
12. Enter the directory path in the Target base dir field.

The Target Base Dir defines the absolute path of a base directory on the destination IBM Storage Scale system to which files from the source system are to be downloaded. It must be a directory path that is expressed as absolute path under the link path of the destination IBM Storage Scale fileset. The field name must

begin with a '/'. If not specified, the link path of the IBM Storage Scale AFM fileset that is configured with IBM Storage Scale connection, is used as the `target_base_dir`.

13. Click Proceed to Schedule to configure a schedule to the policy.

14. Click the slider control to select one of the following policy status:

Active

An active policy is run whenever its scheduling event is reached.

Inactive

An inactive policy is not run even when its scheduling event is reached, including the Now event.

15. Select a policy schedule under Frequency.

The schedule indicates when you want to schedule the policy for an execution.

16. Click Proceed to review to review the policy.

17. Click Submit to create the policy.

- When the policy is completed, you can update the IBM Data Cataloging catalog for the destination IBM Storage Scale connection by manually starting a scan of the connection.
- If the destination IBM Storage Scale connection is already created enabling live events, then the IBM Data Cataloging catalog automatically gets updated in a while with the entries relevant to the newly copied files from the Cloud Object Storage datasource by using the ScaleAFM data management policy, recently executed.

- [Viewing ScaleAFM application logs](#)

Procedure to view ScaleAFM application logs.

Viewing ScaleAFM application logs

Procedure to view ScaleAFM application logs.

Procedure

1. Issue the following command to view the ScaleAFM application logs:

```
oc -n ibm-data-cataloging logs deployment/isd-scaleafmdatamover
```

2. Any failures that occur while the files are processed for copying by ScaleAFM Data Mover application, are logged in the application log file. A sample error log from the ScaleAFM Data Mover application when a file (object) does not exist in the vault. The vault is configured with the source Cloud Object Storage data source, while the application is processing the Copy policy.

```
2020-09-30 15:07:47,032 - __main__ - ERROR - Failed queuing the file 'vault1/lws3711.txt' during AFM data transfer
```

This error log occurs when the IBM Storage Scale AFM Fileset name entered in the policy definition, does not exist on the IBM Storage Scale filesystem that is configured as datasource in the destination IBM Storage Scale connection:

```
2020-09-30 15:02:12,549 - __main__ - ERROR - An exception occurred while processing message: Fileset 'DAAA_ICOS123' not found in file system 'fs1'
```

3. Run the following command to view policy engine pod logs:

```
oc -n ibm-data-cataloging logs deployment/isd-policyengine
```

A sample policy engine pod log error from the ScaleAFM Data Mover application when a Copying policy is processed and when a file is not found on the specified 'source_connection':

```
2020-09-30 15:07:47,080 - policy.policyapiservice - ERROR - [policy_id: DAAA_Poll]: Agent reported 'status: failed' for fkey: 'vault1lws3711.txt', path: 'vault1/lws3711.txt', reason: 'Failed queuing the file 'vault1/lws3711.txt' during AFM data transfer', errno: 'ENOENT'
```

A sample error log from the policy engine pod logs, when the IBM Storage Scale AFM Fileset name entered in the policy definition, does not exist on the IBM Storage Scale filesystem. The IBM Storage Scale filesystem is configured as datasource in the destination IBM Storage Scale connection:

```
2020-09-30 15:02:13,100 - policy.policyapiservice - ERROR - [policy_id: DAAA_InvFileset]: Agent reported 'status: failed' for fkey: 'vault1analyt ics_results1.txt', path: 'vault1/analytics_results1.txt', reason: 'An exception occurred while processing message: Fileset 'DAAA_ICOS123' not found in file system 'fs1'', errno: 'EIO'
```

Exporting metadata to IBM Watson® Knowledge Catalog

IBM Data Cataloging Watson Knowledge Catalog (WKC) connector supports export of the metadata to either an IBM Cloud® instance or to an On-Premise Instance of the Watson Knowledge Catalog .

The default deployment of the WKC connector contains the parameters that are associated with the IBM Cloud instance of Watson Knowledge Catalog . On start, the IBM Data Cataloging WKC connector waits for WKC credential values. In the absence of appropriate credentials, the Export button is not visible on the IBM Data Cataloging user interface. For more information, see [Configuring Watson Knowledge Catalog connector](#).

- [Configuring Watson Knowledge Catalog connector](#)

A utility script is provided to simplify and automate the Watson Knowledge Catalog connector configuration. Alternatively, you can configure the Watson Knowledge Catalog connector manually.

- [Exporting metadata](#)

Export data with relevant metadata tags from IBM Data Cataloging to Watson Knowledge Catalog .

- [Mapping similar source connections in Watson Knowledge Catalog](#)
IBM Data Cataloging supports mapping source connections with Watson Knowledge Catalog connections (WKC) through WKC connector App.
- [Troubleshooting export issues](#)
This topic describes some issues faced while exporting data by using the Watson Knowledge Catalog.

Configuring Watson Knowledge Catalog connector

A utility script is provided to simplify and automate the Watson Knowledge Catalog connector configuration. Alternatively, you can configure the Watson Knowledge Catalog connector manually.

Before you begin

Collect details of the IBM Cloud® Watson Catalog instance. The details that are required can vary depending on whether the IBM Watson® Catalog is on Cloud or On-premise.

To add IBM Cloud Watson Catalog details to the IBM Data Cataloging, obtain the following details:

1. Obtain the API key for accessing the Watson Knowledge Catalog application. To access WKC application on the IBM® Cloud, [Log in to IBM Cloud](#) and select Create an IBM Cloud API key.
2. Export or copy the key.
3. Copy the base URI of your WKC instance. For IBM Cloud, the WKC instance URI is based on the geographical location.

To add the IBM on-premises Watson Knowledge Catalog details to IBM Data Cataloging, obtain the following details:

- Obtain the values for the following Watson Knowledge Catalog (WKC) parameters from the systems administrator of the On-Premises instance:
 - WKC_USER
 - WKC_PASSWORD
 - WKC_BASE_URI
 - WKC_AUTH_URI

To successfully export document-related metadata from IBM Data Cataloging to the Watson Knowledge Catalog, WKC application must have access to the original documents. This step is achieved by using either a linked or a non-linked data source. Exporting metadata from a linked data source indicates that both Watson Knowledge Catalog and IBM Data Cataloging have access to the original data source location, eliminating the need to copy the original files.

Exporting metadata from a non-linked data source is used when Watson Knowledge Catalog does not have access to original IBM Data Cataloging data source location. In this case, IBM Data Cataloging copies the files that are associated with the export metadata to a location where the Watson Knowledge Catalog service can access these documents. A Watson Knowledge Catalog Cloud Object Storage (COS) connection must be available to export from non-linked data sources.

You must know the details of linked or non-linked data sources before you start configuring the WKC Connector. For more information, see [Mapping similar source connections in Watson Knowledge Catalog](#).

- [Configuring Watson Knowledge Catalog using the utility script](#)
Utility script is used to configure the Watson Knowledge Catalog (WKC) and the script automates the WKC connector app configuration process.
- [Configuring Watson Knowledge Catalog manually](#)
Procedure to configure Watson Knowledge Catalog (WKC) connector app manually.

Configuring Watson Knowledge Catalog using the utility script

Utility script is used to configure the Watson Knowledge Catalog (WKC) and the script automates the WKC connector app configuration process.

Procedure

Log in to the IBM Data Cataloging instance and run the following command:

```
/opt/ibm/metaocean/utility-scripts/configureWKC.sh
```

The script prompts for credentials and data source connections and configures the WKC application.

The script can be rerun to change the configuration. This is applicable for the following scenarios:

- Exporting from IBM Data Cataloging to a new or different Watson Knowledge Catalog connection.
- A new connection is added to IBM Data Cataloging.

Configuring Watson Knowledge Catalog manually

Procedure to configure Watson Knowledge Catalog (WKC) connector app manually.

Before you begin

Before you perform any changes to the Watson Knowledge Catalog (WKC) connector application configuration, ensure that no WKC export policies are in running state. If you do any changes in the WKC connector application configuration, while policies are running it can cause the WKC connector application to fail to start and resulting in a **CrashLoopBackoff** state. If you face this issue, stop any WKC export policies that are running and the WKC connector application starts normally.

Procedure

1. Log in to the IBM Data Cataloging instance and issue the following command to configure the WKC connector app:

```
oc -n ibm-data-cataloging edit deploy/isd-wkconnector
```

2. For IBM® Watson Knowledge Catalog cloud deployment, define the following parameters:

- name:WKC_API_KEY
- value:<API-KEY-VALUE>

For cloud deployment, ensure that **WKC_USER** and **WKC_PASSWORD** value remain undefined in the environment. To delete WKC connector secret, issue the following command:

```
oc delete secret wkconnector --ignore-not-found
```

You can set **WKC_BASE_URI** value for WKC cloud, depending on the on-premises geographical location. The parameter value is the default when **WKC_BASE_URI** is not defined.

Example

```
name: WKC_BASE_URI
value:https://api.dataplatform.cloud.ibm.com/v2/
```

3. For IBM Watson Knowledge Catalog on deployment, add the parameter details in the following sample format:

```
name:WKC_BASE_URI
value:https://<wkc_hostname>/v2/
name:WKC_AUTH_URI
value:https://<wkc_hostname>/icp4d-api/v1/authorize
```

- a. To define the WKC connector secret manually, issue the following command:

```
oc create secret generic wkconnector --from-literal="user=$WKC_USER" --from-literal="password=$WKC_PASSWORD"
```

4. Configure any linked data sources if needed by setting the value of the **WKC_CONNECTION_MAP** field.

For more information see, [Mapping similar source connections in Watson Knowledge Catalog](#), [Mapping similar source connections in Watson Knowledge Catalog](#) on page 40.

Note:

- If you switch to a different IBM Watson Knowledge Catalog, you can edit the relevant WKC environment variables in the deployment editor to add the values that are associated with the new account. The application automatically restarts and recognizes the new account that is linked.
- If you add new catalogs to the WKC instance, IBM Data Cataloging retains the old registration information and continues to point to the old catalog IDs. To resolve this issue, follow the procedure:
 - Go to metadata > Applications.
 - To restart the WKC application instance, issue the following commands:

```
oc -n ibm-data-cataloging delete isd-wkconnector
```

Exporting metadata

Export data with relevant metadata tags from IBM Data Cataloging to Watson Knowledge Catalog.

About this task

The Watson Knowledge Catalog is a data catalog system that is not always able to scan relevant data sources and capture the relevant metadata from those files. IBM Data Cataloging helps to bridge this critical gap by helping to export data to Watson Knowledge Catalog with all relevant metadata tags.

Procedure

1. On the IBM Data Cataloging Dashboard, search for the data to be exported by using a specific filter criteria.
2. Click Export Data. The Export Data to Watson Knowledge Catalog window appears.
3. Under Destination Catalog, select the catalog in Watson Knowledge Catalog where you want to export the data.
4. Select the tags that you want to export from the list in Metadata Tags to Export.
5. Click Submit.
6. After completion of the process, the exported data is displayed in the Watson Knowledge Catalog with the tags that are imported from IBM Data Cataloging.
Now you have an alternative option to create a data management policy to export data to the Watson Knowledge Catalog by using the **DATASET_EXPORT** policy type.
Note: Tags in IBM Data Cataloging represent a name (for example, SizeRange) and a value (for example, small, large, or medium). In Watson Knowledge Catalog, the tags represent a value. The exported data maps both of these attributes and it creates a single label.
For example, SizeRange:Small.

Mapping similar source connections in Watson Knowledge Catalog

IBM Data Cataloging supports mapping source connections with Watson Knowledge Catalog connections (WKC) through WKC connector App.

When metadata is being exported to WKC, IBM Data Cataloging might use a source connection that WKC can also connect to. In such a scenario, you can configure the connection mapping within the WKC Connector App.

The connections that can be linked to are:

- Amazon S3
- IBM Cloud® Object Storage
- IBM Storage Scale

Note: Connections with IBM Storage Scale are established through an S3 connection as WKC does not support IBM Storage Scale directly. The details for configuring the connection maps with each of these source connections are described.

S3

For an IBM Data Cataloging S3 connection, the WKC connection must contain the following details:

Bucket

If the bucket name is configured, then you do not need to provide any further configuration details. The WKC Connector App can infer the details from the global namespace of Amazon S3 buckets.

If the bucket name is not provided, then configure the *WKC_Connection_Map* environment variable by using the following format: `<datasource>;<cluster>:<wkc connection name>`. A sample variable value is shown. All documents, that the WKC App receives in its work message corresponding to the data source and cluster pair that is defined in the variable, maps to the WKC connection of that name.

```
WKC_CONNECTION_MAP=testbucket1.sd.ibm.com;s3.eu-west-1.amazonaws.com:s3_con_no_bucket
```

Note: It is mandatory to provide the bucket name while you are configuring details in IBM Data Cataloging but it is optional for WKC.

IBM Cloud Object Storage Infrastructure

For an IBM Data Cataloging IBM Cloud Object Storage connection the WKC connection must contain the following details:

Login URL

The login URL must be that of the accessor defined in IBM Data Cataloging. The data source for IBM Cloud Object Storage is the vault. However, since it is not possible to provide a vault here, you must provide the mapping within the environment variable *WKC_CONNECTION_MAP* in the following format: `<datasource>;<cluster>:<wkc connection name>`. A sample variable value is shown.

```
WKC_CONNECTION_MAP=vault1;e09cdac0-80f8-73be-00ed-cb8edeede242:local_cos_con
```

Multiple IBM Cloud Object Storage connections to the same system can map to the same WKC connection (as it is at a higher level and can see all vaults).

IBM Storage Scale

Connection mapping with IBM Storage Scale must be done through an S3 connection as WKC cannot connect directly with it.

To establish an S3 connection, configure the following details in the WKC connector app:

Endpoint URL

The S3 Endpoint URL on the IBM Storage Scale mode. For example, `http://modevml9.tuc.stglabs.ibm.com:9000`.

Access Key

Type the S3 access key.

Secret Key

Type the S3 secret key.

Bucket

Do not enter values in the bucket field.

Define the mapping within the environment variable *WKC_CONNECTION_MAP* in the following format: `<datasource>;<cluster>:<wkc connection name>`. A sample variable value is shown:

```
WKC_CONNECTION_MAP=scale0;modevml9.tuc.stglabs.ibm.com:s3_scale
```

Mapping multiple connections

You can map multiple connections within the same environment variable by using commas to separate the values. A sample is shown:

```
WKC_CONNECTION_MAP=vault1;e09cdac0-80f8-73be-00ed-cb8edeede242:local_cos_con,scale0;modevml9.tuc.stglabs.ibm.com:s3_scale,testbucket1.sd.ibm.com;s3.eu-west-1.amazonaws.com:s3_con_no_bucket
```

Run the following command to edit the WKC Connector app deployment and add the mapping:

```
oc -n spectrum-discover edit deploy/spectrum-discover-wkcconnector
```

The WKC connections are configured in the following format:

```
name: WKC_CONNECTION_MAP
value: vault1;e09cdac0-80f8-73be-00ed-cb8edeede242:local_cos_con,scale0;modevml9.tuc.stglabs.ibm.com:s3_scale,testbucket1.sd.ibm.com;s3.eu-west-1.amazonaws.com:s3_con_no_bucket
```

Note: The **edit** command configures the WKC connection mapping and automatically restarts the WKC pod.

Troubleshooting export issues

This topic describes some issues faced while exporting data by using the Watson Knowledge Catalog.

- [Authentication failure with Watson Knowledge Catalog - both on-Premise and IBM Cloud](#)
Resolve authentication failure with the Watson Knowledge Catalog (WKC).
- [Incorrect WKC URL configuration](#)
Resolve the errors that occur due to an incorrect WKC URL configuration.
- [Invalid connection type in catalog](#)
Resolve the error that occurs due to an invalid connection type in catalog.
- [No linked connection type](#)
Resolve the errors that occur when links cannot be identified for the connection type.
- [WKC connector pod in CrashLoopBackoff state](#)
Check the following settings if the Watson Connector pod is in the CrashLoopBackoff or Error state.
- [S3 connection issues](#)
Resolve the issues faced owing to S3 connection.

Authentication failure with Watson Knowledge Catalog - both on-Premise and IBM Cloud

Resolve authentication failure with the Watson Knowledge Catalog (WKC).

The following error is displayed on the Watson Knowledge Catalog connector logs, when the connector fails to authenticate with the Watson Knowledge Catalog instance.

```
2020-07-16 12:46:04,870 - WKCCorrelator - ERROR - User authentication failed with response code 401
2020-07-16 12:46:04,871 - WKCCorrelator - INFO - No valid token available, cannot connect to WKC. Please set API Key or User Credentials
```

When the WKC authentication fails, check to ensure that the correct values are defined for the following environment variables for the on-premises connection:

WKC_USER, WKC_PASSWORD

If you are using an IBM Cloud® connection type, you must check the value of the environment variable **WKC_API_KEY**.

Run the following command to check and confirm the configuration for the specified environment variables in the pod helm chart: **oc edit deployment spectrum-discover-wkccorrelator**

Incorrect WKC URL configuration

Resolve the errors that occur due to an incorrect WKC URL configuration.

The following errors occur:

```
HTTPSConnectionPool(host='machine.ibm.com', port=443): Max retries exceeded with url: /v2/catalogs (Caused by
NewConnectionError('<urllib3.connection.HTTPSConnection object at 0x7f63e7973c18>: Failed to establish a new connection: [Errno
-2] Name or service not known',))
2020-07-09 22:59:29,412 - WKCCorrelator - ERROR - Cannot communicate with WKC to retrieve catalog information. Check config
URIs.
```

A possible reason for the error is that invalid values are defined for the environment variable **WKC_BASE_URI**. You can get similar errors if you define incorrect values for the **WKC_AUTH_URI** environment variable.

Run the following command to check and confirm the configuration of the said environment variables in the pod helm chart: **oc edit deployment spectrum-discover-wkccorrelator**.

The following error occurs, when incorrect API key is provided for WKC cloud connections:

```
2020-09-28 13:29:30,189 - WKCCorrelator - ERROR - Supplied API Key failed with response code 400
2020-09-28 13:29:30,190 - WKCCorrelator - ERROR - Unable to connect to WKC, resetting agent registration
```

The following error occurs, when incorrect user/password is provided for WKC on-premises connections:

```
2020-09-28 13:34:24,530 - WKCCorrelator - INFO - API Key not set, checking for user/password
2020-09-28 13:34:24,767 - WKCCorrelator - ERROR - User authentication failed with response code 401
2020-09-28 13:34:24,768 - WKCCorrelator - ERROR - Unable to connect to WKC, resetting agent registration
```

Invalid connection type in catalog

Resolve the error that occurs due to an invalid connection type in catalog.

When a valid connection type cannot be detected, the following error occurs:

```
2020-06-30 22:37:09,628 - WKCCorrelator - ERROR - Could not find a supported connection in the supplied catalog
```

This error might occur in the scenario when the connection type within the Watson Knowledge catalog (WKC) does not match the connection type on Spectrum Discover. For example, if you try to export metadata from an IBM Data Cataloging Cloud Object Storage (COS) source to a WKC catalog, which does not have an IBM Cloud® Object Storage connection. The error can also occur if you have an IBM Cloud Object Storage bucket on WKC mapped to an on-Premises IBM Cloud Object Storage bucket that is configured on IBM Data Cataloging.

No linked connection type

Resolve the errors that occur when links cannot be identified for the connection type.

The following errors can occur resulting in an export failure:

```
2020-07-01 13:58:34,129 - WKCCConnector - ERROR - Cannot export /Changing ACEs/Not for Luke and Amy/Full Gamora/Partial Luke/Partial Amy/No Clara/I mean not clara/TinyDoc.txt as document is not on a linked connection, and was unable to be downloaded from the SD connection for copy
2020-07-01 13:58:34,129 - WKCCConnector - ERROR - Failed to export /Changing ACEs/Not for Luke and Amy/Full Gamora/Partial Luke/Partial Amy/No Clara/I mean not clara/TinyDoc.txt
```

An exported document must either be on a linked connection, or must be available for copying to backup IBM Cloud® Object Storage in the WKC catalog, if that exists.

WKC connector pod in CrashLoopBackoff state

Check the following settings if the Watson Connector pod is in the CrashLoopBackoff or Error state.

Check that there are no Watson Knowledge Catalog export policies that are in running state when you perform any changes to Watson Knowledge Catalog connector application configuration.

Check the settings for the following environment variables if you are using IBM Cloud® Watson Knowledge Catalog:

WKC_API_KEY

Check the correct value for the following parameter if you are using IBM Cloud Watson Knowledge Catalog:

WKC_BASE_URI

Check the settings for the following environment variables if you are using an on-premises Watson Knowledge Catalog :

WKC_BASE_URI
WKC_AUTH_URI
WKC_CONNECTION_MAP

After successfully exporting records, if you change an environment variable to an invalid value and then export records again, you can end up with unprocessed messages in the Kafka buffer. You must clear these messages before you can change the invalid environment variable to the correct value. Run the following commands to clear the Kafka queue and then restart the Watson Knowledge Catalog connector application.

Clear Queue

```
/opt/kafka/bin/kafka-topics.sh --delete --zookeeper localhost:2181 --topic WKCCConnector_work
```

Recycle Pod

```
oc -n ibm-data-cataloging delete pod -l role=wkccconnector
```

If the Watson Knowledge Catalog connector pod remains down after you have performed the preceding steps, do the following:

1. If the Watson Knowledge Catalog connector (WKC connector) pod in IBM Data Cataloging cannot be started, delete the existing pod using the following command:

```
oc -n ibm-data-cataloging delete pod -l role=wkccconnector
```

2. Retrieve the logs from the WKC connector pod using the following command:

```
oc -n ibm-data-cataloging logs deployment/isd-wkccconnector
```

3. Check for errors in the logs by running the following command:

```
oc -n ibm-data-cataloging logs deployment/isd-wkccconnector | grep error
```

4. If the log terminates with an exception, check the policy engine log for errors by using the following command:

```
pollog | grep error
```

5. Check if the following error message appears at the time of the exception:

```
<time_stamp> - policy.policyapiservice - ERROR - b'Error: Cannot update application, 'WKCCConnector, it is in use by the follow
```

6. The WKC connector pod might not start until the error shown in step 5 is resolved.

Go to the Tag Management Policies section in the user interface and stop all running policies.

7. After the policies are stopped, then restart the WKC connector pod by deleting it:

```
oc -n ibm-data-cataloging delete pod -l role=wkccconnector
```

S3 connection issues

Resolve the issues faced owing to S3 connection.

To enable export of IBM Storage Scale file metadata without copying the actual file to Watson Knowledge Catalog, the latter must be connected to IBM Storage Scale through an S3 interface.

If you are experiencing issues with IBM Storage Scale file exports, check whether the connection is present in the connector connection map and that the details are made available in Watson Knowledge Catalog. You must check to see that correct values are defined for the IP, port, access, and secret key. To preview the documents in the catalog, you must check that the S3 interface is available on the IBM Storage Scale system.

Importing externally curated tags for COS/S3 using import tags application

The import tags application is used to import a set of externally curated tags for Cloud Object Storage and S3 services.

Before you begin

The S3/COS (Cloud Object Storage) data source that is associated with the objects in the external tags file must be scanned before you run an import tags policy.

Tag names must be defined in IBM Data Cataloging before the Import Tags policy is run. You must refrain from using Restricted tag type and use Open or Characteristics tag types.

Note:

- You can create limited number of Open type tags and the tags must correspond to values in the header row of the comma-separated values (CSV) file. Tags that are not defined before you trigger the policy are not imported.
- The CSV file must be in the bucket that is defined in the data source.
- Only a single tag file is supported per policy.

Requirements of the external CSV file are listed as shown.

- The tags file must be in CSV format.
- The first row in the file must be a header row or line.
- The first column must be the full object path or name. For example, if the bucket is auto_data, and the object name is car1/image1.png, then the first column entry is auto_data/car1/image1.png.
- The value in the header row for the first column is not restricted by IBM Data Cataloging.
- The subsequent columns in the CSV file represent the tag values that can be imported into IBM Data Cataloging for the associated object records.
- The second through Nth entries in the header row must correspond to valid tags in IBM Data Cataloging that are defined before you run the import tags policy.
- Each entry in the CSV file must represent a unique file in the data source.

```
Example contents of a CSV file:
objectname,bus,tree,stop_sign,red_light,yellow_light,green_light,pedestrian
auto_data/car1/image1.png,1,3,0,1,1,0,1
auto_data/car2/image1.png,1,6,0,0,0,0,12
auto_data/car2/image2.png,1,3,0,2,1,0,1
auto_data/car3/image1.png,1,3,0,2,1,0,2
```

The following tags can be defined in IBM Data Cataloging from the records available in the CSV file:

- bus
- tree
- stop_sign
- red_light
- yellow_light
- green_light
- pedestrian

Note: Only a single tag import policy can be run at a time.

About this task

The IBM Data Cataloging import tags application allows a user with DATA ADMIN role to apply a pre-curated set of labels (tags) that are available in an external CSV file to S3/COS object records stored in IBM Data Cataloging.

For example, an external analytics job might generate tag information for a set of S3/COS objects, and save this information into a CSV file. The CSV file comprises an entry for each object that contains an object name and an associated list of labels or tags.

The import tags application can merge these tags into the associated object records in IBM Data Cataloging, extending the records with new information.

Procedure

1. Configure a COS/S3 data source connection for IBM Data Cataloging, with the vault or bucket that gets scanned later. The resulting system metadata that is indexed in IBM Data Cataloging is then enriched with the imported tag data.

Example

COS/S3 datasource connection name is **camera_vault** and the vault or bucket name is **camera_lidar_semantic**. Connection is created and scan is run.

For more information about configuring and scanning COS/S3 data sources, see [Configure data source connections](#). For more information about configuring and scanning COS/S3 data sources, see *Configure data source connections* in the *IBM Data Cataloging: Concepts, Planning, and Deployment Guide*

2. Place external tag file on to the data source so that IBM Data Cataloging can access it. A single CSV file comprises a list of objects and tags. The objects and tags are applied to the indexed records for a COS/S3 data source. These objects and tags must be uploaded to the configured source storage bucket by using any IBM® COS/S3 compatible data management utility.

Example

IBM Data Cataloging data source with connection name **camera_vault** is configured to scan vault and bucket **camera_lidar_semantic**.

3. Define tag names in IBM Data Cataloging.
 - a. Use the headers from the CSV file, starting with the second column.
 - b. Create corresponding tags in IBM Data Cataloging for any of the columns where you want to import data.

For example, for a column you want to import with header value ColumnA, create a tag ColumnA. The columns for which you do not want to import data, must not store tags that are defined with the header value.

Example

CSV file comprises columns with header values front, rear, center, car, bicycle, pedestrian, and truck that you want to import. Characteristics tags are created with names: front, rear, center, car, bicycle, pedestrian, and truck.

For more information about creating tags, see [Creating tags](#).

For more information about creating multiple tags through REST API see, [/policyengine/v1/tags/:POST](#). For more information about creating multiple tags through REST API, see [/policyengine/v1/tags/:POST](#) in the *IBM Data Cataloging: REST API Guide*.

4. Initiate the policy by the using REST API interface. For more information, see [Initiating Policy Using REST API](#).

- **Initiating Policy Using REST API**

Initiating a policy using the REST API triggers the import tag policy engine to process metadata tags for the configured data sources.

Initiating Policy Using REST API

Initiating a policy using the REST API triggers the import tag policy engine to process metadata tags for the configured data sources.

- [Registering import tags application](#)
The process of registering an import tags application.
- [Defining the import tag policy type](#)
Procedure to define the import tags policy in a JSON payload.
- [Viewing the policy status](#)
You can view policy status either from the IBM Data Cataloging GUI or by running read (GET) request.
- [Viewing the import tags application log](#)
You can view the import tag application logs through a simple procedure.

Registering import tags application

The process of registering an import tags application.

About this task

The import tags application is built-in and pre-registered in IBM Data Cataloging. To view the registered application, you can use the IBM Data Cataloging GUI.

For more information, see [Managing applications](#). [Managing applications](#) on page 63.

Defining the import tag policy type

Procedure to define the import tags policy in a JSON payload.

About this task

You can create the import tags policies by using the policy management REST API. A sample policy that is defined in a JSON payload is shown:

```
{
  "pol_id": "importtags_pol",
  "action_id": "IMPORT_TAGS",
  "action_params": {
    "agent": "Import Tags",
    "source_connection": "camera_vault",
    "tag_file_path": "camera_lidar_semantic/A2D2_labels.csv",
    "tag_file_type": "csv"
  },
  "schedule": "NOW",
  "pol_state": "active",
  "pol_filter": "datasource=' camera_lidar_semantic'"
}
```

The following table lists the action parameters for defining the import tags policy type:

Table 1. List of action parameter for an import tags policy type

Action Parameter	Description
source_connection	The Cloud Object Storage (COS) or S3 connection name that is defined in IBM Data Cataloging for the records that the imported tags can be applied to.
tag_file_path	The absolute path (bucket or object name) of the CSV file that contains the list of objects and associated tags to import.

IMPORT_TAGS is the new action_id that is defined for the import tags policies.

Procedure

1. Send the following query request to list all the supported action IDs on IBM Data Cataloging node:

```
curl -H "Authorization:Bearer<token>" -k https://<data_cataloging_host>:443/policyengine/v1/action_ids
```

2. Send the following query request to the IBM Data Cataloging node to obtain the current Import Tags application schema:

```
curl -H "Authorization: Bearer <token>" -k https://<data_cataloging_host>:443/policyengine/v1/applications/ImportTags/schema?
action_id=I MPORT_TAGS
```

3. To define the policy, and schedule or run it immediately, use the /policyengine/v1/policies -d '<data>': POST endpoint to process the request.
For more information, see [/policyengine/v1/policies -d '<data>': POST](#)
For more information, see [/policyengine/v1/policies -d '<data>': POST](#) in the *IBM Data Cataloging: REST API Guide*.

Example

Send the following request to create an Import Tags policy for data source connection camera_vault that runs immediately by using the external tag file A2D2_labels.csv:

```
curl -k -H 'Authorization: Bearer <token>'
https://<data_cataloging_host>/policyengine/v1/policies-d'
{
  "pol_id": "importtags",
  "action_id": "IMPORT_TAGS",
  "action_params": {
    "agent": "Import Tags",
    "source_connection": "camera_vault",
    "tag_file_path": "camera_lidar_semantic/A2D2_labels.csv",
    "tag_file_type": "csv"
  },
  "schedule": "NOW",
  "pol_state": "active",
  "pol_filter": "datasource='camera_lidar_semantic' "
}
'-XPOST -H" Content-Type:application/json"
```

The following response is returned:

```
Policy 'importtags_ut' added
```

Viewing the policy status

You can view policy status either from the IBM Data Cataloging GUI or by running read (GET) request.

About this task

Follow the procedure shown to view the policy status:

Procedure

1. Log in to IBM Data Cataloging GUI.
2. Go to Administration > Data Management tab.

The policy status can also be checked with the following REST API read request:

```
/policyengine/v1/policies: GET and /policyengine/v1/policies/<policy_name>: GET
```

For more information, see [/policyengine/v1/policies: GET](#) and [/policyengine/v1/policies/<policy_name>: GET](#) in the *IBM Data Cataloging: REST API Guide*.

Note: As import tags policies rely on an external list of objects/file and not on a policy filter, the policy preview service does not apply to this policy type. The number of records updated in IBM Data Cataloging will be no more than the number of entries in the external tag file.

3. Go to Policies tab.
Policies are listed with their status as active or inactive.

Example

A sample REST API request for checking import tag policy and the corresponding response is shown:

```
curl -k -H 'Authorization: Bearer <token>'
https://<data_cataloging_host>/policyengine/v1/policies/importtags_ut

Response:
{
  "pol_id": "importtags_ut",
  "action_id": "IMPORT_TAGS",
  "action_params": {
    "agent": "Import Tags",
    "source_connection": "camera_vault",
    "tag_file_path": "camera_lidar_semantic/A2D2_labels.csv",
    "tag_file_type": "csv"
  },
  "schedule": "NOW",
  "pol_filter": "datasource='camera_lidar_semantic' ",
  "pol_state": "active",
  "pol_status": "running",
  "explicit": "true",
  "execution_info": {
    "start_time": "2020-09-17 21: 04: 35",
    "total_count": 350,
    "submitted_count": 400,
    "failed_count": 8,
    "completed_count": 300,
    "skipped_count": 0,
    "import_tags_count": 0,
    "run_id": "a3b0f7647647443e8c5237aebc2c5408"
  },
  "policy_owner": "sdadmin",
  "last_updated_by": "sdadmin",
  "last_updated": "2020-09-17T21:04:35.000Z",
  "collections": []
}
```

During processing, the import tags application does some basic checking on the CSV file. If a row has fewer columns than the header row, the row is skipped. If a header value contains an invalid or missing tag name, the values for that column are not imported. These records are added to the failed count in the policy.

Viewing the import tags application log

You can view the import tag application logs through a simple procedure.

About this task

Follow the procedure to view the import tag application logs:

Procedure

Issue the following command to view the import tag application logs:

```
oc -n ibm-data-cataloging logs deployment/isd-importtags
```

A sample error log from the import tag application is shown in the following section. This error occurs when there exist rows in the CSV file that contain fewer columns than the header row:

```
2020-09-17 21:04:41,538-Import Tags-ERROR-Skipped entry. Ragged row: expected 44 columns, found 36
```

A sample error log from the import tag application is shown in the following section. This error occurs when there exist empty rows in the CSV file (newline):

```
2020-09-17 21:04:41,540-Import Tags-ERROR-Skipped entry. Empty row.
```

A sample error log from the import tag application is shown in the following section. This error occurs when there exist rows with an invalid file/object name in the first column:

```
2020-09-17 21:04:56,239-Import Tags-ERROR-Skipped entry. Object/file name not found in csv column 0 (camera_lidar_semantic).
```

Performing retention analytics on IBM Storage Protect archive data

Use IBM Data Cataloging to perform retention analytics on archive data managed by IBM Storage Protect.

Before you begin

You must have an admin role to do this task.

About this task

IBM Data Cataloging feature is used to perform search, analytics, and reporting on the retention period for archive data managed by the IBM Storage Protect.

The existing IBM Storage Protect data connection and scan function in the IBM Data Cataloging is enhanced to obtain the additional retention information from the IBM Storage Protect servers for the archive data.

Grouping expiration values to tag values

You can group the expiration values and run SQL queries to track the retention time period for the archive data managed by IBM Storage Protect. The custom tags are applied by AUTOTAG policies that look for all the data that is about to expire by a certain time period. The tagged policies can be scheduled to run periodically. After you apply AUTOTAG policies, the IBM Data Cataloging GUI and REST APIs can be used to search, discover, and perform analytics on the data that is going to expire during the various time periods.

Perform the following steps to apply retention analytics on the IBM Storage Protect archive data.

Procedure

1. Enable retention analytics feature. For more information, see, [Enabling the retention analytics feature](#).
2. Add IBM Storage Protect data source and initiating a scan. For more information, see [Adding IBM Storage Protect data source and initiating scan](#).
3. Search the expiry time. For more information, see [Searching expiry time](#).

- [Enabling the retention analytics feature](#)
Enable the retention analytics feature in IBM Data Cataloging.
- [Adding IBM Storage Protect data source and initiating scan](#)
Add IBM Storage Protect data source before you initiate a scan on the archive data.
- [Searching expiry time](#)
Search the expiration time for the IBM Storage Protect archive data that is going to expire in certain time.

Enabling the retention analytics feature

Enable the retention analytics feature in IBM Data Cataloging.

About this task

To enable the retention analytics for IBM Storage Protect archive data feature in IBM Data Cataloging, you must first set an environment variable in IBM Data Cataloging.

Following are the list of environment variable that you can set in the IBM Data Cataloging. The expiration data is not scanned if the expiration variables are not set.

PROTECT_ARCHIVE_WITH_EXPIRE_ONLY

When the variable is set to 'True', the IBM Storage Protect scan feature scans the archive data only and includes the expiration data that is needed for the expiration date analysis. When the variable is set to 'False' or not set at all, the IBM Storage Protect performs the default action of scanning all the backup and archive records without including the expiration data that is needed for the expiration date analysis.

Important: When the variable value is set, the IBM Data Cataloging server performs IBM Data Cataloging scans on the archive data only that includes the expiration data. This action takes precedence over any other environment variables that are defined for the retention analytics feature.

PROTECT_ARCHIVE_EXPIRATION

When the variable is set to 'True', IBM Storage Protect scans the archive data and checks that expiration data is also scanned. When the variable is set to 'False' or not set at all, the expiration data is not included, unless the value of `PROTECT_ARCHIVE_WITH_EXPIRE_ONLY` is set to true.

PROTECT_ARCHIVE_DISABLED

When the variable value is set to 'True', IBM Storage Protect scan feature does not scan the archive data unless the value of `PROTECT_ARCHIVE_WITH_EXPIRE_ONLY` is set to true. When set to 'False' or not set at all, IBM Storage Protect scan feature scans the archive data.

PROTECT_BACKUP_DISABLED

When the variable is set to 'True', IBM Storage Protect scan feature does not scan the backup data. When set to 'False' or not set at all, IBM Storage Protect scan feature scans the backup data unless the value of `PROTECT_ARCHIVE_WITH_EXPIRE_ONLY` is set to true.

Important: The `PROTECT_ARCHIVE_EXPIRATION` value must be set to "True", if a complete scan of the IBM Storage Protect connection with the archive retention feature is to be completed.

Perform the following steps for enabling retention analytics feature in the IBM Data Cataloging environment:

Procedure

1. Issue the following command to log in to the IBM Data Cataloging by using ssh:

```
ssh <adminuser>@<data_cataloging_host>
```

Note: The `<adminuser>` is a IBM Data Cataloging server user who is assigned with an administrator role and the `<data_cataloging_host>` is either the FDQN or IP of the IBM Data Cataloging server.

2. Issue the following command to edit the configmap:

```
oc edit configmap connmgr
```

After you run the preceding command, the output looks similar to the following as shown here. You can modify the following file and add or update the variables and its value in the `data` section.

```
apiVersion: v1
data:
  CONNMGR_ENDPOINT: /connmgr/v1/
  CONNMGR_PROTOCOL: http
  PROTECT_ARCHIVE_WITH_EXPIRE_ONLY: "True"
kind: ConfigMap
metadata:
  creationTimestamp: "2022-08-26T19:55:39Z"
  name: connmgr
  namespace: spectrum-discover
  ownerReferences:
  - apiVersion: spectrum-discover.ibm.com/v1alpha1
    kind: SpectrumDiscover
    name: spectrumdiscover
    uid: 001fb331-c2ef-4b28-8827-5c7d6a702904
  resourceVersion: "13761646"
  uid: bf621847-4c00-44c9-a7f2-4d3430ede67b
```

3. Save the preceding updated file and issue the following command to verify that the data is updated.

```
oc get configmap connmgr -o yaml
```

4. Issue the following commands to verify that the update is made in the connection manager pod:

```
oc -n ibm-data-cataloging delete sts/isd-connmgr
```

Adding IBM Storage Protect data source and initiating scan

Add IBM Storage Protect data source before you initiate a scan on the archive data.

About this task

After the retention analytics feature is enabled in the IBM Data Cataloging, you can add one, or more IBM Storage Protect data sources and initiate a scan. For more information, see [Creating an IBM Storage Protect data source connection](#).

Important: After the scan is complete, the database needs to be refreshed before you add the tags and the policies. Do the following to tag expiry time:

Procedure

1. Log in to the IBM Data Cataloging GUI.

2. Click  and go to Metadata > Tag Management

3. On the Tags tab, click the Add Tag.

4. In the New organizational tags window, enter the tag name in the Name field.

For example, enter `ExpirationDate`, `ExpirationDays`, or `Expiration` as a tag name.

5. Select `Restricted` from the tag Type list.

Restricted

A Restricted tag can be anything that describes groups of records, but is restricted to a set of pre-defined values, such as data classification or billing department number.

6. Enter the expiration values into the Values field and press Enter key to save each expiration value.

For example, to group all the data that is going to expire by the end of a year, create a tag that is called 'Expiration Year'. Similarly, to group all the data that is going to expire after few days from now, create a tag that is called 'ExpirationDays'.

Each saved expiration values (date or number of days) are grouped and displayed underneath the Values field. These expiration values are grouped and associated with a custom tag that is created. For example, tag values can be 01-January-2021 for a date-specific expiration or, 1 day, 1 month, and 1 year for days-specific expiration.

7. Click Submit.

The tag name, types, and values are displayed on the Tags tab after you submit the record.

Important: You must add all the expected values before you submit the record.

8. Go to the Policies tab and click Add policy.

9. On the Define page, enter the policy name in the Name field.

10. Select `AUTOTAG` from Policy Type list.

11. On the Policy page, enter the values in Filter field.

Sample filter input for 30-days from today as expiration period

```
mtime > NOW() AND mtime < (NOW() + 30 DAYS) AND platform like 'Spectrum Protect' and state like 'Archive'
```

Sample filter input for all data that is going to expire by the end of year 2021

```
State in 'Archive' AND mtime between '2021-01-01' and '2021-12-31'
```

Important: The date in the query must be in the format of 'YYYY-MM-DD'.

12. Choose the custom tag created to track the expiration time period from Tag list.

The tag list contains all the custom tags created with their saved tag name, type, and value details created on Tags tab. You can add more than one tag here to tag a policy.

13. Choose the expiration value (date or number of day's) from the Values list.

The expiration values that you choose from the Values list are tagged with custom tag that you choose from the Tag list.

For example, if you choose `ExpirationDays` as custom tag, you can choose the expiration value `30DayExpiration` as the number of days for data to expire to tag with the custom tag. Alternatively, if you want to group records by all the data that is going to expire by the end of a year, select the 'ExpirationYear' value.

14. Schedule the policy to run periodically by using the available schedule options.

Schedule options

Now

Daily

Weekly

Monthly

15. Verify the policy details on Review page before you submit the save the policy.

Sample policy detail on review page as shown

Name:

`30DayExpirationPolicy`

Action id:

`AUTOTAG`

Pol filter:

```
mtime > NOW() AND mtime < (NOW() + 30 DAYS) AND platform like '%Spectrum Protect%' and state like '%Archive%'
```

Pol state:

`active`

Searching expiry time

Search the expiration time for the IBM Storage Protect archive data that is going to expire in certain time.

About this task

After the IBM Storage Protect archive record expiration dates are tagged, do the following to search and apply further analytics on the records.

Important: Each policy that is defined must be executed before you perform search.

Procedure

1. Log in to the IBM Data Cataloging GUI.

2. Click  and go to Search > Query builder > SQL query page.

3. Choose groupings based on the tag that is created from Group by list.

For example, `ExpirationDate`.

4. Enter the SQL query in the query box.

For example, State in 'Archive' AND mtime between '2021-01-01' and '2021-12-31'

Important: The mtime date in the query must be in the format of 'YYYY-MM-DD'.

5. Set the limit for the number of records returned from the Limit results list.

6. Click View results.

The Query Results page displays the grouped results with expiration time, total files filtered, and the total size.

Note: Where, Total size represents the original size of the files that are stored in the backend. Total size that is returned in the report does not account for space savings from compression and data deduplication. Therefore, can over-state the amount of storage that is going to expire on the IBM Storage Protect server.

Currently, the data expiration support within the IBM Data Cataloging does not consider the amount of space that is saved in the size of the file for container pools that supports compression or data deduplication.

7. To generate a report, select the checkbox and click Generate report. On the Generate report dialog, Enter the report name in the Name field, and click Submit.

8. To view the report, go to Search > Reports.

After you submit the report, the new report gets generated and listed on Reports page in a table with following metadata details:

- Report name
- Last run
- Duration
- Status
- Output size

9. Select a report from the table lists and click Report summary.

A View Data Report window is displayed with all the details of a report.

Sample report details as shown

Managing tags

A tag is a custom metadata field used to enhance system metadata with organization-specific information. For instance, an organization may categorize its storage by project, cost center, or region but the attributes not provided by the storage system itself. Tags enable data classification, search, and reporting based on these organizational dimensions. Use tags to store this additional information and to manage or locate data using metadata that reflects your organizational context.

Permissions

Security Administrators

Cannot create, update, delete or list any type of tag.

Data Administrators

Can create, modify, delete, and list both **Label** and **Tag** tags.

Data Users

Can list all tags.

Cannot create, modify or delete **Tag** tags.

Can create and modify **Label** tags.

Types of tags

Label

Lightweight identifiers used for simple tagging. Useful for short descriptors like **project**, **region**, or **team**. Value size can be up to **256**, **1024**, or **4096** characters.

Tag

Structured tags with a predefined list of accepted values. Ideal for controlled vocabularies such as **status**, **compliance level**, or **department**. Value size is always limited to **4096** characters.

• [Creating tags](#)

Use the following information when you create tags.

• [Viewing and searching tags](#)

View and search tags from the Tags tab on the Metadata page to locate specific tags by name, type, or value, and sort or filter results as needed.

• [Editing tags](#)

Edit tag values from the Tags tab on the Metadata page to update the allowed values for existing organizational tags in IBM Spectrum Discover.

- [Deleting tags](#)

Delete tags from the Tags tab on the Metadata page to remove metadata classifications that are no longer needed from the IBM Spectrum Discover catalog.

Creating tags

Use the following information when you create tags.

About this task

Use the Tags tab to create new tags. The table lists the tag name in the Field Name column, the Type, and the tag values in the Tags column. Use the icons to Edit or Delete a tag.

Procedure

1. Go to Metadata > Tag Management
2. Under Tags, click the Add Tag button.

3. In the Create a new tag page, select the type of tag you want to create.

Label

A lightweight tag used to describe records with simple identifiers such as project name, department, or device ID. Labels are not restricted to predefined values unless explicitly configured.

Tag

A structured tag that enforces a predefined set of accepted values. Useful for controlled vocabularies like classification levels or billing codes.

4. Enter the name of the tag in the Name field.

Tag management

Create a new tag

Tags allow you to enrich with additional metadata ingested files records with 95 tags limit.

The tags, their types, and values are displayed in the table on the Tags tab.

Viewing and searching tags

View and search tags from the Tags tab on the Metadata page to locate specific tags by name, type, or value, and sort or filter results as needed.

About this task

You can see a list of all tags or search for a specific ones from the Tags tab on the Metadata page.

Procedure

1. Go to Metadata > Tag Management.
2. Under Tags tab, a list of tag **Names**, **Types**, and **Values** are displayed.

3. Click the column headers to sort tags in ascending or descending alphabetical order.

The screenshot shows the 'Tag management' page in the IBM Fusion Data Cataloging application. The page has a header with the application name and navigation icons. Below the header, there are tabs for 'Tags', 'Policies', and 'Policy history'. A search bar and an 'Add Tag' button are located in the top right. The main content area displays a table with columns for 'Tag name', 'Type', and 'Value'. The table lists several tags: 'TEMPERATURE' (Label(256)), 'ANIMAL' (Tag), 'SizeRange' (Bucket), 'TimeSinceAccess' (Bucket), and 'FileGroup' (Bucket). The 'Value' column for 'ANIMAL' shows a list of animal types: zebra, Pony, Horse, Donkey. The 'SizeRange' tag shows a list of size categories: extra small, small, medium, large, extra large. The 'TimeSinceAccess' tag shows a list of time intervals: 1 week, 1 month, 1 quarter, 1 year, 1 year+. The 'FileGroup' tag shows a list of file formats: pdf, doc, xls, image, ppt, +7. At the bottom of the table, there is a pagination control showing 'Items per page: 20' and '1-5 of 5 items'.

4. Enter text into the Search box to find tags that begin with the entered text.

The screenshot shows the 'Tag management' page with a search filter applied. A blue banner at the top of the table area indicates 'ANIMAL Selected'. The table now only displays the 'ANIMAL' tag. The 'Value' column for 'ANIMAL' shows the same list of animal types: zebra, Pony, Horse, Donkey. The pagination control at the bottom shows 'Items per page: 20' and '1-1 of 1 item'.

As you type, a filtered list of tags containing the text string is automatically displayed.

5. Select a tag and click Edit or Delete from the header row to perform the desired action.

Editing tags

Edit tag values from the Tags tab on the Metadata page to update the allowed values for existing organizational tags in IBM Spectrum Discover.

About this task

You can edit tag values from the **Tags** tab on the **Metadata** page.

Procedure

1. Go to Metadata > Tag Management.
2. Select the tag you want to edit and click the Edit icon in the header row.

Tag management

The modified values are listed in the table under the Tags tab.

Deleting tags

Delete tags from the Tags tab on the Metadata page to remove metadata classifications that are no longer needed from the IBM Spectrum Discover catalog.

About this task

You can delete tags from the Tags tab on the Metadata page.

Procedure

1. Go to Metadata > Tag Management.

2. Find a tag by using the Search box, by sorting a column, or by navigating by using the page arrows at the bottom of the table.

3. Select the tag that you want to delete and click the Delete "trashcan" icon that appears on the header row.

4. Click Delete in the confirmation box.

The tag is removed from the table in the Tags tab.

Discover data

By discovering your data, you can apply policies that assign tags to your data. You can apply tags to the results of a single search, or you can use policies to automatically apply tags on a periodic basis.

There are three ways to discover data:

- Content-based keyword and tagging. The search is based on regular expression patterns that are defined within IBM Data Cataloging. For more information, see [Creating a content search policy](#).
- Create a policy by using tags with known values. A policy is automatically run against all data that meets criteria that are specified in a filter. For more information about creating and using policies, see [Managing metadata policies](#).
- Search your data by using a query in standard SQL grammar or do a visual exploration of tags by point-and-click. For more information, see [Searching system and custom metadata fields](#).
- **Searching**
Build visual or SQL queries in the Query Builder to search for data in IBM Spectrum Discover, then filter, sort, and group the results to drill down to the relevant records.
- **Grouping data by file type**
Create policies to group data by file type.
- **Searching system and custom metadata fields**
Search system and custom metadata fields using SQL queries in the Query Builder to filter, sort, and retrieve file records from the IBM Spectrum Discover data catalog.

Searching

Build visual or SQL queries in the Query Builder to search for data in IBM Spectrum Discover, then filter, sort, and group the results to drill down to the relevant records.

About this task

You can build a visual query or a custom SQL query to begin the search. In a visual query, you can add tags from the search page and view the values in the form of charts, tables, or directories for a more enhanced experience. The following procedure helps you build queries to search for relevant results.

Procedure

1. Click  on the upper left of the IBM Data Cataloging interface and then click Search.
The Query Builder page appears.
2. To build a visual query, click Add corresponding to the Tag that you want to include in your search.
3. On the Select Values page, select the values in the table that is displayed beneath the chart to build your query.
4. Click Update Query to preview your query on the Query Builder page.
Note:
 - The Potential Record Count under Query Summary reflects the expected count of records in the search result that is displayed for the selected tags.
 - Click Reset Query to delete your current selection and build the query again.
 - Click  on the Query Preview box to copy the icon for future use.
5. Click View Results to display the search results.

6. To build a custom query, click the SQL Query tab on the Query Builder page.

7. Type your query in the text area provided.

Note:

- Click the + icon on the right to select from the query field suggestions.

- Click  to view all recent search queries that were previously used.

8. Click View Results to display the search results.

On the Query Result page, the search results are displayed under the Individual tab.

9. Select the tags that are provided under the Grouped By list on the left to drill down the results further.

The Query results are now displayed under the Condensed tab.

Note:

- Click  to edit the displayed columns from the list that appears.
- Select a search result row and then click Generate Report to generate a report for the set of records.
- Select a search result row and then click View Individual Records to view the records with no grouping selected.
- Click Back to query builder to return to the query builder screen from any search query pages.

Grouping data by file type

Create policies to group data by file type.

About this task

You can create AUTOTAG policies and run them on a periodic basis to group data by specific file types.

Procedure

1. Create an Open tag to group data. For example, FileTypeGroup.
 - a. Go to Metadata > Tag Management
 - b. Under Tags click Add Tags.
 - c. Select Open in the Type menu.
 - d. Click Submit.
2. Create an AUTOTAG policy with a relevant filter criteria. For example, Filetype = 'pdf'.
 - a. Go to Metadata > Tag Management.
 - b. Under Policies click Add Policy.
 - c. Enter a name for the policy in the Name box. For example, FileTypeGroupTagging.
 - d. Select Autotag from the Policy Type menu.
 - e. Click Next step.
 - f. Type filetype = 'pdf' as the filter criteria.

Note: You can modify the filter criteria based on the file type you want to group. For example, if you want to group all JPG images, type filetype = 'jpg'.
 - g. Click Add Tag.
 - h. Select the file type group tag that you previously defined. In this example, the tag name is FileTypeGroup.
 - i. Match the tag value with the filetype in the filter criteria. For example, if the filter criteria is filetype = 'pdf' use pdf as the tag value and then click Next step.
 - j. Click the slider control to set the policy status to active.
 - k. Under Schedule select the frequency for running the policy and then click Next step. For example, Now, Daily, Weekly, Monthly
 - l. Review the policy and click Save to run the AUTOTAG policy.

Note: You can manually refresh the IBM Data Cataloging database to confirm whether the policy is run properly. Refreshing the database is optional and not an essential prerequisite for the process. To manually refresh the database, follow the procedure shown:

 - a. Go to Data Connections > Discover Databases.
 - b. Click Run table refresh under the Metadata Summarization database
3. Create a policy to group data with a different file type tag value or modify the existing policy.
4. Define a schedule to rerun policies on a periodic basis.

Searching system and custom metadata fields

Search system and custom metadata fields using SQL queries in the Query Builder to filter, sort, and retrieve file records from the IBM Spectrum Discover data catalog.

1. On the Query Builder page, click SQL query.
 - a. Enter your query directly and click View results. Use the standard grammar that is used in an SQL query.
 - b. Click + icon to select a suggested field from the list that appears, complete your query, and click View results.
 - c. Click  and select from the search queries that were previously used.
 - d. Modify the query if necessary, and click View results.

The query language is SQL. The underlying code takes care of certain semantics, for example,

- Keyword
- Columns to select
- Name of the databases
- Where clause
- Limits
- Offsets
- Order by clauses

The search clause that is input by the user is only the body of the query that would appear after the where clause and before the limit/offset/order qualifiers.

- [System metadata fields to search on](#)
The list in this section provides definitions of items on which you can search system metadata fields.
- [Access control list metadata to search on](#)
Access Control List (ACL) metadata is collected from SMB/CIFS data source search results.
- [Search on custom metadata fields](#)
You can do a search on custom metadata fields.
- [Examples of search filters](#)
This section provides a list of examples for search filters.
- [Search results table](#)
The search results table displays information about the records that met the search criteria.
- [Refine search results](#)
After a set of search results is returned, you can further refine the data by using the following options:
- [Sort search results](#)
You can sort search results by column.
- [Tag search results manually](#)
After a filtered set of records is displayed on the search pane, you can select all or some of those documents and apply organizational tags to them.

System metadata fields to search on

The list in this section provides definitions of items on which you can search system metadata fields.

The following list shows search filters that you can use for a search.

Datasource	The name of the datasource where the record originated. The datasource refers to the label of the source storage system that was defined in the IBM Data Cataloging connection management panel.
Platform	The type of storage system from which this record originated.
Site	The physical site for the data as input by the user at scan time.
Cluster	The name of the IBM Storage Scale cluster to which the record belongs. This term applies only to IBM Storage Scale.
NodeName	For IBM Storage Protect, this indicates the node or client system to which the backup or archive record belongs.
Fileset	The file set to which the record belongs for IBM Storage Scale. This term applies only to IBM Storage Scale.
MgmtClass	For IBM Storage Protect, this indicates the management class to which the backup or archive record belongs.
Owner	The system metadata owner of the record (file only).
Group	The system metadata group owner of the record (file only).
UID	The numeric ID of file owner (file only).
GID	The numeric ID of file group (file only).
Path	The file path or object storage bucket of the file that is represented by this record.
Filename	The name of the file or object represented by the record.
Filespace	For IBM Storage Protect, this indicates the file space to which the backup or archive record belongs.
Filetype	The type of the file or <code>object.MtimeLast</code> modified time for the file (file only).
State	The state of the file or object. Possible values for IBM Storage Scale are: <pre> premig Premigrated migrttd Migrated resdnt Resident </pre> Possible values for IBM Storage Protect are: <pre> ACTIVE Active backup copy INACTIVE Inactive backup copy ARCHIVE Archive copy </pre>
Mtime	Last modified time for the file (file only).
Atime	Last accessed time for the file (file only).
Time	

Creation time of the file (file only).
Size
Size of the file or object.
Inode
The inode of the file (file only).
Permissions
The permissions of the file (file only).
sizeConsumed
The size of the consumed capacity (file only).
recordversion
The version enabled for the cloud storage system buckets or vaults. IBM Data Cataloging stores the S3 versioning identifier in the recordversion tag of the corresponding object. Cloud versioning enables you to store multiple copies, or versions, of the same object.

Access control list metadata to search on

Access Control List (ACL) metadata is collected from SMB/CIFS data source search results.

For SMB/CIFS data sources, IBM Data Cataloging collects Access Control List (ACL) metadata in addition to the standard system metadata. This information is stored in two tables, which are the Access Control Owner and Group (ACOG) and the Access Control Entries (ACES).

Important: Since ACL data is not displayed by default and is unavailable using the "visual query", a special SQL query is needed to view ACL data. Follow the steps to view ACL data for an SQL query:

1. Log in to IBM Data Cataloging GUI.
2. From the main menu, click Search > Query builder
The Query builder page is displayed.
3. Click SQL query tab.
4. In the Select * from Spectrum Discover where field, use the following query and click View results to view all ACL data.

```
"aces.entrytype like '%ACL'"
```

Note:

- To limit the ACL results to NFS or SMB, use the following query:

```
"aces.entrytype = 'NFS4ACL'", "aces.entrytype = 'DACL'", or "aces.entrytype = 'SACL'"
```

- For any other specific aces or acog query, use the following query:

```
"aces.accesstype = 'AUDIT'" or "acog.groupname = 'UNIX_GROUPS\wheel'"
```

For information on how ACL data is used in policies, see [How to use ACL data in policies](#).

Type the criteria in the search bar to search the ACL metadata. Possible fields to search on are:

acog.ownername
Indicates the owner of the file.

acog.ownerid
Indicates the security identifier for the owner of the file.

Note: To search for files based on owner name or security identifier, see the following example:

```
acog.ownername='DOMAIN\user'
acog.ownerid='S-1-1-1-1000'
```

acog.groupname
Indicates the group of owner of the file.

acog.groupid
Indicates the security identifier for the group of the owner of the file.

aces.username
Indicates the user or group name for which this ACE applies.

aces.userid
Indicates the security identifier for the user or group name for which this ACE applies.

aces.entrytype
Indicates that the entry type can either be DACL or SACL and NFS4ACL for NFSv4.

aces.accesstype
Indicates that the access type can be either one of the following options:

- ALLOWED
- DENIED
- AUDIT

Note: To search files with an access control entry that allows everyone to access, see the following example:

```
aces.username='\Everyone' and aces.entrytype='DACL' and aces.access_type='ALLOWED'
```

To search for files that are on a particular data source and display a Deny Access Control Entry, see the following example:

```
datasource in ('smb1') and aces.entrytype='DACL' and aces.accesstype='DENIED'
```

aces.permissions

Indicates the possible permission levels that include:

- R - Read
- W - Write
- X - Execute
- D - Delete
- P - Write access controls
- O - Owner

The valid permission combinations are:

- READ - R + X
- CHANGE - R + W + X + D
- FULL - R + W + X + D + P + O

For NFSv4 the permissions vary as shown:

- r - read-data
- w - write-data
- a - append-data
- x - execute
- d - delete
- t - read the attributes of the file
- T - write the attribute of the file
- n - read the named attributes of the file
- N - write the named attributes of the file
- c - read the file ACL
- C - write the file ACL
- o - change ownership of the file

Multiple NFSv4 permissions can be used in combinations like "rxtncy" for every entry.

aces.flags

Indicates the flags displaying the type of access control entry (ACE).

Note: A file can have more than one access control entry (ACE) associated with it. Search results that contain ACL metadata, repeat the file metadata for each ACE. Therefore, reports are the preferred method for using IBM Data Cataloging search results with ACL metadata.

- [How to use ACL data in policies](#)
This topic describes how to use ACL data in your policies.

How to use ACL data in policies

This topic describes how to use ACL data in your policies.

The user must specify the following query to view all ACL data as shown in the following screenshot:

Note: ACL grouping is not supported. To perform such groupings, an external DB client like the DB2 warehouse client should be used against the Spectrum Discover database.

Important: When using acog or aces data to make tagging policies, it is important to understand that a single selection of acog or aces data may result in tags not being meaningful.

For example, the following tag is defined to show that a row has a permission type of either read-write, read-execute, or read only:

Tag management

Tags Policies Policy history

Tag name Type Value

TEMPERATURE Open

Permission Restricted Read-Write Read-Execute Read-Only

The following policies are intended to set the permission tag based on the permissions flag:

Tag management

Tags Policies Policy history

Policy added Accept_Read_Only_Permissions has been added

Policy Type Schedule (UTC) State Status Collections Last modified by Last modified

Accept_Read_Execute_Permissions AUTOTAG Done Inactive spectrum-discover sdadmin 12/8/2022, 8:29:50 PM

Accept_Read_Only_Permissions AUTOTAG Done Inactive spectrum-discover sdadmin 12/8/2022, 8:30:50 PM

Accept_Read_Write_Permissions AUTOTAG Done Inactive spectrum-discover sdadmin 12/8/2022, 8:29:01 PM

After running the Read Only policy, the Permission tag is populated, but as seen from the following row for the same file, the tag does not match the real permissions (only the permissions with rt should be "read only"):

Results view: ②

Matched 8,142 records from metaobject_view table in 0.718405 seconds

Inspecting records 8,142

Grouped By

Access Cluster Datasource Filegroup Filename Show more...

path filename filetype datasource permission aces permissions aces flags

/ifs/sdiscover/Data/nfs4test/Nilesh/mail_files/ 2mails_mail.docx docx Isilon-NFSv4Test Read-Only rwatTnNcCy NULL

/ifs/sdiscover/Data/nfs4test/Nilesh/mail_files/ 2mails_mail.docx docx Isilon-NFSv4Test Read-Only rtncy g

/ifs/sdiscover/Data/nfs4test/Nilesh/mail_files/ 2mails_mail.docx docx Isilon-NFSv4Test Read-Only rwadxtTnNcCoy NULL

/ifs/sdiscover/Data/nfs4test/Nilesh/mail_files/ 2mails_mail.docx docx Isilon-NFSv4Test Read-Only rtncy NULL

/ifs/sdiscover/Data/nfs4test/Nilesh/mail_files/ 2mails_mail.docx docx Isilon-NFSv4Test Read-Only rtncy NULL

/ifs/sdiscover/Data/nfs4test/Nilesh/mail_files/ 2mails_mail.jpg jpg Isilon-NFSv4Test Read-Only rwadxtTnNcCoy g

After running the Read Execute policy, the Permission tag is populated but the permission tag is changed from Read-Only to Read-Execute which makes it meaningless and effectively useless:

☐	/ifs/sdiscover/Data/nfs4test/Nilesh/mail_files/	2mails_mail.docx		docx	Isilon-NFSv4Test	Read-Execute	rtncy	NULL
☐	/ifs/sdiscover/Data/nfs4test/Nilesh/mail_files/	2mails_mail.jpg		jpg	Isilon-NFSv4Test	Read-Execute	rwadxtTnNcCoy	g

To solve this problem, you can create tags and set the value as "True" if the condition exists.

Note: You cannot add a "false" value because if you were to run a policy that found a condition that does not exist, you would run into the same meaningless results. When tags have a "True" value, you can now set the policies to have a "True" value. By doing this, you can determine what permissions are allowed for each file.

Note: You can customize your own tags and use aces/acog information that is meaningful to you.

Search on custom metadata fields

You can do a search on custom metadata fields.

Comparators

To do a search, you can also use the following comparators:

- =
- Is equal to.
- <>
- Is not equal to.
- <
- Is less than.
- >
- Is greater than.
- <=
- Is less than or equal to.
- >=
- Is greater than or equal to.
- is
- When you search for null values:
- is null
- Indicates a null (or no) value.
- is not null
- Indicates a valid value that is not null.

Conjunctions

You can also use conjunctions.

- AND
- Tie together multiple filter criteria.
- OR
- Meet at least one of multiple filter criteria.

Helpers

You can also use helpers.

- NOW()
- Get the current TIMESTAMP.
- DAYS/MONTHS/YEARS
- Compares TIMESTAMP/DATE values.

Wildcards

You can also use a wildcard.

- %
- You can use a wildcard like % with the keyword LIKE to form a wildcard search.

Note: Both single quotation marks (') and backslashes (\) need to be escaped with a leading backslash. For example, if the search statement is: `mytag in ('first', 'can't', 'with\slash')`, the following convention needs to be followed to escape it: `mytag in ('first', 'can\'t', 'with\\slash')`.

Examples of search filters

This section provides a list of examples for search filters.

Note: You must wrap string values in single quotation marks but you cannot wrap numeric values in single quotes.

```
Owner='bob'
# All files owned by 'bob'.
Fileset='bobs_project'
# All files in the file set bobs_project.
Filetype = 'pdf' AND size > 500000
# All PDF files that are larger than 500000 bytes.
Filetype is ('txt', 'pdf', 'doc')
# All files of type TXT, PDF, or DOC.
Atime < (NOW() - 180 DAYS)
# All files not accessed in the last 180 days.
Filesystem = 'big_fs' AND owner <> 'root'
# All files in the big_fs filesystem that are not owned by root.
collection = 'proj_xylem'
Search for all records that are tagged with the user-defined tag 'Project' set to 'proj_xylem'.
collection <> ""
Search for all records that have a collection that is assigned.
filename LIKE 'the_quick_brown_%'
Returns all records for which the file name begins with "the_quick_brown_".
department= 'department_xylem'
Search for all records that are tagged with the user-defined tag 'Department' set to 'proj_xylem'.
custom_tag is null
# All files for which custom_tag is not set to any value.
```

Search results table

The search results table displays information about the records that met the search criteria.

By default, certain columns are shown, and others are hidden. Click  next to the search bar to customize the column view.

Refine search results

After a set of search results is returned, you can further refine the data by using the following options:

- Under Grouped By, click the relevant criteria to group the search results.
- Select a record row and click View individual record on the header to view the record details.
- Click Back to Query builder and select the size of search results you want to view from Limit results.
- Click  and select the Used capacity column to view a comparative study of the file size that is reported and the amount of space that is being used in the storage.

You can use a combination of any or all of the filtering criteria. The search results are immediately refined based on the criteria you select.

Sort search results

You can sort search results by column.

When you click the column header, you can sort the results in ascending order. When you click the column a second time, you can sort the column in descending order. The time it takes to sort depends on the size of the result set.

Note: Sorting by a second column loses the order of the data in the first column. A combination sort view is not supported.

Tag search results manually

After a filtered set of records is displayed on the search pane, you can select all or some of those documents and apply organizational tags to them.

For example, if a drill-down search result identifies all of the records for a particular project, you can assign a specific tag to it. Click Add Tags and specify that an organizational tag called 'Project' is set to the name of the project that is represented by the filtered set. The tag application runs as a background task and you get a notification when the processing is complete.

You can apply more than one tag at the same time.

Managing applications

An application is a program that interfaces with IBM Data Cataloging and can access the source storage. There are many use cases for application, including data content inspection for enriching metadata, data movement or migration, data scrubbing or sanitation, and more. Data is identified by IBM Data Cataloging by policy filter and passed to the application as pointers through a messaging queue. Then, the application performs whatever work is appropriate on the source data and returns a completion status back to IBM Data Cataloging, which might or might not include enriched metadata for the records. If it does include enriched metadata, IBM Data Cataloging catalogs that metadata and makes it immediately searchable.

Permissions

- Data Administrator
 - Create (register), update, delete (unregister), and view the applications.
- Data User
 - View the applications created by a Data Administrator.
- Security Administrator
 - Cannot create, modify, view, or delete any application.

Management

Applications might be viewed and deleted by navigating to Metadata > Applications. You can define an application when you are creating a new **DEEP-INSPECT** policy. In addition, you can add Parameters for an application during the process of creating a **DEEP-INSPECT** policy. For more information, see [Adding deep-inspection policy parameters](#).

Figure 1. Applications table

Application	Parameters	Action ID
ImportTag		"IMPORT_TAG"
ScaleAFM		["COPY"]
ScaleEDH		"TIER"
ContentSearchAgent		"CONTENTSEARCH"
AFMDataMover		["COPY", "MOVE"]

The Applications table displays the following information:

- Application
 - The name of the application.
- Parameters
 - The parameters that were assigned to the application when the policy was created.
- Action ID
 - AUTOTAG** or **deepinspect** - the policy type that the application is assigned to.

For more information, see [Application management by using APIs](#).

Reports

Reports can be generated upon applying tags to a set of data.

Procedure

1. Reports can be generated by using the following methods:
 - Discover data by performing a Search in IBM Data Cataloging. The search results provide an option to Generate Reports. For more information, see [Searching](#) for details.
 - Use the Graphical User Interface (GUI) [Graphical User Interface \(GUI\)](#) to automatically run the reports during deployment.
2. Click  menu and go to Search > Reports.

Figure 1. Reports table

Age Report Summary, 90-180 Days... selected

- Click See on table to view all the records of a report. The Query Results window displays the results of the search.

Download report

Click Download report to open a report with a text editor, or to save the report to local storage.

Run report

To run a report, select a report and click Run report.

Remove report

To remove a report, select a report and click Remove report.

Creating a IBM Data Cataloging application for metadata-based policies

Provides information about how to create IBM Data Cataloging application for metadata-based policies.

By default, a IBM Data Cataloging application creates a privileged container prepared to process a policy that requires both metadata and content inspection, which oftentimes mounts a data source to fetch the required files. To modify this behavior and create non-root applications for metadata-only policies, we can add the non-root annotation to the resource.

For example:

```
apiVersion: spectrum-discover.ibm.com/v1alpha1
kind: SpectrumDiscoverApplication
metadata:
  annotations:
    nonroot: 'true'
  name: non-root-app
  namespace: ibm-data-cataloging
spec:
  application_name: nonroot
```

```
log_level: DEBUG
replicas: 1
repo_name: <PRIVATE_REGISTRY>/metadata-example-application
tag: v1.0.0
```

Graceful shutdown

Provides detailed instructions to put IBM Data Cataloging in idle state on an OpenShift® environment.

About this task

The procedure might be helpful in situations where IBM Data Cataloging is behaving unexpectedly or there is a maintenance window of not more than one hour.

Procedure

1. Stop or wait for all running scans and policies to stop. Do not skip this step until everything looks stopped.
2. Do **oc** login to your OpenShift Container Platform cluster.
3. Do **oc project <project>** to select namespace where IBM Data Cataloging service is installed.
4. Stop all pods and set replicas to zero for the following deployments. and respect the following order:
Note: Follow the suggested sequence.

a. Consumers

- i. Run the following command to get the list of the deployments and filter by consumer.

```
$oc get deployments |grep consumer
```

Example output:

isd-consumer-ceph-le	10/10	10	10	6d20h
isd-consumer-cos-le	10/10	10	10	6d20h
isd-consumer-cos-scan	10/10	10	10	6d20h
isd-consumer-file-scan	10/10	10	10	6d20h
isd-consumer-protect-scan	10/10	10	10	6d20h
isd-consumer-scale-le	10/10	10	10	6d20h
isd-consumer-scale-scan	10/10	10	10	6d20h

- ii. Run the following to command to scale down replicas to 0 for every consumer deployment.

```
$oc scale --replicas=0 deployment <deployment_name>
```

Example output:

```
$oc scale --replicas=0 deployment isd-consumer-file-scan
deployment.apps/ isd-consumer-file-scan scaled
```

- iii. Ensure you scale down replicas to 0 for every consumer deployment.

Example output:

```
$oc get deployments|grep consumer-cos-scan
isd-consumer-file-scan          0/0      0      0      6d20h
```

b. Producers

- i. Run the following command to get the list of the deployments and filter by producer.

```
$oc get deployments |grep producer
```

Example output:

isd-producer-ceph-le	1/1	1	1	6d20h
isd-producer-cos-le	1/1	1	1	6d20h
isd-producer-cos-scan	1/1	1	1	6d20h
isd-producer-file-scan	1/1	1	1	6d20h
isd-producer-protect-scan	1/1	1	1	6d20h
isd-producer-scale-le	1/1	1	1	6d20h
isd-producer-scale-scan	1/1	1	1	6d20h

- ii. Run the following to command to scale down replicas to 0 for every producer deployment.
Important: Ensure that you scale down replicas to 0 for every producer deployment.

```
$oc scale --replicas=0 deployment <deployment_name>
```

Example output:

```
$oc scale --replicas=0 deployment isd-producer-file-scan
deployment.apps/ isd-producer-file-scan scaled
```

- iii. Ensure that you have scale down replicas to 0 for every producer deployment.

Example output:

```
$oc get deployments|grep producer-cos-scan
isd-producer-cos-scan          0/0      0      0      6d20h
```

c. Connection manager

- i. Run the following command to get the list of the statefulsets and filter by connection manager.

```
$oc get statefulsets |grep connmgr
```

Example output:

```
$oc get statefulsets |grep connmgr
connmgr          0/0      0          0          6d20h
```

- ii. Run the following to command to scale down replicas to 0 for every connection manager statefulset.
Important: Ensure that you have scale down replicas to 0 for every connection manager statefulset.

```
$oc scale --replicas=0 statefulset
```

Example output:

```
$oc scale --replicas=0 statefulset connmgr
statefulset.apps/ connmgr scaled
```

- iii. Ensure that you have scale down replicas to 0 for every connection manager statefulset.
Example output:

```
$oc get statefulsets |grep connmgr
connmgr          0/0      0          0          6d20h
```

- d. Check whether db2whrest stopped inserting data properly

Ensure that no database activity is present before stopping db2whrest. It is necessary to check that specific csv files created are empty, which means there are no pending jobs being processed.

- i. Run the following command to go to db2whrest.

```
oc rsh deployment/isd-db2whrest
```

Now, list all CSV files related to merging that are empty.

For example:

```
$for file in $(find /gpfs/gpfs0/db2wh/home/bluadmin -name *LOAD*.csv); do file $file; done |grep data
/gpfs/gpfs0/db2wh/home/bluadmin/ACOG_LOAD4.csv: data
/gpfs/gpfs0/db2wh/home/bluadmin/ACOG_LOAD1.csv: data
$
```

- ii. Wait for a few seconds and try again until you get an empty list.

- e. DB2WHRest

- i. Run the following command to get the list of the deployments and filter by db2whrest.

```
$oc get deployments |grep db2whrest
```

Example output:

```
$oc get deployments |grep db2whrest
isd-db2whrest    1/1      1          1          6d20h
```

- ii. Run the following command to scale down replicas to 0 for every db2whrest deployment.

```
$oc scale --replicas=0 deployment <deployment_name>
```

Example output:

```
$oc scale --replicas=0 deployment db2whrest
deployment.apps/ db2whrest scaled
```

- iii. Ensure that all scale down replicas are 0 for every db2whrest deployment.
Example output:

```
$oc get deployments |grep db2whrest
isd-db2whrest    0/0      0          0          6d20h
```

5. Stop Db2 instance. For procedure, see [Stopping and starting a Db2 instance](#).

6. After checking that everything is down, IBM Data Cataloging is successfully in an idle state. It is recommended to be in this state for a short period, not more than one hour. Warning messages on other IBM Data Cataloging pods are expected.

- [Flushing Kafka topics](#)

You must have kafka to avoid issues related to restore the specified flushed out topic.

- [Returning IBM Data Cataloging to a running state](#)

Provides detailed instructions to put IBM Data Cataloging in running state on an OpenShift environment.

Flushing Kafka topics

You must have kafka to avoid issues related to restore the specified flushed out topic.

Procedure

1. Run the following command to get Kafka topics.

```
oc get kafkatopic |grep file-scan-topic
```

Example output:

```
File-scan-topic          isd      10        1        True
```

2. Run the following command to back up Kafka topic.

```
oc get kafkatopic file-scan-topic -o yaml
```

Example output:

```
apiVersion: kafka.strimzi.io/v1beta2
kind: KafkaTopic
metadata:
  resourceVersion: '15457887'
  name: file-scan-topic
  namespace: ibm-data-cataloging
  ownerReferences:
    - apiVersion: spectrum-discover.ibm.com/v1alpha1
      kind: SpectrumDiscover
      name: discover-instance
      uid: 52fd9b6c-0823-4f88-b43d-525dd6992b1b
  labels:
    strimzi.io/cluster: isd-ssl
spec:
  partitions: 10
  replicas: 1
```

3. Run the following command to delete the Kafka topic to flush the data.

```
oc delete kafkatopic file-scan-topic
```

4. Run the following command to apply the backed-up YAML file on the cluster to recreate the topic until it deletes the Kafka topic.

```
oc apply -f <topic.yaml>
```

Example output:

```
apiVersion: kafka.strimzi.io/v1beta2
kind: KafkaTopic
metadata:
  resourceVersion: '15457887'
  name: file-scan-topic
  namespace: ibm-data-cataloging
  ownerReferences:
    - apiVersion: spectrum-discover.ibm.com/v1alpha1
      kind: SpectrumDiscover
      name: discover-instance
      uid: 52fd9b6c-0823-4f88-b43d-525dd6992b1b
  labels:
    strimzi.io/cluster: isd-ssl
spec:
  partitions: 10
  replicas: 1
```

Returning IBM Data Cataloging to a running state

Provides detailed instructions to put IBM Data Cataloging in running state on an OpenShift® environment.

About this task

Follow the steps in a specific sequence to put IBM Data Cataloging in to a running state from idle.

Procedure

1. Start Db2 instance. For procedure, see [Stopping and starting a Db2 instance](#).

2. It is needed to come back to a running state and ensure that you make replicas back to the previous state in the following order.

Note: It is important to scale up smoothly for those deployments that have two or more replicas and wait for them to be at the ready stage to scale up the next two replicas.

a. DB2WHRest

i. Run the following command to get the list of the deployments and filter by db2whrest.

```
$oc get deployments |grep db2whrest
```

Example output:

```
$oc get deployments |grep db2whrest
isd-db2whrest          0/0      0      0      6d20h
```

ii. Run the following command to scale up replicas to 1 for every db2whrest deployment.

```
$oc scale --replicas=1 deployment <deployment_name>
```

Example output:

```
$oc scale --replicas=1 deployment db2whrest
deployment.apps/ db2whrest scaled
```

iii. Ensure that you have scale up replicas to 1 for every db2whrest deployment.

Example output:

```
$oc get deployments |grep db2whrest
isd-db2whrest          1/1      1          1          6d20h
```

b. Connection manager

- i. Run the following command to get the list of the deployments and filter by connection manager.

```
$oc get deployments |grep connmgr
```

Example output:

```
$oc get deployments |grep connmgr
isd-connmgr            0/0      0          0          6d20h
```

- ii. Run the following to command to scale down replicas to 1 for every connection manager deployment.

```
$oc scale --replicas=1 deployment <deployment_name>
```

Example output:

```
$oc scale --replicas=1 deployment connmgr
deployment.apps/ connmgr scaled
```

- iii. Ensure that you have scale up replicas to 1 for every connection manager deployment.

Example output:

```
$oc get deployments |grep connmgr
isd-connmgr            1/1      1          1          6d20h
```

c. Producers

- i. Run the following command to get the list of the deployments and filter by producer.

```
$oc get deployments |grep producer
```

Example output:

```
isd-producer-ceph-le      0/0      0          0          6d20h
isd-producer-cos-le       0/0      0          0          6d20h
isd-producer-cos-scan     0/0      0          0          6d20h
isd-producer-file-scan    0/0      0          0          6d20h
isd-producer-protect-scan 0/0      0          0          6d20h
isd-producer-scale-le     0/0      0          0          6d20h
isd-producer-scale-scan   0/0      0          0          6d20h
```

- ii. Run the following to command to scale up replicas to 1 for every producer deployment.

```
$oc scale --replicas=1 deployment <deployment_name>
```

Example output:

```
$oc scale --replicas=1 deployment isd-producer-file-scan
deployment.apps/ isd-producer-file-scan scaled
```

- iii. Tip: It is recommended to scale up replicas for two producers and continue with the next two only when they are ready, up-to-date, and available. The object of this is to give OpenShift time to handle these requests properly.

Ensure that you have scale up replicas to 1 for every producer deployment.

Example output:

```
$oc get deployments |grep producer-cos-scan
isd-producer-cos-scan    1/1      1          1          6d20h
```

d. Consumers

- i. Run the following command to get the list of the deployments and filter by consumer.

```
$oc get deployments |grep consumer
```

Example output:

```
isd-consumer-ceph-le      0/0      0          0          2d
isd-consumer-cos-le       0/0      0          0          2d
isd-consumer-cos-scan     0/0      0          0          2d
isd-consumer-file-scan    0/0      0          0          2d
isd-consumer-protect-scan 0/0      0          0          2d
isd-consumer-scale-le     0/0      0          0          2d
isd-consumer-scale-scan   0/0      0          0          2d
```

- ii. Run the following to command to scale up replicas to 2 for every consumer deployment.

```
$oc scale --replicas=2 deployment isd-consumer-file-scan
```

Example output:

```
$oc scale --replicas=2 deployment isd-consumer-file-scan
deployment.apps/isd-consumer-file-scan scaled
```

- iii. Tip: It is recommended to scale up replicas for two producers and continue with the next two only when they are ready, up-to-date, and available. The object of this is to give OpenShift time to handle these requests properly.

Ensure that you have scaled up replicas to 10 for every consumer deployment, but you must scale up two at a time.

Example output:

```
$oc get deployments |grep isd-consumer-file-scan
isd-consumer-file-scan   2/2      2          2          2d
```

- iv. Some pods might face issues when scaling up the replicas back to 10 in a row. If that happens, then you need to wait for a few minutes, but if it is back to the Running or Ready (1/1) state for a long time, then you need to check for failing pods and delete them. OpenShift will create them

again after you delete them.

1. Run the following to get the list of pods that are not running.

```
$oc get pods | grep -v Running
```

Example output:

isd-consumer-file-scan-6d6bbf8487-2asd3	0/1	Pending	0	2h
isd-consumer-file-scan-6d6bbf8487-1jkws	0/1	Pending	0	2h
isd-consumer-file-scan-6d6bbf8487-m96hc	0/1	Pending	0	2h
isd-consumer-file-scan-6d6bbf8487-w551r	0/1	Pending	0	2h
isd-consumer-file-scan-6d6bbf8487-z8hqd	0/1	Pending	0	2h

2. Run the following command to delete pods that are not running.

```
$oc delete pod isd-consumer-file-scan-6d6bbf8487-1jkws
```

Example output:

```
$oc delete pod isd-consumer-file-scan-6d6bbf8487-1jkws
pod "isd-consumer-file-scan-6d6bbf8487-1jkws" deleted
```

NAME	READY	STATUS	RESTARTS	AGE
isd-consumer-file-scan-6d6bbf8487-1jkws	1/1	Terminating	0	2h

3. OpenShift will create them again after you delete them.

For example:

```
$oc get pods | grep consumer-file-scan
isd-consumer-file-scan-6d6bbf8487-41x8r 0/1 Running 0
64s

#Check until having 1/1 Running state

$oc get pods | grep consumer-file-scan
isd-consumer-file-scan-6d6bbf8487-41x8r 1/1 Running 0
2m39s
```

REST API for IBM Data Cataloging

REST API reference documentation provides endpoint specifications, request and response formats, and authentication details for programmatic access to IBM Spectrum Discover services.

- **[IBM Data Cataloging REST APIs](#)**
The Data Cataloging REST APIs are REST-style APIs that provide interoperability between a client and server over a network. These APIs allow authenticated users to perform management tasks.
- **[Endpoints for working with a Db2 Warehouse](#)**
The Db2® Warehouse API provides endpoints for working with a Db2 Warehouse.
- **[Endpoints for working with policy management](#)**
With the policy management API service, you can create, list, update, and delete the policies.
- **[Endpoints for working with connection management](#)**
With the connection management API service you can create, update, delete, and get information about data source connection entries in the connection table.
- **[Application management by using APIs](#)**
The application management APIs provide options to get the details of the available applications, install or upgrade an application, and delete an application. You must have the Admin role to access the application management endpoints.
- **[RBAC management by using APIs](#)**
The IBM Data Cataloging resource-based access control (RBAC) is a REST API service that enables role-based access to the IBM Data Cataloging services. This service uses OpenStack Keystone as a backend for providing Identity and Access Management (IAM) across multiple domains that are attached to the IBM Data Cataloging.

IBM Data Cataloging REST APIs

The Data Cataloging REST APIs are REST-style APIs that provide interoperability between a client and server over a network. These APIs allow authenticated users to perform management tasks.

The following list shows the significant features of REST-style APIs:

- REST-style APIs are resource-based.
- REST-style APIs are stateless.
- REST-style APIs are client or server.
- REST-style APIs are cacheable.
- REST-style APIs are a layered system.

A representational state transfer (REST) system is a resource-based service system in which requests are made to the resource's universal resources identifier (URI). These requests start a response from the resource in the JSON or CSV format.

The operations that you can perform on the resources or a resource element are directed by the HTTP methods such as GET, POST, PUT, and DELETE and in some cases by the parameters of the HTTPS request. The following list provides the meanings of the basic HTTP methods that are used in the requests:

GET

Reads a specific resource or a collection of resources and provides the details as the response.

PUT

Updates a specific resource or a collection of resources.

DELETE

Removes or deletes a specific resource.

POST

Creates a resource.

- [API endpoints](#)

The Data Cataloging REST APIs include several API services for monitoring data and performing other management tasks.

- [Asynchronous endpoints](#)

Some REST API endpoints run asynchronously.

- [Status codes](#)

Each API request that is sent to the server returns a response that includes an HTTP status code and any requested information.

- [Authentication process](#)

The REST API services require token-based authentication rather than authentication with a user ID and password.

API endpoints

The Data Cataloging REST APIs include several API services for monitoring data and performing other management tasks.

IBM Data Cataloging provides the following REST APIs:

- An API for working with a DB2® warehouse
- A policy management API and an autotags API
- A connection management API
- An application management API
- A resource-based access control (RBAC) API

The endpoints of each API have a characteristic basic syntax. In the following code blocks, `data_cataloging_host` is the host name or IP address of the API server:

- Endpoints for the Db2® Warehouse API:

```
https://<data_cataloging_host>/db2whrest/v1/<endpoint_ID>
```

For example:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/ sql_query_async?<sql>
```

- Endpoints for the policy management API:

```
https://<data_cataloging_host>/policyengine/v1/policies/<endpoint_ID>
```

For example:

```
curl -k -H 'Authorization: Bearer <token>' "https://<data_cataloging_host>/policyengine/v1/ policies/<policy_ID>
```

- Endpoints for the resource-based access control (RBAC) API:

```
https://<data_cataloging_host>/auth/v1/<endpoint_ID>
```

For example:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/auth/v1/users
```

Asynchronous endpoints

Some REST API endpoints run asynchronously.

This behavior is helpful if the action that is performed has a long waiting period or has a negative impact on system performance. Some endpoints are explicitly asynchronous, such as the `/db2whrest/v1/sql_query_async?<sql>`: **GET** endpoint. Other endpoints are initially synchronous but are automatically converted by the system to asynchronous operations if they take more than 10 seconds to complete.

When you start an endpoint that results in an asynchronous operation, you must poll the asynchronous operation until it is complete. Follow these steps:

1. Find the *location URI* of the asynchronous operation. In response to the request that starts the endpoint, the system returns a synchronous response that indicates that asynchronous operation is accepted for processing but is not yet complete. This response includes a status code of **202 ACCEPTED** and a response header that contains the location of the asynchronous operation. In the following example, the status code appears at line 2 and the location URI appears in line 5:

```
* HTTP 1.0, assume close after body
< HTTP/1.0 202 ACCEPTED
< Content-Type: text/html; charset=utf-8
< Content-Length: 28
< Location: https://labsrv04/db2whrest/v1/task_status/9c0db090-bd33-41c5-969f-a1603ddf49ab
< Server: Werkzeug/0.14.1 Python/3.4.5
< Date: Thu, 15 Feb 2018 20:37:10 GMT
```

2. Run the `/db2whrest/v1/task_status/<task_id>`: **GET** endpoint on the location URI to get the status of the asynchronous operation. The following example uses the location URI from the example in Step 1:

```
curl -k -H 'Authorization: Bearer <token>' https://labsrv04/db2whrest/v1/task_status/9c0db090-bd33-41c5-969f-a1603ddf49ab
-X GET
```

3. If the status code that is returned from the `task_status` endpoint in Step 2 is **303**, then the asynchronous operation is not completed. Repeat Step 2.

- If the status code of the task_status endpoint in Step 2 is **200**, then the asynchronous operation completes and the response header contains the location URI of the results. Run the `/db2whrest/v1/task_status/<task_id>`: GET endpoint on this location URI to get the results.

For more information see the topic [/db2whrest/v1/task_status/<task_id>: GET and <task_id>/peek](#).

Status codes

Each API request that is sent to the server returns a response that includes an HTTP status code and any requested information.

The following are some of the common HTTP status codes:

200 OK

The endpoint operation was successful.

201 Created

The endpoint operation was successful and resulted in the creation of a resource.

202 Accepted

The request is accepted for processing, but the processing is not yet completed. Asynchronous endpoints return this status code in the response to the original request.

204 No content

The endpoint operation was successful, but no content is returned in the response.

303 [interim response status]

The endpoint operation is in progress. Asynchronous endpoints return this status code in response to a request for status.

The following are some common HTTP status error codes:

400 Bad Request

403 Forbidden

404 Not Found

500 Internal Server Error

Along with the HTTP status codes, the Db2® Warehouse API service also returns an error reason in the **reason** field of a JSON dictionary. In the following example, a request to add a record to a database is rejected with the status error code 400 "BAD REQUEST". The reason code contains more information, including the following error message:

```
curl -k -v -H 'Authorization: Bearer <token>'
https://data_cataloging_host/db2whrest/v1/sql_query -X POST -d"select *
from labsrv04 where ownerzzz='root'"
<HTTP/1.1 400 BAD REQUEST
{"reason": "('42S22', '[42S22] [IBM] [CLI Driver] [DB2/LINUX8664] SQL0206N \"OWNERZZZ\" is not
valid in the context where it is used. SQLSTATE=42703\\n')", "status": "error"}
```

Authentication process

The REST API services require token-based authentication rather than authentication with a user ID and password.

Users who need to access the IBM Data Cataloging APIs need to get an authentication token first by using their username and password. Then, use that token to get authenticated to the IBM Data Cataloging system to perform various operations by using APIs.

Authentication is achieved in IBM Data Cataloging through the following steps:

- The administrator registers an enterprise domain, which can be either Lightweight Directory Access Protocol (LDAP) or Cloud Storage Object, with the authentication service. Registering the enterprise domain with the authentication service includes the following steps:
 - The administrator gets an authentication token by using the credentials.

When the administrator (who is in the LDAP domain) logs in to IBM Data Cataloging, the credentials are passed from IBM Data Cataloging to LDAP for authentication. Then, the administrator gets an authentication token by using the credentials.

Note: Users from an external LDAP or Cloud Storage Object domain, need to include domain name in the user name as `"<domain>/<user>"` to get an authentication token by using the REST APIs.
 - Register the domain by using the obtained authentication token.

IBM Data Cataloging integrates with both LDAP users and Cloud Storage Object users. Administrators can add the Cloud Storage Object domain to IBM Data Cataloging and the users are imported into IBM Data Cataloging where the administrator can add the users to the appropriate collections.

In this case, the Cloud Storage Object users can either use their user name and password or the Cloud Storage Object native Amazon Simple Storage Service (Amazon S3) access key and secret key pair to get authenticated with the IBM Data Cataloging authentication service to get an authentication token.

Like the users from LDAP domain, the Cloud Storage Object domain users can use this authentication token to access the IBM Data Cataloging services and their scope is restricted to the projects to which they can access.

- The administrator adds collections to the authentication service and adds users to these collections by assigning them appropriate roles. The records that the users can see or apply policies to are restricted according to the collections to which they have access.
- The user requests for an authentication token by using their user name and password.

The IBM Data Cataloging RESTful service like DB2WH REST, policy engine, tags, applications, and the various authentication service endpoints require a bearer auth-token to be passed to it in the authorization header.

The authentication token needs to be obtained by using the authentication token service endpoint, which is the endpoint for a user to log in with user name and password credentials, by using HTTP basic authentication. This token then can be used for authorization across various service endpoints. After a user receives the authentication token, it is valid for 1 hour. Using this token, a user can use various IBM Data Cataloging services.

- Users can access the IBM Data Cataloging services by using the authentication token.

Endpoints for working with a Db2 Warehouse

The Db2® Warehouse API provides endpoints for working with a Db2 Warehouse.

- [/db2whrest/v1/search: POST](#)
Searches a database for data.
- [/db2whrest/v1/report: POST](#)
Creates a curation report definition and runs it immediately.
- [/db2whrest/v1/report: GET](#)
Gets information on all the curation reports that are available in the system.
- [/db2whrest/v1/report/<report_id>: GET](#)
Gets information about a single curation report.
- [/db2whrest/v1/report/<report_id>/download: GET](#)
Downloads the output file of the specified curation report.
- [/db2whrest/v1/bucket: GET](#)
Gets information on all buckets that are supported.
- [/db2whrest/v1/buckets/<bucket>: GET](#)
Gets information on a specific bucket that is supported.
- [/db2whrest/v1/report/<report_id>: PUT](#)
Runs the specified curation report. The old output file is replaced by the new one.
- [/db2whrest/v1/buckets/<bucket>: PUT](#)
Modifies the bucket details.
- [/db2whrest/v1/report/<report_id>: DELETE](#)
Deletes the specified curation report definition and its output file.
- [/db2whrest/v1/sql_query?<sql>: GET](#)
Retrieves data from a database with an SQL query in a GET command. You can use any standard SQL query. You must include the SQL query as a parameter of the URL.
- [/db2whrest/v1/sql_query: POST](#)
Gets data from a database with an SQL query in a POST command. You can use any standard SQL query. You must include the SQL query in the message body of the POST command.
- [/db2whrest/v1/sql_query_async?<sql>: GET](#)
Gets data from a database asynchronously with an SQL query in a GET command.
- [/db2whrest/v1/sql_query_async: POST](#)
Gets data from a database asynchronously with an SQL query in a POST command. You can use any standard SQL query. You must include the SQL query in the message body of the POST command.
- [/db2whrest/v1/task_status/<task_id>: GET and <task_id>/peek](#)
Gets the status of the specified asynchronous task.
- [/db2whrest/v1/summary_tables -X GET](#)
Gets information on all the summary tables that are available in the system.
- [/db2whrest/v1/summary_tables/<table> -X GET](#)
Gets information for a particular summary table available in the system.
- [/db2whrest/v1/summary_tables/<table> -X PUT](#)
Change the summary table configuration for a particular summary table available in the system.
- [/db2whrest/v1/summary_tables/<table>/<action> -X PUT](#)
Triggers a start or scheduled start action for a particular summary table.
- [/db2whrest/v1/bulk_add_tags/docs: POST](#)
Searches a database for data.

/db2whrest/v1/search: POST

Searches a database for data.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	✓ ¹	✓ ¹	X	X

¹The search is restricted to documents that are tagged with collections to which the user ID has a datauser role assigned.

The **search** endpoint has the following format:

```
/db2whrest/v1/search -H 'Authorization: Bearer <token>' -X POST -d@<data.json>
-H "Content-Type: application/json"
```

The endpoint accepts requests in JSON format and returns a response in a self-describing data set. It also returns the query time and number of elements in the result set. If an endpoint operation takes more than 10 seconds to complete it is converted to an asynchronous operation. For more information on asynchronous endpoint operations, see [Asynchronous endpoints](#).

You can modify a **search** endpoint with the following fields. An example follows this list:

query

Specifies a search query string.

filters

Specifies an array of dictionaries that filter the results of the query. Each dictionary must contain the following three fields:

key

The name of the field or column to be returned.

operator
One of the following operators: =, >, <, <>, <=, >=, in, like.

value
The value of the field or column to filter on.

group_by

Specifies a list of fields to be used to summarize search results. If the group_by field is not specified, the search returns record-level information.

Note: The combination "group_by": ["filename"] causes the query to be applied to the duplicate file table. All other group_by combinations cause the query to be applied to the summary tables.

sort_by

Specifies an array of dictionary objects. Each dictionary object must specify a field or column name to be sorted on and a sort direction. Valid sort directions are asc and desc.

limit

Specifies the maximum number of rows that can be returned by the response.

The following example illustrates how to specify these fields:

```
{
  "query": "platform='Spectrum Scale'",
  "filters": [
    {
      "key": "project",
      "operator": "is",
      "value": "null"
    }
  ],
  "group_by": ["Filesystem", "Owner", "Site"],
  "sort_by": [{"Filesystem": "asc"}, {"Owner": "asc"}],
  "limit": 100000
}
```

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/search -X POST -d@search.json -H
'Content-Type: application/json'
```

Supported request types and response formats

Supported request types:

- POST

Supported response formats:

- JSON

Examples

1. The following example shows how to define search parameters and format the data that is returned:

a. Step 1: Define the search parameters in a file named search.json:

```
{
  "query": "platform='Spectrum Scale'",
  "filters": [
    {
      "key": "project",
      "operator": "is",
      "value": "null"
    }
  ],
  "group_by": ["Filesystem", "Owner", "Site"],
  "sort_by": [{"Filesystem": "asc"}, {"Owner": "asc"}],
  "limit": 100000
}
```

b. Step 2: Submit the request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/search -X POST -d@search.json
-H 'Content-Type: application/json'
```

The following response is returned:

```
{
  "facet_tree": {
    "OWNER": " [{\"owner\": \"nobody\", \"count\": 8}, {\"owner\": \"benjamin\", \"count\": 2}, {\"owner\": \"_NULL_\", \"count\": 989}, {\"owner\": \"borgato\", \"count\": 2}, {\"owner\": \"boston\", \"count\": 4554}, {\"owner\": \"root\", \"count\": 366104932}, {\"owner\": \"beale\", \"count\": 203545}, {\"owner\": \"baldwin\", \"count\": 2}, {\"owner\": \"behr\", \"count\": 785144}, {\"owner\": \"babcock\", \"count\": 9082943}, {\"owner\": \"broadwood\", \"count\": 375}] ",
    "PLATFORM": " [{\"platform\": \"Spectrum Scale\", \"count\": 376182496}] ",
    "FILESYSTEM": " [{\"filesystem\": \"fs11-lm-me1\", \"count\": 185493076}, {\"filesystem\": \"fs10-lm-me1\", \"count\": 10077057}, {\"filesystem\": \"fs10-lm-me1\", \"count\": 180612363}] ",
    "CLASSIFICATION": " [{\"classification\": null, \"count\": 376182496}] ",
    "DEPARTMENT": " [{\"department\": null, \"count\": 376182496}] ",
    "CLUSTER": " [{\"cluster\": \"host.ibm.com\", \"count\": 366105439}, {\"cluster\":
```

```

\ "filesystem": "university.edu", \ "count": 10077057 } ],

{ \ "filesystem": \ "filesys1", \ "owner": \ "babcock", \ "site": \ " ", \ "count": 9082943,
\ "sum": 48534270142857 }, { \ "filesystem": \ "filesys1", \ "owner": \ "borgato",
\ "site": \ " ", \ "count": 2, \ "sum": 4415704787 } ], "count": 15, "doc_count": 376182496
}

```

In the following code block, the information from the rows field of the response is reflowed so that it is easier to read. The sum column is omitted. You can see that the rows are grouped by file system, owner, and site and are sorted by file system and owner:

```

"rows": " [
{ \ "filesystem": \ "fs10-1m-mel", \ "owner": \ " NULL ", \ "site": \ "host", \ "count": 468,
{ \ "filesystem": \ "fs10-1m-mel", \ "owner": \ "nobody", \ "site": \ "host", \ "count": 4,
{ \ "filesystem": \ "fs10-1m-mel", \ "owner": \ "root", \ "site": \ "host", \ "count": 1806,
{ \ "filesystem": \ "fs11-1m-mel", \ "owner": \ " NULL ", \ "site": \ "host", \ "count": 521,
{ \ "filesystem": \ "fs11-1m-mel", \ "owner": \ "nobody", \ "site": \ "host", \ "count": 4,
{ \ "filesystem": \ "fs11-1m-mel", \ "owner": \ "root", \ "site": \ "host", \ "count": 1854,
{ \ "filesystem": \ "filesys1", \ "owner": \ "baldwin", \ "site": \ " ", \ "count": 2,
{ \ "filesystem": \ "filesys1", \ "owner": \ "behr", \ "site": \ " ", \ "count": 785144,
{ \ "filesystem": \ "filesys1", \ "owner": \ "boston", \ "site": \ " ", \ "count": 4554,
{ \ "filesystem": \ "filesys1", \ "owner": \ "beale", \ "site": \ " ", \ "count": 203545,
{ \ "filesystem": \ "filesys1", \ "owner": \ "root", \ "site": \ " ", \ "count": 490,
{ \ "filesystem": \ "filesys1", \ "owner": \ "broadwood", \ "site": \ " ", \ "count": 375,
{ \ "filesystem": \ "filesys1", \ "owner": \ "benjamin", \ "site": \ " ", \ "count": 2,
{ \ "filesystem": \ "filesys1", \ "owner": \ "babcock", \ "site": \ " ", \ "count": 9082943,
{ \ "filesystem": \ "filesys1", \ "owner": \ "borgato", \ "site": \ " ", \ "count": 2,

```

2. The following example shows how to search for duplicate files with a size greater than 1 MiB:

- a. Step 1: Define the search parameters in a file named search.json:

```

{
  "query": "",
  "filters": [
    {
      "key": "size",
      "operator": ">",
      "value": 1048576
    }
  ],
  "group_by": ["size", "filename"],
  "sort_by": [{"size": "asc"}, {"filename": "asc"}],
  "limit": 100
}

```

- b. Step 2: Submit the request:

```

curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/ search -X POST -d@search.json
-H 'Content-Type: application/json'

```

The following response is returned. Some of the rows of the response are omitted:

```

{
  "facet_tree": { "OWNER": " [ { \ "owner": \ "behr", \ "count": 160096 }, { \ "owner": \ "babcock",
\ "count": 14609 }, { \ "owner": \ "beale", \ "count": 612 }, { \ "owner": \ "root", \ "count": 34 } ],
"DEPARTMENT": " [ { \ "department": \ null, \ "count": 175351 } ], "FILESYSTEM": " [ { \ "filesystem": \ "
\ filesys1", \ "count": 175351 } ], "PROJECT": " [ { \ "project": \ "TCGA_kirc", \ "count": 86 },
{ \ "project": \ "TCGA_ucs", \ "count": 14 }, { \ "project": \ "TCGA_stad", \ "count": 21 },

{\size":1054721,\filename":"asm_g3384.asm",\count":2,\sum":2109442}],\count":
100,\doc_count":4318
}

```

In the following code block, the information from the rows field of the response is reflowed so that it is easier to read. You can see that the rows are grouped by size and file name and that they are sorted by size and file name in ascending order:

```

"rows":
[
  {\size":1048608,\filename":"NA-C-ms22-cm0.mcdat",\count":4106,\sum":4305584448},
  {\size":1048608,\filename":"asm_g100-C-ms22-cm0.mcdat",\count":2,\sum":2097216},
  {\size":1048608,\filename":"asm_g1083-C-ms22-cm0.mcdat",\count":2,\sum":2097216},
  {\size":1048608,\filename":"asm_g111-C-ms22-cm0.mcdat",\count":2,\sum":2097216},
  {\size":1048608,\filename":"asm_g1122-C-ms22-cm0.mcdat",\count":2,\sum":2097216},
  {\size":1048608,\filename":"asm_g134-C-ms22-cm0.mcdat",\count":2,\sum":2097216},
  {\size":1048608,\filename":"asm_g145-C-ms22-cm0.mcdat",\count":2,\sum":2097216},
  {\size":1048608,\filename":"asm_g147-C-ms22-cm0.mcdat",\count":3,\sum":3145824},
  {\size":1048608,\filename":"asm_g149-C-ms22-cm0.mcdat",\count":4,\sum":4194432},
  {\size":1048608,\filename":"asm_g151-C-ms22-cm0.mcdat",\count":2,\sum":2097216},
  {\size":1048608,\filename":"asm_g153-C-ms22-cm0.mcdat",\count":2,
  ...
  {\size":1053910,\filename":"asm_g2981.asm",\count":2,\sum":2107820},
  {\size":1053914,\filename":"seqDB.v006.dat",\count":2,\sum":2107828},
  {\size":1054721,\filename":"asm_g3384.asm",\count":2,\sum":2109442}
]

```

3. The following example shows how to perform a nongrouped search (record level results) for files owned by **benjamin**:
 - a. Step 1: Define the search parameters in a file named search.json:

```

{
  "query": "",
  "filters": [
    {
      "key": "owner",
      "operator": "=",
      "value": "benjamin"
    }
  ],
  "group_by": [],
  "sort_by": [],
  "limit": 100
}

```

- b. Step 2: Submit the following request:

```

curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/ search -X POST -d@search.json
-H 'Content-Type: application/json'

```

The following response is returned:

```

* Connection #0 to host localhost left intact
{
  "query time secs": 1422.651552,"rows": "[{\filesystem":"filesys1",\revision":"M01",
  \site":"",\platform":"Spectrum Scale",\cluster":"filesys1.university.edu",
  \inode":257173,\owner":"benjamin",\group":"iacs",\permissions":"-r--r--",

```

In the following code block, the information from the rows field of the response is reflowed for better viewing. Many columns are omitted. You can see that the response returns two rows in which the owner field is benjamin:

```
"rows": "[
{"filesystem":"filesys1\","revision":"MO1\","site":"","...owner":"benjamin",...
{"filesystem":"filesys1\","revision":"MO1\","site":"","...owner":"benjamin",...
]"
```

/db2whrest/v1/report: POST

Creates a curation report definition and runs it immediately.

The following table shows which roles can access this REST API endpoint:

Table 1. Access by role

Data admin	Data user	Collection Admin	Admin	Service user
✓	X	X	X	X

Synopsis of the request URL

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/report -X POST -d@report.json -H
'Content-Type: application/json'
```

This endpoint has the same parameters as the `/db2whrest/v1/search` endpoint and also has a name parameter:

query

Specifies a search query string.

filters

Specifies an array of dictionaries that filter the results of the query. Each dictionary must contain the following three fields:

key

The name of the field or column to be returned.

operator

One of the following operators: `=`, `>`, `<`, `<>`, `<=`, `>=`, `is`, `like`.

value

The value of the field or column to filter on.

group_by

Specifies a list of fields to be used to summarize search results. Grouped queries return output columns for count and sum, whereas nongrouped queries return all columns for each row. If the `group_by` field is not specified, the search returns record-level information.

sort_by

Specifies an array of dictionary objects. Each dictionary object must specify a field or column name to be sorted on and a sort direction. Valid sort directions are `asc` and `desc`.

limit

Specifies the maximum number of rows that can be returned by the response.

name

Specifies a name for the report output file. If this parameter is not specified, the endpoint uses the randomly generated UUID as the file name base.

The following example illustrates how to specify these fields:

```
{
  "name": "Unassigned Project Report",
  "query": "platform='Spectrum Scale'",
  "filters": [
    {
      "key": "project",
      "operator": "is",
      "value": "null"
    }
  ],
  "group_by": ["Filesystem", "Owner", "Site"],
  "sort_by": [{"Filesystem": "asc"}, {"Owner": "asc"}],
  "limit": 100000
}
```

Supported request types and response formats

Supported request types:

- POST

Supported response formats:

- JSON

Status codes

The operation is successful.

All other status code values

The operation failed.

- 201: The operation is successful.
- All other status code values: The operation failed.

Examples

1. The following example shows how to create a report:
 - a. Step 1: Define the search parameters in a file named report.json:

```
{
  "name": "Unassigned Project Report",
  "query": "platform='Spectrum Scale'",
  "filters": [
    {
      "key": "project",
      "operator": "is",
      "value": "null"
    }
  ],
  "group_by": ["Filesystem", "Owner", "Site"],
  "sort_by": [{"Filesystem": "asc"}, {"Owner": "asc"}],
  "limit": 100000
}
```

- b. Step 2: Submit the following request:

```
curl -k -H 'Authorization: Bearer <token>' https://<data_cataloging_host>/db2whrest/v1/report -X POST -d@report.json
-H "Content-Type: application/json"
```

2. The response includes the ID of the new report and the status of the operation ("report created"):

```
{ "report": "b5ff3126-353d-4d7d-857a-750cc20b8bab", "status": "report created" }
```

Report scripts

IBM Data Cataloging contains a set of predefined JSON and scripts to generate specific reports.

1. JSON Examples

- The following example lists the files or objects that are accessed in last 0 - 30 days. This report is created in the UI.

age_report_0-30_days_since_access_detail.json

```
{
